(57) **ABSTRACT**

At least a system for providing telematics data associated with a vehicle being driven by a driver is described. The vehicular telematics data may be obtained by tracking the movements of a wireless communications device of a driver of the vehicle. The telematics data may provide, among other things, speed, acceleration, deceleration, times of operation, duration of operation, mileage driven per day, and day of the week the vehicle has been used. At least a system for determining risk behavior of a driver is also described. While a vehicle is being driven, data is obtained related to the position and movement of a wireless communications device. The data may indicate the type of behavior exhibited by the driver while the vehicle is being driven.

TELEMATICS BASED ON HANDSET MOVEMENT WITHIN A MOVING VEHICLE

This application is a continuation of and claims priority to U.S. application Ser. No. 14/803,446 titled "TELEMATICS BASED ON HANDSET MOVEMENT WITHIN A MOVING VEHICLE" which is a continuation of U.S. application Ser. No. 13/802,088, titled "TELEMATICS BASED ON HANDSET MOVEMENT WITHIN A MOVING VEHICLE," filed on Mar. 13, 2013. The aforementioned application is herein incorporate by reference in its entirety.

CROSS-REFERENCE TO RELATED-APPLICATIONS

This application related to U.S. application Ser. No. 13/802,252, titled "RISK BEHAVIOR DETECTION BASED ON TRACKING HANDSET MOVEMENT WITHIN A MOVING VEHICLE", filed on Mar. 13, 2013.

This application is also related to U.S. application Ser. No. 13/802,193, titled "RISK BEHAVIOR DETECTION METHODS BASED ON TRACKING HANDSET MOVEMENT WITHIN A MOVING VEHICLE", filed on Mar. 13, 2013.

TECHNICAL FIELD

Aspects of the disclosure relate to generating telematics data from a handset or wireless communication device used by a driver of a vehicle. More specifically, aspects of the disclosure relate to using one or more portable handsets of one or more occupants in a vehicle to track or measure movements of a vehicle. The handset or wireless communications device may act as a telematics device to track/monitor how the vehicle is being driven.

BACKGROUND

Telematics devices are used by insurance companies to monitor driving behavior for the purpose of setting insurance premiums based on an analysis of the monitored data. These devices transmit various types of information to a data analysis server, including information such as the time of day in which a vehicle is most frequently operated, the mileage reading of the vehicle, the number of times the vehicle is driven over a predetermined threshold (e.g., 80 mph, etc.), and instances of hard braking and quick acceleration, among other things.

A telematics device often has to be ordered for an insured so that the insured may be able to install the device in his vehicle. The telematics device may need to be ordered by the insurance company from a vendor or manufacturer and subsequently delivered to the insured. The insured may have to wait some amount of time before receiving the device.

The insurance company must provide a telematics device that is compatible with the vehicle. Otherwise, the data that is transmitted back to the data analysis server may not be accurate. If the telematics device reports back inaccurate or incorrect information, the insured may be dissatisfied with the reporting performed by the telematics device and may decide to discontinue using the device.

Furthermore, the insurance company may need to manufacture or procure the telematics devices for its insureds. Since there are a large number of vehicle makes and models on the road, the manufacturing and procurement process associated with these telematics devices may present a challenge to the insurance company.

After a telematics device is received by an insured, the insured may need assistance to install the device in his or her vehicle. The insurance company may need to establish and train personnel in a customer service department that can address installation questions the insured may have.

Thus, the deployment of such telematics devices may incur significant costs to the insurance company.

Telematics programs by insurance companies may offer participants the opportunity to reduce the cost of their insurance premium based on their driving behavior. While information such as the time of day and mileage reading may be helpful, additional information may be valuable to an insurance company when determining the cost of the insurance premium.

SUMMARY

In light of the foregoing background, the following presents a simplified summary of the present disclosure in order to provide a basic understanding of some aspects of the disclosure. This summary is not an extensive overview of the disclosure. It is not intended to identify key or critical elements of the disclosure or to delineate the scope of the disclosure. The following summary merely presents some concepts of the disclosure in a simplified form as a prelude to the more detailed description provided below.

Aspects of the exemplary embodiments provide at least a system for determining a risk associated with a vehicle being driven by a driver based on data received by a computer based system. The system may comprise a plurality (e.g., more than one, at least three, four, or more) localization devices attached to a vehicle, a wireless communication device for transmitting a signal to each of the localization devices, where each of the localization devices processes the signal to determine a first movement of the wireless communication device relative to the vehicle over time. The system further comprises a computing device for adjusting the first movement using a second movement. The second movement corresponds to the absolute movement of the wireless communication device obtained from a position detecting device, such as a global positioning system (GPS). An actual movement of the vehicle is determined after the adjusting is performed.

The various aspects of the exemplary embodiments are substantially shown in and/or described in connection with at least one of the following figures, as set forth more completely in the claims.

These and other advantages, aspects, and novel features of the present disclosure, as well as details of illustrated embodiments, thereof, will be more fully understood from the following description and drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete understanding of aspects described herein and the advantages thereof may be acquired by referring to the following description in consideration of the accompanying drawings, in which like reference numbers indicate like features, and wherein:

FIG. 1 depicts a system block diagram in accordance with aspects of the disclosure.

FIG. 2 depicts a diagram of an exemplary operating environment in accordance with an embodiment of the disclosure.

FIG. 3 depicts an operational flow diagram of a method for describing the placement and calibration of the localization devices in a vehicle in accordance with an exemplary embodiment.

FIG. 4 depicts an operational flow diagram of a method in which telematics data is generated in accordance with an embodiment of the disclosure.

FIG. 5 is an operational flow diagram describing how movements of the driver's mobile communication device are processed in accordance with an exemplary embodiment.

It will be apparent to one skilled in the art after review of the entirety disclosed that the steps illustrated in the figures listed above may be performed in other than the recited order, and that one or more steps illustrated in these figures may be optional.

DETAILED DESCRIPTION

In the following description of the various embodiments, reference is made to the accompanying drawings, which form a part hereof, and in which is shown by way of illustration various embodiments in which aspects described herein may be practiced. It is to be understood that other embodiments may be utilized and structural and functional modifications may be made without departing from the scope and spirit of the present disclosure.

FIG. 1 depicts an illustrative operating environment in accordance with aspects of the disclosure. The operating environment comprises a vehicle 100 and telecommunications/computing system 101. The vehicle 100 comprises one or more communications devices 102, 104 and one or more localization devices 103. The localization devices may be appropriately attached to the interior surface of the vehicle to allow for unobstructed wireless communication between the one or more communications devices 102, 104 and the one or more localization devices 103. Telematics data may be wirelessly transmitted from the one or more communications devices 102, 104 and/or the one or more localization devices 103. The telematics data may provide information pertaining to the location, movement, and behavior of the vehicle being driven. Each of the one or more localization devices 103 may comprise an RFID node, a Bluetooth Low Energy (BLE) locator, or any other type of receiver, transmitter, or transceiver. Each of the one or more localization devices 103 may comprise a processor and memory.

A user of wireless communication devices 102, 104 may communicate with a wireless access point 106. The wireless access point 106 may comprise a cell site or cellular tower, for example. The wireless communication device 102 may comprise a mobile telephone with applications and other functionality (e.g., APPLE® iPhone, RESEARCH IN MOTION® Blackberry, Windows® mobile device, a mobile device using an Android based operating system, or other mobile telephone). The mobile telephone may be configured with an enhanced roadside assistance application installed, or other portable electronic device. The wireless communication device 104 may comprise a handheld mobile communications device with Wi-Fi connectivity (e.g., APPLE® iPad, Android tablet, Kindle, or the Samsung Galaxy, etc.). The wireless communication devices 102, 104 may be configured to communicate with the wireless access point 106 such as a cellular tower operated which may be owned and operated by a cellular service provider. Alternatively, the wireless access point 106 may be a Wi-Fi (i.e., compatible with IEEE 802.11a/b/g/n etc. wireless communication standards) hotspot where each of the wireless communication devices 102, 104 may obtain access to the Internet (e.g., to communicate using online chat applications or voice-over-IP applications).

