The present disclosure relates to a solid-state imaging device, an electronic apparatus, and a driving method for reducing power consumption of pixels, and achieving an increase in the number of pixels. Provided is a solid-state imaging device including a pixel array unit that includes pixels arranged in a matrix. From each of the pixels an output signal indicating a logarithmic characteristic is acquired. Each of the pixels includes: a photoelectric conversion unit; a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal; a first amplification transistor that amplifies a signal received from the photoelectric conversion unit; a selection transistor that selects a signal received from the first amplification transi-

TECHNICAL FIELD

The present disclosure relates to a solid-state imaging device, an electronic apparatus, and a driving method, and more particularly to a solid-state imaging device, an electronic apparatus, and a driving method capable of reducing power consumption of pixels, and achieving an increase in the number of pixels.

BACKGROUND ART

A logarithmic sensor (Logarithmic Image Sensor) which operates a photodiode using an open circuit and measures an output voltage of the photodiode similarly to a solar cell is known (e.g., see NPL 1).

The logarithmic sensor in the solar cell mode of this type utilizes such a relation that a potential difference produced when a current flows in a forward direction of PN junction, i.e., a voltage, is proportional to a logarithm of the current. The current in the forward direction is replaced with a photocurrent generated by photoelectric conversion, and a voltage in the forward direction of PN junction is monitored. In this case, the monitored voltage becomes a signal of logarithmically compressed photocurrent.

SUMMARY

Technical Problem

Meanwhile, a logarithmic sensor in a solar cell mode generally adopts a two-stage amplifier structure including two stage amplifiers for a structure of each pixel so as not to superimpose potential variations of a vertical signal line (VSL) on a transient response of a photodiode.

In the case of adoption of this two-stage amplifier structure, a current source needs to be provided within a pixel. However, the current source provided within the pixel in this manner generates a steady flow of a through current. This flow of the through current raises power consumption, and also produces an obstacle to an increase in the number of pixels.

2

The present disclosure has been developed in consideration of the aforementioned circumstances, and provides a logarithmic sensor in a solar cell mode, which sensor is capable of reducing power consumption of pixels, and achieving an increase in the number of pixels.

Solution to Problem

A solid-state imaging device according to one aspect of the present disclosure is a solid-state imaging device including a pixel array unit that includes pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired. Each of the pixels includes a photoelectric conversion unit, a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal, a first amplification transistor that amplifies a signal received from the photoelectric conversion unit, a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal, a second amplification transistor that amplifies a signal received from the selection transistor and applies the amplified signal to a vertical signal line, and a bias transistor that is connected to the selection transistor and the second amplification transistor and functions as a current source. The first amplification transistor and the second amplification transistor are each connected to a power source voltage.

An electronic apparatus according to one aspect of the present disclosure is an electronic apparatus including a solid-state imaging device that includes a pixel array unit including pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired. Each of the pixels includes a photoelectric conversion unit, a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal, a first amplification transistor that amplifies a signal received from the photoelectric conversion unit, a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal, a second amplification transistor that amplifies a signal received from the selection transistor and applies the amplified signal to a vertical signal line, and a bias transistor that is connected to the selection transistor and the second amplification transistor and functions as a current source. The first amplification transistor and the second amplification transistor are each connected to a power source voltage.

The solid-state imaging device and the electronic apparatus of the one aspect of the present disclosure includes the pixel array unit including the pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired. Each of the pixels includes the photoelectric conversion unit, the reset transistor that resets the photoelectric conversion unit in accordance with the reset signal, the first amplification transistor that amplifies the signal received from the photoelectric conversion unit, the selection transistor that selects the signal received from the first amplification transistor in accordance with the selection signal, the second amplification transistor that amplifies the signal received from the selection transistor and applies the amplified signal to the vertical signal line, and the bias transistor that is connected to the selection transistor and the second amplification transistor and functions as the current source. The first amplification transistor and the second amplification transistor are each connected to the power source voltage.

Note that each of the solid-state imaging device or the electronic apparatus of the one aspect of the present disclosure

sure may be either an independent device, or an internal block constituting one device.

A driving method according to one aspect of the present disclosure is a driving method of a solid-state imaging device that includes a pixel array unit, the pixel array unit including pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired. Each of the pixels includes a photoelectric conversion unit, a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal, a first amplification transistor that amplifies a signal received from the photoelectric conversion unit, a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal, a second amplification transistor that amplifies a signal received from the selection transistor and applies the amplified signal to a vertical signal line, and a bias transistor that is connected to the selection transistor and the second amplification transistor and functions as a current source. The first amplification transistor and the second amplification transistor are each connected to a power source voltage. The driving method includes driving such that the reset transistor comes into an on-state during a shutter driving period before an exposure period, driving such that the selection transistor comes into an on-state during a readout period after the exposure period, and driving such that the reset transistor comes into the on-state at a readout time of a reset level during the readout period.

The driving method according to the one aspect of the present disclosure includes driving such that the reset transistor comes into the on-state during the shutter driving period before the exposure period, driving such that the selection transistor comes into the on-state during the readout period after the exposure period, and driving such that the reset transistor comes into the on-state at the readout time of the reset level during the readout period.

A driving method according to one aspect of the present disclosure is a driving method of a solid-state imaging device that includes a pixel array unit, the pixel array unit including pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired. Each of the pixels includes a photoelectric conversion unit, a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal, a first amplification transistor that amplifies a signal received from the photoelectric conversion unit, a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal, a second amplification transistor that amplifies a signal received from the selection transistor and applies the amplified signal to a vertical signal line, and a bias transistor that is connected to the selection transistor and the second amplification transistor and functions as a current source. The first amplification transistor and the second amplification transistor are each connected to a power source voltage. The driving method includes driving such that the reset transistor comes into an on-state during a shutter driving period before an exposure period, driving such that the selection transistor comes into an on-state during a readout period after the exposure period, driving such that the reset transistor comes into the on-state at a readout time of a reset level during the readout period, and driving such that the bias transistor comes into an off-state during periods except for the readout period.

The driving method according to the one aspect of the present disclosure includes driving such that the reset transistor comes into the on-state during the shutter driving period before the exposure period, driving such that the

selection transistor comes into the on-state during the readout period after the exposure period, driving such that the reset transistor comes into the on-state at the readout time of the reset level during the readout period, and driving such that the bias transistor comes into the off-state during periods except for the readout period.

Advantageous Effect of Invention

According to an aspect of the present disclosure, reduction of power consumption of pixels, and an increase in the number of pixels are achievable.

Note that advantageous effects to be produced are not limited to the advantageous effect described herein, but may be any advantageous effects described in the present disclosure.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a diagram depicting a configuration of a pixel of an ordinary logarithmic sensor in a solar cell mode.

FIG. 2 is a timing chart explaining a driving method of the pixel of the ordinary logarithmic sensor in the solar cell mode.

FIG. 3 is a block diagram depicting a configuration example of a solid-state imaging device to which a technology according to the present disclosure has been applied.

FIG. 4 is a circuit diagram depicting a configuration example of a pixel according to a first embodiment.

FIG. 5 is a timing chart explaining a driving method of a pixel according to the first embodiment.

FIG. 6 is a circuit diagram depicting a configuration example of a pixel according to a second embodiment.

FIG. 7 is a timing chart explaining a driving method of a pixel according to the second embodiment.

FIG. 8 is a circuit diagram depicting a configuration example of a pixel according to a third embodiment.

FIG. 9 is a circuit diagram depicting a configuration example of a pixel according to a fourth embodiment.

FIG. 10 is a circuit diagram depicting a configuration example of a pixel according to a fifth embodiment.

FIG. 11 is a block diagram depicting a configuration example of an electronic apparatus including a solid-state imaging device to which the technology according to the present disclosure has been applied.

FIG. 12 is a cross-sectional view depicting a configuration example of a solid-state imaging device to which the technology according to the present disclosure is applicable.

FIGS. 13A, 13B, and 13C are diagrams depicting an outline of a configuration example of a stacked solid-state imaging device to which the technology according to the present disclosure is applicable.

FIG. 14 is a cross-sectional view depicting a first configuration example of the stacked solid-state imaging device.

FIG. 15 is a cross-sectional view depicting a second configuration example of the stacked solid-state imaging device.

FIG. 16 is a cross-sectional view depicting a third configuration example of the stacked solid-state imaging device.

FIG. 17 is a cross-sectional view depicting another configuration example of the stacked solid-state imaging device to which the technology according to the present disclosure is applicable.

FIG. 18 is a block diagram depicting an example of a schematic configuration of a vehicle control system.

FIG. 19 is a diagram of assistance in explaining an example of installation positions of an outside-vehicle information detecting section and an imaging section.

FIG. 20 is a block diagram depicting an example of a schematic configuration of an in-vivo information acquisition system.

DESCRIPTION OF EMBODIMENTS

Embodiments of a technology according to the present disclosure (present technology) will be hereinafter described with reference to the drawings. Note that the description is presented in a following order.

1. Outline of technology of present disclosure
2. Configuration example of solid-state imaging device to which technology of present disclosure has been applied
3. First embodiment: Basic configuration
4. Second embodiment: Configuration driving gate input voltage of Bias
5. Third embodiment: Configuration including PD and two-stage amplifier having inversed polarities of transistors
6. Fourth embodiment: Configuration including Bias and AMP2 shared by plural pixels
7. Fifth embodiment: Configuration including shared pixels and including PD and two-stage amplifier having inversed polarities of transistors
8. Configuration example of electronic apparatus including solid-state imaging device to which technology of present disclosure has been applied
9. Cross-sectional configuration example of solid-state imaging device to which technology of present disclosure is applicable
10. Configuration example of stacked solid-state imaging device to which technology of present disclosure is applicable
11. Example of application to mobile body
12. Example of application to in-vivo information acquisition system

1. Outline of Technology of Present Disclosure

(Configuration of Pixel of Logarithmic Sensor)

FIG. 1 is a diagram depicting a configuration of a pixel of an ordinary logarithmic sensor in a solar cell mode.

Note that a pixel 900 of the ordinary logarithmic sensor depicted in FIG. 1 corresponds to one of a plurality of pixels arranged in a matrix in a pixel array unit of a solid-state imaging device such as a CMOS (Complementary Metal Oxide Semiconductor) image sensor.

The pixel 900 of the ordinary logarithmic sensor in FIG. 1 includes a photodiode 911, a reset transistor 912, an amplification transistor 913, a bias transistor 914, an amplification transistor 915, and a selection transistor 916.

The photodiode 911 is a photoelectric conversion unit including n-type and p-type semiconductor regions. The reset transistor 912 controls reset of the photodiode 911 in accordance with on-off of a reset signal (RST) applied to a gate electrode of the reset transistor 912.

The amplification transistor 913 amplifies a signal sent from the photodiode 911 and applied to a gate electrode of the amplification transistor 913, and outputs the amplified signal to the amplification transistor 915. The bias transistor 914 functions as a current source.

The amplification transistor 915 amplifies a signal sent from the photodiode 911 and applied to a gate electrode of the amplification transistor 915, and outputs the amplified signal to the selection transistor 916. The selection transistor

916 outputs a signal received from the amplification transistor 915 to a vertical signal line 921 in accordance with on-off of a selection signal (SEL) applied to a gate electrode of the selection transistor 916.

