(57) **ABSTRACT**

Wind energy systems, such as an Airborne Wind Turbine (“AWT”), may be used to facilitate conversion of kinetic energy to electrical energy. An AWT may include an aerial vehicle that flies in a path to convert kinetic wind energy to electrical energy. The aerial vehicle may be tethered to a ground station with a tether that terminates at a tether termination mount. In one aspect, the tether may be a conductive tether that can transmit electricity and/or electrical signals back and forth between the aerial vehicle and the ground station. The tether termination mount may include one or more gimbals that allow for the tether termination mount to rotate about one or more axis. In a further aspect, the tether termination mount may include a slip ring that allows for rotation of the tether without twisting the tether.

SYSTEMS AND APPARATUS FOR TETHER TERMINATION MOUNT FOR TETHERED AERIAL VEHICLES

CROSS REFERENCE TO RELATED APPLICATION

This application claims priority to U.S. patent application Ser. No. 14/102,483, filed Dec. 10, 2013, entitled "Systems and Apparatus for Tether Termination Mount for Tethered Aerial Vehicles," the contents of which are incorporated by reference herein for all purposes.

BACKGROUND

Unless otherwise indicated herein, the materials described in this section are not prior art to the claims in this application and are not admitted to be prior art by inclusion in this section.

Power generation systems may convert chemical and/or mechanical energy (e.g., kinetic energy) to electrical energy for various applications, such as utility systems. As one example, a wind energy system may convert kinetic wind energy to electrical energy.

SUMMARY

The present disclosure generally relates to systems and methods that incorporate a ground station for tethering aerial vehicles such as those employed in crosswind aerial vehicle systems. Crosswind aerial vehicle systems may extract useful power from the wind for various purposes such as, for example, generating electricity, lifting or towing objects or vehicles, etc. Deploying and receiving the aerial vehicles to generate power may present difficulties due to, for example, changing wind conditions and/or turbulent wind conditions. Beneficially, embodiments described herein may allow for more reliable, safe, and efficient deployment and reception of aerial vehicles. These as well as other aspects, advantages, and alternatives will become apparent to those of ordinary skill in the art by reading the following detailed description, with reference where appropriate to the accompanying drawings.

In one aspect, a tether termination mount is provided. The tether termination may include a gimbal system. The gimbal system may include a first gimbal with a primary bearing system and configured for movement substantially about a primary axis. The gimbal system may further include a second gimbal with a secondary bearing system and configured for movement substantially about a second axis. The tether termination mount may include a slip ring with a stationary portion and a rotatable portion. The stationary portion of the slip ring may be coupled to the second gimbal and may be electrically coupled to the rotatable portion of the slip ring. The rotatable portion of the slip ring may be electrically coupled to a tether containing one or more insulated conductors. The tether termination mount may further include a spindle. The spindle may include a proximate spindle end and a distal spindle end. The spindle may be configured to constrain a portion of the tether. The proximate spindle end may be coupled to the rotatable portion of the slip ring.

In another aspect, a tether termination mount capable of reporting position and/or velocity data is provided. The tether termination may include a gimbal system. The gimbal system may include a first gimbal with a primary bearing system and a primary encoder. The first gimbal may be configured for movement substantially about a primary axis. The gimbal system may further include a second gimbal with a secondary

bearing system and a secondary encoder. The second gimbal may be configured for movement substantially about a second axis. The tether termination mount may include a slip ring with a stationary portion and a rotatable portion. The stationary portion of the slip ring may be coupled to the second gimbal and may be electrically coupled to the rotatable portion of the slip ring. The rotatable portion of the slip ring may be electrically coupled to a tether containing one or more insulated conductors. The tether termination mount may further include a spindle. The spindle may include a proximate spindle end and a distal spindle end. The spindle may be configured to constrain a portion of the tether. The proximate spindle end may be coupled to the rotatable portion of the slip ring.

In another aspect, a system is provided. The system may include a tether with a proximate tether end, a main tether body, and a distal tether end. The distal tether end may be connected to an aerial vehicle. The tether may include one or more insulated electrical conductors. The one or more conductors may each have a proximate conductor end and a distal conductor end. The distal conductor end may be coupled to the aerial vehicle. The system may also include a gimbal system with an altitude axis gimbal and an azimuth axis gimbal. The altitude axis gimbal may include an altitude bearing system and an altitude encoder and may be configured for movement substantially about an altitude axis. The azimuth axis gimbal may include an azimuth bearing system and an azimuth encoder and may be configured for movement substantially about an azimuth axis. The system may further include a slip ring with a stationary portion and a rotatable portion. The stationary portion of the slip ring may be coupled to the azimuth axis gimbal and may be electrically coupled to the rotatable portion of the slip ring. The rotatable portion of the slip ring may be electrically coupled to the tether via the proximate conductor end of the one or more conductors. The system may include a servomotor that is coupled to the slip ring and configured to rotate the slip ring in response to rotation of the tether. The system may further include a spindle with a proximate spindle end and a distal spindle end. The spindle may be configured to constrain a portion of the main tether body. The proximate spindle end may be coupled to the rotatable portion of the slip ring.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates an Airborne Wind Turbine (AWT), according to an example embodiment.

FIG. 2 illustrates a simplified block diagram illustrating components of an AWT, according to an example embodiment.

FIG. 3A illustrates a perspective view of a ground station for an aerial vehicle of an AWT.

FIG. 3B illustrates a perspective view of a ground station for an aerial vehicle of an AWT.

FIG. 3C illustrates a cross-sectional view of a tether with insulated electrical conductors, according to an example embodiment.

FIG. 4 illustrates a perspective view of an alternative embodiment of a tether termination mount for a ground station of an aerial vehicle of an AWT.

