(57) **ABSTRACT**

The present invention suggests a power control apparatus and method of a vehicle which switch the switching frequency component generated in the power supply module to odd-number times of a Nyquist frequency which is the most ignorable in the frequency domain which is used for the FMCW radar, thereby preventing the erroneous detection due to the switching frequency in the FMCW. The present invention provides a power control apparatus of a vehicle radar, including: a first frequency signal generating unit which generates a first frequency signal with a predetermined amplitude; a second frequency signal obtaining unit which converts a frequency value of the first frequency signal to obtain a second frequency signal; and a power supply control unit which controls the power to operate a vehicle radar based on the second frequency signal.

APPARATUS AND METHOD FOR CONTROLLING POWER OF VEHICLE RADAR

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims priority to and the benefit of Korean Patent Application No. 10-2014-0157154 filed in the Korean Intellectual Property Office on Nov. 12, 2014, the entire contents of which are incorporated herein by reference.

TECHNICAL FIELD

The present invention relates to an apparatus and a method for controlling a power which is supplied to a radar system, and more particularly, to an apparatus and a method for controlling a power which is supplied to a vehicle radar system.

BACKGROUND ART

According to the related art, since a bandwidth of a frequency domain used in the vehicle radar system is not so broad, a component of a switching frequency generated in a power supply module does not cause a problem.

However, in recent years, as a usable bandwidth is gradually increased, the switching frequency is included in a frequency domain used in a frequency modulated continuous wave (FMCW) radar, which may cause a problem.

In order to solve the above-mentioned problem, U.S. Pat. No. 7,079,073 discloses a method which shifts a switching frequency component of a power supply device of an FMCW radar into an assignable band to move the switching frequency component to the outside of a frequency domain where data exists, thereby avoiding a noise.

However, the above method has the following problems:

First, in order to change a switching frequency, a switching signal output module which includes a clock generator and a frequency setter as hardware is required. Since a mixer and a local oscillator (LO) which outputs various frequencies are further required, adverse influences such as an increased size of the hardware, an increased material cost, and increased complexity are generated.

Second, when a maximum value of a Nyquist frequency and a maximum value of a beat frequency are equal to each other, the switching frequency is unconditionally shifted only to f_N . However, in this case, only a part of a function of the switching signal output module is used, so that the other part may be wasted. In an actual system, the maximum value of the Nyquist frequency and the maximum value of the beat frequency are equal to each other in many cases and a width of allocation bands is narrow.

Third, the method used an aliasing bands may vulnerable to Electro Magnetic Compatibility (EMC) than the method used the lowest specific band.

SUMMARY OF THE INVENTION

The present invention has been made in an effort to provide a power control apparatus and a method of a vehicle radar which moves a switching frequency component generated in a power supply module to an odd number multiple of a Nyquist frequency which is the least problematic in a

2

frequency domain which is used by an FMCW radar to prevent erroneous detection due to the switching frequency in the FMCW radar.

However, an object of the present invention is not limited to the above description and other objects which have not been mentioned above will be more apparent to those skilled in the art from a reading of the following description.

An exemplary embodiment of the present invention provides a power control apparatus of a vehicle radar, including: a first frequency signal generating unit which generates a first frequency signal with a predetermined amplitude; a second frequency signal obtaining unit which converts a frequency value of the first frequency signal to obtain a second frequency signal; and a power supply control unit which controls a power source to operate a vehicle radar based on the second frequency signal.

The first frequency signal generating unit may configure the vehicle radar and may be provided in a signal processor which processes frequency signals generated in the vehicle radar or provided separately from the vehicle radar.

The first frequency signal generating unit may be a clock source for sampling an analog to digital converter which configures the vehicle radar.

The second frequency signal obtaining unit may divide or multiply the frequency to convert the frequency value of the first frequency signal to generate sampling frequencies and obtain the second frequency signal.

The second frequency signal obtaining unit may divide the frequency value of the first frequency signal at odd number times or multiply the frequency value at the odd number times to generate the sampling frequencies.

The second frequency signal obtaining unit may generate a Nyquist frequency with the sampling frequencies.

The second frequency signal obtaining unit may detect intermediate frequencies having an intermediate value between the maximum value and the minimum value among the sampling frequencies and obtain the second frequency signal based on the frequency having the minimum value among the intermediate frequencies.