In this manner, the pixel 900 of the ordinary logarithmic sensor adopts a two-stage amplification structure which includes the amplification transistor 913 corresponding to an initial-stage amplifier (AMP1), and the amplification transistor 915 corresponding to a second-stage amplifier (AMP2) so as not to superimpose potential variations of a vertical signal line (VSL) 921 on a transient response of the photodiode 911.

In addition, in the case of adoption of this two-stage amplification structure, the bias transistor 914 functioning as a current source needs to be provided within the pixel 900. The bias transistor 914 thus provided produces such a state that a bias current I_{Bias} steadily flows within the pixel 900. (Driving Method of Pixel of Logarithmic Sensor)

FIG. 2 is a timing chart explaining a driving method of the pixel 900 of the ordinary logarithmic sensor in the solar cell mode (FIG. 1).

The timing chart in FIG. 2 depicts levels of a selection signal (SEL) applied to the gate electrode of the selection transistor 916, and a reset signal (RST) applied to the gate electrode of the reset transistor 912 in time series in the pixel 900 of the ordinary logarithmic sensor (FIG. 1). In addition, the timing chart in FIG. 2 depicts a level of a signal (VSL) applied to the vertical signal line 921 in time series.

Note that Pre Shutter represents a shutter driving period, Exposure represents an exposure period, and Readout represents a readout period in FIG. 2. In addition, it is assumed that a time proceeds in a direction from the left side to the right side in the figure. Periods shift in an order of the shutter driving period, the exposure period, and the readout period.

As depicted in FIG. 2, the reset signal (RST) reaches an H level in the shutter driving period. In this case, the photodiode 911 is reset to a low potential by the reset transistor 912.

In the subsequent exposure period, charges are accumulated in the photodiode 911. In the exposure period, a source potential of each of the amplification transistor 913 as the initial-stage amplifier (AMP1) and the amplification transistor 915 as the second-stage amplifier (AMP2) varies. At this time, the bias current I_{Bias} constantly flows in the bias transistor 914 as indicated by an arrow in an upper part of the figure.

In the subsequent readout period, the selection signal (SEL) reaches an H level, and the selection transistor 916 comes into an on-state. In this case, a signal generated from the amplification transistor 915 is output to the vertical signal line (VSL) 921.

The selection transistor 916 herein initially reads out charges accumulated in the photodiode 911 as a signal level (S: Signal). Thereafter, the reset signal (RST) reaches the H level, and the photodiode 911 is reset. In this state, the selection transistor 916 reads out a noise level (N: Noise). A difference (S-N) between the signal level (S) and the noise level (N) obtained in this manner corresponds to an output signal (Output).

Subsequently, the selection signal (SEL) reaches an L level, and the selection transistor 916 comes into an off-state. Thereafter, an output from the amplification transistor 915 is cut off. As a result, the potential of the vertical signal line (VSL) 921 decreases to a potential near a ground potential (GND) Even after this state, the bias current I_{Bias} continues to constantly flow in the bias transistor 914.

Thereafter, a linear signal (a signal proportional to intensity of light) is output until charges are accumulated in the photodiode **911** in the pixel **900** of the logarithmic sensor (FIG. 1). When charges are accumulated in the photodiode **911**, a current exponentially flows in accordance with a generated voltage. Accordingly, a logarithmic relation between the voltage and the current is established, wherefore output of a logarithmic signal starts.

The foregoing points can be summarized as follows. Specifically, the pixel **900** of the ordinary logarithmic sensor adopts the two-stage amplification structure which includes the amplification transistor **913** as the initial-stage amplifier (AMP1), and the amplification transistor **915** as the second-stage amplifier (AMP2) to prevent superimposition of potential variations of the transient response VSL of the photodiode **911**.

In the case of adoption of this two-stage amplifier structure, the bias transistor **914** functioning as a current source needs to be provided within the pixel **900**.

On the other hand, in the state that the bias transistor **914** is provided, the amplification transistor **913** as the initial-stage amplifier (AMP1) constantly operates. In this case, the bias current I_{bias} steadily flows within the pixel **900** (a current constantly flows in the bias transistor **914**), wherefore power consumption rises. This rise of power consumption therefore becomes a parameter which limits an increase in the number of pixels, and consequently becomes an obstacle to an increase in the number of pixels.

Accordingly, for solving the aforementioned problems, the technology according to the present disclosure (present technology) proposes a logarithmic sensor in a solar cell mode (a solid-state imaging device) capable of reducing power consumption of pixels, and increasing the number of pixels. A solid-state imaging device including a structure for solving these problems will be hereinafter described.

2. Configuration Example of Solid-State Imaging Device to which Technology of Present Disclosure has been Applied

(Configuration Example of Solid-State Imaging Device)

FIG. 3 is a diagram depicting a solid-state imaging device according to an embodiment to which the present technology has been applied.

A solid-state imaging device **10** in FIG. 3 is a solid-state imaging device using a CMOS (Complementary Metal Oxide Semiconductor). The solid-state imaging device **10** introduces incident light (image light) received from an object via an optical lens system (not depicted), converts a light amount of the incident light into an electric signal in units of a pixel with an image of the incident light formed on an imaging surface, and outputs the electric signal as a pixel signal.

In FIG. 3, the solid-state imaging device **10** includes a pixel array unit **11**, a vertical driving circuit **12**, column signal processing circuits **13**, a horizontal driving circuit **14**, an output circuit **15**, a control circuit **16**, and an input/output terminal **17**.

The pixel array unit **11** includes a plurality of pixels **100** arranged two-dimensionally (in a matrix). Each of the pixels **100** includes a photodiode (PD) as a photoelectric conversion region, and a plurality of pixel transistors.

The vertical driving circuit **12** includes a shift register, for example. The vertical driving circuit **12** selects a predetermined pixel driving line **21**, supplies a pulse for driving the pixels **100** to the selected pixel driving line **21**, and drives the pixels **100** in units of a row. More specifically, the

vertical driving circuit **12** selectively scans the respective pixels **100** of the pixel array unit **11** in units of a row sequentially in the vertical direction, and supplies, to the column signal processing circuits **13** via the vertical signal lines **22**, a pixel signal based on a signal charge (charge) generated in accordance with a received light amount at the photodiode of each of the pixels **100**.

The column signal processing circuits **13** each arranged for the corresponding column of the pixels **100** perform signal processing such as noise removal in units of a pixel column for signals output from the pixels **100** of each row. For example, the column signal processing circuits **13** perform signal processing, such as CDS (Correlated Double Sampling) and A/D (Analog/Digital) conversion, for removing fixed pattern noise peculiar to pixels.

The horizontal driving circuit **14** includes a shift register, for example, and sequentially outputs a horizontal scanning pulse to sequentially select the column signal processing circuits **13**, and causes each of the selected column signal processing circuits **13** to output a pixel signal to a horizontal signal line **23**.

The output circuit **15** performs signal processing for signals sequentially supplied from the respective column signal processing circuits **13** via the horizontal signal line **23**, and outputs the processed signals. Note that the output circuit **15** only performs buffering in some cases, or performs black level control, column variation correction, various types of digital signal processing or the like in other cases, for example.

The control circuit **16** controls operations of respective parts of the solid-state imaging device **10**. For example, the control circuit **16** receives an input clock signal, data for commanding an operation mode and the like, and outputs data such as internal information associated with the solid-state imaging device **10**. More specifically, the control circuit **16** generates a clock signal and a control signal as references of operations of the vertical driving circuit **12**, the column signal processing circuits **13**, the horizontal driving circuit **14** and the like on the basis of a vertical synchronous signal, a horizontal synchronous signal, and a master clock signal. The control circuit **16** outputs the clock signal or the control signal thus generated to the vertical driving circuit **12**, the column signal processing circuit **13**, the horizontal driving circuit **14** and the like.

The input/output terminal **17** exchanges signals with the outside.

The solid-state imaging device **10** in FIG. 3 configured as described above constitutes a logarithmic sensor in a solar cell mode, which sensor acquires output signals indicating logarithmic characteristics from the pixels **100** arranged two-dimensionally (in a matrix) on the pixel array unit **11**.

In addition, pixel configurations of a first embodiment to a fifth embodiment described below may be adopted as the configuration of the pixels **100** arranged two-dimensionally on the pixel array unit **11** of the solid-state imaging device **10**. Configuration examples of pixels arranged on the pixel array unit **11** according to the first embodiment to the fifth embodiment will be hereinafter described.

Note that each of the pixels of the first embodiment in the following description is expressed as a pixel **100** to make distinction from pixels of the other embodiments for convenience of explanation. Similarly, pixels of the second embodiment to the fifth embodiment are expressed as pixel **200**, pixel **300**, pixel **400**, and pixel **500**, respectively. These

pixels are similarly arranged two-dimensionally on the pixel array unit **11** of the solid-state imaging device **10** (FIG. 1).

3. First Embodiment

(First Circuit Configuration)

FIG. 4 is a circuit diagram depicting a configuration example of a pixel according to the first embodiment.

The pixel **100** in FIG. 4 includes a photodiode **111**, a reset transistor **112**, an amplification transistor **113**, a bias transistor **114**, an amplification transistor **115**, and a selection transistor **116**.

The photodiode **111** is a photoelectric conversion unit including n-type and p-type semiconductor regions. A cathode electrode of the photodiode **111** is connected to an intermediate potential V_{mid} and a drain of the reset transistor **112**, while an anode electrode of the photodiode **111** is connected to a source of the reset transistor **112** and a gate of the amplification transistor **113**.

The drain of the reset transistor **112** is connected to the intermediate potential V_{mid} and the cathode electrode of the photodiode **111**, while the source of the reset transistor **112** is connected to the anode electrode of the photodiode **111** and the gate of the amplification transistor **113**. In addition, a reset signal (RST) is applied to a gate electrode of the reset transistor **112**. When the reset signal (RST) comes into an active state, a reset gate of the reset transistor **112** comes into a conductive state. As a result, the potential of the photodiode **111** is reset.

A drain of the amplification transistor **113** is connected to a power source voltage V_{dd} , while a source of the amplification transistor **113** is connected to a drain of the selection transistor **116**. The gate of the amplification transistor **113** is connected to the photodiode **111** and the source of the reset transistor **112**. A signal sent from the photodiode **111** is applied to the gate of the amplification transistor **113**. Accordingly, the amplification transistor **113** amplifies the applied signal and outputs the amplified signal to the selection transistor **116**.

The drain of the selection transistor **116** is connected to the source of the amplification transistor **113**, while a source of the selection transistor **116** is connected to a drain of the bias transistor **114** and a gate of the amplification transistor **115**. In addition, a selection signal (SEL) is applied to a gate electrode of the selection transistor **116**. When the selection signal (SEL) comes into an active state, the selection transistor **116** comes into a conductive state. As a result, the pixel **100** comes into a selected state. Accordingly, a signal output from the amplification transistor **113** is output to the amplification transistor **115** via the selection transistor **116**.