DETAILED DESCRIPTION

Example methods and systems are described herein. It should be understood that the words "example," "exemplary," and "illustrative" are used herein to mean "serving as an example, instance, or illustration." Any embodiment or fea-

ture described herein as being an “example,” being “exemplary,” or being “illustrative” is not necessarily to be construed as preferred or advantageous over other embodiments or features. The example embodiments described herein are not meant to be limiting. It will be readily understood that the aspects of the present disclosure, as generally described herein, and illustrated in the figures, can be arranged, substituted, combined, separated, and designed in a wide variety of different configurations, all of which are explicitly contemplated herein.

I. Overview

Example embodiments relate to aerial vehicles, which may be used in a wind energy system, such as an Airborne Wind Turbine (AWT). In particular, example embodiments may relate to or take the form of methods and systems for facilitating an aerial vehicle in the process of conversion of kinetic energy to electrical energy.

By way of background, an AWT may include an aerial vehicle that flies in a path, such as a substantially circular path, to convert kinetic wind energy to electrical energy via onboard turbines. In an example embodiment, the aerial vehicle may be connected to a ground station via a tether. While tethered, the aerial vehicle may: (i) fly at a range of elevations and substantially along the path, and return to the ground, and (ii) transmit electrical energy to the ground station via the tether. In some embodiments, the ground station may transmit electricity to the aerial vehicle for take-off and/or landing.

In an AWT, an aerial vehicle may rest in and/or on a ground station when the wind is not conducive to power generation. When the wind is conducive to power generation, such as when a wind speed may be 10 meters per second (m/s) at an altitude of 200 meters (m), the ground station may deploy (or launch) the aerial vehicle. In addition, when the aerial vehicle is deployed and the wind is not conducive to power generation, the aerial vehicle may return to the ground station.

Moreover, in an AWT, an aerial vehicle may be configured for hover flight and crosswind flight. Crosswind flight may be used to travel in a motion, such as a substantially circular motion, and thus may be the primary technique that is used to generate electrical energy. Hover flight in turn may be used by the aerial vehicle to prepare and position itself for crosswind flight. In particular, the aerial vehicle could ascend to a location for crosswind flight based at least in part on hover flight. Further, the aerial vehicle could take-off and/or land via hover flight.

In hover flight, a span of a main wing of the aerial vehicle may be oriented substantially parallel to the ground, and one or more propellers of the aerial vehicle may cause the aerial vehicle to hover over the ground. In some embodiments, the aerial vehicle may vertically ascend or descend in hover flight.

In crosswind flight, the aerial vehicle may be propelled by the wind substantially along a path, which as noted above, may convert kinetic wind energy to electrical energy. In some embodiments, the one or more propellers of the aerial vehicle may generate electrical energy by slowing down the incident wind.

The aerial vehicle may enter crosswind flight when (i) the aerial vehicle has attached wind-flow (e.g., steady flow and/or no stall condition (which may refer to no separation of air flow from an airfoil)) and (ii) the tether is under tension. Moreover, the aerial vehicle may enter crosswind flight at a location that is substantially downwind of the ground station.

Some previous tethered systems have used a varying length tether. An example embodiment, in contrast, facilitates the use of a fixed length tether. For example, a fixed length tether

may be approximately 500 meters long and approximately 20 millimeters in diameter. The tether may include one or more insulated conductors to transmit electrical energy, or other electrical signals, along the tether length.

A tether termination mount at the ground station may be desirable for various reasons. For example, the aerial vehicle in cross-wind flight may oscillate many times over the life of the system (for e.g., 30 million cycles of aerial vehicle and tether rotation) so a tether termination mount may be desirable that does not wear, or rub, the tether. In the case of rigid or semi-rigid tethers, a tether termination mount may be desirable that does not impart significant bending loads onto the tether.

In the case of a tether with one or more conductors, a tether termination mount may be desirable that does not accumulate twists in the tether. Tether twisting may be a problem because a twisted tether may have reduced conductivity due to the twisting or eventual breaking of the conductor(s). For example, the tether termination mount may either actively or passively rotate to align the tether at the ground-side system with the motion of the aerial vehicle. The tether termination mount may include a servomotor or other drive mechanism to manually rotate the tether and reduce the likelihood of significant tether twisting. Additionally in the case of a tether with one or more conductors, a tether termination mount may be desirable that communicates power either into the ground side system or out to the aerial vehicle.

II. Illustrative Systems

A. Airborne Wind Turbine (AWT)

FIG. 1 depicts an AWT 100, according to an example embodiment. In particular, the AWT 100 includes a ground station 110, a tether 120, and an aerial vehicle 130. As shown in FIG. 1, the aerial vehicle 130 may be connected to the tether 120, and the tether 120 may be connected to the ground station 110. In this example, the tether 120 may be attached to the ground station 110 at one location on the ground station 110, and attached to the aerial vehicle 130 at two locations on the aerial vehicle 130. However, in other examples, the tether 120 may be attached at multiple locations to any part of the ground station 110 and/or the aerial vehicle 130.

The ground station 110 may be used to hold and/or support the aerial vehicle 130 until it is in an operational mode. The ground station 110 may also be configured to allow for the repositioning of the aerial vehicle 130 such that deploying of the device is possible. Further, the ground station 110 may be further configured to receive the aerial vehicle 130 during a landing. The ground station 110 may be formed of any material that can suitably keep the aerial vehicle 130 attached and/or anchored to the ground while transitioning between hover and crosswind flight.

In addition, the ground station 110 may include one or more components (not shown), such as a winch, that may vary a length of the tether 120. Such components will be described in greater detail later in this disclosure. For example, when the aerial vehicle 130 is deployed, the one or more components may be configured to pay out and/or reel out the tether 120. In some implementations, the one or more components may be configured to pay out and/or reel out the tether 120 to a predetermined length. As examples, the predetermined length could be equal to or less than a maximum length of the tether 120. Further, when the aerial vehicle 130 lands in the ground station 110, the one or more components may be configured to reel in the tether 120.