Further, another exemplary embodiment of the present invention provides a power control method of a vehicle radar, including: generating a first frequency signal with a predetermined amplitude; converting a frequency value of the first frequency signal to obtain a second frequency signal; and controlling a power supply to operate a vehicle radar based on the second frequency signal.

The generating may include generating the first frequency signal using a clock source for sampling an analog to digital converter which configures the vehicle radar.

The obtaining may include dividing or multiplying the frequency to convert the frequency value of the first frequency signal to generate sampling frequencies and obtain a second frequency signal.

The obtaining may include dividing the frequency value of the first frequency signal at odd number times or multiplying the frequency value at the odd number times to generate the sampling frequencies.

The obtaining may include generating a Nyquist frequency with the sampling frequencies.

The obtaining may include detecting intermediate frequencies having an intermediate value between the maximum value and the minimum value among the sampling frequencies and obtaining the second frequency signal based on the frequency having the minimum value among the intermediate frequencies.

According to the exemplary embodiment, the following effects may be obtained by moving a switching frequency

component generated in a power supply module to an odd-number multiple of the Nyquist frequency which is the least problematic in a frequency domain which is used in an FMCW radar.

First, erroneous detection due to the switching frequency is not generated in the FMCW radar, so that a detection performance may be improved.

Second, the methods of the related art further require an element for generating an additional frequency and a module for selecting the frequency, but in the present invention, there is no need to provide an element for generating a frequency, which contributes to reduce the number of parts.

Third, when one radar is used to perform various functions, the switching frequency for products in accordance with the individual functions may be changed. However, the present invention automatically changes the switching frequency of the power supply module, so that the production cost may be reduced through mass production.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a conceptual diagram illustrating a radar system according to an exemplary embodiment of the present invention.

FIG. 2 is a conceptual diagram illustrating a radar system according to another exemplary embodiment of the present invention.

FIG. 3 is a frequency domain view illustrating a frequency domain which is used in an FMCW radar according to an exemplary embodiment of the present invention.

FIG. 4 is a flowchart illustrating a first operating method of a radar system according to an exemplary embodiment of the present invention.

FIG. 5 is a flowchart illustrating a second operating method of a radar system according to an exemplary embodiment of the present invention.

FIG. 6 is a conceptual view illustrating an internal configuration of a power control system which configures a radar system according to an exemplary embodiment of the present invention.

FIG. 7 is a first frequency domain view illustrating a frequency domain where a switching frequency of a power supply module is located, according to an exemplary embodiment of the present invention.

FIG. 8 is a second frequency domain view illustrating a frequency domain where a switching frequency of a power supply module is located, according to an exemplary embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Hereinafter, exemplary embodiments of the present invention will be described in detail with reference to the accompanying drawings. In the figures, even though the parts are illustrated in different drawings, it should be understood that like reference numbers refer to the same or equivalent parts of the present invention throughout the several figures of the drawing. Furthermore, when it is judged that specific description on known configurations or functions related in the description of the present invention may unnecessarily obscure the essentials of the present invention, the detailed description will be omitted. Furthermore, hereinafter, exemplary embodiments of the present invention will be described. However, it should be understood that the technical spirit of the invention is not limited

to the specific embodiments, but may be changed or modified in various ways by those skilled in the art.

The present invention relates to a method and an apparatus for reducing a probability of erroneous detection of a frequency modulated continuous wave (FMCW) radar system including a power supply module which operates at a switching frequency.

The FMCW radar is currently used as a necessary element for various intelligent vehicle technologies such as a smart parking assistance system (SPAS), a lane keeping assistance system (LKAS), or a smart cruise control (SCC) system and is continuously being studied and developed.

Such an FMCW radar detects from a near target to a far distance target in accordance with a used frequency domain to obtain and provide information for adjusting a speed of the vehicle and a distance and applicability thereof may be further broaden.

In order to detect a precise position of an object to be detected, the FMCW radar uses information on a frequency domain with a predetermined bandwidth which is transmitted from an RF module to a signal processing module. In the related art, since the bandwidth of the used frequency domain is not so broad, a component of the switching frequency which is generated in a power supply module can be ignored. However, in recent years, as the bandwidth is gradually increased, the switching frequency is included in the frequency domain which is used in the FMCW radar. When the switching frequency component invades the frequency domain used in the FMCW radar, a probability of erroneous detection is increased and an erroneous warning for a target which does not actually exist is generated to threat safety of a passenger.