The drain of the bias transistor **114** is connected to the source of the selection transistor **116** and the gate of the amplification transistor **115**, while a source of the bias transistor **114** is grounded. A predetermined signal is applied to a gate electrode of the bias transistor **114** to set a reference current. The bias transistor **114** functions as a current source.

A drain of the amplification transistor **115** is connected to the power source voltage V_{dd} , while a source of the amplification transistor **115** is connected to a vertical signal line (VSL) **121** (the vertical signal line **22** in FIG. 3). In addition, the gate of the amplification transistor **115** is connected to the source of the selection transistor **116** and the drain of the bias transistor **114**.

When the selection signal (SEL) comes into a conductive state in the selection transistor **116** herein, a signal output from the amplification transistor **113** is applied to the gate of the amplification transistor **115** via the selection transistor

116. The amplification transistor **115** amplifies the signal applied to the gate of the amplification transistor **115**, and outputs the amplified signal to the vertical signal line **121**.

Concerning the amplification transistor **113** and the amplification transistor **115** in the pixel **100**, the amplification transistor **113** provided on the photodiode **111** side corresponds to the initial-stage amplifier (AMP1), while the amplification transistor **115** provided on the vertical signal line (VSL) **121** side corresponds to the second-stage amplifier (AMP2). The initial-stage amplifier (AMP1) and the second-stage amplifier (AMP2) constitute a two-stage amplifier. This configuration is different from the pixel **900** of the ordinary logarithmic sensor (FIG. 1) in that the selection transistor **116** is shifted from the second-stage amplifier (AMP2) side to the initial-stage amplifier (AMP1) side.

In addition, the photodiode **111**, the amplification transistor **113**, the bias transistor **114**, the amplification transistor **115**, and the selection transistor **116** in the pixel **100** have inversed polarities with respect to the polarities of the photodiode **911**, the amplification transistor **913**, the bias transistor **914**, the amplification transistor **915**, and the selection transistor **916** in the pixel **900** of the ordinary logarithmic sensor (FIG. 1), respectively.

More specifically, carriers generated in the photodiode **111** are positive charges corresponding to holes. Accordingly, the polarities are inversed as depicted in FIG. 4 to handle the positive charges as electrons in the transistors of the following stage (the amplification transistor **113**, the bias transistor **114**, the amplification transistor **115**, and the selection transistor **116**). This inversion of the polarities allows automatic switching between on and off of the amplification transistor **115**.

(First Driving Method)

FIG. 5 is a timing chart explaining a driving method of a pixel according to the first embodiment.

The timing chart in FIG. 5 depicts levels of a selection signal (SEL) applied to the gate electrode of the selection transistor **116**, a reset signal (RST) applied to the gate electrode of the reset transistor **112**, and a bias signal (Bias) applied to the gate electrode of the bias transistor **114** in the pixel **100** of the logarithmic sensor (FIG. 4) in time series.

In addition, the timing chart in FIG. 5 depicts levels of a signal (AMP1_S) applied to the source of the amplification transistor **113**, and a signal (VSL) applied to the vertical signal line **121** in time series.

Note that Pre Shutter represents a shutter driving period, Exposure represents an exposure period, and Readout represents a readout period in FIG. 5 similarly to FIG. 2. In addition, it is assumed that a time proceeds in a direction from the left side to the right side in the figure. Periods are shifted in an order of the shutter driving period, the exposure period, and the readout period.

In the shutter driving period, the reset signal (RST) reaches an H level, and the photodiode **111** is reset to a low potential by the reset transistor **112** as depicted in FIG. 5. When light enters at an end of the shutter driving period, the period shifts to the exposure period.

In the exposure period, charges are accumulated in the photodiode **111**. In the exposure period, a signal from the photodiode **111** is applied to the gate of the amplification transistor **113** as the initial-stage amplifier (AMP1), and the applied signal is amplified. Accordingly, the potential of the source (AMP1_S) of the amplification transistor **113** varies as indicated by a dotted line in the figure.

The selection signal (SEL) herein reaches an L level, and the selection transistor **116** comes into an off-state during the

shutter driving period and the exposure period. Accordingly, the bias transistor **114** comes into a state disconnected from the power source voltage Vdd connected to the drain of the amplification transistor **113**. As a result, the through current (the bias current) generated in the pixel **900** of the ordinary logarithmic sensor (FIG. **1**) is cut off. Power consumption of the pixel **100** (FIG. **4**) therefore is more reduced than in the pixel **900** (FIG. **1**). When the entrance of the light ends after completion of the exposure period, the period shifts to the readout period.

In the readout period, the selection signal (SEL) reaches an H level. The charges accumulated in the photodiode **111** are read out by the selection transistor **116**. The charges accumulated in the photodiode **111** are herein initially read out as a signal level (S: Signal) by the selection transistor **116** at a readout time of the D phase (the signal level).

Subsequently, the reset signal (RST) reaches the H level, and the photodiode **111** is reset at a readout time of the P phase (the reset level). In this state, a noise level (N: Noise) is further read out by the selection transistor **116**. A difference (S-N) between the signal level (S) and the noise level (N) thus obtained corresponds to an output signal (Output), and is output to the vertical signal line **121** via the amplification transistor **115** as the second-stage amplifier (AMP2).

At this time, the amplification transistor **115** as the second-stage amplifier (AMP2) is naturally activated by an output of the amplification transistor **113** as the initial-stage amplifier (AMP1) at the time of readout of the D phase in a case where the selection transistor **116** comes into the on-state (the selection signal (SEL) reaches the H level).

Meanwhile, when the selection transistor **116** comes into an off-state (the selection signal (SEL) reaches an L level), the potential of the drain of the bias transistor **114** lowers to a potential near the ground potential (GND). Accordingly, the amplification transistor **115** as the second-stage amplifier (AMP2) is naturally deactivated by a current from the bias transistor **114**. As a result, the two-stage amplifier including the initial-stage amplifier (AMP1) and the second-stage amplifier (AMP2) in the pixel **100** (FIG. **4**) automatically comes into an off-state.

Thereafter, a linear signal (a signal proportional to intensity of light) is output until charges are accumulated in the photodiode **111** in the pixel **100** of the logarithmic sensor (FIG. **4**). When charges are accumulated in the photodiode **111**, a current exponentially flows in accordance with a generated voltage. Accordingly, a logarithmic relation between the voltage and the current is established, wherefore output of a logarithmic signal starts.

According to the pixel **100** of the first embodiment as described above, the selection transistor **116** is provided not on the second-stage amplifier (AMP2) side, but on the initial-stage amplifier (AMP1) side. Accordingly, the bias transistor **114** comes into the state disconnected from the power source voltage Vdd connected to the drain of the amplification transistor **113** when the selection transistor **116** comes into the off-state.

As a result, the through current (the bias current) generated in the pixel **900** of the ordinary logarithmic sensor (FIG. **1**) can be cut off, wherefore more reduction of power consumption is achievable in the pixel **100** of the first embodiment than in the pixel **900** (FIG. **1**). Accordingly, a rise of power consumption does not constitute a parameter limiting an increase in the number of pixels, wherefore an increase in the number of pixels is achievable.

The description of the first embodiment has been now completed.

4. Second Embodiment

(Second Circuit Configuration)

FIG. **6** is a circuit diagram depicting a configuration example of a pixel according to the second embodiment.

The pixel **200** in FIG. **6** includes a photodiode **211**, a reset transistor **212**, an amplification transistor **213**, a bias transistor **214**, an amplification transistor **215**, and a selection transistor **216**.

The photodiode **211** to the selection transistor **216** in the pixel **200** in FIG. **6** are configured similarly to the photodiode **111** to the selection transistor **116** in the pixel **100** in FIG. **4**. However, driving of the bias transistor **214** is different from driving of the bias transistor **114** in FIG. **4**.

More specifically, the pixel **200** in FIG. **6** is different from the pixel **100** in FIG. **4** in that a bias signal (Bias) applied to a gate electrode of the bias transistor **214** is controlled such that the bias transistor **214** is driven to come into an off-state in periods except for the readout period.

(Second Driving Method)

FIG. **7** is a timing chart explaining a driving method of a pixel according to the second embodiment.

The timing chart in FIG. **7** depicts levels of a selection signal (SEL) of the selection transistor **216**, a reset signal (RST) of the reset transistor **212**, and a bias signal (Bias) of the bias transistor **214** in the pixel **200** of the logarithmic sensor (FIG. **6**) in time series. In addition, the timing chart in FIG. **7** depicts levels of a signal (AMP1_S) applied to a source of the amplification transistor **213**, and a signal (VSL) applied to a vertical signal line **221** in time series.

Note that a time in FIG. **7** proceeds in a direction from the left side to the right side in the figure similarly to FIG. **2** and FIG. **5**. Periods are shifted in an order of the shutter driving period (Pre Shutter), the exposure period (Exposure), and the readout period (Readout).

In the shutter driving period, the reset signal (RST) reaches an H level, and the photodiode **211** is reset to a low potential by the reset transistor **212** as depicted in FIG. **7**.

Subsequently, in the exposure period, charges are accumulated in the photodiode **211**. In the exposure period, a signal sent from the photodiode **211** is applied to a gate of the amplification transistor **213** as the initial-stage amplifier (AMP1), and the applied signal is amplified. Accordingly, the potential of the source (AMP1_S) of the amplification transistor **213** varies as indicated by a dotted line in the figure.

At this time, the bias signal (Bias) reaches an L level, and the bias transistor **214** comes into an off-state during the shutter driving period and the exposure period. Accordingly, no bias current flows in the bias transistor **214**. As a result, the through current (the bias current) generated in the pixel **900** of the ordinary logarithmic sensor (FIG. **1**) is cut off. Accordingly, power consumption of the pixel **200** (FIG. **6**) is more reduced than in the pixel **900** (FIG. **1**).

Subsequently, in the readout period, the selection signal (SEL) and the bias signal (Bias) each reach an H level, and the selection transistor **216** and the bias transistor **214** each come into an on-state. Accordingly, the charges accumulated in the photodiode **211** are readout by the selection transistor **216**. The charges accumulated in the photodiode **211** are herein initially read out as a signal level (S) by the selection transistor **216** at the time of readout of the D phase.

Subsequently, the reset signal (RST) reaches the H level, and the photodiode **211** is reset at the readout time of the P

phase. In this state, a noise level (N) is further read out by the selection transistor **216**. A difference (S-N) between the signal level (S) and the noise level (N) thus obtained corresponds to an output signal (Output), and is output to the vertical signal line **221** via the amplification transistor **215** as the second-stage amplifier (AMP2).

At this time, the amplification transistor **215** as the second-stage amplifier (AMP2) is naturally activated by an output of the amplification transistor **213** as the initial-stage amplifier (AMP1) at the time of readout of the D phase in a case where the selection transistor **216** comes into the on-state (the selection signal (SEL) reaches the H level).

Meanwhile, the reset transistor **212** comes into the on-state (the reset signal (RST) reaches the H level), and the photodiode **211** is reset to a low potential at the readout time of the P phase and in a case where the selection transistor **216** comes into the on-state (the selection signal (SEL) reaches the H level). As a result, the amplification transistor **215** as the second-stage amplifier (AMP2) is deactivated.