Vehicular telematics data may be wirelessly transmitted from the one or more communications devices 102, 104

and/or the one or more localization devices 103. The telematics data may provide information pertaining to the location, movement, and behavior of the vehicle being driven. For example, the telematics data may comprise vehicular acceleration data transmitted from the wireless communication devices 102, 104 back to the servers 108, 110. The vehicular telematics data may be transmitted to one or more servers 108, 110 by way of the cell tower 106. The telematics data may be transmitted from the cell tower 106 to the one or more servers 108, 110 by way of using one or more a wide area network (WANs), metropolitan area networks (MANs), and/or local area networks (LANs) 109

Each of the servers 108, 110 (e.g., a computer) may include a memory 112, 120 storing computer-readable instructions and a processor 114, 116 for executing the computer-readable instructions to perform method steps in accordance with aspects of the disclosure. The data may be communicated to the servers 108, 110 from the wireless communication devices 102, 104 by way of transmission over the WANs, MANs, and LANs 109 by way of using the wireless access point 106. The memories 112, 120 may also store data that may be useful to applications running on the mobile devices 102, 104 or the servers 108, 110. For example, the computer data files may provide position information describing the locations of one or more mobile communication devices 102, 104 over time relative to one or more localization devices. The position information of driver's mobile communication device over time may be used to provide a measure of risk associated with a driver of a vehicle. The data collected and stored in memory 112, 120 may be used to support one or more of the numerous features disclosed throughout this disclosure. Other data stored in the memory 112, 120 may include data that identifies the one or more wireless communication devices used in the vehicles, identifies one or more owners of the one or more wireless communication devices, identifies the one or more vehicles they are currently driving, and provides vehicular performance and handling data such as speed, acceleration, and braking information, mileage per trip, and time of day the one or more vehicles are driven, among other things. The data may be transmitted by the one or more mobile communication devices 102, 104 and/or localization devices 103. The data may be received by the servers 108, 110 and stored into memory 112, 120. Additional data may comprise any type of telematics or sensor data capable of being transmitted to the servers 108, 110 by way of the mobile communication devices and/or localization devices in the one or more vehicles.

One skilled in the art will appreciate that each of the servers 108, 110 is not limited to a single computer, a single computer based system, single machine, or device. The server may be embodied as a web server or Internet-accessible server. Furthermore, the term server refers to any system of computers and/or devices (e.g., firewalls, routers, caching systems, proxy servers, networked computers, or combination thereof) that may be used to provide access to services and features available for use. As such, reference to a server performing particular steps does not require that the same machine/device perform all the steps.

Servers 108, 110, data storage device 122, and wireless access point 106 may communicate over wired and/or wireless connections. In some instances, a private, secure connection may be established between one or more of these components. For example, servers 108, 110 may communicate by way of a network cloud representing the Internet. Alternatively, servers 108, 110 and the data storage device 122 may communicate over a secure WAN or a dedicated TI

(or other telecommunications) line. The data storage device **122** may store any data used by the processors **114**, **116** and memories **112**, **120**.

Each of the wireless communication devices **102**, **104** may include a processor, memory, Bluetooth and Wi-Fi transceivers and corresponding antennae, RFID and/or other electromagnetic transceivers and corresponding antennae, display screen (e.g., touchscreen), keypad, sensors (e.g., motion, optical, etc.), camera, global positioning system (GPS) chip, audio output/input devices, and other electronic components configured for use in mobile phones, PDAs, tablets, and mini-laptops. The wireless communication devices **102**, **104** may also include one or more accelerometers for detecting and measuring acceleration over one or more axes.

An insurance company may utilize GPS information provided by a GPS chip inside a communication device **102**, **104** to track the movement of the communication device. The movement of the vehicle may be determined by subtracting movement of the communication device **102**, **104** relative to the vehicle, from the movement of the communication device **102**, **104**. The one or more accelerometers may be used to measure the communication device's acceleration over one or more axes. Vehicular acceleration may be determined by adjusting the acceleration of the communication device by the acceleration associated with the movement of the communication device relative to the vehicle. The localization devices **103** may be used with the communication device to determine the acceleration associated with the movement of the communication device relative to the vehicle.

In one embodiment, each of the one or more communication devices **102**, **104** may also comprise an optical sensor and/or transceiver which may be used to determine the location or position of each of the one or more communications devices relative to optical signals emitted by the localization devices **103**. Each of the one or more communication devices **102**, **104** may reflect the received optical signal back to the localization devices **103**. The movement of each of the one or more communication devices **102**, **104** may be monitored and tracked based on the movement of the reflected signal from each of the one or more communication devices **102**, **104**. By way of using radio frequency and/or optical signals, the location of each of the one or more communication devices may be tracked over time.

In another example, one or more servers **108**, **110** may include a processor, RAM, ROM, communications module, and/or memory storing an operating system, applications, and/or data. Each of the one or more servers may have a processor for controlling overall operation of the server and its associated components, including random access memory, read-only memory, communications module, and memory. Such a server may include a variety of computer readable media. Computer readable media may be any available media, both tangible and intangible, that may be accessed by the server and include both volatile and non-volatile media, and removable and non-removable media. By way of example, and not limitation, computer readable media may comprise a combination of computer storage media and communication media. Computer storage media include volatile and nonvolatile, removable and non-removable media implemented in any method or technology for storage of information such as computer readable instructions, object code, data structures, program modules or other data. Computer storage media include, but are not limited to, random access memory (RAM), read only memory (ROM), electronically erasable programmable read only memory

(EEPROM), flash memory or other memory technology, CD-ROM, digital versatile disks (DVD) or other optical disk storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other medium that can be used to store the desired information and that can be accessed by each of the servers **108**, **110**.

The aforementioned one or more servers **108**, **110** may store one or more applications for using the application data stored in RAM memory while the server is on and corresponding software applications (e.g., software tasks) are running on the server. The one or more servers **108**, **110** may include hardware, software, and network components. Execution of the software by the hardware may cause the one or more servers **108**, **110** to perform one or more algorithms. The one or more algorithms may be used to determine a risk behavior of a driver of a vehicle. The risk behavior may be based on position data associated with movement of a handheld communication device. In an exemplary embodiment, the one or more servers **108**, **110** may comprise a risk assessment module that automatically executes the computation of the risk behavior of the driver based position or location data of the one or more communication devices **102**, **104**. The risk assessment module at the server **108**, **110** may process the received data to determine the risk behavior of the driver. The localization devices **103** and one or more servers **108**, **110** described in connection with FIG. 1 may be described as a "driver behavior risk assessment system." Thus, by way of using radio frequency and/or optical signals, the location of each of the one or more communication devices may be tracked over time.

In an exemplary embodiment, the one or more servers **108**, **110** may comprise a telematics processing module that automatically receives data associated with the movements of the one or more communication devices **102**, **104**, including acceleration data and position or location data from the one or more communications devices **102**, **104**. The telematics processing module at the server **108**, **110** may process the received data to determine the behavior of the vehicle which may include speed, acceleration, cornering, and braking, for example. The acceleration may be computed over various axes. Vehicle telematics may be computed by the telematics processing module by way of using the data associated with the movements of the one or more communication devices **102**, **104**. The telematics processing module may compute the movement of the vehicle by subtracting the movement of the communication device **102**, **104** relative to the vehicle from the movement of the communication device **102**, **104**.

The movement of the handheld communication device provides an indication of the risk behavior of the driver. Typical vehicular telematics data may provide information concerning the behavior of the vehicle itself. Vehicular telematics data may be supplemented by using the driver behavior risk assessment system. Thus, the behavior of the driver as well as the behavior of the vehicle may be tracked and monitored by an insurance company or other entity/person.