Therefore, the present invention suggests a method and an apparatus which move the switching frequency component to an odd-number multiple of a Nyquist frequency which is the most ignorable in the frequency domain which is used in the FMCW radar, thereby preventing the erroneous detection due to the switching frequency in the FMCW.

The present invention has advantages in that the FMCW radar makes the most of the sampling frequency and an ADC clock signal which already exists is used without using an additional source for generating a frequency to divide or multiply a frequency, so that additional cost is reduced.

Further, clock sources of a plurality of elements are unified to reduce deterioration which is additionally generated due to EMC and desynchronization.

Hereinafter, an exemplary embodiment of the present invention will be described in detail with reference to the drawings.

FIG. 1 is a conceptual diagram illustrating a radar system according to an exemplary embodiment of the present invention.

FIG. 1 is a diagram of a radar system illustrating a structure using basic configurations **111** to **142** and **153**, an ADC clock source **151**, and a frequency converting module **152** according to a first exemplary embodiment of the present invention.

As illustrated in FIG. 1, the radar system **100** according to the first exemplary embodiment of the present invention includes M transmitting antennas **111**, N receiving antennas **131**, M amplifiers **121**, an RF frequency generating module **120**, a mixer **132**, a filter **133**, a programmable gain amplifier (PGA) **134**, an analog to digital converter **141**, a signal processor **142**, an ADC clock source **151**, a frequency converting module **152**, and a power supply module **153**.

The M transmitting antennas **111** transmit a high frequency band electromagnetic wave to detect a surrounding object.

The N receiving antennas **131** receives a reflected wave which is reflected from a target to return.

The M amplifiers **112** amplifies a signal which is transmitted to the transmitting antennas **111**.

The RF frequency generating module **120** generates a reference frequency to provide the reference frequency to the amplifier **112**, the mixer **132**, and the signal processor **142**.

The RF frequency generating module **120** includes a voltage control oscillator (VCO) **121**, a phase lock loop (PLL), and a chirp generator. A PLL and chirp generator **122** refers a configuration in which the PLL and the chirp generator are coupled.

The chirp generator determines a waveform of the FMCW radar which is transmitted through the transmitting antenna and the waveform is generated in the VCO **121** which generates the reference frequency.

The PLL fixes a phase of the reference frequency to allow the VCO **121** to stably generate a frequency.

The mixer **132** extracts a beat signal which contains information on targets in a region which is detected by the radar using a difference between the reflected wave and the reference frequency. Here, the reflected wave and the electromagnetic wave are transmitting and receiving band (high frequency band) of the radar and the beat signal includes information of base band frequencies.

The filter **133** removes a noise in the beat signal by filtering the beat signal.

The PGA **134** amplifies the beat signal at an amplification gain in accordance with a predetermined setting.

The ADC **141** transmits amplitude data, which is obtained by converting an amplitude of the amplified beat signal into a digital signal, to the signal processor **142**.

The ADC clock source **151** is a reference clock required to sample the ADC **141**.

The power supply module **153** supplies power to the signal processor **141** and the RF frequency generating module **120** of the radar system **100**.

The frequency converting module **152** receives a single frequency signal of the ADC clock source **151** and divides or multiplies the single frequency component signal with a signal having only a single frequency component which is an odd-number multiple of the Nyquist frequency, and then the power supply module **153** operates with the switching frequency based on the divided signal or the multiplied signal. A frequency component of the switching signal of the power supply module **153** which is changed by the frequency converting module **152** is located at a frequency which does not act as a noise on the beat signal or may cause the least adverse influence, thereby removing or minimizing the adverse influence on the performance of the FMCW radar system due to the switching signal.

FIG. 2 is a conceptual diagram illustrating a radar system according to another exemplary embodiment of the present invention.

Similarly to FIG. 1, FIG. 2 is a diagram of a radar system illustrating a structure using basic configurations **111** to **142** and **153**, an ADC clock source **201**, and a frequency converting module **152** according to a second exemplary embodiment of the present invention.

