### "Radar Signal Processing" («Обработка РЛ сигналов»)

Публикации в трудах конференций

#### "Amplitude modulation issues in Doppler radar heart signal extraction"

Medical Doppler radar research has largely been limited to obtaining respiratory and heart rates. While this information is vital for many applications, medical Doppler radar signatures carry significant other information that could lead to cardiopulmonary volume assessments, including cardiac stroke volume (SV), and cardiac output (CO). Accurate recovery of heart signal amplitude is required for these assessments. This paper presents the first analysis of amplitude modulation artifacts on heart signal recovery in Doppler radar systems. The sources of amplitude modulation artifacts are identified, including limitations of linear demodulation, and inherent affects of respiratory signal harmonics on heart signals. Experimental and simulation results demonstrate the validity of this analysis, and outline the path towards successful heart signal amplitude recovery. [C1]

#### "UWB microwave imaging system with a novel calibration approach for breast cancer detection"

A microwave imaging system prototype has been developed for early breast cancer detection. The system is based on impulse Ultra-Wideband (UWB) radar technology. A novel, practical calibration method has been applied in our system to remove the large received signals due to both skin backscattering and Tx/Rx antenna coupling, and to underline the reflection/scattering from object of interest. This calibration method is crucial to identify the malignant tissues in a low-contrast condition that the difference of dielectric properties between malignant tissues and healthy tissues is not more than 10%. The system has been used to detect the cylindrical targets from a breast model. With this novel calibration approach, our system has successfully detected and localized the targets with a diameter of 5mm in a low-contrast condition. Details of the experimental setup and experimental imaging results will be discussed in this paper. [C2]

#### "Time-of-arrival calibration for improving the microwave breast cancer imaging"

In radar based confocal microwave imaging for breast cancer detection, recorded data are synthetically focused to a confocal point within the breast. This is the basis for both data-independent and data adaptive methods to form the breast image and can be enhanced by multistatic approach. This approach inherently assumes that the propagation velocity depends only on the average dielectric property of the breast. However, in real cases, the breast tissues are inhomogeneous and therefore the propagation velocities vary for different propagation paths. Thus, use of an average propagation velocity can result in false localization. This paper proposes an auto-calibration method to compensate the time-of-arrival from confocal point to the receiving antennas. We demonstrate using simulations on FDTD numerical breast phantoms that the proposed method helps to form an enhanced image for inhomogeneous breast. [C3]

#### "Body-worn passive planar harmonic tag design for use with Doppler radar"

A body-worn passive planar harmonic tag for sensing and uniquely isolating human respiratory motion using a Doppler radar has been designed, fabricated and tested. Agilent's advanced design system 2006 provided a simulation and performance evaluation platform. This design flow is applicable for any tag design and not just dipoles which has been the design of choice for others in the past. The tag has been designed for 2.45/4.9 ghz and shown to work at distances greater than 1 meter with transmitted power levels of 10 mw. The implications of this result is that the designed tag can be used to monitor and isolate a subject's cardiopulmonary chest motion from extraneous motion, as well as enable positive identification of the subject in a suitable environment (in home or hospital). [C4]

#### "3D Multiple Maneuvering Targets Tracking in Active and Passive Radar Composite Guidance"

Active and passive radar composite guidance has been developed into a promising technology for target tracking in the electronic counter measurements (ECM) environment. Based on the technology, this paper investigates the problem of 3D multiple maneuvering targets tracking in the presence of sea clutter and jamming. We present a set of algorithms and establish a complete tracking system composed of measurement generation, data

association, track initiation, track filtering, track management, track correlation and missile guidance. The simulation results indicate that the proposed algorithms can offer significant tracking and anti-jamming performance. The ideas and methods presented will also bear important significance for developing similar tracking systems in practice. [C5]

#### "Tracking a moving target in wireless sensor networks using PDR sensors"

The Pulse-Doppler radar (PDR) is an ultrawideband radar system capable of not only detecting target location, but also measuring its radial velocity by using the Doppler Effect. However, the traditional radar signal processing techniques are mismatch with the limit computational and storage resources available on typical wireless sensor mote. In this paper, we explore the compatibility of PDRs and mote-class wireless sensor nodes by designing a new tracking system that utilizes small PDRs as sensor nodes. The system consists of several PDR sensor nodes to detect the presence and position of a moving target, a base-station node to collect the detecting data of sensor nodes, and an algorithm to estimate the location of the target from aggregated data. Our experiments which were taken place outdoor (real environment) show that the proposed system performed well to track moving objects with the average deviation error down to 0.18m. [C6]