The tether 120 may transmit electrical energy generated by the aerial vehicle 130 to the ground station 110. In addition, the tether 120 may transmit electricity to the aerial vehicle 130 in order to power the aerial vehicle 130 for takeoff,

landing, hover flight, and/or forward flight. The tether **120** may be constructed in any form and using any material which may allow for the transmission, delivery, and/or harnessing of electrical energy generated by the aerial vehicle **130** and/or transmission of electricity to the aerial vehicle **130**. The tether **120** may also be configured to withstand one or more forces of the aerial vehicle **130** when the aerial vehicle **130** is in an operational mode. For example, the tether **120** may include a core configured to withstand one or more forces of the aerial vehicle **130** when the aerial vehicle **130** is in hover flight, forward flight, and/or crosswind flight. The core may be constructed of any high strength fibers. In some examples, the tether **120** may have a fixed length and/or a variable length. For instance, in at least one such example, the tether **120** may have a length of 140 meters. However other lengths may be used as well.

The aerial vehicle **130** may be configured to fly substantially along a path **150** to generate electrical energy. The term "substantially along," as used in this disclosure, refers to exactly along and/or one or more deviations from exactly along that do not significantly impact generation of electrical energy as described herein and/or transitioning an aerial vehicle between certain flight modes as described herein.

The aerial vehicle **130** may include or take the form of various types of devices, such as a kite, a helicopter, a wing and/or an airplane, among other possibilities. The aerial vehicle **130** may be formed of solid structures of metal, plastic and/or other polymers. The aerial vehicle **130** may be formed of any material which allows for a high thrust-to-weight ratio and generation of electrical energy which may be used in utility applications. Additionally, the materials may be chosen to allow for a lightning hardened, redundant and/or fault tolerant design which may be capable of handling large and/or sudden shifts in wind speed and wind direction. Other materials may be used in the formation of aerial vehicle as well.

The path **150** may be various different shapes in various different embodiments. For example, the path **150** may be substantially circular. And in at least one such example, the path **150** may have a radius of up to 265 meters. The term "substantially circular," as used in this disclosure, refers to exactly circular and/or one or more deviations from exactly circular that do not significantly impact generation of electrical energy as described herein. Other shapes for the path **150** may be an oval, such as an ellipse, the shape of a jelly bean, the shape of the number of 8, etc.

As shown in FIG. 1, the aerial vehicle **130** may include a main wing **131**, a front section **132**, rotor connectors **133A-B**, rotors **134A-D**, a tail boom **135**, a tail wing **136**, and a vertical stabilizer **137**. Any of these components may be shaped in any form which allows for the use of components of lift to resist gravity and/or move the aerial vehicle **130** forward.

The main wing **131** may provide a primary lift for the aerial vehicle **130**. The main wing **131** may be one or more rigid or flexible airfoils, and may include various control surfaces, such as winglets, flaps, rudders, elevators, etc. The control surfaces may be used to stabilize the aerial vehicle **130** and/or reduce drag on the aerial vehicle **130** during hover flight, forward flight, and/or crosswind flight.

The main wing **131** may be any suitable material for the aerial vehicle **130** to engage in hover flight, forward flight, and/or crosswind flight. For example, the main wing **131** may include carbon fiber and/or e-glass. Moreover, the main wing **131** may have a variety of dimensions. For example, the main wing **131** may have one or more dimensions that correspond with a conventional wind turbine blade. As another example, the main wing **131** may have a span of 8 meters, an area of 4

meters squared, and an aspect ratio of 15. The front section **132** may include one or more components, such as a nose, to reduce drag on the aerial vehicle **130** during flight.

The rotor connectors **133A-B** may connect the rotors **134A-D** to the main wing **131**. In some examples, the rotor connectors **133A-B** may take the form of or be similar in form to one or more pylons. In this example, the rotor connectors **133A-B** are arranged such that the rotors **134A-D** are spaced between the main wing **131**. In some examples, a vertical spacing between corresponding rotors (e.g., rotor **134A** and rotor **134B** or rotor **134C** and rotor **134D**) may be 0.9 meters.

The rotors **134A-D** may be configured to drive one or more generators for the purpose of generating electrical energy. In this example, the rotors **134A-D** may each include one or more blades, such as three blades. The one or more rotor blades may rotate via interactions with the wind and which could be used to drive the one or more generators. In addition, the rotors **134A-D** may also be configured to provide a thrust to the aerial vehicle **130** during flight. With this arrangement, the rotors **134A-D** may function as one or more propulsion units, such as a propeller. Although the rotors **134A-D** are depicted as four rotors in this example, in other examples the aerial vehicle **130** may include any number of rotors, such as less than four rotors or more than four rotors that may be spaced along main wing **131**.

The tail boom **135** may connect the main wing **131** to the tail wing **136**. The tail boom **135** may have a variety of dimensions. For example, the tail boom **135** may have a length of 2 meters. Moreover, in some implementations, the tail boom **135** could take the form of a body and/or fuselage of the aerial vehicle **130**. And in such implementations, the tail boom **135** may carry a payload.

The tail wing **136** and/or the vertical stabilizer **137** may be used to stabilize the aerial vehicle and/or reduce drag on the aerial vehicle **130** during hover flight, forward flight, and/or crosswind flight. For example, the tail wing **136** and/or the vertical stabilizer **137** may be used to maintain a pitch of the aerial vehicle **130** during hover flight, forward flight, and/or crosswind flight. In this example, the vertical stabilizer **137** is attached to the tail boom **135**, and the tail wing **136** is located on top of the vertical stabilizer **137**. The tail wing **136** may have a variety of dimensions. For example, the tail wing **136** may have a length of 2 meters. Moreover, in some examples, the tail wing **136** may have a surface area of 0.45 meters squared. Further, in some examples, the tail wing **136** may be located 1 meter above a center of mass of the aerial vehicle **130**.