As illustrated in FIG. 2, the radar system **200** according to the second exemplary embodiment of the present invention includes M transmission antennas **111**, N reception antennas **131**, M amplifiers **112**, an RF frequency generating module

120, a mixer **132**, a filter **133**, a programmable gain amplifier (PGA) **134**, an analog to digital converter **141**, a signal processor **142**, an ADC clock source **201**, a frequency converting module **152**, and a power supply module **153**.

A difference between the radar system **200** according to the second exemplary embodiment of the present invention and the radar system **100** according to the first exemplary embodiment of the present invention is that the ADC clock source **201** is provided in the signal processor **142** in the radar system **200** according to the second exemplary embodiment.

Functions of other components are the same as the functions described with reference to FIG. 1.

The ADC clock source (or an ADC clock output) **201** is used as a reference clock of the ADC sampling frequency. The ADC clock source **201** is located in the signal processor **142** and also transmits a clock signal having a single frequency component to the frequency converting module **152**.

In the meantime, Equation of a Nyquist frequency in accordance with a sampling frequency used in the ADC **141** of the FMCW radar according to the exemplary embodiment of the present invention is as follows:

$$f_{Nyquist} = 1/2 \times f_{sampling}$$

In Equation, $f_{Nyquist}$ refers to a Nyquist frequency and $f_{sampling}$ refers to a sampling frequency of the ADC **141**.

According to Nyquist Theorem, a Nyquist frequency is half the sampling frequency in a maximum frequency domain which is available for the FMCW radar.

FIG. 3 is a view of a frequency domain illustrating a frequency domain which is used in an FMCW radar according to an exemplary embodiment of the present invention.

FIG. 3 is a view of a frequency domain illustrating a frequency domain which is used by the beat signal of the FMCW radar according to an exemplary embodiment of the present invention.

In FIG. 3, an x-axis is a frequency and a y-axis is an amplitude domain. f_{beat_max} refers to a maximum value of the frequency range used by the beat signal and $f_{sampling}$ refers to a sampling frequency of the ADC. $f_{Nyquist}$ refers to a Nyquist frequency in accordance with the sampling frequency and an aliasing band refers to a frequency domain which may influence on the beat signal.

When a frequency domain **310** which is used in the FMCW and a frequency domain **320** which is available in the FMCW radar are as illustrated in FIG. 3, a maximum frequency which is used by the beat signal of the FMCW radar is f_{beat_max} and it should be $f_{beat_max} = f_{Nyquist}$. Aliasing bands **330** and **340** which are prohibition domains are generated in accordance with f_{beat_max} . Widths of the aliasing bands **330** and **340** are $2 \times f_{beat_max}$ and a center axis is an integer multiple of $f_{sampling}$. When a signal other than the beat signal exists in the domain of the aliasing bands **330** and **340**, the signal acts as a noise on the beat signal which may cause erroneous detection of the FMCW radar.

FIG. 4 is a flowchart illustrating a first operating method of a radar system according to an exemplary embodiment of the present invention.

FIG. 4 is a flowchart of a method which processes the reference clock signal of the ADC in the frequency converting module **152** according to the exemplary embodiment of the present invention to determine an optimized switching frequency. Hereinafter, FIG. 4 will be described with the configuration of FIG. 1, but the configuration of FIG. 2 may be also applicable.

First, the ADC clock source **151** generates a reference clock of the ADC in step **S410**.

Next, the frequency converting module **152** receives the reference clock of the ADC in step **S420**.

Next, the frequency converting module **152** determines an optimized switching frequency of the switching signal in step **S430**.

Next, the frequency converting module **152** transmits the optimized switching frequency to the power supply module **153**.

Next, the power supply module **153** generates power using the optimized switching frequency in step **S450**.

Next, the power supply module **153** supplies the generated power to individual components of the radar system **100**.

FIG. **5** is a flowchart illustrating a second operating method of a radar system according to an exemplary embodiment of the present invention.

FIG. **5** is a flowchart that the reference clock signal of the ADC **141** is input to an input of the frequency converting module **152**, according to the exemplary embodiment of the present invention, to dispose the switching frequency to be an odd number multiple of the Nyquist frequency. Hereinafter, FIG. **4** will be described with the configuration of FIG. **1**, but the configuration of FIG. **2** may be also applicable.