#### "Doppler radar respiration measurement for gated lung cancer radiotherapy"

Respiration-gated radiation therapy is a promising treatment modality that precisely delivers prescribed radiation dose to the lung tumor while minimizing the incidence and severity of normal tissue complications. Conventional gating techniques either rely on implanted fiducial markers or external surrogates such as markers placed on patients' abdomen. They are either invasive to the patients or do not have sufficient accuracy. In this paper, we present a non-contact Doppler radar method to non-invasively measure the respiration signals, from which, accurate gating signals can be derived to control the linac. No marker is needed in our method, which makes it very convenient in use. We measured the respiration using a 5.8 GHz quadrature radar. Analysis of the measured signal is presented. It has been shown that the non-contact means of respiration measurement is able to supply reliable breathing motions and accurate gating signals for radiotherapy of mobile tumors. [C7]

#### "POLARSAR Image Classification Based on Polarimetric Decomposition and Generalized Discriminant Analysis"

In this paper, a new classification scheme of fully polarimetric SAR images is proposed. This is based on the joint use of the Freeman-Durden decomposition and generalized discriminant analysis, a new method for Feature extraction. After getting the powers of the three scattering mechanism components through Freeman-Durden decomposition, the Feature extraction algorithm is introduced to well exploit the information available in the full polarimetric coherency matrix. The experimental results show that using this exploited information as new features of Fisher classification, can provides fine performance and good compactness. [C8]

#### "SAR Automatic Target Recognition Based on Classifiers Fusion"

Synthetic aperture radar automatic target recognition (SAR ATR) remains a challenging problem in military and civil field. Much work has been done to improve the performance of SAR ATR systems, both in feature extraction and classifier designing. This paper designs a multiple classifier system to solve the target classification problem in the area of SAR ATR. The proposed multiple classifier system trains three classifiers on different feature sets using three leaning algorithms. The outputs of the three classifiers are combined through evidence combination rule and discounting operation of Dempster-Shafer theory of evidence. Experiments on MSTAR public data set demonstrate that the proposed multiple classifier system significantly outperforms single classifiers and also excels adaptive boosting with RBF network as base learner. [C9]

#### "On the origins of RF-based location"

This paper will provide a brief survey of the origins of RF-based location technology through the beginning of the Second World War. Direction finding (DF) was invented by John Stone Stone in 1902 and improved upon by Lee de Forest, Ettore Bellini and Alessandro Tosi. Both radar and amplitude ranging date to 1904, although these concepts were in advance of the ability of RF technology to implement. DF played a critical role in the First World War, most notably in the naval Battle of Jutland. The requirement for accurate night-time direction led classicist and cryptographer Frank Adcock to invent an improved DF system. In the 1920's, DF and related concepts came of age for civilian applications like navigation. Inventors of the period introduced a variety of other techniques were introduced including time-of-flight or transponder ranging. By the time of the Second World War, DF was a mature field and additional novel RF-based technologies were ready to be developed. [C10]

### **"A software-defined multifunctional radar sensor for linear and reciprocal displacement measurement"**

A software-defined multifunctional radar sensor is developed in this paper for linear and reciprocal displacement measurement. Experiments were performed to demonstrate the high accuracy of the two measurement methodologies. When configured in arctangent-demodulated interferometry mode with a 5.46 GHz carrier frequency, the sensor can measure the displacement with sub-millimeter error at a detection distance of 1.2 m. When configured in nonlinear vibrometer mode, the sensor can measure amplitudes of reciprocal motions with a resolution of 0.4 millimeter and less than 3% average error. [C11]

### **"Adaptive RFI Suppression Algorithm Based on CEMD for SAR Data"**

This paper proposes a novel adaptive filtering method based on complex empirical mode decomposition (CEMD) for narrowband radio frequency interference (RFI) suppression applied to SAR. This method decomposes the RFI contaminated signal into a finite and often small number of Intrinsic Mode Function (IMF). The sum of some selected IMF components is taken as reference input of adaptive filter based on the characteristics of CEMD. Experiment results show that CEMD provides an effective way to obtain reference input. The proposed method can effectively subtract RFI component from the RFI contaminated signal, which is the primary input of the adaptive interference canceller. The point-target simulation is used to show the working principle of the proposed algorithm. Experimental results based on SAR real data are also shown to verify the proposed algorithm. [C12]

### **"Considerations in measuring vital signs cross section with Doppler radar"**

This paper describes the different considerations and challenges in measuring human cardiopulmonary radar cross section (RCS). The effect of clutter on the received signal is explained as well as the importance of preserving baseband dc content for valid readings. The center estimation algorithm with dc-cancellation is presented as a solution to restore dc content in the baseband signals and to exclude clutter contribution. The far-field conditions for the target range are revisited. By modeling the human torso as a half-cylinder and assuming unity reflectivity, the ratio of the RCS of the back of the torso with respect to the front is a function of wavelength. At 2.4 GHz and for a chest breadth of 30 cm, the back is expected to have an RCS that is 10 times that of the front while the RCS of the side is expected to be 4 times smaller. [C13]

### **"A multilateral synthetic aperture wireless positioning approach to precise 3D localization of a robot tool center point"**