While the aerial vehicle **130** has been described above, it should be understood that the methods and systems described herein could involve any suitable aerial vehicle that is connected to a tether, such as the tether **120**.

B. Illustrative Components of an AWT

FIG. 2 is a simplified block diagram illustrating components of the AWT **200**. The AWT **200** may take the form of or be similar in form to the AWT **100**. In particular, the AWT **200** includes a ground station **210**, a tether **220**, and an aerial vehicle **230**. The ground station **210** may take the form of or be similar in form to the ground station **110**, the tether **220** may take the form of or be similar in form to the tether **120**, and the aerial vehicle **230** may take the form of or be similar in form to the aerial vehicle **130**.

As shown in FIG. 2, the ground station **210** may include one or more processors **212**, data storage **214**, and program instructions **216**. A processor **212** may be a general-purpose processor or a special purpose processor (e.g., digital signal processors, application specific integrated circuits, etc.). The one or more processors **212** can be configured to execute

computer-readable program instructions **216** that are stored in data storage **214** and are executable to provide at least part of the functionality described herein.

The data storage **214** may include or take the form of one or more computer-readable storage media that may be read or accessed by at least one processor **212**. The one or more computer-readable storage media may include volatile and/or non-volatile storage components, such as optical, magnetic, organic or other memory or disc storage, which may be integrated in whole or in part with at least one of the one or more processors **212**. In some embodiments, the data storage **214** may be implemented using a single physical device (e.g., one optical, magnetic, organic or other memory or disc storage unit), while in other embodiments, the data storage **214** can be implemented using two or more physical devices.

As noted, the data storage **214** may include computer-readable program instructions **216** and perhaps additional data, such as diagnostic data of the ground station **210**. As such, the data storage **214** may include program instructions to perform or facilitate some or all of the functionality described herein.

In a further respect, the ground station **210** may include a communication system **218**. The communications system **218** may include one or more wireless interfaces and/or one or more wireline interfaces, which allow the ground station **210** to communicate via one or more networks. Such wireless interfaces may provide for communication under one or more wireless communication protocols, such as Bluetooth, WiFi (e.g., an IEEE 802.11 protocol), Long-Term Evolution (LTE), WiMAX (e.g., an IEEE 802.16 standard), a radio-frequency ID (RFID) protocol, near-field communication (NFC), and/or other wireless communication protocols. Such wireline interfaces may include an Ethernet interface, a Universal Serial Bus (USB) interface, or similar interface to communicate via a wire, a twisted pair of wires, a coaxial cable, an optical link, a fiber-optic link, or other physical connection to a wireline network. The ground station **210** may communicate with the aerial vehicle **230**, other ground stations, and/or other entities (e.g., a command center) via the communication system **218**.

In an example embodiment, the ground station **210** may include communication systems **218** that may allow for both short-range communication and long-range communication. For example, ground station **210** may be configured for short-range communications using Bluetooth and may be configured for long-range communications under a CDMA protocol. In such an embodiment, the ground station **210** may be configured to function as a “hot spot”; or in other words, as a gateway or proxy between a remote support device (e.g., the tether **220**, the aerial vehicle **230**, and other ground stations) and one or more data networks, such as cellular network and/or the Internet. Configured as such, the ground station **210** may facilitate data communications that the remote support device would otherwise be unable to perform by itself.

For example, the ground station **210** may provide a WiFi connection to the remote device, and serve as a proxy or gateway to a cellular service provider’s data network, which the ground station **210** might connect to under an LTE or a 3G protocol, for instance. The ground station **210** could also serve as a proxy or gateway to other ground stations or a command station, which the remote device might not be able to otherwise access.

Moreover, as shown in FIG. 2, the tether **220** may include transmission components **222** and a communication link **224**. The transmission components **222** may be configured to transmit electrical energy from the aerial vehicle **230** to the ground station **210** and/or transmit electrical energy from the ground station **210** to the aerial vehicle **230**. The transmission

components **222** may take various different forms in various different embodiments. For example, the transmission components **222** may include one or more insulated conductors that are configured to transmit electricity. And in at least one such example, the one or more conductors may include aluminum and/or any other material which may allow for the conduction of electric current. Moreover, in some implementations, the transmission components **222** may surround a core of the tether **220** (not shown).

The ground station **210** may communicate with the aerial vehicle **230** via the communication link **224**. The communication link **224** may be bidirectional and may include one or more wired and/or wireless interfaces. Also, there could be one or more routers, switches, and/or other devices or networks making up at least a part of the communication link **224**.

Further, as shown in FIG. 2, the aerial vehicle **230** may include one or more sensors **232**, a power system **234**, power generation/conversion components **236**, a communication system **238**, one or more processors **242**, data storage **244**, and program instructions **246**, and a control system **248**.

The sensors **232** could include various different sensors in various different embodiments. For example, the sensors **232** may include a global positioning system (GPS) receiver. The GPS receiver may be configured to provide data that is typical of well-known GPS systems (which may be referred to as a global navigation satellite system (GNSS)), such as the GPS coordinates of the aerial vehicle **230**. Such GPS data may be utilized by the AWT **200** to provide various functions described herein.

As another example, the sensors **232** may include one or more wind sensors, such as one or more pitot tubes. The one or more wind sensors may be configured to detect apparent and/or relative wind. Such wind data may be utilized by the AWT **200** to provide various functions described herein.