The frequency converting module **152** receives a reference clock of the ADC having a single frequency component in step **S510**.

Next, the frequency converting module **152** starts at a Nyquist frequency $f_{Nyquist}$ which is half the sampling frequency in step **S520**.

Next, the frequency converting module **152** calculates an odd number multiple of $f_{Nyquist}$ as $f_{optimized}$ in step **S530**.

Next, the frequency converting module **152** compares $f_{optimized}$ and $f_{switching,max}$ in step **S540**. $f_{switching,min}$ and $f_{switching,max}$ are determined in advance. $f_{switching,min}$ refers to a minimum value of the switching frequency which is available in the power supply module **153** and $f_{switching,max}$ refers to a maximum value of the switching frequency which is available in the power supply module **153**.

When it is determined that $f_{optimized}$ is larger than $f_{switching,max}$ the frequency converting module **152** increments a k value in step **S550** to repeat step **S530**.

In contrast, when it is determined that $f_{optimized}$ is equal to or smaller than $f_{switching,max}$ the frequency converting module **152** compares $f_{optimized}$ and $f_{switching,min}$ in step **S540**.

When it is determined that $f_{optimized}$ is equal to or larger than $f_{switching,min}$ the frequency converting module **152** determines $f_{optimized}$ as a switching frequency in step **S570**.

In contrast, when it is determined that $f_{optimized}$ is smaller than $f_{switching,min}$ the frequency converting module **152** performs step **S550** again.

In the meantime, the frequency converting module **152** repeatedly performs step **S520** to **S570** several times while changing the k value to determine the least frequency in a combination which is larger than $f_{switching,min}$ and smaller than $f_{switching,max}$ among the odd number multiple of $f_{Nyquist}$ as a switching frequency.

In the meantime, the following Equation relates to a method of calculating switching frequencies which may be applied by changing the input ADC clock signal by the frequency converting module **152**.

$$f_{switching} = f_{sampling} / 2 \times (2k - 1) = f_{Nyquist} \times (2k - 1)$$

The switching frequency $f_{switching}$ is determined as an odd number multiple of half of the sampling frequency $f_{sampling}$

or an odd number multiple of the Nyquist frequency. k is a natural number and the simplest circuit configuration may be obtained when $k=1$.

FIG. **6** is a conceptual view illustrating an internal configuration of a power control system which configures a radar system according to an exemplary embodiment of the present invention.

FIG. **6** is a block diagram of a frequency converting module **152** in which the reference clock signal of the ADC is input to an input of the frequency converting module **152** to convert the switching frequency into the odd number multiple of the Nyquist frequency.

In the ADC clock source **151** or **201** which is a module of generating an ADC reference clock, a periodic signal only having a single frequency component $f_{sampling}$ is transmitted to the ADC **141** and the frequency converting module **152**. $CLK_{ADC}(t)$ refers to an ADC reference clock signal.

The frequency converting module **152** converts the ADC reference clock signal into an optimized signal having only one of odd number multiple frequencies of the Nyquist frequency which is half $f_{sampling}$ as a frequency component and transmits the converted signal to the power supply module **153**. $CLK_{switching}(t)$ refers to a periodic signal only having a switching frequency optimized by the frequency converting module **152** as a single frequency component.

The power supply module **153** generates power at an optimized switching frequency using a signal received from the frequency converting module **152** to supply the power to the radar system.

FIG. **7** is a first frequency domain view illustrating a frequency domain where a switching frequency of a power module is located, according to an exemplary embodiment of the present invention.

The switching frequency is changed into a frequency obtained by dividing the frequency of the ADC clock signal input to the frequency converting module **152** by two and then multiplying by odd number multiple. Reference numeral **710** refers to a frequency domain which is used in the FMCW radar, reference numeral **720** refers to a frequency domain which is available in the FMCW radar, and reference numeral **730** refers to an available switching frequency according to the present invention.

In FIG. **7**, since not all the available frequency domain is used in the FMCW radar, the switching frequency is located at $f_{Nyquist}$ which does not cause erroneous detection in the FMCW radar. Therefore, the detection precision of the FMCW radar is improved and even when phenomenon due to the frequency shaking of the switching frequency is generated, the phenomenon may not affect the detection performance.