In this paper, a novel multilateral synthetic aperture secondary radar concept and its application for precise 3D localization of a robot tool center point (TCP) are introduced. A backscatter transponder is attached to the TCP of a robot. Spatially distributed FMCW secondary radar units pick up the backscattered phase coherent transponder signals. Based on assisting relative sensors, a synthetic aperture is created with the TCP. The developed multilateral inverse synthetic aperture reconstruction algorithm then determines a probability density function (PDF) of the spatial transponder position. By simulations and experimental results using a 5.8 GHz system with 140 MHz bandwidth it is shown, that 3D localization precision in the mm range can be achieved with the novel wireless local positioning concept even with narrowband radar systems in dense multipath environments. Heretofore, accuracies of this magnitude were only attainable with ultrawideband (UWB) systems utilizing a ten times wider bandwidth. It is shown, that the multilateral synthetic aperture locating system has the potential for a quantum leap in precise 3D wireless local positioning. [C14]

### **"Fusion of High Resolution Satellite SAR and Optical Images"**

This paper proposes a methodology for fusion of high resolution satellite SAR and Optical Panchromatic images. The main objective of fusion is to bring together complementary information contained in SAR and Optical images. The paper discusses and illustrates the issues involved in merging and choosing of suitable approaches to overcome them. The choosing of proper fusion method was explained from the point of nature of SAR and Optical wave interaction with the surface and objective of fusion. Two methods are proposed in this paper one is based on Fourier filtering and the other is based on multiresolution pyramid. The methodologies are applied on Cartosat-1 Panchromatic and TerraSAR-X images. The results and evaluation of the fusion based on entropy are presented. [C15]

### **"Robust DOA estimation of SSR signals for aircraft positioning"**

Methods to estimate Directions of Arrival (DOA) on radio signals are susceptible to hardware and signal deficiencies. In the following, the robustness of four algorithms is evaluated by numerical and experimental tests. The focus lies thereby on Secondary Surveillance Radar (SSR) signals, but the algorithms can generally be

used on any kind of radio signal. It will be shown that variants of the ESPRIT algorithm provide highly accurate DOA estimates on SSR signals even without calibration. [C16]

#### "A heterodyne 77-GHz FMCW radar with offset PLL frequency stabilization"

This contribution describes the realization of a heterodyne frequency-modulated continuous-wave (FMCW) radar system operating in the frequency band from 76 GHz to 77 GHz. To implement the heterodyne principle two voltage controlled oscillators (VCOs) are operated in order to produce frequency ramp signals with a fixed frequency offset. This allows to mitigate effects occurring in homodyne systems like, e.g., DC-offsets or low-frequency noise components. To avoid large divider values in the control loop the presented system is based on an offset phase-locked-loop configuration. In the presented implementation the same downconverter is used to implement the offset-loop for both VCOs, which has the positive effect that errors and noise influences in the downconversion process-at least partly-cancel out in the final FMCW output signal. [C17]

#### "Design and implementation of automotive 77GHz FMCW radar system based on DSP and FPGA"

In this paper, we design and implement the automotive FMCW radar based on FPGA and DSP. The proposed signal processing module and RF transceiver for 77GHz FMCW radar are integrated into an experimental vehicle and tested in a real road environment. This paper presents the designed signal processing architecture and implemented processing algorithms. [C18]

#### "High Resolution Radar Imaging Based on Compressed Sensing and Fast Bayesian Matching Pursuit"

Recently the rapid imaging based on the compressive sensing (CS) theory have attracted increasing interests, which simultaneously sampling and compressing signals or images. Radar imaging based CS is a potential way to obtain the high-resolution radar images without the constraint of Nyquist sampling rate. In this paper, we proposed a radar remote-sensing imaging approach based on compressive sensing and fast Bayesian matching pursuit (FBMP) recovery algorithm. Some experiments are taken and the results indicate that an accurate reconstruction of high-resolution radar images are obtained, with fewer measurements than most its counterparts(e.g., MP, OMP, StOMP, GPSR),but resulting in lower normalized MSE(NMSE). Although BCS obtains lower NMSE than FBMP,simultaneously with higher time complexity and sparsity. [C19]

#### "Ship Detection after Removal of Ambiguities by Using PolSAR Images"

Ambiguities in SAR image are very common phenomena. For maritime applications, as the high intensities of the ambiguities in low radar backscatter background of sea environments, they can be mistaken as targets and cause false alarms in ship detection. Thus, through the analysis of polarimetric characteristics of ships and ambiguities, we propose a ship detection method which applies the eigenvalue to differentiating the ship target and azimuth ambiguities. One set of Cband JPL AIRSAR polarimetric data covered Kojimawan Bay, Japan has been chosen to evaluate the method that can effectively remove false alarms caused by the azimuth ambiguities. [C20]