The aforementioned communications module may include a microphone, keypad, touch screen, and/or stylus through which a user of the server may provide input, and may also include one or more of a speaker for providing audio output and a video display device for providing textual, audio/visual and/or graphical output. Software may be stored within the memory and/or storage to provide instructions to the processor for enabling the risk assessment module of the server to perform various functions. For example, memory may store software used by the risk

assessment module of the server, such as an operating system, application programs, and/or an associated database. Alternatively, some or all of the computer executable instructions used by the one or more servers **108**, **110** may be embodied in hardware or firmware. Moreover, the data storage device **122** may provide centralized storage of data. The one or more servers **108**, **110** may operate in a networked environment supporting connections to one or more remote computing devices. The remote computing devices may be personal computing devices or servers that include many or all of the elements described above relative to the server. Remote computing devices may be a mobile device communicating over wireless carrier channel. The network connections depicted in the figures may include a local area network (LAN) **109** and/or a wide area network (WAN) **109**, but may also include other networks. When used in a LAN networking environment, the server may be connected to the LAN **109** through a network interface or adapter in the communications module. When used in a WAN networking environment, the server may include a modem in the communications module or other means for establishing communications over the WAN **109**, such as the Internet. It will be appreciated that the network connections shown and described are illustrative and other means of establishing a communications link between the computing devices may be used. The existence of any of various well-known protocols such as TCP/IP, Ethernet, FTP, HTTP and the like is presumed, and the system can be operated in a client-server configuration to permit a user to retrieve web pages from a web-based server. Any of various commonly known web browsers can be used to display and manipulate data on web pages.

FIG. 2 is a diagram of an exemplary operating environment in accordance with an embodiment of the disclosure. The diagram illustrates the use of a wireless communication device **208** such as a mobile phone handset being operated by a driver of a vehicle **204**. The driver may hold the mobile phone while driving. The driver may hold the phone close to his mouth while speaking. The driver may hold the mobile phone with one or two hands while texting or text messaging someone. The driver may hold the phone in one or more positions depending on how he wishes to use the phone while driving. The wireless communication device **208** may communicate with a wireless access point such as a cell tower as was previously shown in connection with FIG. 1. The vehicle **204** may comprise an automobile, truck, minivan, bus, sport utility vehicle (SUV), recreational vehicle, boat, airplane, train, motorcycle, or any other type of vehicle.

The wireless communication device **208** may communicate with one or more localization devices **212**, **213**, **214** that are placed within the vehicle. The localization devices **212**, **213**, **214** may correspond to the localization devices **103** previously described in connection with FIG. 1. For example, the one or more localization devices **212**, **213**, **214** may be positioned symmetrically within the vehicle. The localization devices **212**, **213**, **214** may be placed, for example, at the sides of the front windshield and midline on the rear windshield as shown in FIG. 2. Alternatively, the localization devices **212**, **213**, **214** may be placed or positioned at various other locations within the vehicle. While the localization devices **212**, **213**, **214** may be positioned symmetrically within the vehicle, it is contemplated that the localization devices **212**, **213**, **214** may be placed asymmetrically within the car.

Aspects of the invention utilize the one or more localization devices **212**, **213**, **214** to determine the location of the

wireless communication device **208** within the vehicle. Use of a single localization device (**212** or **213** or **214**) may provide location information of the mobile communication device **208** in a single dimension. Use of two localization devices (e.g., **213**, **214**) may provide location information of the mobile communication device in a two dimensional plane. Use of three localization devices **212**, **213**, **214** may provide location information of the mobile communication device in three dimensional space. The localization devices **212**, **213**, **214** may utilize a wireless personal area network (WPAN) to communicate with the wireless communication device **208**. In a representative embodiment, the strength of a signal (e.g., a radio frequency and/or electromagnetic signal) that is received by the wireless communication device **208** may be used to determine the distance between the wireless communication device **208** and each of the localization devices **212**, **213**, **214**. The signal may comprise a radio frequency, electromagnetic, optical, visual light spectrum or audio signal, for example. The frequency components of the signal may be associated with any frequency. One or more of the localization devices **212**, **213**, **214** may transmit one or more signals or beacons to the wireless communication device **208**, for example. Each of the signals may be received by the wireless communication device **208**. The location of the wireless communication device **208** may be determined from measurements of the amplitude and phase of the received signals, for example. Given the fixed locations of the localization devices **212**, **213**, **214**, the angle of reception, amplitude, and/or phase of each of the three received signals may be used to triangulate and determine the location of the wireless communication device **208** within the vehicle **204**. Of course the use of additional localization devices, such as a fourth localization device, may be used to improve triangulation accuracy when determining the location of the wireless communication device **208**. In an example, audio spectrum signals such as voices in a vehicle, ambient noises within a vehicle (wind, road noise or other ambient noises) or sounds from a radio can provide the signals used in determining the location of the wireless communication device.

The localization devices **212**, **213**, **214** may communicate with the wireless communication device **208** using Wi-Fi (IEEE 802.11a/b/g/n), Bluetooth, NFC (Near Field Communication), GSM, UMTS, and/or BLE (Bluetooth Low Energy) technologies. The localization devices **212**, **213**, **214** may transmit one or more signals using the one or more technologies. The one or more signals may be received by a receiver resident in the wireless communication device **208**. In one embodiment, the transmission times of one or more received signals may be measured by the wireless communication device **208** to determine one or more distances between one or more localization devices **212**, **213**, **214** to the wireless communication device **208**. The distances from the localization devices may be used to determine the location of the communication device **208**.

In one embodiment, the localization devices **212**, **213**, **214** may be used to reflect a signal transmitted by the wireless communication device **208**. The wireless communication device may be able to compute its distance from the localization device based on the time it takes the signal to be reflected back to the wireless communication device **208**. The localization devices **212**, **213**, **214** may comprise a reflective material (e.g., reflective paint, reflective sticker, etc.) to allow the signal to be reflected back to the wireless communication device **208**. The reflective material may comprise special properties (e.g., nano-properties) that absorb and/or reflect radio waves in a non-standard manner.

In some aspects, the reflective material, instead of absorbing the signal, may reflect or amplify certain or all frequencies associated with the signal. The wireless communication device 208 may comprise an antenna array for measuring the angle in which the reflected signals is received. At least one benefit of using reflective materials in some embodiments may be a reduced/non-existent requirement for a power source to operate the localization devices.

In one embodiment, the various aspects of the invention may employ the use of a combination of communication technologies. For example, the wireless communication device 208 may employ both Wi-Fi and Bluetooth technologies. The wireless communication device 208 may comprise a Wi-Fi transceiver and a Bluetooth transceiver. The Wi-Fi transceiver may be located at an optimal distance, such as far apart from the Bluetooth transceiver as possible, to minimize interference. For example, the Wi-Fi transceiver may be positioned on the top portion of the wireless communication device 208 while the Bluetooth transceiver may be positioned on the bottom portion of the wireless communication device 208.

In one embodiment, each of the localization devices 212, 213, 214 comprises a BLE transceiver (e.g., a low energy transceiver). The BLE transceiver may comprise a switched antenna array. BLE packets may be transmitted at regular intervals by the one or more localization devices 212, 213, 214. The wireless communication device 208 may receive the transmitted packets and process the received packets to compute its location relative to the one or more localization devices 212, 213, 214. The wireless communication device 208 may comprise a memory and a processor. Computer-executable instructions, software, or code may be stored in a memory of the wireless communication device 208. The processor may be used to execute the instructions, software, or code. When executed, the computer-executable instructions, software, or code, may perform the processing of the one or more received BLE packets. The processing may comprise computing the location of the wireless communication device 208 relative to the one or more localization devices 212, 213, 214.

When each of the localization devices 212, 213, 214 comprises a BLE transceiver, the BLE transceiver may be powered by a small battery, such as a coin sized battery. In other embodiments, each of the localization devices 212, 213, 214 may be powered by a vehicle's battery or by one or more solar panels attached to the vehicle.

In a one embodiment, the processing performed by the processor in the wireless communication device 208 may also utilize other data inputs to provide better granularity and accuracy in determining the position of the wireless communication device 208 within the vehicle 204. For example, GPS (global positioning system) data received by the wireless communication device 208 may be used to supplement the location data derived from the processing of the signals received from the localization devices 212, 213, 214. Furthermore, for example, data provided by cell tower triangulation algorithms may be used to further supplement the location data derived from the processing of the signals received from the localization devices 212, 213, 214.