FIG. **8** is a second frequency domain view illustrating a frequency domain where a switching frequency of a power module is located, according to an exemplary embodiment of the present invention.

FIG. **8** is a view of a frequency domain where the switching frequency of the power supply module **152** is located when all available frequency domains are used at the sampling frequency provided in the FMCW radar, according to the exemplary embodiment of the present invention.

This case means that when the converting frequency uses the frequency domain to $f_{Nyquist}$ in the FMCW radar. In this case, the position **820** of the switching frequency may not be set to be distant from the domain which is used in the FMCW radar. Reference number **810** refers to a frequency used in the FMCW radar and reference numbers **830** and **840** refer to an aliasing band **1** and an aliasing band **2**.

In the exemplary embodiment of the present invention, the frequency converting module **153** designates $f_{Nyquist}$ which the least affects on the detecting performance of the radar as the switching frequency, so that the probability of erroneous detection caused by the switching frequency may be the lowest.

The exemplary embodiment of the present invention has been described above with reference to FIGS. **1** to **8**. Hereinafter, differences between the related art and the present invention will be described again.

First, no switching frequency exists in a frequency domain where data exists so that erroneous detection rate of the radar sensor is reduced.

Further, multiple high angle (vertical direction) alignment is possible.

Further, multiple correcting targets are used so as to compare reception vertical angles of signals which are input at various angles to calculate an angle to be corrected, and thus the prediction may be allowed at high reliability.

Second, differently from the related art, only one IC which divides or converts an input frequency by $(f_{sampling}/2) \times (2k-1)$ (k is a natural number) is used.

The frequency component which is input to the divider as an input is a signal which is necessarily used in the radar sensor and a signal having a single frequency component which is input to the ADC to be used as a sampling frequency of the ADC is used in the present invention. Therefore, an additional module which generates a frequency in a broader range is not necessary and only a module which divides the frequency by 2 and then multiplies the frequency to be odd number multiple is necessary.

Further, a necessary H/W structure is simplified, to reduce production cost, reduce a size of the radar, and reduce the complexity.

Third, optimization is generated when $f_{beat_max} = f_{Nyquist}$ and all the Nyquist frequency domains are used to perform the radar signal processing, so that data loss in the frequency domain is minimized.

In the related art, more complex and expensive clock oscillator is necessary when $f_{beat_max} = f_{Nyquist}$. However, in the present invention, regardless of the range of f_{beat_max} , one IC which divides the frequency by 2 or one IC which multiplies the frequency to be odd number multiple is sufficient.

Further, when the switching frequency is oscillated, in the related art, the location of the frequency is not fixed, so that the erroneous detection may occur. However, in the present invention, the switching frequency is located at all times at $f_{Nyquist}$ so that low probability of erroneous detection may be solidly secured.

Fourth, the clock signal which is used in the radar sensor is also used as a switching frequency of the power supply.

In the radar sensor, all ICs operate by the single clock signal so that the EMC and the system stability may be improved.

Fifth, the present invention may be used to be applied to the FMCW radar sensor and improve the performance and a probability of erroneous operation in the entire system may be reduced through synchronization of clocks.

Therefore, the present invention suggests a method and an apparatus which switch the switching frequency component generated in the power supply module to odd-number times of a Nyquist frequency which is the most ignorable in the frequency domain which is used for the FMCW radar, thereby preventing the erroneous detection due to the switching frequency in the FMCW.

In the related art, since the bandwidth of the used frequency domain is not so broad, a component of the switching frequency which is generated in a power supply module can be ignored. However, in recent years, as the bandwidth is gradually increased, the switching frequency is included in the frequency domain which is used for the FMCW radar.

According to the present invention, the FMCW radar uses the sampling frequency at most, so that there is no waste. Further, for the purpose of mass production, an ADC clock signal which is already provided is used to divide or multiply the frequency without providing an additional source to generate a frequency, so that additional cost may be reduced. Further, clock sources of a plurality of elements are unified, to reduce deterioration which is additionally generated due to the EMC and desynchronization.

Lastly, in a system in which the sampling frequency is continuously changed, the method may contribute to improve the performance so that when the sampling frequency is changed to detect various distances in one radar, the method is essential.