#### "A New Method of Fixed Single Observer Passive Location Based on Phase Difference Rate-of-Change"

Aimed at the disadvantages of DFRC method such as low observability and big relative error, so this paper accedes phase difference rate-of-change, put forward the DPFRC method. Combined with the extended Kalman filter (EKF) and unscented Kalman filter (UKF) algorithm, this paper proved the advantages of the UKF algorithm which applied to DPFRC method verified with the computer simulation. [C21]

#### "A New Method for Sorting Radar Signals Based on Coherency"

Radar can work on different wave bands in different period of time, which result in the Increasing-batch problem based on the existing methods of signal sorting. In order to solve this problem, Slope Discriminance was proposed in this paper. Error analysis of this proposed method shows its availability when the measurement error of frequency of receiver is below 100MHz. Simulations on same and different radiant points was given. The results show that this new method decreases the possibility of Increasing-batch and also it can be a supplement of present methods. [C22]

#### "Roof Detection in Lidar Data"

Lidar is widely used in many fields in recent years. Consequently, research of feature extraction in lidar data has

intensified. Roof of building as a stable line feature is widely used in many fields. But there is yet not a good algorithm to finish this work. In this paper, we propose a new method to extract roof of building. The roof is modeled by a symmetric exponential roof edge model and the altitude image which generated from original lidar point cloud data is smoothed by a low-pass filter ISEF which is optimal for the symmetric exponential model. And then an algorithm for roof detection and a grouping and fitting method are proposed for line feature extraction. In order to depress the effect of the noise a fusion method is used for multi-images. In the end of the paper the method is proved useful through the lidar data comes from Calgary University in the end of the paper. [C23]

#### **"A Novel Polarimetric CFAR Target Detection Method"**

A new polarimetric synthetic aperture radar (PolSAR) image CFAR target detector is proposed in this paper. By introducing the inverse Gamma distribution which is extensively used in modeling, the distribution of polarimetric matched filter (PMF) metric, denoted as  $P_{G0}$ , is derived on the product model; Furthermore, a fast and exact parameter estimation method of  $P_{G0}$  distribution is presented using the "second kind statistics" based on the Mellin transform; Finally the formula of the CFAR detection threshold is deduced, and the target detection using the proposed constant alarm rate (CFAR) detector is performed on the RADARSAT-2 PolSAR data. Experimental results demonstrate the great efficiency of the  $P_G$  distribution and the corresponding parameter estimation method in data fitting of areas with different degree of homogeneity. Moreover, the successive CFAR detector can successfully complete the automatic target detection with low false alarm rate and high detection rate in complex clutter environment where the homogeneity of terrain varies sharply. [C24]

#### **"Multitask Learning and Sparse Representation Based Super-Resolution Reconstruction of Synthetic Aperture Radar Images"**

In earth observing remote sensing fields, to recognize objects whose size approaches the limiting spatial resolution scale especially in Synthetic Aperture Radar (SAR) images, spatial resolution enhancement is usually required. In this paper, we proposed a multi-task learning and K-SVD based Superresolution image restoration method where K-SVD algorithm is employed to learn a redundant dictionary from some example image patches. In order to learn more accurate dictionary and reduce the complexity of dictionary learning, multitask learning concept is adopted to learn multiple dictionaries from the samples classified by K-means clustering. Some experiments are taken to investigate the performance of our proposed method, and the visual result and numerical guidelines both prove its superiority to some start-of-art SRIR methods. [C25]

#### **"Cooperative Synthetic Aperture Radar Image Segmentation Using Learning Sparse Representation Based Clustering Scheme"**

Based on a recent proposed and popular sparse representation based classifier (SRC), in this paper we presented a novel Learning Sparse Representation based Clustering (LSRC) scheme for Synthetic Aperture Radar (SAR) segmentation. LSRC introduces the examples-based dictionary learning technology in SRC to find a dictionary that is adaptable to sparsely representing samples, which is liable to provide more accurate approximation of samples and subsequently achieve higher classification accuracy rate. Moreover, for the intrinsic supervised nature of LSRC, we adopt an unsupervised-clustering cooperative approach to provide training samples for LSRC, in which some "good" samples with higher membership degrees are selected from the clustering result of K-means algorithm. Some experiments are taken on segmentation of both the texture images and SAR images to investigate the performance of our proposed method, and the results prove its superiority to its counterparts. [C26]

#### **"A Novel SAR Signal Reconstruction Method from Non-uniform Sampling Associated with Fractional Fourier Transform"**

A contradiction between wide swath and high spatial resolution exists in synthetic aperture radar (SAR) imaging processing. Displaced phase centers multiple azimuth beams (DPC-MAB) system can make a tradeoff between them, but it arises non-uniform sampling in the azimuth direction. In this paper, a novel reconstruction method associated with the fractional Fourier transform is proposed, which has better performance compared with the traditional one. Moreover, it can reconstruct under sampled signal successfully while the traditional method fails. Simulations verify the efficiency of the proposed method. [C27]