In one embodiment, the presence of other wireless communication devices (not shown in FIG. 2) provides additional sources for providing location information for the wireless communication device 208. The other wireless communication devices may be located within the vehicle 204. Each of the other wireless communication devices may act as a positional reference to the wireless communication device 208 based on its relative location to the localization

devices 212, 213, 214. Thus, each of the other wireless communication devices may be used as a reference to supplement the location data based on the signals received from the localization devices 212, 213, 214.

In one embodiment, movement of the wireless communication device 208 may be tracked using an RFID tracking system. In this embodiment, the localization devices 212, 213, 214, may comprise RFID (radio frequency identification) nodes. An RFID node may comprise a scanning antenna and a transceiver for decoding any received RFID signals. An RFID tag may be attached to the mobile communication device 208. The RFID tag may comprise an active or a passive transceiver or transponder that transmits a radio signal in response to RF signals generated by the RFID nodes. When the RFID tag is an active device, it may be powered by a small battery (such as a small coin sized battery or it may be powered by some other source of energy, such as the vehicle's battery or alternator or solar panels positioned on the vehicle). Alternatively, the localization devices 212, 213, 214 may be powered using a 12 volt accessory adapter found in many vehicles. An active RFID tag may periodically transmit the radio signal to the reader while a passive RFID tag transmits a signal in response to a radio signal received from one or more nodes. While the illustration of FIG. 2 shows three locations where RFID nodes may be positioned inside a vehicle, there may be any number of RFID tags attached to the vehicle in other embodiments. The nodes may be positioned inside the vehicle or on the exterior of the vehicle. The one or more RFID nodes may receive the radio signals transmitted by the RFID tag and facilitate the processing of these signals to determine the location of the tag, and hence the location of the mobile communication device 208. The location of the tag may be determined using triangulation, based on the amplitude and direction of the radio signals received at each node. Each node may be communicatively coupled to a RFID processor that processes the received radio signals transmitted by the RFID tag. The RFID processor may determine the location of the tag using a triangulation technique, for example. While not shown in FIG. 2, the RFID processor may be located anywhere in the vehicle. The RFID processor may transmit data regarding the position of the mobile communication device 208 to the one or more servers previously described in connection with FIG. 1. Using the foregoing technique, the movement of the mobile communication device may be monitored by the insurance company.

In some embodiments, the foregoing techniques may be used to monitor the movement of the wireless communication device may be monitored and may be used by an entity/person (e.g., an insurance company to adjust a user's current and/or future premiums). The insurance premium of a driver may be adjusted based on vehicle speed, time of day the vehicle is used, number of hours the vehicle is operated per day, and braking and acceleration events, for example. The insurance premium may be determined by assessing the number and types of risk related events occurring over a time period and weighting the number for a type of risk event based on a relative risk factor, for example. The number of events (for a particular type of risk) that exceeds a threshold value may be determined and used to compute a component of a driver's score. For example, a telematics processing module at a server or the wireless communication device may tabulate the number of occurrences in which a vehicle exceeded a speed limit of 65 miles per hour. If the number of such speeding events is 10 and the threshold value is 2 events, the difference, 8, is used to compute the

risk component related this particular type of risk event. The value 8 may be multiplied by a relative weighting factor (such as 0.4, for example) and the product, 3.2, may be used in the computation of the driver's score. In this manner, other types of risk related events (e.g., hard braking/acceleration, among other things) may be monitored and the number of occurrences exceeding a corresponding threshold may be determined for each type of risk related event. Each number may be multiplied by its respective weighting factor. In one embodiment, the weights of all the weighting factors may sum to the value 1. The components of the different types of risk events may be summed to yield an overall driver score.

In other embodiments, the driver's wireless communication device **208** may be tracked using a plurality of other wireless communication devices that are in close proximity to the driver's mobile communication device **208**. The plurality of other wireless communication devices may be able to detect the presence of the driver's wireless communication device and determine an associated signal strength and direction. The signal may comprise a Bluetooth or IEEE 802.11xx type of signal, for example. As additional wireless communication devices are used, a mesh network may be implemented, allowing for improved accuracy in the determination of the location of the driver's wireless communication device **208** relative to the other wireless communication devices. The signal strength and direction data obtained from each of the other wireless communication devices may be collected and processed by a server such as the servers **108**, **110** described in connection with FIG. **1**. Based on this data, triangulation techniques may be employed to determine the location of the driver's wireless communication device **208** relative to the other wireless communication devices. The other wireless communication devices may be located within the driver's vehicle or may be located in another vehicle in the vicinity of the driver's vehicle. The server may be able to distinguish and identify the driver's wireless communication device from the other communication devices based on one or more features, characteristics, and historical data associated with the use of the driver's wireless communications device and/or use of applications (resident on the driver's wireless communication device). The applications may have been previously downloaded by the driver from the one or more servers of the insurance company. The applications may allow the driver to input a driver profile and establish a good driver scorecard.

Referring to FIGS. **1** and **2**, the one or more servers **108**, **110** may determine the location of the vehicle **204** being driven based on a first location data provided by the wireless communication device **208** and/or a second location data provided by the localization devices **212**, **213**, **214**. The wireless communication device **208** may provide its location information using one or more localization devices **212**, **213**, **214** and a GPS system (global positioning system). The one or more servers **108**, **110** may utilize the first location data and/or second location data to determine the location of the vehicle being driven.

The localization devices **212**, **213**, **214** may be attached to the vehicle **204** by an owner of the vehicle **204**. Furthermore, as a participant in a driver risk behavior program using the driver behavior risk assessment system and/or as a participant in an insurance company's telematics program, an insured may be incentivized to properly place the localization devices in the appropriate places in his vehicle so that data may be properly acquired by the insurance company. For example, if the one or more localization devices are

billed to the insured, the insured may be given a rebate for properly positioning the localization devices in his vehicle **204**. Otherwise, the insured may direct an automobile dealership or other service facility to install the localization devices for him. It is contemplated that the localization devices may be installed as an option when a vehicle is purchased at a dealership. After installation, the insured may also be given an initial discount on his insurance premium. Future discounts or adjustments to the insured's premium may be based telematics data and/or on an ongoing assessment of the driver's risk behavior as determined by the servers **108**, **110** of the driver behavior risk assessment system.

FIG. **3** is an operational flow diagram describing the placement and calibration of the localization devices in a vehicle in accordance with an exemplary embodiment. The localization devices were previously described in connection with FIGS. **1** and **2**.

At step **304**, one or more localization devices may be placed in or around a vehicle. The one or more localization devices may be positioned in locations to maximize a direct line of sight view of a wireless communication device. The one or more localization devices may be positioned symmetrically within the vehicle to equalize the transceiver's sensitivity of signals received by each localization device. Use of two localization devices may facilitate measurement over two axes in a plane. Use of at least three localization devices may facilitate measurement over three axes in space. At least three localization devices may be used to determine the location or position of a wireless communication device in space. When using three localization devices, for example, two localization devices may be placed symmetrically at the top of a windshield while the third localization device may be positioned at the center top location of the rear windshield, as was previously shown in connection with FIG. **2**. While the localization devices may be positioned asymmetrically, the vehicle's owner may prefer positioning the localization devices symmetrically for aesthetic reasons. If the localization devices are placed asymmetrically, calibration software resident within the one or more servers or in the one or more wireless communication devices may be executed by one or more processors to determine whether the localization devices have been appropriately placed to allow detection of a wireless communication device placed within the vehicle.

Optionally, at step **308**, application software may be downloaded into the one or more wireless communication devices. The application software may allow a participant of the driver risk behavior program and/or a participant of the telematics program to register his cell phone with the insurance company's server. Furthermore, data identifying each of the one or more wireless communication devices may be communicated to the insurance company's server. A user, such as an insured, may associate each of the one or more communication devices to each of one or more vehicles.

Optionally, at step **312**, each of the one or more localization devices may be placed at fixed positions within the vehicle as an aid to the calibration of the localization devices. For example, each of the localization devices may be positioned at corners of the roofline of the vehicle as a way to expedite the calibration procedure.