Still as another example, the sensors **232** may include an inertial measurement unit (IMU). The IMU may include both an accelerometer and a gyroscope, which may be used together to determine the orientation of the aerial vehicle **230**. In particular, the accelerometer can measure the orientation of the aerial vehicle **230** with respect to earth, while the gyroscope measures the rate of rotation around an axis, such as a centerline of the aerial vehicle **230**. IMUs are commercially available in low-cost, low-power packages. For instance, the IMU may take the form of or include a miniaturized MicroElectroMechanical System (MEMS) or a Nano-ElectroMechanical System (NEMS). Other types of IMUs may also be utilized. The IMU may include other sensors, in addition to accelerometers and gyroscopes, which may help to better determine position. Two examples of such sensors are magnetometers and pressure sensors. Other examples are also possible.

While an accelerometer and gyroscope may be effective at determining the orientation of the aerial vehicle **230**, slight errors in measurement may compound over time and result in a more significant error. However, an example aerial vehicle **230** may be able mitigate or reduce such errors by using a magnetometer to measure direction. For example, vehicle **230** may employ drift mitigation through fault tolerant redundant position and velocity estimations. One example of a magnetometer is a low-power, digital 3-axis magnetometer, which may be used to realize an orientation independent electronic compass for accurate heading information. However, other types of magnetometers may be utilized as well.

The aerial vehicle **230** may also include a pressure sensor or barometer, which can be used to determine the altitude of the aerial vehicle **230**. Alternatively, other sensors, such as

sonic altimeters or radar altimeters, can be used to provide an indication of altitude, which may help to improve the accuracy of and/or prevent drift of the IMU.

As noted, the aerial vehicle **230** may include the power system **234**. The power system **234** could take various different forms in various different embodiments. For example, the power system **234** may include one or more batteries for providing power to the aerial vehicle **230**. In some implementations, the one or more batteries may be rechargeable and each battery may be recharged via a wired connection between the battery and a power supply and/or via a wireless charging system, such as an inductive charging system that applies an external time-varying magnetic field to an internal battery and/or charging system that uses energy collected from one or more solar panels.

As another example, the power system **234** may include one or more motors or engines for providing power to the aerial vehicle **230**. In some implementations, the one or more motors or engines may be powered by a fuel, such as a hydrocarbon-based fuel. And in such implementations, the fuel could be stored on the aerial vehicle **230** and delivered to the one or more motors or engines via one or more fluid conduits, such as piping. In some implementations, the power system **234** may be implemented in whole or in part on the ground station **210**.

As noted, the aerial vehicle **230** may include the power generation/conversion components **236**. The power generation/conversion components **236** could take various different forms in various different embodiments. For example, the power generation/conversion components **236** may include one or more generators, such as high-speed, direct-drive generators. With this arrangement, the one or more generators may be driven by one or more rotors, such as the rotors **134A-D**. And in at least one such example, the one or more generators may operate at full rated power in wind speeds of 11.5 meters per second at a capacity factor which may exceed 60 percent, and the one or more generators may generate electrical power from 40 kilowatts to 600 megawatts.

Moreover, as noted, the aerial vehicle **230** may include a communication system **238**. The communication system **238** may take the form of or be similar in form to the communication system **218**. The aerial vehicle **230** may communicate with the ground station **210**, other aerial vehicles, and/or other entities (e.g., a command center) via the communication system **238**.

In some implementations, the aerial vehicle **230** may be configured to function as a “hot spot”; or in other words, as a gateway or proxy between a remote support device (e.g., the ground station **210**, the tether **220**, other aerial vehicles) and one or more data networks, such as cellular network and/or the Internet. Configured as such, the aerial vehicle **230** may facilitate data communications that the remote support device would otherwise be unable to perform by itself.

For example, the aerial vehicle **230** may provide a WiFi connection to the remote device, and serve as a proxy or gateway to a cellular service provider’s data network, which the aerial vehicle **230** might connect to under an LTE or a 3G protocol, for instance. The aerial vehicle **230** could also serve as a proxy or gateway to other aerial vehicles or a command station, which the remote device might not be able to otherwise access.

As noted, the aerial vehicle **230** may include the one or more processors **242**, the program instructions **244**, and the data storage **246**. The one or more processors **242** can be configured to execute computer-readable program instructions **246** that are stored in the data storage **244** and are executable to provide at least part of the functionality

described herein. The one or more processors **242** may take the form of or be similar in form to the one or more processors **212**, the data storage **244** may take the form of or be similar in form to the data storage **214**, and the program instructions **246** may take the form of or be similar in form to the program instructions **216**.

Moreover, as noted, the aerial vehicle **230** may include the control system **248**. In some implementations, the control system **248** may be configured to perform one or more functions described herein. The control system **248** may be implemented with mechanical systems and/or with hardware, firmware, and/or software. As one example, the control system **248** may take the form of program instructions stored on a non-transitory computer readable medium and a processor that executes the instructions. The control system **248** may be implemented in whole or in part on the aerial vehicle **230** and/or at least one entity remotely located from the aerial vehicle **230**, such as the ground station **210**. Generally, the manner in which the control system **248** is implemented may vary, depending upon the particular application.

While the aerial vehicle **230** has been described above, it should be understood that the methods and systems described herein could involve any suitable vehicle that is connected to a tether, such as the tether **230** and/or the tether **110**.

C. Illustrative Components of a Ground Station

FIG. 3A illustrates a perspective view of a ground station for an aerial vehicle of an AWT, such as the aerial vehicle **130** illustrated in FIG. 1. The ground station **300** may be the same or similar to ground station **210** of FIG. 2, or ground station **110** of FIG. 1. FIG. 3A is representational only and not all components are shown. For example, additional structural or restraining components may not be shown.

Ground station **300** may include vertical tower **302**, platform **305**, winch assembly **306**, tether termination mount **350**, and perch assembly **314**. Tower **302** and platform **305** may be used to facilitate the perch and launch of an aerial vehicle, such as aerial vehicle **130** of the AWT illustrated in FIG. 1. In some embodiments, platform **305** may be a perch platform upon which an aerial vehicle, such as aerial vehicle **130**, can perch (e.g., when landing).