#### **"The Impact of High-Order Phase in Ballistic Missiles Detection"**

According to characteristic of ballistic missiles and their velocity, acceleration and jerk in radar echo, we establish the echo signal model with high-order phase echo signal characteristics, then analyze the target detection

performance by numerical simulation to get the relationship among the optimal number of pulses, signal-to-noise ratio and jerk. Finally, the simulations verify the principle of the method is correct and can provide guidance for practical applications. [C28]

### "Research on the Interference Cancelation in SFN Based Passive Radar"

It is important to get a high-quality reference signal for the cancellation and correlation detection in passive radar. The single frequency network (SFN) configuration of transmitters will cause the interference in the reference channel. The infinite impulse response filter based on the normalized least mean square rule (IIR\_NLMS) can improve the cancellation gain and signal noise ratio (SNR) of the target echo, but it has limited capability in suppressing co-channel interference. In order to solve this problem, a type of equalization filter is proposed, and then combining with the IIR\_NLMS filter, the equalization IIR\_NLMS filter is obtained. Simulation results verify the efficiency of the algorithm. [C29]

### "Determination of LIDAR Points Cloud Filtering Parameters Using Distance Image"

Filtering of LIDAR points cloud is the key of obtaining precise DEM and it has become a studying focus. Determination of the filtering parameters affects the results directly. Within this paper, it is proposed that making use of pixel position and grey information in distance image to guide determination of the filtering parameters like the block size and the threshold value. And the method is validated by a kind of filtering using the determined parameters. In experiment it is shown that this method is available. [C30]

### "The Intelligent Embedded Control Warning System for Car Reversing"

Most of the car drivers used the reverse radar or a reverse camera to detect the road situation behind the vehicle when it is engaged in reverse gear. As a matter of fact, the pedestrians can virtually know if the vehicle is backing up or not only by seeing the permanent bright reverse lamps. And as there is not much change with the reverse lamp to be seen, therefore their warning function for pedestrians seems to be still insufficient eventually. Therefore, this research tries to design a set of embedded intelligent car backup warning system so as to promote the safety of the walkers or the other drivers on the road. This embedded system uses Microsoft Win CE operating system and matches with the Mini2440 developing board. It also uses the Visual Studio 2005 for developing the intelligent touch panel operating mode. The UART interface on the Mini 2440 developing board controls the frequency converter, RC server and LED by using PIC16F877 to transform the signal of the sensors. And then, connecting to the sensors of angle, luminosity and distance so as to read the voltage value of the sensor and transferring them into actual values and followed by using 27 fuzzy logic rules to carry on the fuzzy logic deduction. And the angle of the LED reverse lamp bracket is adjusted and driven automatically according to the results of this logic deduction eventually. This research tries to do the simulated test by using a mobile frame in the same height as a real automobile. To let the test mobile frame being located 240 cm away from the obstacle and then start the driven motor and set the frequency of it to be with 60 Hz. (in other words, its speed is approximately in 2.52 Km/h.) the let the test mobile frame to stop at 40 cm in front of the obstacle. We found out that the warning lamp bracket installation angle will be changed correspondently with the distance between test mobile frame and obstacle and being declined automatically from 90 degree to 0 degree. Apparently, from the test results, it has been proven that this system can reach the goal of automatically controlled car back-up warning function truly. [C31]

### "Detection Algorithm of Laser Radar Target Based on Wavelet Transform"

Given the different transmission characteristics under the wavelet transform (WT) domain and the different distribution characteristics of frequency domain of the signal and noise, a novel approach for detecting laser radar target based on wavelet transform has been proposed. Usually, wavelet decomposition has been used to de-noise a digital signal corrupted by noise. In our approach, we applied the wavelet decomposition and modulus maximum detect the locations of laser radar echo signal. Simulations show that the proposed algorithms are more efficient than only utilizing wavelet decomposition in a big clutter background. [C32]

### "Analysis and Design of Three Loop Radar Servo System for Air Defense Missile"

In order to design a radar servo system with satisfactory response for an air defense missile, the three loop form was chosen, and the frequency domain method was used. The design approach and criteria for the three loop radar servo system was outlined in this paper. With the criteria, a servo system was designed. Then the effect of every loop was analyzed. The results shows that, with the frequency domain method and the design criteria, the designed radar servo system can obtain good response and every loop of the three loop form can't be omitted due to their essential effect. [C33]

### "New Technology and Applications on Microwave Sensors"

Presently, various microwave sensors have emerged. They have powerful performance and quite wide application domain. New technology and applications on microwave sensors are presented. A novel microwave sensor for measuring the properties of a liquid drop has been invented. A microwave based in-line sensor for steam quality is described, and test result is reported. Development a new tunable multiband UWB radar sensor and its applications to subsurface sensing is presented. Finally the technical challenges and developing prospect of microwave sensors are discussed. [C34]