At step **316**, initialization software may be executed by a processor of a server or a processor resident within a wireless communication device. The owner of the vehicle may initiate the calibration procedure by way of an input selection on one of the one or more wireless communication

devices. For example, the owner may depress a keypad button that initiates the calibration procedure. The calibration procedure may include pairing each of the wireless communication devices to each of the localization devices by way of signals transmitted from each wireless communication device to each localization device. The owner may initiate calibration of the one or more localization devices based on an initialization procedure. The owner may initiate the calibration procedure using his wireless communication device while he is in his normal seating position in the vehicle. The localization devices may infer a range of locations where a wireless communication device may be found in the interior of the vehicle when the vehicle is being driven.

In some embodiments, a user of a wireless communication device may periodically assess his vehicular performance by way of using the application software. For example, a user may be able to access a vehicular scorecard reporting vehicular behavior over a period of time. The scorecard may provide a measure of vehicular behavior as a function of which wireless communication device was used. This may provide an indication of which driver was responsible for a high risk vehicular behavior over the period of time. The scorecard may also provide a daily score and an overall score for the time period. Parameters such as speed, acceleration, and braking information, mileage per trip, and time of day the vehicle is driven, may be monitored and stored in the server's memory or within a data storage device located in a network communicatively coupled to the insurance company's server.

The scorecard may be used to re-evaluate and adjust the premium for the insured. Based on the driving scores for each behavioral risk, a resulting driving score may be accessed and displayed to a user of a wireless communication device. The ability to access the overall telematics based score and monitor one's prospective insurance premium discount or possible increase may act as an incentive to an insured to modify his behavior while driving.

While the operational flow diagram illustrated in FIG. 3 presents a representative embodiment of a process of the invention, the sequence of the steps illustrated in FIG. 3 may be changed in accordance with the various aspects of the invention. For example step 308 may be performed before step 304 and step 312 may be performed before either step 304 or step 308.

FIG. 4 depicts an operational flow diagram of a method in which telematics data is generated in accordance with an embodiment of the disclosure.

At step 404, localization devices within the vehicle detect wireless communication devices. The localization devices may determine which of the wireless communication devices are associated with the driver based on identifying information associated with the driver's wireless communication device. Bluetooth and/or RFID signals may be used to identify the wireless communication devices present in the vehicle. The localization devices may detect and monitor any wireless communication device that is found within a three dimensional space that corresponds to the location where the wireless communication device would be operated by the driver.

At step 408, radio frequency or electromagnetic signals may be transmitted between the localization devices and the wireless communication device. The signals may be transmitted from the localization devices when a wireless communication device has been detected. Otherwise, periodic signals may be transmitted from the wireless communication

device to the localization devices when the wireless communication device detects the presence of at least one, two, or three localization devices.

In a representative embodiment, the signals may comprise Bluetooth Low Energy (BLE) packets, for example when BLE transceivers are used. In one embodiment, the signals may be transmitted periodically to the wireless communication device. The wireless communication device may receive the transmitted packets and process the received packets to compute its location relative to the one or more localization devices. Triangulation techniques may be used by the localization devices to determine the location of the wireless communication device, and at least three localization devices may be used to insure an accurate determination of the location of the wireless communication device.

In another representative embodiment, the signals may comprise RFID signals reflected or transmitted by a passive or active RFID tag attached to the wireless communication device. The location of the tag, and hence the wireless communication device, may be determined using triangulation techniques based on the amplitude and direction of the radio signals received at each node (localization device). The signal received at each node may be reflected from a passive tag or generated by an active tag. The location of the wireless communication device may also be determined from the RFID signal reflected from the tag by determining the time in which the reflected signal is received back at a node. The time is proportional to the distance of the wireless communication device from the node. Using triangulation, the three nodes may provide the location of the wireless communication device within the vehicle.

At step 412, the relative movement between the wireless communication device and the localization devices may be determined based on signal processing performed by the wireless communication device and/or the localization devices. One or more processors in the wireless communication device and/or the localization devices may process the signals. The one or more processors may utilize one or more parameters, such as amplitude, phase, angle of reception, elapsed time, for example, to determine the movement or the position of the wireless communication device over time. Thus, the movement of the wireless communication device relative to the stationary localization devices may be determined.

At step 416, the movement of the wireless communication device relative to the localization devices may be subtracted from the absolute movement of the wireless communication device. The subtraction or adjustment yields the actual movement of the vehicle. A processor in the wireless communication device may compute the difference between the two values. The absolute movement of the wireless communication device may be determined through the global positioning system (GPS) by way of using the GPS chip in the wireless communication device. The term "GPS" or "GPS chip" is intended to include devices which utilize signals received from satellites of the Global Positioning System developed by the United States Department of Defense, as well as systems which utilize signals received from satellites of the Global Orbiting Navigation Satellite System ("GLONASS") developed by the former Soviet Union (or any other satellite-based positioning system which receives and processes electromagnetic signals from three or more satellites). For example, an electronic positioning device which detects radio wave and/or microwave signals from at least three sources may be used, wherein the received signals are processed in a manner similar to the processing of GPS signals in order to determine the subject's

location, altitude, heading, velocity, pace and/or distance traveled. Even signals from cellular phone towers may be employed.

At step **420**, the difference is computed over time and the values for velocity acceleration, and deceleration, may be determined for the direction the vehicle is traveling. The difference may be computed at the one or more servers previously described in connection with FIG. 1. The data pertaining to the movement of the wireless communication device relative to the localization devices may be transmitted to the one or more servers from one or more transceivers of the localization devices. In addition, the data pertaining to the absolute movement of the wireless communication device may be transmitted to the one or more servers from the wireless communication device. Such telematics data may be used by the insurance company to determine insurance rates for the insured.

At step **424**, the values for velocity, acceleration, and deceleration values may be transmitted to the one or more servers. These values may be mapped and indexed by date and time and used in the computation of risk in determining insurance rates for the insured. The one or more servers may be owned and operated by an insurance company. The telematics data may be mapped over the times of the day to determine if the vehicle is being used at irregular hours or hours late at night. Sudden deceleration may correspond to strong braking events. High vehicle speeds, sudden acceleration, and deceleration may be used to re-evaluate the insured's premium. Thus, the telematics data may be used to modify the insured's premium.

In one embodiment, vehicular telematics data may be generated by way of communicatively coupling a wireless communication device to the on-board diagnostics (OBD) module of the vehicle. The OBD module may be able to wirelessly communicate with the wireless communication device by way of a wireless interface connected to a port of the OBD module, for example. In some aspects, the wireless communication device may comprise an accelerometer for measuring the acceleration and/or deceleration of the vehicle being driven by a driver. In one embodiment, in order to obviate components of acceleration resulting from, for example, the driver's use of the wireless communication device, the wireless communication device may be placed in a speakerphone cradle before the vehicular telematics data is processed by a telematics processing module located in a server. In some aspects, other sensors or devices, such as an electronic compass in the wireless communication device, may provide navigational or directional data (e.g., north, south, east, and west, and intermediate directions) associated with a direction the wireless communication device is pointing to. The navigational data provided by the compass may be used to supplement data generated by the OBD module and the accelerometer.

In some aspects, the wireless communication device may utilize the data it receives from the OBD module with the acceleration and/or deceleration data provided by the accelerometer. The OBD module may provide data related to speed, vehicle idling times, and over-revving of the engine, among other things. The entire data may be processed by the wireless communication device and transmitted to a telematics processing module for further processing by a server. The processed data may provide vehicular telematics data which may be transmitted to the driver's insurance company or any other organization. The insurance company may use the vehicular telematics data to assess the behavior of the driver. The vehicular telematics data may be used to generate a driver scorecard for rating the driver and determining

whether the driver receives a discount or a premium in his next bill. Any electronic device or sensor that is communicatively coupled to the OBD module may provide data that is used to determine risk behavior of the driver. For example, data associated with a vehicle's brakes (e.g., temperature of brake or rotor, thickness of brake rotor), data related to a driver's use of his seat heater, data associated with radio such as volume (loudness) or repeated switching or changing of radio channels, data providing seat position, data indicating whether traction control is one or off, data providing temperature of the vehicle's engine and/or transmission, data related to the date and miles since last oil change or other service and/or required maintenance, and data corresponding to the operation or function of headlamps, taillights, and brake lights, may be used individually or in combination to assess the risk behavior of the driver.