The exemplary embodiment of the present invention has been described above with reference to FIGS. **1** to **8**. Hereinafter, an exemplary embodiment of the present invention which may be deducted from the exemplary embodiment will be described below.

A power supply control apparatus of a vehicle radar according to an exemplary embodiment of the present invention includes a first frequency signal generating unit, a second frequency signal obtaining unit, a power supply control unit, a power supply, and a main control unit.

The power supply supplies power to individual components of the power supply control device of the vehicle radar. The main control unit controls overall operation of the individual components of the power supply control device of the vehicle radar. When it is considered that the power supply control device of the vehicle radar is provided in the vehicle, the power supply and the main control unit may be implemented by a vehicle battery and an MCU (or an ECU), so that in the exemplary embodiment, the power supply and the main control unit may not be provided.

The first frequency signal generating unit generates a first frequency signal with a predetermined amplitude. The first frequency signal generating unit is a concept corresponding to the ADC clock sources **151** and **201** of FIGS. **1** and **2**.

The first frequency signal generating unit configures the vehicle radar and may be provided in the signal processor which processes frequency signals generated in the vehicle radar. Further, the first frequency signal generating unit may be provided separately from the vehicle radar.

The first frequency signal generating unit may be implemented as a clock source for sampling of the analog to digital converter which configures the vehicle radar.

The second frequency signal obtaining unit changes the frequency value of the first frequency signal to obtain a second frequency signal. The second frequency signal obtaining unit is a concept corresponding to the frequency converting module **152** of FIG. **1**.

The second frequency signal obtaining unit divides or multiplies the frequency to convert the frequency value of the first frequency signal to generate sampling frequencies and obtain a second frequency signal.

The second frequency signal obtaining unit divides the frequency of the first frequency signal at odd number times or multiplies the frequency at the odd number times to generate the sampling frequencies.

The second frequency signal obtaining unit may generate the Nyquist frequency as sampling frequencies.

11

The second frequency signal obtaining unit may detect intermediate frequencies having an intermediate value between the maximum value and the minimum value among the sampling frequencies and obtain the second frequency signal based on the frequency having the minimum value among the intermediate frequencies.

The power supply control unit controls the power to operate the vehicle radar based on the second frequency signal. The power supply control unit is a concept corresponding to the power supply module 153 of FIG. 1.

Next, an operating method of a power supply control device of a vehicle radar will be described.

First, the first frequency signal generating unit generates a first frequency signal with a predetermined amplitude.

Next, the second frequency signal obtaining unit converts the frequency value of the first frequency signal to obtain a second frequency signal.

Next, the power supply control unit controls the power supply to operate the vehicle radar based on a second frequency signal.

Even though it has been described above that all components of the exemplary embodiment of the present invention are combined as one component or operate to be combined, the present invention is not limited to the exemplary embodiment. In other words, one or more components may be selectively combined to be operated within a scope of the present invention. Further, all components may be implemented as one independent hardware but a part or all of the components are selectively combined to be implemented as a computer program which includes a program module which performs a part or all functions combined in one or plural hardwares. Further, such a computer program may be stored in a computer readable media such as a USB memory, a CD disk, or a flash memory to be read and executed by a computer to implement the exemplary embodiment of the present invention. The recording media of the computer program may include a magnetic recording medium, an optical recording medium, or a carrier wave medium.

If it is not contrarily defined in the detained description, all terms used herein including technological or scientific terms have the same meaning as those generally understood by a person with ordinary skill in the art. A generally used terminology which is defined in a dictionary may be interpreted to be equal to a contextual meaning of the related technology but is not interpreted to have an ideal or excessively formal meaning, if it is not apparently defined in the present invention.

The above description is illustrative purpose only and various changes, modifications, and substitutions become apparent to those skilled in the art within a scope of an essential characteristic of the present invention. Therefore, as is evident from the foregoing description, the exemplary embodiments and accompanying drawings disclosed in the present invention do not limit the technical spirit of the present invention and the scope of the technical spirit is not limited by the exemplary embodiments and accompanying drawings. The protection scope of the present invention should be interpreted based on the following appended claims and it should be appreciated that all technical spirits included within a range equivalent thereto are included in the scope of the present invention.