### "LIDAR Depth Indicator of the Design and Research"

According to rope friction hoist in the process of ascension, because the steel wire slips or peristalsis and becomes tensile deformation by long-term usage. There will cause deviation between the display of the indicator and the actual location of lifting container. That may even cause accidents. This paper introduces a composition of new depth indicator, working principle and designing method which based on laser infrared radar technology. It can realize many functions, such as the precise indicating of the location of the lifting container and real-time monitoring, etc. Have no assistant calibration switch, without measuring transmission error, fast response and intuitive, convenient operation, etc. [C35]

### "Airport Detection in SAR Image Based on Perceptual Organization"

Being one of the key transportation targets, airport detection is of great importance in military and civil applications. In this paper we propose a new method based on perceptual organization for airport detection in large SAR image. Since the runways are the most obvious characteristic of the airport, we first design belief functions for the runway features, which include collinearity, proximity, width and texture similarity. Then we propose to use the DS-evidence theory for the fusion of all belief functions, which can serve as a criterion to decide whether the two region units can be grouped. The candidate airport can be found by grouped region growing and detected by airport knowledge. Experimental results showed the effectiveness of the proposed approach for airport detection in large complex SAR image. [C36]

### "Maximum likelihood synthetic aperture radar image formation for highly nonlinear flight tracks"

This paper develops a flexible time-domain SAR imaging algorithm that is capable of accounting for somewhat arbitrary flight track geometries and platform orientations. The proposed technique casts SAR imaging as a maximum likelihood estimation problem where the ground reflectivities are taken as the parameters to be estimated. It is shown that conventional back projection is one of two steps required to form the optimal maximum likelihood image. Simulation examples are given that compare images and impulse response functions for back projection and the maximum likelihood algorithm. [C37]

### "Forming regularized maximum likelihood strip-map synthetic aperture radar images using the block RLS algorithm"

The data matrix that is needed for forming the maximum likelihood (ML) image in strip-map synthetic aperture radar (SAR) has block structure. This structure allows for a recursive way of forming a regularized ML image using the block recursive least-squares (RLS) algorithm. The regularization serves three purposes: Properly chosen, it provides a more stable solution; it combats noise; and it allows the block RLS algorithm to be initialized. In this paper, it is shown that an optimal regularization parameter exists for this problem and that the solution to the regularized normal equations for the strip-map SAR model is solved by the block RLS algorithm. Simulated results are shown. [C38]

### "Measure of smartness"

The traditional power- and energy system is going to be smart. Smart means a set of well defined devices and techniques but nowadays smart is used as a synonym of the expression 'modern' and 'up-to-date'. Believing that the smart philosophy supports the better energy supply we should measure it. Due to the fact that today every gauge and technique is called smart, we should make distinction between different smart objectives, levels and techniques. This paper aims at introducing a quantifying technique that helps orientate in this field. We can use it if we are going to apply new smart technologies or we are going to invest into the less smart part of the network. In the following parts we summarize the elements of the smart characteristics, we measure them and we form a smartness measuring factor capable of comparing two networks or two parts of the network. Finally we show a novel visualization method, the "radar screen" of the smartness. [C39]

### "Angle-Doppler Estimation in Heavy Correlated Interference"

In this paper, a Prony estimation method on wavelet-transformed space-time signal is proposed with Adaptive Simulated Annealing (ASA) algorithm as a global optimizer. In addition to denoising property of wavelet transformation, the proposed approach appeals to its decor relating nature. Our method improves the performance of radar systems with large array antenna, such as OTH radars in STAP applications. We show that the conglomeration of Prony estimator and ASA algorithm achieve good performance in terms of detection and resolution in comparison with the classical STAP algorithm in the presence of powerful external correlated interference. Moreover, we present how to apply STAP technique to parameter estimation of target in the correlated non-Gaussian interference environments that causes Maximum Likelihood (ML) function be nonlinear with respect to the angle and Doppler. In the following, ASA algorithm is employed for global optimization of all nonlinear functions. Extensive simulations demonstrate that our proposed algorithm outperforms that previously reported estimators with extremely low computational cost. [C40]

### "Implementation of Adaptive FIR Filter for Pulse Doppler Radar"

Digital Signal Processing (DSP) systems involve a wide spectrum of DSP algorithms and their realizations are often accelerated by use of novel VLSI design techniques. Now-a-days various DSP systems are implemented on a variety of programmable signal processors or on application specific VLSI chips. This paper presents the design of Adaptive Finite Impulse Response (FIR) filter for moving target detection in various clutter conditions in Radar Receiver. The design uses pipelined COordinate Rotation Digtal Computer (CORDIC) unit and pipelined multiplier to get high system throughput and reduced latency in each of the pipelined stage. Saving area on silicon substrate is essential to the design of any pipelined CORDIC. The area reduction in proposed design can be achieved through optimization in the number of micro rotations. For better adaptation and performance of Adaptive Filters and to minimize quantization error, the numbers of iterations are also optimized. [C41]