Ground station **300** may also include a winch drum **310** and winch assembly (not shown), both of which may be coupled to platform **305**. Platform **305** may be coupled to a rotating member **304** and thereby rotatably coupled to vertical tower **302**. Via rotating member **304**, winch assembly, winch drum **310**, and platform **305** may rotate around an axis such as around a vertical axis (e.g., rotate in the azimuth plane). Rotating member **304** may be, for example, a passive slewing ring or an active slewing ring with a motor drive. In this manner, platform **305** may be rotated actively or passively around a vertical axis (representatively shown in FIG. 3A by arrow **304a**). While disclosed embodiments make use of a slewing ring, any rotational bearing or other configuration may be used that may allow platform **305** to rotate around tower **302**. Tower **302** may be a tubular steel structure, although any structure that can resolve aerial flight loads may be used.

Tether **320** may be connected to ground station **300** via tether termination mount **350** and wound onto winch drum **310** when winch drum rotates. Tether **320** may include a distal tether end connected to an aerial vehicle of an AWT, a main tether body, and a proximate tether end. Tether **320** may include one or more insulated conductors that have a proximate conductor end and a distal conductor end that is coupled to the aerial vehicle of an AWT. The distal conductor end may be coupled to the aerial vehicle of an AWT. The tether termination mount **350** may be coupled to the winch drum **310** in

11

various ways. For example, the tether termination mount may be connected to a support structure 360 that is connected to the winch drum 310. The tether 320 may be guided onto winch drum 310 via a levelwind (not shown).

Advantageously, platform 305 (and winch assembly including winch drum 310) may rotate in response to bias pressure applied by tether 320 to tether termination mount 350. For example, if an AWT attached to tether 320 changes its azimuth angle relative to winch drum 310 (or platform 305), tether 320 may apply bias pressure to tether termination mount 350, which may in turn cause platform 305 to rotate passively towards the bias direction.

Alternatively or additionally, tether termination mount 350 may include sensors to detect bias pressure applied by tether 320 to tether termination mount 350. The sensors may be pressure sensors, force sensors, vibrational sensors, or any other sensors configured to detect bias pressure. In response to detecting bias pressure, a motor (not shown) or other active component may then cause platform 305 to rotate relative to tower 302 and in the direction of the bias. Allowing or causing platform 305 and winch assembly to rotate around tower 302 and to face a tension force applied by tether 320 is advantageous because it may, among other advantages, reduce side loading forces and other undesirable forces acting on components of ground station 300.

D. Illustrative Components of a Tether Termination Mount

FIG. 3B illustrates a perspective view of a ground station for an aerial vehicle of an AWT, such as the aerial vehicle 130 illustrated in FIG. 1. The ground station 300 may be the same or similar to ground station 300 for FIG. 3A, ground station 210 of FIG. 2, or ground station 110 of FIG. 1. FIG. 3B is representational only and not all components are shown. For example, additional structural or restraining components may not be shown.

As illustrated in FIG. 3B, tether termination mount 350 may be coupled to the winch drum 310 and may include one or more gimbals, for example gimbals 352A and 352B, a slip ring 354, and a spindle 356. Each gimbal, such as gimbals 352A and 352B, may be a structural support that allows the tether termination mount 350 to rotate about an axis. In an example embodiment, the tether termination mount 350 may have two gimbals 352A and 352B that allow the tether termination mount 350 to rotate about two axes. For example, gimbal 352A may be configured to allow the tether termination mount 350 to rotate about a primary axis, such as an altitude axis or a z-axis with a range of angles η to $-\eta$ (representatively shown in FIG. 3B as arrow 352z, for the current orientation of the tether termination mount). Additionally, gimbal 352B may be configured to allow the tether termination mount 350 to rotate about a secondary axis, such as an azimuth axis or an x-axis, with a range of angles ϕ to $-\phi$ (representatively shown in FIG. 3B as arrow 352x, for the current orientation of the tether termination mount). In FIG. 3B, gimbals 352A and 352B are shown with rotational axes oriented perpendicular to each other; however, the primary and secondary axes may be aligned at some orientation other than perpendicular. Also, gimbals 352A and 352B may additionally or alternatively be configured to rotate without limitation as to the range of angles (i.e., a gimbal could rotate completely about its axis) or with varying limits to the range of angles. Additionally, there may be more or less than two gimbals in the system.

Each gimbal 352A and 352B may include a bearing system. The bearing system may advantageously have a low overturning moment to allow for easy rotation. In an example embodiment, the bearing system includes two radial bearings, with one bearing located near each end of gimbal sys-

12

tem. Each gimbal 352A and 352B may further include an encoder, such as a rotary encoder. The encoder may provide feedback related to speed, motion, and/or position of the gimbal about its axis of rotation.

The tether termination mount 350 may include a slip ring 354 that includes a stationary portion 354A and a rotatable portion 354B. The slip ring may be any electromechanical device that allows transmission of power and electrical signals from a rotating structure to a stationary structure, and may be used during unrestrained, intermittent or continuous rotation.

As illustrated in FIG. 3B, the slip ring 354 may be directly connected to the tether termination mount 350. For example, the stationary portion 354A of slip ring 354 may be mechanically coupled to gimbal 352A. The stationary portion 354A may further be electrically coupled to the rotatable portion 354B, which in turn may be electrically coupled to the tether 320, thereby allowing the tether 320 to rotate while still communicating power and/or electrical signals to the ground station 300. For example, the proximate conductor end of one or more insulated conductors 358 included in tether 320 may be electrically coupled to the rotatable portion 354B of the slip ring 354. FIG. 3C illustrates an enlarged cross-sectional view of tether 320 and one or more insulated conductors 358. Slip ring 354 may be rotated actively (e.g., with a servomotor) or rotated passively (e.g., with potential energy stored by the action of a rotating tether in a torsion spring).