What is claimed is:

1. A power control apparatus of a vehicle radar, comprising:
a first frequency signal generating unit which generates a first frequency signal with a predetermined amplitude;

12

a second frequency signal generating unit which converts a frequency value of the first frequency signal to generate a second frequency signal; and

a power supply control unit which controls a power supply to operate the vehicle radar based on the second frequency signal,

wherein the second frequency signal generating unit divides the frequency value of the first frequency signal at an odd number of times or multiplies the frequency value of the first frequency signal at an odd number of times, thereby generating a plurality of sampling frequency signals, and

wherein the second frequency signal generating unit detects intermediate frequencies each having an intermediate value between a maximum value and a minimum value among frequencies of the plurality of sampling frequency signals, and generates the second frequency signal based on sampling frequency signals having the detected intermediate frequencies among the plurality of sampling frequency signals.

2. The power control apparatus of claim 1, wherein the first frequency signal generating unit is provided in a signal processor, which is included in the vehicle radar and processes frequency signals generated in the vehicle radar, or the first frequency signal generating unit is provided separately from the vehicle radar.

3. The power control apparatus of claim 1, wherein the first frequency signal generating unit is a clock source for sampling an analog to digital converter included in the vehicle radar.

4. The power control apparatus of claim 1, wherein the second frequency signal generating unit generates a Nyquist frequency signal using the plurality of sampling frequency signals.

5. The power control apparatus of claim 1, wherein the second frequency signal generating unit generates the second frequency signal based on a sampling frequency signal having a minimum value among the intermediate frequencies.

6. A power control method of a vehicle radar, comprising:
generating a first frequency signal with a predetermined amplitude;

converting a frequency value of the first frequency signal to generate a second frequency signal; and
controlling a power supply to operate the vehicle radar based on the second frequency signal,

wherein the generating of the second frequency signal includes generating a plurality of sampling frequency signals by dividing the frequency value of the first frequency signal at an odd number of times or multiplying the frequency value of the first frequency signal at an odd number of times, and

wherein the generating of the second frequency signal further includes detecting intermediate frequencies having an intermediate value between a maximum value and a minimum value among frequencies of the plurality of sampling frequency signals, and generating the second frequency signal based on the sampling frequency signals having the detected intermediate frequencies among the plurality of sampling frequency signals.

7. The power control method of claim 6, wherein the generating of the first frequency signal includes generating the first frequency signal using a clock source for sampling an analog to digital converter included in the vehicle radar.

13

8. The power control method of claim 6, wherein the generating of the second frequency signal includes generating a Nyquist frequency signal using the plurality of sampling frequency signals.

9. The power control method of claim 6, wherein the generating of the second frequency signal includes generating the second frequency signal based on a sampling frequency signal having a minimum value among the intermediate frequencies.

10. A power control apparatus of a vehicle radar, comprising:

- a first frequency signal generating unit which generates a first frequency signal with a predetermined amplitude;
- a second frequency signal generating unit which converts a frequency value of the first frequency signal to generate a second frequency signal; and

- a power supply control unit which controls a power supply to operate the vehicle radar based on the second frequency signal,

wherein the first frequency signal generating unit is provided in a signal processor, which is included in the vehicle radar and processes frequency signals generated in the vehicle radar, or the first frequency signal generating unit is provided separately from the vehicle radar,

14

wherein the second frequency signal generating unit generates a plurality of sampling frequency signals by sampling the frequency value of the first frequency signal at a number of times, and

wherein the second frequency signal generating unit detects intermediate frequencies having an intermediate value between a maximum value and a minimum value among frequencies of the plurality of sampling frequency signals, and generates the second frequency signal based on sampling frequency signals having the detected intermediate frequencies among the plurality of sampling frequency signals.

11. The power control apparatus of claim 10, wherein the first frequency signal generating unit is a clock source for sampling an analog to digital converter included in the vehicle radar.

12. The power control apparatus of claim 10, wherein the second frequency signal generating unit generates a Nyquist frequency signal using the plurality of sampling frequency signals.

13. The power control apparatus of claim 10, wherein the second frequency signal generating unit generates the second frequency signal based on a sampling frequency signal having a minimum value among the intermediate frequencies.