### "A novel space cloth using resistor grid network for radar absorbers in stealth applications"

We report novel resistor grid network based space cloth for application in single and multi layer radar absorbers. The space cloth is analyzed and relations are derived for the sheet resistance in terms of the resistor in the grid network. Design curves are drawn using MATLAB and the space cloth is analyzed using HFSS™ software in a Salisbury screen for S, C and X bands. Next, prediction and simulation results for a three layer Jaumann absorber using square grid resistor network with a Radar Cross Section Reduction (RCSR) of -15 dB over C, X and Ku bands is reported. The simulation results are encouraging and have led to the fabrication of prototype broadband radar absorber and experimental work is under progress. [C42]

### "Non-contact heart rate detection using periodic variation in Doppler frequency"

Remote heart rate detection without body-attached probes is a promising technology for health care, monitoring of elderly people, emergency, and security. In this paper, we use a continuous wave (CW) microwave Doppler radar. It is important to eliminate the effect of body movement that is irrelevant to heartbeat such as respiration. In general, the displacements of them are larger than those of heartbeat. Therefore, we focus on the periodic variation of velocity of body movement due to heartbeat rather than the displacement variation of it. We detect a heart rate from a part of the wavelet frequency components with high periodicity. As a result of performance evaluation, our system enables to extract more accurate heartbeat interval than the traditional approach using the periodicity of an original Doppler signal. [C43]

### "Mathematical analysis of interpolation step of Omega-K Algorithm for GPR and its implementation"

GROUND-penetrating radar (GPR) is a mature remote sensing technique employed by engineers and scientists to obtain information from subsurface structures. These structures range from manmade objects, such as buried utilities, pavements, and unexploded ordnance, to geological formations. GPR data collection may be viewed as a mapping from the object space  $(x,y,z)$ , characterized by the object's spatial location and reflectivity, to the image space. The image space may be viewed in the space-time domain  $(x,y,t)$ , where the recorded scattered signals are displayed as a function of lateral position and time, or in the Omega-K domain  $(k_x,k_y,f)$ , where the two image sets are related by spatial-temporal Fourier transforms (FTs). Additionally, data may be recorded in the space-frequency domain  $(x,y,f)$ , as would be the case with a frequency-domain GPR. Fourier transforms allow easy conversions between the three image domains. [C44]

### "Waveform-agile mimo radar for urban terrain tracking"

We investigate the problem of tracking a moving target in urban terrain using a multiple-input and multiple-output

(MIMO) radar system. Our proposed method aims to maximize the target information using an optimal configuration of MIMO widely-separated radar sensors while exploiting multipath returns from all the sensors. Furthermore, we adaptively configure the parameters of the transmit waveforms of the MIMO system at each time step in order to minimize the overall mean-squared tracking error. We demonstrate our results using a realistic urban environment, by varying the regions of obscuration and the number of bounce path returns. An important advantage of the MIMO system is that, based on the radar configuration, it is possible to completely eliminate the obscuration regions. [C45]

#### "Heart-beat detection and ranging through a wall using ultra wide band radar"

Heart-beat detection has found many applications in military and bio-medical areas. Many of these applications focus on the use of impulse based ultra wide band (UWB) radars. This in-turn requires expensive hardware and consumes more power (for a given range) compared to stepped frequency continuous wave (SFCW) radars. However, the micro-Doppler characteristic of human body can be detected by SFCW radar at much lower sampling rates and power. It can help in distinguishing a living and a non-living target. In addition, SFCW radar can help separate Doppler signatures in down-range, thus enabling it to look for multiple human targets. UWB radars operate at a bandwidth higher than 0.5 GHz and have the benefit of high range resolution. This paper focuses on the experimentation of a technique to obtain the range and Doppler of a human body using UWB-SFCW radar and moving target indicator (MTI) filter, in the presence of an interfering wall. [C46]

#### "A Novel Image Based Multi-Channel SAR-GMTI Algorithm"

A novel three-channel SAR-GMTI algorithm based on the compressed image rather than the azimuth-uncompressed raw data is proposed, which employs the classical DPCA technique and FrFT. The chirp characteristics of DPCA signal of the moving target in the SAR image domain is investigated for the first time in this paper. The scheme introduce FrFT to detect the moving target and estimate the position, velocity and radial acceleration, which lead to a more overall description on motion parameters than that of the majority of estimation algorithms. The excellent anti-noise ability of FrFT and the ideal clutter cancellation of DPCA technique results in great GMTI performance during a clutter-rich and low SNR environment. The simulation results indicate the efficiency and availability of the novel algorithm. [C47]