FIG. 5 is an operational flow diagram describing how movements of the driver's wireless communication device are processed in accordance with an exemplary embodiment.

The process starts at step **504** where one or more localization devices may be configured to transmit one or more signals to a driver's wireless communication device. Alternatively, the driver's wireless communication device may be configured to transmit one or more signals to the one or more localization devices. The one or more signals may comprise Bluetooth Low Energy (BLE) packets, for example. The BLE packets may be transmitted either from the one or more localization devices or from the driver's wireless communication device at regular intervals using a transmission antenna. The antenna for each of the one or more localization devices may comprise a switched antenna array. In an illustrative embodiment, the BLE packets may be received by the driver's wireless communication device, and the angle of departure of the BLE packets may be calculated by the driver's wireless communication device. The angle of departures of the one or more BLE packets transmitted by the switched antenna arrays of the one or more localization devices may be used to determine the location of the driver's wireless communication device relative to the one or more localization devices. In another illustrative embodiment, the driver's wireless communication device transmits one or more BLE packets to the switched antenna array and the angle of arrival of each of the BLE packets may be calculated by each of the switched antenna arrays.

At step **508**, the location of the driver's wireless communication device relative to the one or more localization devices may be determined using the angle of departure of each of the BLE packets received. In this illustrative embodiment, the driver's wireless communication device may compute the angle of departure for each BLE packet that it receives. Based on the one or more angles of departure, the driver's wireless communication device may generate location data to determine its location relative to the one or more localization devices. In another illustrative embodiment, each of the one or more localization devices computes an angle of arrival for each of the BLE packets. The one or more localization devices utilize these angles of arrival to generate the location of the driver's wireless communication device. The location data is used to determine the location or position of the driver's wireless communication device relative to the one or more localization devices.

Next, at step **512**, the location or position may be transmitted to one or more servers and/or computing devices for storage (e.g., in a memory) and processing (e.g., by a processor). The location or position data or information may

be transmitted by the driver's wireless communication device or the one or more localization devices situated within the vehicle.

At step 516, the one or more servers may analyze and/or process the location or position information of the wireless communication device over time.

Next, at step 518, the one or more servers may use or employ one or more algorithms to determine the behavior of the driver of the vehicle over time. For example, the risk behavior of the driver may be inferred or determined based on applying an algorithm using the movements of the driver's wireless communication device. It is contemplated that movement of the phone in certain ways may signify unsafe behavior. Therefore, the one or more servers may analyze the position of the driver's wireless communication device over time using one or more algorithms. A person having ordinary skill in the art after review of the entirety disclosed herein will appreciate that numerous deterministic, algorithmic, formulaic and/or stochastic approaches are contemplated by the reference to "algorithm" herein. In addition, machine learning, prediction, and/or statistical clustering methods may also be employed by the algorithm in some embodiments.

In a representative embodiment, an algorithm is used to determine the type of behavior performed by a driver based on where the driver's wireless communication device (or handset) is located relative to the attached localization devices. One or more locations and/or positions of the handset may correspond to a particular event. Thus, an event may be associated with a range of handset positions. Thus, the algorithm may map a particular range of handset positions to a particular event. The probability of one or more events occurring over a large period of time may be determined by the algorithm. As the driver drives his vehicle over a period of time, the one or more events accumulate and the percentage of occurrence for each event may be tabulated. Thus, over a large enough sample set, the probability of the occurrence of one or more events will be determined or predicted. Thus, the insurance company will be able to establish a risk profile based on the driver's behavioral history. The behavioral history may be specific to just the data collected from the driver, or may generally include data collected from other drivers (e.g., all drivers with the same vehicle type, all drivers of a particular demographic, etc.) that meet a particular criteria.

The algorithm may collect data associated with variations in the z axis of a three dimensional xyz coordinate system. After a significant number of samples are collected over time, a histogram of data points along the z axis may be generated to allow one to categorize a range of one or more ranges of points along the z axis as representing a particular type of behavioral event. For example, a handset positioned at z=0 may correspond to a first event in which the handset located at safe position (i.e., a low height such as in the center console of the vehicle or inside the pant pocket of the driver). A handset positioned at z=1/2 may correspond to a second event in which the handset is located at a height suitable for the driver to text or for view the screen of the handset. Occurrence of the second event may be considered an unsafe condition by the insurance company. A handset positioned at z=1 may correspond to a third event in which the handset is located at a height that is suitable for the driver to talk with the handset next to his ear. The height at z=1 may correspond to the height or level of the driver's head while the driver is seated in his vehicle. Occurrence of the third event may also be considered an unsafe condition by the insurance company.

The algorithm may determine that an event corresponding to the handset positioned at z=0 has occurred if the handset is below z=1/4, for example. The algorithm may determine that the event corresponding to z=1/2 has occurred if the handset has been between z=1/4 and z=3/4 for a certain minimum duration of time (i.e., a minimum threshold value). Likewise, the algorithm may determine that the event corresponding to z=1 has occurred if the handset has been between z=3/4 and z=5/4 for a certain minimum duration of time.

The algorithm may determine the average durations of time corresponding to a z=1/2 event and a z=1 event. When, for a particular event, the handset is deemed to have occurred for half the average duration of time, the algorithm may determine that the event had occurred with 50% certainty. When, for a particular event, the handset is deemed to have occurred for exactly the average duration of time, the algorithm may determine that the event had occurred with 100% certainty. The probability of an event occurring may be computed by dividing the duration of an event by the average duration of that event.

In one embodiment, the occurrence of an event may be multiplied by its certainty and the probability of occurrence of an event may be computed. For example, the algorithm may compute the probability of occurrence of a z=1/2 event (a driver texting or viewing his/her handset). Likewise, the algorithm may compute the probability of occurrence of the z=1 event (a driver talking with handset to his/her ear).

Based on the event outcome over time, the percentages or probabilities for each of the z=0, z=1/2, and z=1 event categories may be computed, and the algorithm may assign the driver into a particular risk profile based on these probabilities or event percentages. A driver may be classified as a "good driver" when the z=0 event occurs 100% of the time (e.g., the driver leaves his handset on the center console of his vehicle 100% of the time). On the other hand, the driver may be classified as a "bad driver" when z=1/2 or z=1 events occur for a significant amount of time (e.g., the driver texts or speaks for a significant amount of time, such as texting for 5% of the time and speaking for 10% of the time). In one example, the algorithm may determine a corresponding risk profile based on the following event percentages:

Risk	Event Percentages
Good	z = 0, 100%; z = 1/2, 0%, z = 1, 0%
Bad	z = 0, 85%; z = 1/2, 5%, z = 1, 10%
Bad	z = 0, 80%; z = 1/2, 0%, z = 1, 20%
Bad	z = 0, 80%; z = 1/2, 20%, z = 1, 0%

The foregoing table indicates that a driver is considered a "good" risk if he always has his handset on his center console or in his pant pocket while driving in his vehicle. If the driver has his phone on his console for 85% of the time, texts or surfs the Internet for 5% of the time, and talks with his phone placed on his ear for 10% of the time, then the driver is considered to be a "bad" risk. If the driver has his phone on his console for 80% of the time and talks with his phone placed on his ear for 20% of the time, then the driver is considered to be a "bad" risk. If the driver has his phone on his console for 80% of the time and talks with his phone placed on his ear for 20% of the time, then the driver is considered to be a "bad" risk.

A driver may be categorized into one or more risk categories based on one or more probabilities of occurrence of one or more behavioral risk events. The foregoing exem-

plary table describes two risk categories, “good” and “bad”. In other embodiments, a driver may be assigned to one of a plurality of risk categories.

In addition to the foregoing embodiment, similar methods may be applied to the x and/or y axes where handset positions along these axes may be associated with one or more types of events. The percentage of occurrence of events along these axes may also have an influence in determining a particular driver risk profile.