The tether termination mount may also include a spindle 356. The spindle 356 may be a length of housing that extends from the tether termination mount 350 and which the tether 320 passes through or is fixed along. The spindle 356 may have two ends, a proximate spindle end 356a and a distal spindle end 356b.

The proximate spindle end 356a may be attached to the tether termination mount 350. The distal spindle end 356b may extend towards the distal point of the tether for some distance. The distal spindle end 356b may include a bearing system, for example, a radial bearing, which may be used to accommodate rotation of the tether 320 within or about the spindle 356.

In a further aspect, the spindle 356 may help to reduce bending loads on portions of the tether termination mount 350, such as on the gimbals 352A and 352B and/or slip ring 354. For example, if the tether 320 is connected to an aerial vehicle of an AWT in cross-wind flight, the tether 320 may act as a bending load on those, and other, portions of the tether termination mount 350. The spindle 356 may extend the point of contact of the tether 320 on the tether termination mount 350. For example, FIG. 3B illustrates a spindle 356 extending the point of contact of the tether 320 on the tether termination mount 350 by the distance from 356a to 356b. Consequently, the spindle 356 may also increase the leverage the tether 320 has on the tether termination mount 350, which in turn may advantageously help to increase the ability of the tether termination mount 350 to turn and follow the tether 320. As shown in FIG. 3B, the spindle 356 acts as a lever and applies greater leverage from the tether 320 to the tether termination mount 350 than would exist without the spindle 356.

For example, with a tether termination mount that did not include a spindle, a bias pressure from the tether would apply a relatively low amount of rotational torque to the tether termination mount about one or more of the gimbal axes. For example, against an exemplary axis, a biased tether may apply a force vector F at a distance against the tether termination mount, where A may be the displacement vector from where the torque is measured to the point where the force is

applied. The torque, T_1 , may be calculated as the cross product of vectors F and A . ($T_1=A \times F$, where x denotes the cross product).

In contrast, a tether termination mount **350** that does include a spindle **356** will necessarily experience a larger torque for the same applied tether force F at a distance vector greater than A . For example, as shown in FIG. 3B, if the applied tether force F is applied at the distal tether end **356b**, where B may be the displacement vector from where the torque is measured to the point where the force is applied (where B is greater than A), the resulting torque T_2 may be calculated as the cross product of vectors F and B . ($T_2=B \times F$, where x denotes the cross product). Since the displacement vector B has a magnitude larger than displacement vector A , the resulting torque T_2 applied to the tether termination mount **350** will always have a larger magnitude than the torque T_1 that would be applied to the tether termination mount **350** where a spindle **356** is not utilized.

Additionally or alternatively, the spindle **356** may help align the tether **320** and the tether termination mount **350**, which in turn may advantageously help to reduce the likelihood of binding forces on the bearings of the tether termination mount **350**. For example, a tether **320** may follow a path **370** when used with a tether termination mount **350** that does not include a spindle **356**. In contrast, a tether **320** may follow a path **372** when used with a tether termination mount **350** that includes a spindle **356** as illustrated in FIG. 3B. Path **372** has a longer length of tether **320** that is collinear with an axis of the tether termination mount **350**. For example, as shown in FIG. 3B, path **372** has a tether length B that is aligned with the y -axis of the tether termination mount **350**. In comparison, path **370** only has a tether length A that is aligned with the y -axis of the tether termination mount. This alignment of the tether **320** with an axis of the tether termination mount **350** is advantageous because it may help to reduce possible binding forces on the tether termination mount, for example, the alignment along the y -axis may help to reduce possible binding forces on the axis bearings of the one or more gimbals **352**.

Additionally or alternatively, the distal spindle end **356b** may include a sensor (e.g., a force sensor such as a strain gauge or a load cell). For example, a force sensor may be used to determine the force of the tether **320** against the distal spindle end **356b**. This force may be used to determine whether to actively rotate a portion of the ground station **300**. For example, if the determined force of the tether **320** against the distal spindle end **356b** is above a threshold, the winch assembly may actively rotate the winch drum **310** in a direction to reduce force. To help accommodate elongation of the tether **320** when the tether **320** is loaded, the tether **320** may be allowed to slide within or along the sensor.

FIG. 3C illustrates a cross-section view of a tether with insulated electrical conductors, according to an example embodiment. Tether **320** may have one or more insulated electrical conductors **358** as previously described.

FIG. 4 illustrates a perspective view of an alternative embodiment of a tether termination mount for a ground station of an aerial vehicle of an AWT, such as the aerial vehicle **130** illustrated in FIG. 1. Tether termination mount **450** may be the same or similar to tether termination mount **350** of FIG. 3B. FIG. 4 is representative only and not all components are shown. For example, additional structural or restraining components may not be shown.

Tether termination mount **450** may include gimbals **452A** and **452B**, slip ring **454**, spindle **456**, drive mechanism **458**, encoders **460A** and **460B**, gimbal bearing systems **462A** and **462B**, spindle bearing system **464**, and spindle sensor **466**.

These components may operate with tether **420** and ground station in the same or a similar manner to those already described.

As described above, the tether **420** may rotate, for example, due to the cross-wind flight pattern of an aerial vehicle of an AWT. In an example embodiment, the drive mechanism **458** may actively or passively rotate a rotatable portion of the slip ring **454** and/or the spindle **456**. As illustrated in FIG. 4, a drive mechanism **458** may be directly connected to the slip ring **454**, or it may be coupled to the slip ring **454** through a drivetrain or other power transmission system. The drive mechanism **458** may actively rotate the rotatable portion of the slip ring **454** to follow the rotation of the tether **420**. For example, the drive mechanism **458** may be a servomotor. In a further aspect, the drive mechanism **458** may passively rotate the rotatable portion of the slip ring **454** to follow the rotation of the tether **420**. For example, the drive mechanism **458** may be a torsion spring that stores potential energy P from the action of a rotating tether until the potential energy P is greater than an overturning moment M required to turn the rotatable portion of the slip ring **454**.

x. Conclusion

While various aspects and embodiments have been disclosed herein, other aspects and embodiments will be apparent to those skilled in the art. The various aspects and embodiments disclosed herein are for purposes of illustration and are not intended to be limiting, with the true scope and spirit being indicated by the following claims.