Thereafter, in a case where the selection transistor **216** comes into the off-state (the selection signal (SEL) reaches the L level), the bias signal (Bias) reaches the L level. In this case, the bias transistor **214** comes into the off-state. Accordingly, no bias current flows in the bias transistor **214**. As a result, the through current is cut off, wherefore power consumption is reduced.

Thereafter, a linear signal (a signal proportional to intensity of light) is output until charges are accumulated in the photodiode **211** in the pixel **200** of the logarithmic sensor (FIG. 6). When charges are accumulated in the photodiode **211**, a current exponentially flows in accordance with a generated voltage. Accordingly, a logarithmic relation between the voltage and the current is established, wherefore output of a logarithmic signal starts.

According to the pixel **200** of the second embodiment as described above, the selection transistor **216** is provided not on the second-stage amplifier (AMP2) side but on the initial-stage amplifier (AMP1) side, and also driving of the bias transistor **214** is controlled. Accordingly, when the selection transistor **216** comes into the off-state, the bias transistor **214** also comes into the off-state. In this case, no bias current flows in the bias transistor **214**.

As a result, the through current (the bias current) generated in the pixel **900** of the ordinary logarithmic sensor (FIG. 1) can be cut off, wherefore more reduction of power consumption is achievable in the pixel **200** of the second embodiment than in the pixel **900** (FIG. 1). Accordingly, a rise of power consumption does not constitute a parameter limiting an increase in the number of pixels, wherefore an increase in the number of pixels is achievable.

The description of the second embodiment has been now completed.

5. Third Embodiment

(Third Circuit Configuration)

FIG. 8 is a circuit diagram depicting a configuration example of a pixel according to the third embodiment.

The pixel **300** in FIG. 8 includes a photodiode and a two-stage amplifier having inversed polarities of transistors with respect to the polarities of the transistors in the pixel **100** depicted in FIG. 4.

More specifically, a photodiode **311**, an amplification transistor **313**, a bias transistor **314**, an amplification transistor **315**, and a selection transistor **316** of the pixel **300** in FIG. 8 have inversed polarities with respect to the polarities of the photodiode **111**, the amplification transistor **113**, the

bias transistor **114**, the amplification transistor **115**, and the selection transistor **116** of the pixel **100** in FIG. 4.

The pixel **300** thus configured includes the photodiode and the two-stage amplifier having inversed polarities of the transistors with respect to the polarities of the transistors in the pixel **100**. In this case, the selection transistor **316** is shifted from the second-stage amplifier (AMP2) side toward the initial-stage amplifier (AMP1) side. Accordingly, a current power within the pixel **300** can be disconnected in periods except for the readout period by an operation of the selection transistor **316** in accordance with the selection signal (SEL). As a result, a through current steadily generated within the pixel **300** can be cut off, wherefore power consumption can be reduced.

In addition, the amplification transistor **315** as the second-stage amplifier (AMP2) in the image **300** is naturally activated by an output of the amplification transistor **313** as the initial-stage amplifier (AMP1) at the time of readout of the D phase in a case where the selection transistor **316** comes into an on-state.

Meanwhile, when the selection transistor **316** comes into an off-state in the image **300**, the potential of the bias transistor **314** lowers to a potential near the ground potential (GND). Accordingly, the amplification transistor **315** as the second-stage amplifier (AMP2) is naturally deactivated by a current from the bias transistor **314**. As a result, the two-stage amplifier including the initial-stage amplifier (AMP1) and the second-stage amplifier (AMP2) in the image **300** automatically comes into an off-state.

Note that the image **300** may be driven such that the bias transistor **314** comes into an off-state in periods except for the readout period by controlling a gate input voltage of the bias transistor **314** similarly to the driving method of the pixel **200** depicted in FIGS. 6 and 7.

The description of the third embodiment has been now completed.

6. Fourth Embodiment

(Fourth Circuit Configuration)

FIG. 9 is a circuit diagram depicting a configuration example of a pixel according to the fourth embodiment.

A pixel **400-1** and a pixel **400-2** in FIG. 9 are presented as an example of a plurality of pixels arranged two-dimensionally on the pixel array unit **11**, and include, as shared components, a bias transistor **414**, and an amplification transistor **415** as the second-stage amplifier (AMP2).

More specifically, the pixel **400-1** includes the bias transistor **414** and the amplification transistor **415** as transistors shared with the pixel **400-2**, in addition to a photodiode **411-1**, a reset transistor **412-1**, an amplification transistor **413-1**, and a selection transistor **416-1**.

In the pixel **400-1** thus configured, the selection transistor **416-1** is shifted toward the initial-stage amplifier (AMP1-1) side similarly to the pixel **100** in FIG. 4. Accordingly, a current source within the pixel **400-1** can be disconnected in periods except for the readout period by an operation of the selection transistor **416-1** in accordance with the selection signal (SEL). As a result, a through current steadily generated within the pixel **400-1** can be cut off, wherefore reduction of power consumption is achievable.

In addition, the amplification transistor **415** as the second-stage amplifier (AMP2) in the pixel **400-1** is naturally activated by an output of the amplification transistor **413-1** as the initial-stage amplifier (AMP1-1) at the time of readout of the D phase in a case where the selection transistor **416-1** comes into an on-state.

Meanwhile, when the selection transistor **416-1** comes into an off-state in the pixel **400-1**, the potential of the bias transistor **414** lowers to a potential near the ground potential (GND). Accordingly, the amplification transistor **415** as the second-stage amplifier (AMP2) is naturally deactivated by a current from the bias transistor **414**. As a result, the two-stage amplifier including the initial-stage amplifier (AMP1-1) and the second-stage amplifier (AMP2) in the image **400-1** automatically comes into an off-state.

In addition, the pixel **400-2** includes the bias transistor **414** and the amplification transistor **415** as transistors shared with the pixel **400-1**, in addition to a photodiode **411-2**, a reset transistor **412-2**, an amplification transistor **413-2**, and a selection transistor **416-2**.

In the pixel **400-2** thus configured, the selection transistor **416-2** is shifted toward the initial-stage amplifier (AMP1-2) side similarly to the pixel **100** in FIG. 4. Accordingly, a current source within the pixel **400-2** can be disconnected in periods except for the readout period by an operation of the selection transistor **416-2** in accordance with the selection signal (SEL). As a result, a through current steadily generated within the pixel **400-2** can be cut off, wherefore reduction of power consumption is achievable.

In addition, the amplification transistor **415** as the second-stage amplifier (AMP2) in the pixel **400-2** is naturally activated by an output of the amplification transistor **413-2** as the initial-stage amplifier (AMP1-2) at the time of readout of the D phase in a case where the selection transistor **416-2** comes into an on-state.

Meanwhile, when the selection transistor **416-2** comes into an off-state in the pixel **400-2**, the potential of the bias transistor **414** lowers to a potential near the ground potential (GND). Accordingly, the amplification transistor **415** as the second-stage amplifier (AMP2) is naturally deactivated by a current from the bias transistor **414**. As a result, the two-stage amplifier including the initial-stage amplifier (AMP1-2) and the second-stage amplifier (AMP2) in the pixel **400-2** automatically comes into an off-state.

Note that the pixel **400-1** and the pixel **400-2** may be each driven such that the bias transistor **314** comes into an off-state in periods except for the readout period by controlling a gate input voltage of the bias transistor **314** similarly to the driving method of the pixel **200** depicted in FIG. 6 and FIG. 7.

In addition, the example of two pixels, i.e., the pixel **400-1** and the pixel **400-2**, has been presented as a unit of shared pixels in FIG. 9. However, for example, the bias transistor and the amplification transistor as the second-stage amplifier (AMP2) may be shared between a larger number of pixels, such as four pixels and eight pixels.

The description of the fourth embodiment has been now completed.

7. Fifth Embodiment

(Fifth Circuit Configuration)

FIG. 10 is a circuit diagram depicting a configuration example of a pixel according to the fifth embodiment.

A pixel **500-1** and a pixel **500-2** in FIG. 10 each include a photodiode and a two-stage amplifier having inversed polarities of the transistors with respect to the polarities of the pixel **400-1** and the pixel **400-2** depicted in FIG. 9, respectively.

More specifically, a photodiode **511-1**, an amplification transistor **513-1**, a selection transistor **516-1**, and a bias transistor **514** and an amplification transistor **515** as transistors shared with the pixel **500-2** in the pixel **500-1** in FIG.

10 have inversed polarities with respect to the polarities of the photodiode **411-1**, the amplification transistor **413-1**, the selection transistor **416-1**, the bias transistor **414**, and the amplification transistor **415** in the pixel **400-1** in FIG. 9.

In the pixel **500-1** thus configured, the selection transistor **516-1** is shifted toward the initial-stage amplifier (AMP1-1) side similarly to the pixel **100** in FIG. 4. Accordingly, a current source within the pixel **500-1** can be disconnected in periods except for the readout period by an operation of the selection transistor **516-1** in accordance with the selection signal (SEL). As a result, a through current steadily generated within the pixel **500-1** can be cut off, wherefore reduction of power consumption is achievable.

In addition, the amplification transistor **515** as the second-stage amplifier (AMP2) in the pixel **500-1** is naturally activated by an output of the amplification transistor **513-1** as the initial-stage amplifier (AMP1-1) at the time of readout of the D phase in a case where the selection transistor **516-1** comes into an on-state.

Meanwhile, when the selection transistor **516-1** comes into an off-state in the pixel **500-1**, the potential of the bias transistor **514** lowers to a potential near the ground potential (GND). Accordingly, the amplification transistor **515** as the second-stage amplifier (AMP2) is naturally deactivated by a current from the bias transistor **514**. As a result, the two-stage amplifier including the initial-stage amplifier (AMP1-1) and the second-stage amplifier (AMP2) in the image **500-1** automatically comes into an off-state.

In addition, a photodiode **511-2**, an amplification transistor **513-2**, a selection transistor **516-2**, and the bias transistor **514** and the amplification transistor **515** as transistors shared with the pixel **500-1** in the pixel **500-2** in FIG. 10 have inversed polarities with respect to the polarities of the photodiode **411-2**, the amplification transistor **413-2**, the selection transistor **416-2**, the bias transistor **414**, and the amplification transistor **415** in the pixel **400-2** in FIG. 9.

In the pixel **500-2** thus configured, the selection transistor **516-2** is shifted toward the initial-stage amplifier (AMP1-2) side similarly to the pixel **100** in FIG. 4. Accordingly, a current source within the pixel **500-2** can be disconnected in periods except for the readout period by an operation of the selection transistor **516-2** in accordance with the selection signal (SEL). As a result, a through current steadily generated within the pixel **500-2** can be cut off, wherefore reduction of power consumption is achievable.

In addition, the amplification transistor **515** as the second-stage amplifier (AMP2) in the pixel **500-2** is naturally activated by an output of the amplification transistor **513-2** as the initial-stage amplifier (AMP1-2) at the time of readout of the D phase in a case where the selection transistor **516-2** comes into an on-state.