The algorithm may be used to trigger specific alerts to a driver to modify their behavior. For example, the algorithm may be used to monitor speed while the driver is speaking on the handset. When the speed exceeds a certain velocity while the driver is perceived to be talking on the handset, an alert may be transmitted to the handset from the server.

When the expected percentage of events associated with handset position of a driver changes unexpectedly, the algorithm may determine that an impairment or medical emergency may have occurred. For example, erratic changes in handset position over time may indicate that the driver is involved in a struggle with a car jacker. Furthermore, for example, excessive shaking related to alcoholism may be detected when there are constant small changes in handset position over time. Other types of events may be determined or learned through machine learning and/or prediction methods employed by the algorithm.

The insurer may provide insurance premium discounts to an insured based on the absence of risk related events over a specific period. For example, the insured may receive a discount if a negative event does not occur over a month or if there are less than a certain number of negative events per month.

A sudden acceleration of the wireless communication device may also be interpreted as a type of risk behavior. The algorithm may detect an accelerated movement of the wireless communication device or handset over time. When the acceleration computed by the server exceeds a certain threshold, the one or more servers may determine that a certain risk behavior has occurred. The particular risk behavior may be determined based on the acceleration with other data, such as telematics data received using other devices. Movement of the wireless communication device away from the driver’s seat region may also be determined by the one or more servers as a particular risk behavior. The server may determine that the wireless communication device is on the floor of the vehicle. The server may interpret this condition to be a risk behavior. Thus, the location of the wireless communication device may be used by the server to determine whether a risk behavior has occurred.

The circumstances during which a driver uses his handset may determine whether or not the driver exhibits risk behavior. For example, the server may determine that the driver uses his handset only when the vehicle is stopped. In this instance, the talking event may be disregarded and not considered a behavioral risk event. The time of day in which the handset is used may also be a factor which determines whether the driver has engaged in risky behavior. For example, texting at night may be considered far more risky than texting during the daytime. Furthermore, for example, texting during rush hour traffic times may be considered far more risky than texting during non-rush hour traffic times. One or more events, such as sustained talking (either by handset to ear or by speakerphone), texting, Bluetooth use, e-mailing, Internet surfing and/or reading, e-book reading, movie watching, use of handset camera and/or video camera, switching of settings and/or application software, playing of games, checking of e-mails, voicemails, text mes-

sages, and the like, for any period including a period of less than five seconds, three seconds or one second, and positioning of the handset for immediate use (on the driver’s lap, for example) may each be indicative of risky behavior and the occurrence of one or more of these events in sequence or in combination may be determined to be a behavioral risk event. In some aspects, a handset may recognize that the driver’s face is staring at the handset by way of using a facial recognition algorithm. When the handset determines that the driver is staring at the handset (instead of paying attention to traffic), the algorithm may determine that a behavioral risk event has occurred. The duration of a behavioral risk event may also affect the degree of risk behavior. For example, a driver who typically types short text messages may be associated with less risky behavior than a driver who typically types long text messages. The number and/or duration of behavioral risk events or occurrences over a period of time may affect a driver’s risk score. For example, a driver who sends 1 text messages per day while driving would exhibit less risky behavior than a driver who sends 10 text messages per hour.

The localization devices may be capable of receiving RF signals from any communication device within the vehicle. Accordingly, when the localization devices detect the use of multiple devices in the vehicle, the server may determine that a risk behavior has occurred. The movement of the wireless communication device may be monitored over time. When the movement is inconsistent with that of a normal phone conversation, for example, the server may determine that a risk behavior has occurred. The location of the wireless communication device may also determine that the driver is texting while driving. When the server determines that the wireless communication device is in a location within the vehicle that allows the driver to text, read, or dial out using his communication device while the vehicle is determined to be moving, the server may determine that a risk behavior has occurred.

When a risk behavior has determined to have occurred, the one or more servers may generate one or more alerts or notifications to the driver to warn him of the occurrence. The warnings may comprise automated phone calls to the driver’s wireless communication device, for example. If the driver replies back on the automated call with an appropriate response and/or the occurrence or condition is discontinued within a period of time, the risk behavior status may be cancelled and/or the occurrence may be considered a normal driving behavior. Otherwise, the warning may continue to alert the driver and written notifications may be generated and communicated to the driver’s wireless communication device. Based on the number and types of risk behaviors occurring over a period of time, as determined by the one or more servers, the insurance company may document such occurrences and raise the premium of the driver accordingly.

The behavior of one or more passengers situated in the vehicle may also be analyzed by the one or more servers based on the movements of the driver’s wireless communication device. While the driver is driving, the execution of an application resident in a wireless communication device may provide risk behavior information. The driver may execute the application in order to participate in one or more discounts offered by the insurance company. The insurance company may provide the application for download into the wireless communication device as an incentive for the driver to become more conscientious while driving. For example, texting or surfing the Internet while driving may pose a risk hazard. Inputs such as vehicle speed, acceleration, braking information, mileage per trip, duration of trip, and time of

day the vehicle is driven, and other telematics data may be used by the one or more algorithms to measure risk behavior of the driver. When the one or more servers determine that potentially unsafe behavior is occurring in a vehicle, that determination may be used to prompt and/or alert other drivers in other vehicles in the same vicinity to be extra careful. Alerts and/or warnings may be transmitted to various other drivers' wireless communication devices in the immediate vicinity when such an unsafe condition is determined by the one or more servers. The one or more servers may be used to monitor the use of the driver's wireless communication device when the vehicle is in operation or when the vehicle is moving. As an incentive, an insurance company may provide a discount to any driver who agrees not to use his wireless communications device in his vehicle. The one or more servers may continuously or randomly monitor the movement of the driver's communication device to determine if the driver is using his wireless communications device or not. In an illustrative embodiment, inputs such as temperature of the vehicle may be received from the driver's vehicle. Based on such inputs, an insurer may be able to better assess the risk of an insured. These inputs may supplement the position or location information of the driver's wireless communication device.

Next, at step 520, an input that indicates whether the vehicle's ignition is turned on may be received by the one or more servers. If it is determined that the vehicle's ignition is turned off, the process continues with step 521, in which the behavior of the driver may be assessed based on the movement of the driver's wireless communication device while the ignition is off. Otherwise, the process continues with step 522. The movement of the driver's wireless communication device may be monitored starting from the time the driver enters his vehicle, and/or closes the door of his vehicle. In some aspects, the movement of the driver's wireless communication device may be monitored if the driver is within a certain distance of his vehicle.

At step 521, the algorithm determines if there is a potential risk associated with the movement of the driver's wireless communication device while the engine is off. This risk may be determined based on erratic movement of the driver's wireless communication device indicative of driving risks, such as intoxicated behavior movement or potential seizure movement. If the movement of the wireless communication device indicates that a potential risk behavior may occur when the driver operates his vehicle, the process may proceed to step 523. Otherwise, the process ends, as it may be determined that the driver poses no safety risk and may be simply sitting in a parking lot with the ignition turned off waiting for someone to arrive, safely speaking or texting to someone on his wireless communication device away from traffic, or operating an application using his wireless communication device.

At step 523, the ignition of the vehicle may be disabled for a period of time. The ignition may be disabled for a period of time even after the movement (associated with the potential risk) of the wireless communication device stops. The period of time may be determined based on the type of potential risk behavior, as determined by the algorithm at the one or more servers. In some aspects, an alert may be transmitted from the one or more servers to the driver's wireless communication device. The alert may be accompanied by a request to respond if the ignition is to be enabled. If the driver appropriately responds to the request, the ignition may be enabled and the process ends. In some aspects, the ignition may not be enabled until the appropriate response is received by the one or more servers.