We claim:

1. A tether termination mount, comprising:
 - a gimbal system, comprising:
 - a first gimbal, comprising a primary bearing system and wherein the first gimbal is configured for movement substantially about a primary axis;
 - a second gimbal, comprising a secondary bearing system and wherein the second gimbal is configured for movement substantially about a secondary axis;
 - a slip ring, comprising a stationary portion and a rotatable portion, wherein the stationary portion of the slip ring is coupled to the second gimbal, wherein the stationary portion and rotatable portion are electrically coupled, and wherein the rotatable portion is electrically coupled to a tether; and
 - a spindle, comprising a proximate spindle end and a distal spindle end, wherein the spindle is configured to constrain a portion of the tether, and wherein the proximate spindle end is coupled to the rotatable portion of the slip ring.
2. The spindle of claim 1, further comprising a spindle bearing system, wherein the bearing system is located at the distal spindle end, and wherein the bearing system provides a rotatable surface against which the tether may rotate relative to the spindle.
3. The apparatus of claim 1, further comprising:
 - a force sensor connected to the distal spindle end, wherein the force sensor is configured to measure a tether force applied to the spindle by the tether.
4. The apparatus of claim 3, wherein the force sensor is a load cell.
5. The apparatus of claim 4, wherein the force sensor is a strain gauge.
6. The apparatus of claim 1, wherein the secondary axis is substantially perpendicular to the primary axis.
7. The apparatus of claim 1, further comprising:
 - a torsion spring, comprising a proximate spring end and a distal spring end, wherein the proximate spring end is

15

coupled to the rotatable portion of the slip ring and the distal spring end is coupled to the tether.

8. The apparatus of claim 1, further comprising:
 a servomotor connected to the slip ring, wherein the servomotor is configured to rotate the rotatable portion of the slip ring in response to rotation of the tether.

9. The apparatus of claim 1, wherein the tether comprises at least one insulated electrical conductor, and wherein the at least one conductor comprises:
 a proximate conductor end that terminates at the rotatable portion of the slip ring; and
 a distal conductor end.

10. A tether termination mount, comprising:
 a gimbal system, comprising:
 a first gimbal, comprising a primary bearing system and a primary encoder, wherein the first gimbal is configured for movement substantially about a primary axis;
 a second gimbal, comprising a secondary bearing system and a secondary encoder, coupled to the first gimbal, wherein the second gimbal is configured for movement substantially about a secondary axis;
 a slip ring, comprising a stationary portion and a rotatable portion, wherein the stationary portion of the slip ring is coupled to the second gimbal, wherein the stationary portion and rotatable portion are electrically coupled, and wherein the rotatable portion is electrically coupled to a tether; and
 a spindle, comprising a proximate spindle end and a distal spindle end, wherein the spindle is configured to constrain a portion of the tether, and wherein the proximate spindle end is coupled to the rotatable portion of the slip ring.

11. The apparatus of claim 10, wherein the primary encoder is configured to measure a position of the tether termination mount about a primary axis.

12. The apparatus of claim 10, wherein the primary encoder is configured to measure a velocity of the tether about a primary axis.

13. The apparatus of claim 10, wherein the secondary encoder is configured to measure a position of the tether termination mount about a secondary axis.

14. The apparatus of claim 10, wherein the secondary encoder is configured to measure a velocity of the tether termination mount about a secondary axis.

15. A system, comprising:
 a tether, comprising:
 a distal tether end coupled to an aerial vehicle;

16

at least one insulated electrical conductor coupled to the aerial vehicle;
 a main tether body; and
 a proximate tether end; and
 a tether termination mount comprising:
 a gimbal system, comprising:
 an altitude axis gimbal, comprising an altitude bearing system and an altitude encoder, wherein the altitude axis gimbal is configured for movement substantially about an altitude axis;
 an azimuth axis gimbal, comprising an azimuth bearing system and an azimuth encoder, coupled to the altitude axis gimbal, wherein the azimuth axis gimbal is configured for movement substantially about an azimuth axis;
 a slip ring, comprising a stationary portion and a rotatable portion, wherein the stationary portion of the slip ring is coupled to the azimuth axis gimbal, wherein the stationary portion and rotatable portion are electrically coupled, and wherein the rotatable portion is electrically coupled to the at least one insulated electrical conductor;
 a servomotor coupled to the slip ring, wherein the servomotor is configured to rotate the slip ring in response to rotation of the tether; and
 a spindle, comprising a proximate spindle end and a distal spindle end, wherein the spindle is configured to constrain a portion of the main tether body, and wherein the proximate spindle end is coupled to the rotatable portion of the slip ring.

16. The spindle of claim 15, further comprising a spindle bearing system, wherein the spindle bearing system is located at the distal spindle end, and wherein the spindle bearing system provides a rotatable surface against which the main tether body may rotate relative to the spindle distal end.

17. The apparatus of claim 15, further comprising:
 a force sensor connected to the distal spindle end, wherein the force sensor is configured to measure a tether force applied to the spindle by the tether.

18. The apparatus of claim 17, wherein the force sensor is a load cell.

19. The apparatus of claim 17, wherein the force sensor is a strain gauge.

20. The apparatus of claim 15, wherein the altitude axis is substantially perpendicular to the azimuth axis.

* * * * *