Meanwhile, when the selection transistor **516-2** comes into an off-state in the pixel **500-2**, the potential of the bias transistor **514** lowers to a potential near the ground potential (GND). Accordingly, the amplification transistor **515** as the second-stage amplifier (AMP2) is naturally deactivated by a current from the bias transistor **514**. As a result, the two-stage amplifier including the initial-stage amplifier (AMP1-2) and the second-stage amplifier (AMP2) in the pixel **500-2** automatically comes into an off-state.

The description of the fifth embodiment has been now completed.

8. Configuration Example of Electronic Apparatus Including Solid-State Imaging Device to which Technology of Present Disclosure has been Applied

FIG. 11 is a block diagram depicting a configuration example of an electronic apparatus **1000** including a solid-

state imaging device to which the technology according to the present disclosure has been applied.

For example, the electronic apparatus **1000** is an electronic apparatus such as an imaging device including a digital still camera and a video camera, and a portable terminal device including a smartphone and a tablet type terminal.

The electronic apparatus **1000** includes a solid-state imaging element **1001**, a DSP circuit **1002**, a frame memory **1003**, a display unit **1004**, a recording unit **1005**, an operation unit **1006**, and a power supply unit **1007**. In addition, the DSP circuit **1002**, the frame memory **1003**, the display unit **1004**, the recording unit **1005**, the operation unit **1006**, and the power supply unit **1007** in the electronic apparatus **1000** are connected to each other via a bus line **1008**.

The solid-state imaging element **1001** corresponds to the solid-state imaging device **10** (FIG. 3) described above. For example, the pixel **100** disposed on the pixel array unit **11** has the configuration depicted in FIG. 4 and other figures. More specifically, the pixel **100** (or any one of the pixel **200** to the pixel **500**) which includes the selection transistor **116** (or any one of the selection transistor **216** to the selection transistor **516**) shifted from the second-stage amplifier (AMP2) side to the initial-stage amplifier (AMP1) side is arranged on the pixel array unit **11** of the solid-state imaging device **10**.

The DSP circuit **1002** is a camera signal processing circuit which processes a signal supplied from the solid-state imaging element **1001**. The DSP circuit **1002** outputs image data obtained by processing the signal received from the solid-state imaging element **1001**. The frame memory **1003** temporarily retains the image data processed by the DSP circuit **1002** in units of a frame.

For example, the display unit **1004** includes a panel type display device such as a liquid crystal panel and an organic EL (Electro Luminescence) panel, and displays a moving image or a still image captured by the solid-state imaging element **1001**. The recording unit **1005** records the image data such as a moving image and a still image captured by the solid-state imaging element **1001** in a recording medium such as a semiconductor memory, a hard disk or the like.

The operation unit **1006** outputs operation commands associated with various types of functions of the electronic apparatus **1000** in accordance with an operation by a user. The power supply unit **1007** appropriately supplies various types of power sources to supply targets, i.e., the DSP circuit **1002**, the frame memory **1003**, the display unit **1004**, the recording unit **1005**, and the operation unit **1006**, as operation power sources of these supply targets.

The electronic apparatus **1000** is configured as described above. The technology according to the present disclosure is applied to the solid-state imaging element **1001** as described above. More specifically, the solid-state imaging device **10** in FIG. 3 is applicable to the solid-state imaging element **1001**. For example, reduction of power consumption of pixels, and an increase in the number of pixels are achievable by applying the technology according to the present disclosure to the solid-state imaging element **1001**. Accordingly, a higher quality image can be captured.

9. Cross-Sectional Configuration Example of Solid-State Imaging Device to which Technology of Present Disclosure is Applicable

FIG. 12 is a cross-sectional view depicting a configuration example of a solid-state imaging device to which the technology according to the present disclosure is applicable.

According to the solid-state imaging device, a PD (photodiode) **20019** constituting a pixel **20010** receives incident light **20001** entering from the rear surface (the upper surface in the figure) side of a semiconductor substrate **20018**. A flattened film **20013**, a CF (color filter) **20012**, and a microlens **20011** are provided above the PD **20019**. The incident light **20001** sequentially entering the PD **20019** via respective parts is received at a light receiving surface **20017**, and photoelectrically converted in the PD **20019**.

For example, the PD **20019** includes an n-type semiconductor region **20020** formed as a charge accumulation region where charges (electrons) are accumulated. The n-type semiconductor region **20020** in the PD **20019** is provided inside p-type semiconductor regions **20016** and **20041** of the semiconductor substrate **20018**. The p-type semiconductor region **20041** is provided on the front surface (the lower surface) side of the semiconductor substrate **20018** in the n-type semiconductor region **20020**. The p-type semiconductor region **20041** has a higher impurity concentration than an impurity concentration on the rear surface (the upper surface) side. Accordingly, the PD **20019** has a HAD (Hole-Accumulation Diode) structure. The p-type semiconductor regions **20016** and **20041** are formed in such a manner as to reduce generation of a dark current in each of interfaces on the upper surface side and the lower surface side of the n-type semiconductor region **20020**.

Pixel separation portions **20030** are provided inside the semiconductor substrate **20018** to electrically separate the plurality of pixels **20010** from each other. The PD **20019** is provided in each of regions sectioned by the pixel separation portions **20030**. In a case where the solid-state imaging device is viewed from the upper surface side in the figure, the pixel separation portions **20030** are formed in a grid shape and are each interposed between the plurality of pixels **20010**. The PD **20019** is formed within each of the regions sectioned by the pixel separation portions **20030**.

Each anode of the respective PDs **20019** is grounded. Signal charges (e.g., electrons) accumulated in the PD **20019** in the solid-state imaging device are read out via a not-depicted transfer Tr (MOS FET) or the like, and output to a not-depicted VSL (vertical signal line) as an electric signal.

A wiring layer **20050** is provided on the front surface (the lower surface) of the semiconductor substrate **20018** on the side opposite to the rear surface (the upper surface) on which respective parts such as a light shield film **20014**, the CF **20012**, and the microlens **20011** are provided.

The wiring layer **20050** includes wires **20051** and an insulation layer **20052**, and is formed such that the wires **20051** are electrically connected to respective elements within the insulation layer **20052**. The wiring layer **20050** is a so-called multilayer wiring layer, and formed by alternately laminating the wires **20051** and interlayer insulation films constituting the insulation layer **20052** a plurality of times. The wires **20051** herein include a wire to a transfer Tr or other Trs for reading charges from the PD **20019**, and other wires such as a VSL each laminated via the insulation layer **20052**.

A support substrate **20061** is provided on a surface of the wiring layer **20050** on the side opposite to the side where the PD **20019** is provided. For example, a substrate including a silicon semiconductor having a thickness of several hundreds of μm is provided as the support substrate **20061**.

The light shield film **20014** is provided on the rear surface (the upper surface in the figure) side of the semiconductor substrate **20018**.

The light shield film **20014** is configured to shield a part of the incident light **20001** traveling from an upper part of

the semiconductor substrate **20018** toward a lower part of the semiconductor substrate **20018**.

The light shield film **20014** is provided above the pixel separation portion **20030** disposed inside the semiconductor substrate **20018**. The light shield film **20014** herein is provided on the rear surface (the upper surface) of the semiconductor substrate **20018** in such a condition as to protrude from the semiconductor substrate **20018** in a shape of a projection via the insulation film **20015** such as a silicon oxide film. On the other hand, a portion above the PD **20019** provided inside the semiconductor substrate **20018** is not equipped with the light shield film **20014**, but is opened to allow entrance of the incident light **20001** into the PD **20019**.

More specifically, in a case where the solid-state imaging device is viewed from the upper surface side in the figure, the light shield film **20014** has a grid planar shape, and has an opening through which the incident light **20001** passes toward the light receiving surface **20017**.

The light shield film **20014** includes a light shielding material which shields light. For example, the light shield film **20014** is formed by sequentially laminating a titanium (Ti) film and a tungsten (W) film. Alternatively, the light shield film **20014** may be formed by sequentially laminating a titanium nitride (TiN) film and a tungsten (W) film, for example. In addition, the light shield film **20014** may be covered with nitride (N) or the like.

The light shield film **20014** is covered with the flattened film **20013**. The flattened film **20013** includes an insulation material which transmits light.

The pixel separation portion **20030** includes a groove **20031**, a fixed charge film **20032**, and an insulation film **20033**.

The fixed charge film **20032** is so formed as to cover the groove **20031** which separates the plurality of pixels **20010** from each other on the rear surface (the upper surface) side of the semiconductor substrate **20018**.

More specifically, the fixed charge film **20032** is provided in such a condition as to cover an inner surface of the groove **20031** formed on the rear surface (the upper surface) side of the semiconductor substrate **20018** with a fixed thickness. In addition, the insulation film **20033** is provided so as to be buried in the inside of the groove **20031** covered with the fixed charge film **20032** (the inside of the groove **20031** is filled with the insulation film **20033**).

The fixed charge film **20032** herein is formed by using a high dielectric which has negative fixed charges to form a positive charge (hole) accumulation region in an interface portion with the semiconductor substrate **20018** and thereby reduce generation of a dark current. In the state that the fixed charge film **20032** having negative fixed charges is formed, these negative fixed charges add an electric field to the interface with the semiconductor substrate **20018**, and form a positive charge (hole) accumulation region.

For example, the fixed charge film **20032** may be formed by a hafnium oxide film (HfO₂ film). Alternatively, the fixed charge film **20032** may include at least one of oxides such as hafnium, zirconium, aluminum, tantalum, titanium, magnesium, yttrium, and lanthanoid, for example.

The technology according to the present disclosure is applicable to the solid-state imaging device described above.

10. Configuration Example of Stacked Solid-State Imaging Device to which Technology of Present Disclosure is Applicable

FIGS. **13A**, **13B**, and **13C** are diagrams depicting an outline of a configuration example of a stacked solid-state

imaging device to which the technology according to the present disclosure is applicable.

FIG. **13A** depicts a schematic configuration example of a non-stacked solid-state imaging device. As depicted in FIG. **13A**, a solid-state imaging device **23010** includes one die (semiconductor substrate) **23011**. A pixel region **23012** including pixels arranged in an array, a control circuit **23013** performing various controls such as pixel driving, and a logic circuit **23014** for processing signals are mounted on the die **23011**.

FIGS. **13B** and **13C** each depict a schematic configuration example of a stacked solid-state imaging device. As depicted in FIGS. **13B** and **13C**, a solid-state imaging device **23020** includes two dies, i.e., a sensor die **23021** and a logic die **23024** stacked on and electrically connected to each other, and constitutes one semiconductor chip.

FIG. **13B**, the pixel region **23012** and the control circuit **23013** are mounted on the sensor die **23021**, while the logic circuit **23014** which includes a signal processing circuit performing signal processing is mounted on the logic die **23024**.

FIG. **13C**, the pixel region **23012** is mounted on the sensor die **23021**, while the control circuit **23013** and the logic circuit **23014** are mounted on the logic die **23024**.

FIG. **14** is a cross-sectional view depicting a first configuration example of the stacked solid-state imaging device **23020**.