At step 522, the server determines if one or more risk thresholds have been met using the one or more algorithms. For example, movement of the driver's wireless communication device may be monitored by the localization devices. The orientation of the communication device as well as type of usage may be monitored. Furthermore, telematics data may be used to determine if one or more thresholds have been met or exceeded. For example, a vehicle's speed may exceed a particular threshold if the driver drives his vehicle over a certain number of miles per hour. Thus, the velocity of the vehicle may be monitored to determine if it exceeds a certain threshold value. Furthermore, for example, sudden braking of a vehicle may cause deceleration to occur. The deceleration may be monitored to determine when it exceeds a certain threshold value. Likewise, acceleration may be monitored as well. When the driver makes his vehicle accelerate at more than a predetermined threshold value, the acceleration data may be recorded at the vehicle and transmitted to a computing device or server of an insurance company. Other factors and/or inputs may be monitored and may be used in combination with the telematics data previously mentioned. Temperature within the vehicle may also be used as an input. The temperature may also be transmitted back to the insurance company and stored in a computing device or server.

Next, the process continues with step 524 if one or more risk thresholds have been met and/or exceeded. The number of instances in which a threshold has been reached or exceeded may be recorded by the computing devices and/or servers of the insurance company. The computing devices and/or servers may generate a level of risk associated with the behavior. Otherwise, the process reverts back to step 504. At step 524, the driver may be notified or alerted when a threshold has been met or exceeded. The vehicle may be controlled when a threshold has been met or exceeded. The number of such occurrences may be stored in the insurance company's server. The data may be used to modify the premium of the driver. For example, if the number of these occurrences reaches a certain number, the driver's premium may be adjusted upwards. The computing devices and/or servers may generate reports of such occurrences to the driver to alert or notify the driver that such risk behavior has occurred. The computing devices and/or servers may also provide warnings before the driver's premium raised. Thereafter, the process repeats itself by reverting back to step 504.

A user of a wireless communication device may periodically assess his behavioral performance by way of using application software resident in his wireless communication device. For example, a user may be able to access a driver's scorecard reporting his use of the phone while driving a vehicle. The scorecard may rate a driver based on his use of a wireless communication device. The software application may also provide a graphical user interface that informs the driver that he performed one or more risky behaviors over a certain period of time. For example, the driver may have texted while driving, surfed one or more websites, or used one or more applications resident within a smartphone. The software application may also be used to monitor the types of applications the user was accessing while driving. For example, the software application may monitor that the user was shopping at a certain website, playing a card game, or inputting text in an application, for example. The software may report this data back to the insurance company's server where the scorecard may be computed. The scorecard may also provide a daily score and an overall score for the time period. The scorecard may provide a measure of a driver's behavior as a function of which wireless communication

device was used. This may provide an indication of which driver was responsible for a certain behavior over the period of time.

The scorecard may be used to re-evaluate and adjust the premium for the insured. Based on the scores for each behavioral risk, a resulting score may be accessed and displayed to a user of a wireless communication device. The ability to access the overall score and monitor his prospective insurance premium discount may act as an incentive to an insured to modify his behavior while driving. The foregoing presents a simplified summary of the disclosure in order to provide a basic understanding of some aspects. It is not intended to identify key or critical elements of the invention or to delineate the scope of the invention. Although not required, one of ordinary skill in the art will appreciate that various aspects described herein may be embodied as a method, a data processing system, or as a computer-readable medium storing computer-executable instructions. Accordingly, those aspects may take the form of an entirely hardware embodiment, an entirely software embodiment or an embodiment combining software and hardware aspects. For example, a tangible computer-readable medium (e.g., a CD-ROM, RAM, hard drive, flash memory, etc.) storing instructions to cause a processor to perform methods in accordance with aspects of the disclosure is contemplated.

Aspects of the invention have been described in terms of illustrative embodiments thereof. Numerous other embodiments, modifications and variations within the scope and spirit of the disclosed invention will occur to persons of ordinary skill in the art from a review of this entire disclosure. For example, one of ordinary skill in the art will appreciate that the steps illustrated in the illustrative figures may be performed in other than the recited order, and that one or more steps illustrated may be optional in accordance with aspects of the disclosure.

While some embodiments have been described with respect to specific examples, other embodiments include numerous variations and permutations of the above described systems and techniques.

We claim:

1. A method comprising:
 - determining, by a processing module, an actual movement of a vehicle after an adjusting is performed based on movement data obtained from a global positioning system (GPS) associated with the vehicle;
 - periodically receiving data corresponding to a position of a wireless communication device relative to at least three RFID nodes located in the vehicle;
 - analyzing, by a processor, the data to determine one or more occurrences of one or more behavioral risk events, wherein the one or more occurrences is based on the position indicating that the wireless communication device is located at a height suitable for texting by a driver;
 - determining, by the processor, one or more probabilities of occurrence of the one or more behavioral risk events; and
 - based on the one or more probabilities, categorizing, by the processor, a driver of the vehicle into a risk category.
2. The method of claim 1, wherein the data is generated by way of the wireless communication device transmitting a signal to each of the at least three RFID nodes.
3. The method of claim 1, wherein each of the at least three RFID nodes comprise a processor and a memory.

4. The method of claim 1, wherein the position corresponds to the height of the driver seated in the vehicle, and the event corresponds to the driver speaking while the wireless communication device is placed on an ear of the driver.

5. The method of claim 1, wherein the one or more occurrence is based on the position indicating that the wireless communication device is located on a floor of the vehicle.

6. The method of claim 1, wherein insurance premium discounts are provided to an insured of the vehicle if the risk category indicates that the driver is associated with a good risk.

7. The method of claim 1, wherein alerts are transmitted to the wireless communication device if the position changes irregularly over time.

8. The method of claim 1, wherein an insurance premium of an insured is increased if the risk category indicates that the driver is associated with a bad risk.

9. The method of claim 1, further comprising: attaching an RFID tag to the wireless communication device.

10. The method of claim 1, further comprising: affixing a fourth RFID node inside the vehicle, wherein the four RFID nodes are symmetrically attached to the vehicle.

11. A method involving at least three localization devices attached to a vehicle, the method comprising:

transmitting, by a wireless communication device in use in the vehicle, a signal to each of the at least three localization devices, wherein each of the at least three localization devices process the signal to determine a position of the wireless communication device relative to the at least three localization devices over time;

determine, by a telematics processing module located in the vehicle, an actual movement of the vehicle after an adjusting is performed based on movement data obtained from a global positioning system (GPS) in the vehicle;

determine, by a processor, one or more occurrences of one or more events, wherein the one or more occurrences is based on the position indicating that the wireless communication device is located at a height suitable for texting by a driver of the vehicle;

determine one or more probabilities of occurrence of the one or more occurrences of the one or more events; and categorize the driver into a risk category based on the one or more probabilities.

12. The method of claim 11, wherein the at least three localization devices comprise RFID nodes.

13. The method of claim 11, wherein the position corresponds to the height of the driver seated in the vehicle and an event of the one or more events corresponds to the driver speaking while the wireless communication device is placed on an ear of the driver.

14. The method of claim 11, wherein insurance premium discounts are provided to an insured of the vehicle if the risk category indicates that the driver is associated with a good risk.

15. The method of claim 11, wherein an RFID tag is attached to the wireless communication device.

16. The method of claim 11, wherein the signal comprises a Bluetooth Low Energy (BLE) signal.

17. The method of claim 11, wherein the at least three localization devices comprises four localization devices that are attached to said vehicle symmetrically.

18. A method performed by a risk assessment module communicatively coupled with: (i) at least three localization devices attached to a vehicle; (ii) a wireless communication

device configured to transmit a signal to the at least three localization devices, wherein each of the at least three localization devices processes the signal to determine position data of the wireless communication device relative to the at least three localization devices attached to the vehicle 5 over time; and (iii) a telematics processing module of a computing device configured to determine an actual movement of the vehicle after an adjusting is performed based on movement data obtained from a global positioning system (GPS); wherein the method comprises: 10

analyzing the position data of the wireless communication device inside the vehicle to determine an occurrence of a behavioral risk event of a driver of the vehicle, wherein the occurrence is based on the position data indicating that the wireless communication device is 15 located at a height suitable for texting by the driver; determining a probability of the occurrence of the behavioral risk event; and categorizing the driver into a risk category based on the probability. 20

19. The method of claim 18, wherein the occurrence is based on the position data indicating that the wireless communication device is placed at a height corresponding to a head of the driver.

20. The method of claim 18, wherein the signal comprises 25 a Bluetooth Low Energy (BLE) signal.