The sensor die **23021** includes a PD (photodiode) which constitutes pixels corresponding to the pixel region **23012**, an FD (floating diffusion), Trs (MOS FETs), and Trs constituting the control circuit **23013**, and others. The sensor die **23021** further includes a wiring layer **23101** which includes wiring **23110** having a plurality of layers, or three layers in the present embodiment. Note that the control circuit **23013** (Trs constituting the control circuit **23013**) may be provided not on the sensor die **23021** but on the logic die **23024**.

The logic die **23024** includes Trs constituting the logic circuit **23014**. The logic die **23024** further includes a wiring layer **23161** which includes wiring **23170** having a plurality of layers, or three layers in the present embodiment. The logic die **23024** further includes a connection hole **23171** on an inner wall surface of which an insulation film **23172** is formed. A connection conductor **23173** connected to the wiring **23170** and the like is embedded in the connection hole **23171**.

The sensor die **23021** and the logic die **23024** are affixed to each other in such a manner that the wiring layer **23101** of the sensor die **23021** and the wiring layer **23161** of the logic die **23024** face each other to thereby constitute the stacked solid-state imaging device **23020** including the sensor die **23021** and the logic die **23024** stacked on each other. A film **23191** such as a protection film is provided on affixing surfaces of the sensor die **23021** and the logic die **23024**.

The sensor die **23021** includes a connection hole **23111** which extends from the rear surface side (the light entrance side into the PD) (upper side) of the sensor die **23021**, penetrates the sensor die **23021**, and reaches the wiring **23170** on the uppermost layer of the logic die **23024**. The sensor die **23021** further includes a connection hole **23121** which is located in the vicinity of the connection hole **23111**, and reaches the wiring **23110** on the first layer from the rear surface side of the sensor die **23021**. An insulation film **23112** is formed on an inner wall surface of the connection hole **23111**, while an insulation film **23122** is formed on an inner wall surface of the connection hole **23121**. In addition, connection conductors **23113** and **23123** are embedded in

21

the connection holes **23111** and **23121**, respectively. The connection conductor **23113** and the connection conductor **23123** are electrically connected to each other on the rear surface side of the sensor die **23021**. In this manner, the sensor die **23021** and the logic die **23024** are electrically connected to each other via the wiring layer **23101**, the connection hole **23121**, the connection hole **23111**, and the wiring layer **23161**.

FIG. **15** is a cross-sectional view depicting a second configuration example of the stacked solid-state imaging device **23020**.

According to the second configuration example of the solid-state imaging device **23020**, ((the wiring **23110** of) the wiring layer **23101** of) the sensor die **23021** and ((the wiring **23170** of) the wiring layer **23161** of) the logic die **23024** are electrically connected to each other by one connection hole **23211** formed in the sensor die **23021**.

More specifically, in FIG. **15**, the connection hole **23211** is so formed as to extend from the rear surface side of the sensor die **23021**, penetrate the sensor die **23021**, and reach the wiring **23170** in the uppermost layer of the logic die **23024**, and also reach the wiring **23110** in the uppermost layer of the sensor die **23021**. An insulation film **23212** is formed on an inner wall surface of the connection hole **23211**, and a connection conductor **23213** is embedded in the connection hole **23211**. In FIG. **4** described above, the sensor die **23021** and the logic die **23024** are electrically connected to each other via the two connection holes **23111** and **23121**. In FIG. **15**, however, the sensor die **23021** and the logic die **23024** are electrically connected to each other via the one connection hole **23211**.

FIG. **16** is a cross-sectional view depicting a third configuration example of the stacked solid-state imaging device **23020**.

The solid-state imaging device **23020** in FIG. **16** does not include the film **23191**, such as a protection film, on the affixing surfaces of the sensor die **23021** and the logic die **23024**, and therefore is different from the case of FIG. **14** in which the film **23191**, such as a protection film, is provided on the affixing surfaces of the sensor die **23021** and the logic die **23024**.

For constituting the solid-state imaging device **23020** in FIG. **16**, the sensor die **23021** and the logic die **23024** are overlapped with each other with a direct contact between the wiring **23110** and the wiring **23170**. Thereafter, the sensor die **23021** and the logic die **23024** are heated with a predetermined load applied, and the wiring **23110** and the wiring **23170** are directly joined.

FIG. **17** is a cross-sectional view depicting another configuration example of a stacked solid-state imaging device to which the technology according to the present disclosure is applicable.

A solid-state imaging device **23401** in FIG. **17** has a three-layer stacked structure which includes three stacked dies, i.e., a sensor die **23411**, a logic die **23412**, and a memory die **23413**.

For example, the memory die **23413** has a memory circuit which stores data temporarily needed for signal processing performed by the logic die **23412**.

In FIG. **17**, the logic die **23412** and the memory die **23413** are stacked in this order below the sensor die **23411**. However, the logic die **23412** and the memory die **23413** may be stacked in a reverse order, i.e., in the order of the memory die **23413** and the logic die **23412**, below the sensor die **23411**.

22

Note that the sensor die **23411** in FIG. **17** includes a PD corresponding to a photoelectric conversion unit for pixels, and a source/drain region for a pixel Tr.

A gate electrode is provided around the PD via a gate insulation film. A pixel Tr **23421** and a pixel Tr **23422** each include the gate electrode and a pair of source and drain regions.

The pixel Tr **23421** adjacent to the PD corresponds to a transfer Tr. One of the pair of source and drain regions constituting the pixel Tr **23421** corresponds to an FD.

In addition, an interlayer insulation film is provided on the sensor die **23411**. A connection hole is formed in the interlayer insulation film. A connection conductor **23431** connected to the pixel Tr **23421** and the pixel Tr **23422** is provided in the connection hole.

The sensor die **23411** further includes a wiring layer **23433** which includes wiring **23432** having a plurality of layers and connected to the respective connection conductors **23431**.

An aluminum pad **23434** corresponding to an electrode for external connection is further provided in the lowermost layer of the wiring layer **23433** of the sensor die **23411**. More specifically, the aluminum pad **23434** of the sensor die **23411** is disposed at a position closer to a bonding surface **23440** with the logic die **23412** than the wiring **23432** is. The aluminum pad **23434** is provided as one end of wiring associated with input and output of signals to and from the outside.

The sensor die **23411** further includes a contact **23441** provided for electric connection with the logic die **23412**. The contact **23441** is connected to a contact **23451** of the logic die **23412**, and also connected to the aluminum pad **23442** of the sensor die **23411**.

The sensor die **23411** further includes a pad hole **23443** which extends from the rear surface side (the upper side) of the sensor die **23411** and reaches the aluminum pad **23442**.

The technology according to the present disclosure is applicable to the solid-state imaging device described above.

11. Example of Application to Mobile Body

The technology according to the present disclosure (present technology) is applicable to various products. For example, the technology according to the present disclosure may be practiced in the form of a device mounted on a mobile body of any one of types such as a car, an electric car, a hybrid electric car, a motorcycle, a bicycle, a personal mobility, an airplane, a drone, a vessel, and a robot.

FIG. **18** is a block diagram depicting an example of schematic configuration of a vehicle control system as an example of a mobile body control system to which the technology according to an embodiment of the present disclosure can be applied.

The vehicle control system **12000** includes a plurality of electronic control units connected to each other via a communication network **12001**. In the example depicted in FIG. **18**, the vehicle control system **12000** includes a driving system control unit **12010**, a body system control unit **12020**, an outside-vehicle information detecting unit **12030**, an in-vehicle information detecting unit **12040**, and an integrated control unit **12050**. In addition, a microcomputer **12051**, a sound/image output section **12052**, and a vehicle-mounted network interface (I/F) **12053** are illustrated as a functional configuration of the integrated control unit **12050**.

The driving system control unit **12010** controls the operation of devices related to the driving system of the vehicle in accordance with various kinds of programs. For example,

the driving system control unit **12010** functions as a control device for a driving force generating device for generating the driving force of the vehicle, such as an internal combustion engine, a driving motor, or the like, a driving force transmitting mechanism for transmitting the driving force to wheels, a steering mechanism for adjusting the steering angle of the vehicle, a braking device for generating the braking force of the vehicle, and the like.

The body system control unit **12020** controls the operation of various kinds of devices provided to a vehicle body in accordance with various kinds of programs. For example, the body system control unit **12020** functions as a control device for a keyless entry system, a smart key system, a power window device, or various kinds of lamps such as a headlamp, a backup lamp, a brake lamp, a turn signal, a fog lamp, or the like. In this case, radio waves transmitted from a mobile device as an alternative to a key or signals of various kinds of switches can be input to the body system control unit **12020**. The body system control unit **12020** receives these input radio waves or signals, and controls a door lock device, the power window device, the lamps, or the like of the vehicle.

The outside-vehicle information detecting unit **12030** detects information about the outside of the vehicle including the vehicle control system **12000**. For example, the outside-vehicle information detecting unit **12030** is connected with an imaging section **12031**. The outside-vehicle information detecting unit **12030** makes the imaging section **12031** image an image of the outside of the vehicle, and receives the imaged image. On the basis of the received image, the outside-vehicle information detecting unit **12030** may perform processing of detecting an object such as a human, a vehicle, an obstacle, a sign, a character on a road surface, or the like, or processing of detecting a distance thereto.

The imaging section **12031** is an optical sensor that receives light, and which outputs an electric signal corresponding to a received light amount of the light. The imaging section **12031** can output the electric signal as an image, or can output the electric signal as information about a measured distance. In addition, the light received by the imaging section **12031** may be visible light, or may be invisible light such as infrared rays or the like.

The in-vehicle information detecting unit **12040** detects information about the inside of the vehicle. The in-vehicle information detecting unit **12040** is, for example, connected with a driver state detecting section **12041** that detects the state of a driver. The driver state detecting section **12041**, for example, includes a camera that images the driver. On the basis of detection information input from the driver state detecting section **12041**, the in-vehicle information detecting unit **12040** may calculate a degree of fatigue of the driver or a degree of concentration of the driver, or may determine whether the driver is dozing.

The microcomputer **12051** can calculate a control target value for the driving force generating device, the steering mechanism, or the braking device on the basis of the information about the inside or outside of the vehicle which information is obtained by the outside-vehicle information detecting unit **12030** or the in-vehicle information detecting unit **12040**, and output a control command to the driving system control unit **12010**. For example, the microcomputer **12051** can perform cooperative control intended to implement functions of an advanced driver assistance system (ADAS) which functions include collision avoidance or shock mitigation for the vehicle, following driving based on a following distance, vehicle speed maintaining driving, a

warning of collision of the vehicle, a warning of deviation of the vehicle from a lane, or the like.

In addition, the microcomputer **12051** can perform cooperative control intended for automatic driving, which makes the vehicle to travel autonomously without depending on the operation of the driver, or the like, by controlling the driving force generating device, the steering mechanism, the braking device, or the like on the basis of the information about the outside or inside of the vehicle which information is obtained by the outside-vehicle information detecting unit **12030** or the in-vehicle information detecting unit **12040**.

In addition, the microcomputer **12051** can output a control command to the body system control unit **12020** on the basis of the information about the outside of the vehicle which information is obtained by the outside-vehicle information detecting unit **12030**. For example, the microcomputer **12051** can perform cooperative control intended to prevent a glare by controlling the headlamp so as to change from a high beam to a low beam, for example, in accordance with the position of a preceding vehicle or an oncoming vehicle detected by the outside-vehicle information detecting unit **12030**.

The sound/image output section **12052** transmits an output signal of at least one of a sound and an image to an output device capable of visually or auditorily notifying information to an occupant of the vehicle or the outside of the vehicle. In the example of FIG. **18**, an audio speaker **12061**, a display section **12062**, and an instrument panel **12063** are illustrated as the output device. The display section **12062** may, for example, include at least one of an on-board display and a head-up display.

FIG. **19** is a diagram depicting an example of the installation position of the imaging section **12031**.

In FIG. **19**, the imaging section **12031** includes imaging sections **12101**, **12102**, **12103**, **12104**, and **12105**.

The imaging sections **12101**, **12102**, **12103**, **12104**, and **12105** are, for example, disposed at positions on a front nose, sideview mirrors, a rear bumper, and a back door of the vehicle **12100** as well as a position on an upper portion of a windshield within the interior of the vehicle. The imaging section **12101** provided to the front nose and the imaging section **12105** provided to the upper portion of the windshield within the interior of the vehicle obtain mainly an image of the front of the vehicle **12100**. The imaging sections **12102** and **12103** provided to the sideview mirrors obtain mainly an image of the sides of the vehicle **12100**. The imaging section **12104** provided to the rear bumper or the back door obtains mainly an image of the rear of the vehicle **12100**. The imaging section **12105** provided to the upper portion of the windshield within the interior of the vehicle is used mainly to detect a preceding vehicle, a pedestrian, an obstacle, a signal, a traffic sign, a lane, or the like.

Incidentally, FIG. **19** depicts an example of photographing ranges of the imaging sections **12101** to **12104**. An imaging range **12111** represents the imaging range of the imaging section **12101** provided to the front nose. Imaging ranges **12112** and **12113** respectively represent the imaging ranges of the imaging sections **12102** and **12103** provided to the sideview mirrors. An imaging range **12114** represents the imaging range of the imaging section **12104** provided to the rear bumper or the back door. A bird's-eye image of the vehicle **12100** as viewed from above is obtained by superimposing image data imaged by the imaging sections **12101** to **12104**, for example.

At least one of the imaging sections **12101** to **12104** may have a function of obtaining distance information. For

example, at least one of the imaging sections **12101** to **12104** may be a stereo camera constituted of a plurality of imaging elements, or may be an imaging element having pixels for phase difference detection.

For example, the microcomputer **12051** can determine a distance to each three-dimensional object within the imaging ranges **12111** to **12114** and a temporal change in the distance (relative speed with respect to the vehicle **12100**) on the basis of the distance information obtained from the imaging sections **12101** to **12104**, and thereby extract, as a preceding vehicle, a nearest three-dimensional object in particular that is present on a traveling path of the vehicle **12100** and which travels in substantially the same direction as the vehicle **12100** at a predetermined speed (for example, equal to or more than 0 km/hour). Further, the microcomputer **12051** can set a following distance to be maintained in front of a preceding vehicle in advance, and perform automatic brake control (including following stop control), automatic acceleration control (including following start control), or the like. It is thus possible to perform cooperative control intended for automatic driving that makes the vehicle travel autonomously without depending on the operation of the driver or the like.

For example, the microcomputer **12051** can classify three-dimensional object data on three-dimensional objects into three-dimensional object data of a two-wheeled vehicle, a standard-sized vehicle, a large-sized vehicle, a pedestrian, a utility pole, and other three-dimensional objects on the basis of the distance information obtained from the imaging sections **12101** to **12104**, extract the classified three-dimensional object data, and use the extracted three-dimensional object data for automatic avoidance of an obstacle. For example, the microcomputer **12051** identifies obstacles around the vehicle **12100** as obstacles that the driver of the vehicle **12100** can recognize visually and obstacles that are difficult for the driver of the vehicle **12100** to recognize visually. Then, the microcomputer **12051** determines a collision risk indicating a risk of collision with each obstacle. In a situation in which the collision risk is equal to or higher than a set value and there is thus a possibility of collision, the microcomputer **12051** outputs a warning to the driver via the audio speaker **12061** or the display section **12062**, and performs forced deceleration or avoidance steering via the driving system control unit **12010**. The microcomputer **12051** can thereby assist in driving to avoid collision.

At least one of the imaging sections **12101** to **12104** may be an infrared camera that detects infrared rays. The microcomputer **12051** can, for example, recognize a pedestrian by determining whether or not there is a pedestrian in imaged images of the imaging sections **12101** to **12104**. Such recognition of a pedestrian is, for example, performed by a procedure of extracting characteristic points in the imaged images of the imaging sections **12101** to **12104** as infrared cameras and a procedure of determining whether or not it is the pedestrian by performing pattern matching processing on a series of characteristic points representing the contour of the object. When the microcomputer **12051** determines that there is a pedestrian in the imaged images of the imaging sections **12101** to **12104**, and thus recognizes the pedestrian, the sound/image output section **12052** controls the display section **12062** so that a square contour line for emphasis is displayed so as to be superimposed on the recognized pedestrian. The sound/image output section **12052** may also control the display section **12062** so that an icon or the like representing the pedestrian is displayed at a desired position.

The description of the example of the vehicle control system to which the technology according to the present

disclosure is applicable has been now completed. The technology according to the present disclosure is applicable to the imaging section **12101** in the configuration described above. More specifically, the solid-state imaging device **10** in FIG. **3** is applicable to the imaging section **12101**. For example, reduction of power consumption of pixels and an increase in the number of pixels are achievable by applying the technology according to the present disclosure to the imaging section **12101**. Accordingly, a higher quality image can be captured, wherefore an obstacle such as a pedestrian can be more accurately recognized.

12. Example of Application to In-Vivo Information Acquisition System

The technology according to the present disclosure (present technology) is applicable to various products. For example, the technology according to the present disclosure may be applied to an endoscopic surgery system.

FIG. **20** is a block diagram depicting an example of a schematic configuration of an in-vivo information acquisition system of a patient using a capsule type endoscope, to which the technology according to an embodiment of the present disclosure (present technology) can be applied.

The in-vivo information acquisition system **10001** includes a capsule type endoscope **10100** and an external controlling apparatus **10200**.

The capsule type endoscope **10100** is swallowed by a patient at the time of inspection. The capsule type endoscope **10100** has an image pickup function and a wireless communication function and successively picks up an image of the inside of an organ such as the stomach or an intestine (hereinafter referred to as in-vivo image) at predetermined intervals while it moves inside of the organ by peristaltic motion for a period of time until it is naturally discharged from the patient. Then, the capsule type endoscope **10100** successively transmits information of the in-vivo image to the external controlling apparatus **10200** outside the body by wireless transmission.

The external controlling apparatus **10200** integrally controls operation of the in-vivo information acquisition system **10001**. Further, the external controlling apparatus **10200** receives information of an in-vivo image transmitted thereto from the capsule type endoscope **10100** and generates image data for displaying the in-vivo image on a display apparatus (not depicted) on the basis of the received information of the in-vivo image.

In the in-vivo information acquisition system **10001**, an in-vivo image imaged a state of the inside of the body of a patient can be acquired at any time in this manner for a period of time until the capsule type endoscope **10100** is discharged after it is swallowed.

A configuration and functions of the capsule type endoscope **10100** and the external controlling apparatus **10200** are described in more detail below.

The capsule type endoscope **10100** includes a housing **10101** of the capsule type, in which a light source unit **10111**, an image pickup unit **10112**, an image processing unit **10113**, a wireless communication unit **10114**, a power feeding unit **10115**, a power supply unit **10116** and a control unit **10117** are accommodated.

The light source unit **10111** includes a light source such as, for example, a light emitting diode (LED) and irradiates light on an image pickup field-of-view of the image pickup unit **10112**.

The image pickup unit **10112** includes an image pickup element and an optical system including a plurality of lenses

provided at a preceding stage to the image pickup element. Reflected light (hereinafter referred to as observation light) of light irradiated on a body tissue which is an observation target is condensed by the optical system and introduced into the image pickup element. In the image pickup unit **10112**, the incident observation light is photoelectrically converted by the image pickup element, by which an image signal corresponding to the observation light is generated. The image signal generated by the image pickup unit **10112** is provided to the image processing unit **10113**.

The image processing unit **10113** includes a processor such as a central processing unit (CPU) or a graphics processing unit (GPU) and performs various signal processes for an image signal generated by the image pickup unit **10112**. The image processing unit **10113** provides the image signal for which the signal processes have been performed thereby as RAW data to the wireless communication unit **10114**.

The wireless communication unit **10114** performs a predetermined process such as a modulation process for the image signal for which the signal processes have been performed by the image processing unit **10113** and transmits the resulting image signal to the external controlling apparatus **10200** through an antenna **10114A**. Further, the wireless communication unit **10114** receives a control signal relating to driving control of the capsule type endoscope **10100** from the external controlling apparatus **10200** through the antenna **10114A**. The wireless communication unit **10114** provides the control signal received from the external controlling apparatus **10200** to the control unit **10117**.

The power feeding unit **10115** includes an antenna coil for power reception, a power regeneration circuit for regenerating electric power from current generated in the antenna coil, a voltage booster circuit and so forth. The power feeding unit **10115** generates electric power using the principle of non-contact charging.

The power supply unit **10116** includes a secondary battery and stores electric power generated by the power feeding unit **10115**. In FIG. 20, in order to avoid complicated illustration, an arrow mark indicative of a supply destination of electric power from the power supply unit **10116** and so forth are omitted. However, electric power stored in the power supply unit **10116** is supplied to and can be used to drive the light source unit **10111**, the image pickup unit **10112**, the image processing unit **10113**, the wireless communication unit **10114** and the control unit **10117**.

The control unit **10117** includes a processor such as a CPU and suitably controls driving of the light source unit **10111**, the image pickup unit **10112**, the image processing unit **10113**, the wireless communication unit **10114** and the power feeding unit **10115** in accordance with a control signal transmitted thereto from the external controlling apparatus **10200**.

The external controlling apparatus **10200** includes a processor such as a CPU or a GPU, a microcomputer, a control board or the like in which a processor and a storage element such as a memory are mixedly incorporated. The external controlling apparatus **10200** transmits a control signal to the control unit **10117** of the capsule type endoscope **10100** through an antenna **10200A** to control operation of the capsule type endoscope **10100**. In the capsule type endoscope **10100**, an irradiation condition of light upon an observation target of the light source unit **10111** can be changed, for example, in accordance with a control signal from the external controlling apparatus **10200**. Further, an image pickup condition (for example, a frame rate, an

exposure value or the like of the image pickup unit **10112**) can be changed in accordance with a control signal from the external controlling apparatus **10200**. Further, the substance of processing by the image processing unit **10113** or a condition for transmitting an image signal from the wireless communication unit **10114** (for example, a transmission interval, a transmission image number or the like) may be changed in accordance with a control signal from the external controlling apparatus **10200**.

Further, the external controlling apparatus **10200** performs various image processes for an image signal transmitted thereto from the capsule type endoscope **10100** to generate image data for displaying a picked up in-vivo image on the display apparatus. As the image processes, various signal processes can be performed such as, for example, a development process (demosaic process), an image quality improving process (bandwidth enhancement process, a super-resolution process, a noise reduction (NR) process and/or image stabilization process) and/or an enlargement process (electronic zooming process). The external controlling apparatus **10200** controls driving of the display apparatus to cause the display apparatus to display a picked up in-vivo image on the basis of generated image data. Alternatively, the external controlling apparatus **10200** may also control a recording apparatus (not depicted) to record generated image data or control a printing apparatus (not depicted) to output generated image data by printing.

Description of the example of the in-vivo information acquisition system to which the technology according to the present disclosure is applicable has been now completed. The technology according to the present disclosure is applicable to the image pickup unit **10112** in the configuration described above. More specifically, the solid-state imaging device **10** in FIG. 3 is applicable to the image pickup unit **10112**. For example, reduction of power consumption of pixels and an increase in the number of pixels are achievable by applying the technology according to the present disclosure to the image pickup unit **10112**. Accordingly, a higher quality image can be captured, wherefore more accurate in-vivo information associated with a patient can be acquired.

Note that the technology according to the present disclosure (present technology) is not limited to the embodiments described above, but may be modified in various manners without departing from the scope of the subject matters of the technology according to present disclosure.

In addition, the technology according to the present disclosure may have following configurations.

(1)

A solid-state imaging device including:

a pixel array unit that includes pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired, each of the pixels including

a photoelectric conversion unit,

a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal,

a first amplification transistor that amplifies a signal received from the photoelectric conversion unit,

a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal,

a second amplification transistor that amplifies a signal received from the selection transistor, and applies the amplified signal to a vertical signal line, and

a bias transistor that is connected to the selection transistor and the second amplification transistor, and functions as a current source,

in which the first amplification transistor and the second amplification transistor are each connected to a power source voltage.

(2)

The solid-state imaging device according to (1) described above, in which

a gate of the first amplification transistor is connected to the photoelectric conversion unit,

a source of the first amplification transistor is connected to a drain of the selection transistor,

a drain of the first amplification transistor is connected to the power source voltage,

a gate of the second amplification transistor is connected to a source of the selection transistor,

a source of the second amplification transistor is connected to the vertical signal line, and

a drain of the second amplification transistor is connected to the power source voltage.

(3)

The solid-state imaging device according to (2) described above, in which

a source of the bias transistor is grounded, and

a drain of the bias transistor is connected to the source of the selection transistor and the gate of the second amplification transistor.

(4)

The solid-state imaging device according to (3) described above, in which

the reset transistor is so driven as to come into an on-state at a readout time of a reset level during a shutter driving period before an exposure period, and a readout period after the exposure period, and

the selection transistor is so driven as to come into an on-state during the readout period.

(5)

The solid-state imaging device according to (3) described above, in which

the reset transistor is so driven as to come into an on-state at a readout time of a reset level during a shutter driving period before an exposure period, and a readout period after the exposure period,

the selection transistor is so driven as to come into an on-state during the readout period, and

the bias transistor is so driven as to come into an off-state in periods except for the readout period.

(6)

The solid-state imaging device according to any one of (3) to (6) described above, in which polarities of the photoelectric conversion unit, the first amplification transistor, the selection transistor, the second amplification transistor, and the bias transistor are inverted.

(7)

The solid-state imaging device according to any one of (3) to (5) described above, in which the bias transistor and the second amplification transistor are shared by a plurality of the pixels.

(8)

The solid-state imaging device according to (7) described above, in which polarities of the photoelectric conversion unit, the first amplification transistor, the selection transistor, the second amplification transistor, and the bias transistor are inverted.

(9)

The solid-state imaging device according to any one of (1) to (8) described above, in which the solid-state imaging device includes a logarithmic sensor in a solar cell mode.

5 (10)

An electronic apparatus including:

a solid-state imaging device that includes a pixel array unit including pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired, each of the pixels including

a photoelectric conversion unit,

a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal,

15 a first amplification transistor that amplifies a signal received from the photoelectric conversion unit,

a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal,

a second amplification transistor that amplifies a signal received from the selection transistor, and applies the amplified signal to a vertical signal line, and

20 a bias transistor that is connected to the selection transistor and the second amplification transistor, and functions as a current source,

25 in which the first amplification transistor and the second amplification transistor are each connected to a power source voltage.

(11)

30 A driving method of a solid-state imaging device that includes a pixel array unit, the pixel array unit including pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired, each of the pixels including

a photoelectric conversion unit,

35 a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal,

a first amplification transistor that amplifies a signal received from the photoelectric conversion unit,

40 a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal,

a second amplification transistor that amplifies a signal received from the selection transistor, and applies the amplified signal to a vertical signal line, and

45 a bias transistor that is connected to the selection transistor and the second amplification transistor, and functions as a current source,

in which the first amplification transistor and the second amplification transistor are each connected to a power source voltage,

50 the driving method including:

driving such that the reset transistor comes into an on-state during a shutter driving period before an exposure period;

55 driving such that the selection transistor comes into an on-state during a readout period after the exposure period; and

driving such that the reset transistor comes into the on-state at a readout time of a reset level during the readout period.

(12)

A driving method of a solid-state imaging device that includes a pixel array unit, the pixel array unit including pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired, each of the pixels including

65 a photoelectric conversion unit,

a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal,

31

a first amplification transistor that amplifies a signal received from the photoelectric conversion unit,
 a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal,
 a second amplification transistor that amplifies a signal received from the selection transistor, and applies the amplified signal to a vertical signal line, and
 a bias transistor that is connected to the selection transistor and the second amplification transistor, and functions as a current source,
 in which the first amplification transistor and the second amplification transistor are each connected to a power source voltage,
 the driving method including:
 driving such that the reset transistor comes into an on-state during a shutter driving period before an exposure period;
 driving such that the selection transistor comes into an on-state during a readout period after the exposure period;
 driving such that the reset transistor comes into the on-state at a readout time of a reset level during the readout period; and
 driving such that the bias transistor comes into an off-state during periods except for the readout period.

The invention claimed is:

1. A solid-state imaging device, comprising:
 a pixel array unit that includes pixels arranged in a matrix, wherein, from each of the pixels, an output signal indicating a logarithmic characteristic is acquired, and each of the pixels includes;
 a photoelectric conversion unit;
 a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal;
 a first amplification transistor that amplifies a signal received from the photoelectric conversion unit;

32

a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal;
 a second amplification transistor that amplifies a signal received from the selection transistor, and applies the amplified signal to a vertical signal line; and
 a bias transistor that is connected to the selection transistor and the second amplification transistor, and functions as a current source, wherein the first amplification transistor and the second amplification transistor are each connected to a power source voltage.
 2. The solid-state imaging device according to claim 1, wherein
 a gate of the first amplification transistor is connected to the photoelectric conversion unit,
 a source of the first amplification transistor is connected to a drain of the selection transistor,
 a drain of the first amplification transistor is connected to the power source voltage,
 a gate of the second amplification transistor is connected to a source of the selection transistor,
 a source of the second amplification transistor is connected to the vertical signal line, and
 a drain of the second amplification transistor is connected to the power source voltage.
 3. The solid-state imaging device according to claim 2, wherein
 a source of the bias transistor is grounded, and
 a drain of the bias transistor is connected to the source of the selection transistor and the gate of the second amplification transistor.
 4. The solid-state imaging device according to claim 3, wherein
 the reset transistor is so driven as to come into an on-state at a readout time of a reset level during a shutter driving period before an exposure period, and a readout period after the exposure period, and
 the selection transistor is so driven as to come into an on-state during the readout period.
 5. The solid-state imaging device according to claim 3, wherein
 the reset transistor is so driven as to come into an on-state at a readout time of a reset level during a shutter driving period before an exposure period, and a readout period after the exposure period,
 the selection transistor is so driven as to come into an on-state during the readout period, and
 the bias transistor is so driven as to come into an off-state in periods except for the readout period.
 6. The solid-state imaging device according to claim 3, wherein polarities of the photoelectric conversion unit, the first amplification transistor, the selection transistor, the second amplification transistor, and the bias transistor are inverted.
 7. The solid-state imaging device according to claim 3, wherein the bias transistor and the second amplification transistor are shared by a plurality of the pixels.
 8. The solid-state imaging device according to claim 7, wherein polarities of the photoelectric conversion unit, the first amplification transistor, the selection transistor, the second amplification transistor, and the bias transistor are inverted.
 9. The solid-state imaging device according to claim 1, wherein the solid-state imaging device includes a logarithmic sensor in a solar cell mode.

10. An electronic apparatus, comprising:
 a solid-state imaging device that includes a pixel array unit including pixels arranged in a matrix, wherein, from each of the pixels, an output signal indicating a logarithmic characteristic is acquired, and each of the pixels includes:
 a photoelectric conversion unit;
 a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal;
 a first amplification transistor that amplifies a signal received from the photoelectric conversion unit;
 a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal;
 a second amplification transistor that amplifies a signal received from the selection transistor, and applies the amplified signal to a vertical signal line; and
 a bias transistor that is connected to the selection transistor and the second amplification transistor, and functions as a current source, wherein the first amplification transistor and the second amplification transistor are each connected to a power source voltage.

11. A driving method of a solid-state imaging device that includes a pixel array unit, the pixel array unit including pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired, each of the pixels including
 a photoelectric conversion unit,
 a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal,
 a first amplification transistor that amplifies a signal received from the photoelectric conversion unit,
 a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal,
 a second amplification transistor that amplifies a signal received from the selection transistor, and applies the amplified signal to a vertical signal line, and
 a bias transistor that is connected to the selection transistor and the second amplification transistor, and functions as a current source,
 wherein the first amplification transistor and the second amplification transistor are each connected to a power source voltage,

the driving method comprising:
 driving such that the reset transistor comes into an on-state during a shutter driving period before an exposure period;
 driving such that the selection transistor comes into an on-state during a readout period after the exposure period; and
 driving such that the reset transistor comes into the on-state at a readout time of a reset level during the readout period.

12. A driving method of a solid-state imaging device that includes a pixel array unit, the pixel array unit including pixels arranged in a matrix, from each of the pixels an output signal indicating a logarithmic characteristic being acquired, each of the pixels including

a photoelectric conversion unit,
 a reset transistor that resets the photoelectric conversion unit in accordance with a reset signal,
 a first amplification transistor that amplifies a signal received from the photoelectric conversion unit,
 a selection transistor that selects a signal received from the first amplification transistor in accordance with a selection signal,
 a second amplification transistor that amplifies a signal received from the selection transistor, and applies the amplified signal to a vertical signal line, and
 a bias transistor that is connected to the selection transistor and the second amplification transistor, and functions as a current source,
 wherein the first amplification transistor and the second amplification transistor are each connected to a power source voltage,

the driving method comprising:
 driving such that the reset transistor comes into an on-state during a shutter driving period before an exposure period;
 driving such that the selection transistor comes into an on-state during a readout period after the exposure period;
 driving such that the reset transistor comes into the on-state at a readout time of a reset level during the readout period; and
 driving such that the bias transistor comes into an off-state during periods except for the readout period.