#### "Advantages of Airborne Lidar Technology in Power Line Asset Management"

Airborne lidar technology is widely accepted among power utility companies as the most efficient tool for acquiring high-density and high-accuracy geo-referenced spatial data for various applications essential to power line asset management. This paper describes the typical workflow in lidar data collection. It also describes further application steps in the traditional engineering analysis required for power utilities management, including catenary modeling for thermal up-rating and vegetation encroachment analysis. It will be shown that lidar data can have exceptional precision and accuracy, enabling tight-tolerance engineering calculations for power line efficiency modeling. The paper will also briefly discuss change detection in transmission and distribution wires themselves, the underlying surface terrain and surrounding vegetation throughout the transmission corridor, and how lidar technology can help to address monitoring issues. Finally, the performance advantages of airborne laser terrain mapper (ALTM) systems are discussed in the context of applications related to power line asset management. [C48]

#### "Performance evaluation of a GPR system for mine detection using a 3D-SAR algorithm"

Within the "International Test & Evaluation Program" (ITEP) a measurement campaign (ITEP project 2.4.2.13) was held in Oberjettenberg, Germany, to evaluate novel evaluation procedures for the test and evaluation of dual sensor (DS) mine detection devices (metal detector MD and ground penetrating radar GPR). FHR contributed with a UWB GPR sensor and a novel radar data processing algorithm. The improvement of the application of a near field 3D-SAR algorithm compared to standard GPR data processing is shown in terms of the receiver operating characteristics (ROC) curve. [C49]

#### "ISAR imaging of ground moving vehicles in a curve"

The imaging of rotating objects by exploiting the change of the aspect angle is called Inverse Synthetic Aperture Radar (ISAR). The imaging of curving vehicles is done using airborne radar data and information about the vehicle's motion. This paper explains some important processing steps and shows ISAR images resulting from our experiments. [C50]

#### "Toward a network of common radar and EW sensors aboard a single or multiple cooperative

## platforms"

Up to now, combat aircrafts are fitted with Fire Control Radar (FCR), Electronic Warfare System (EWS), and radio links. Each of these systems is dedicated to a particular task and the cooperation is reduced to a minimal exchange of information between them, so far. Major system performance enhancements are to be expected from close co-operations to each other sensors. The future co-operations can be ordered in four stages. The three first ones lead progressively to a common sensor including radar and EW functions. The last one is the deployment, on a given platform, of these common multi-functions sensors on a network basis. Another focus is the cooperation between platforms. Depending on the cooperative application, low, medium or high data rates will be needed. A typical example required by such co-operations is the implementation of "ad hoc" data links using the FCR or the EWS. This kind of co-operations does not need to add specific antennas or other R.F. devices. [C51]

## "Focusing ISAR images of moving targets in real-time using time-frequency-based method"

In this paper, we present a time-frequency S-method-based approach for real-time motion compensation, image formation and image enhancement of moving targets in ISAR and SAR. This approach performs better than the Fourier transform by drastically improving images of fast, manoeuvring targets by increasing the SNR in both low and high noise environments. The method also computationally simple, requiring only slight modifications to the existing Fourier transform based algorithm. The effectiveness of this method is demonstrated through the application to simulated and experimental data sets. [C52]

## "Expedient GPR survey schemes"

Practical GPR survey schemes based on a geometrical migration algorithm are implemented and tested: (1) random GPR data collection from water surface along a tangled path and interpolation to a regular grid for bottom reconstruction; (2) double-pass B-scan with different antennas offset for estimation of the upper ground layer thickness and permittivity. [C53]

## "Digital beam forming concepts with application to spaceborne reflector SAR systems"

The trend in the conception of future spaceborne radar remote sensing is towards the use of Digital Beam Forming (DBF) techniques. These systems will comprise multiple digital channels, where the analog-to-digital converter is moved closer to the antenna. This dispenses the need for analog beam steering and by this the use of transmit/receive modules for phase and amplitude control. Digital beam forming will enable Synthetic Aperture Radar (SAR) which overcomes the coverage and resolution limitations applicable to state-of-the-art systems. Moreover, new antenna architectures, such as reflectors, already implemented in communication satellites, are being reconsidered for SAR applications. This paper is dedicated to the digital signal processing aspects of such reflector based SAR systems. After introducing the hardware concepts the beam forming algorithms are presented and demonstrated by means of numerical simulations. [C54]

## "Software for simulation of electromagnetic waves propagation through the soil with buried objects"

The software for simulation of electromagnetic waves propagation through the soil layered structure with shallow buried objects has been described in the paper. The simulation is based on the finite difference time domain (FDTD) method and allows to define ten layers of soil and four buried cuboid objects. Such virtual ground penetrating radar (GPR) system seems to be useful for test of targets detection level for different soil structure configurations as well as different transmitted radar signals and scanning methods. [C55]

## "Radar signatures of complex buried objects in ground penetrating radar"

The evaluation of radar signatures of buried objects for three experimental ground penetrating radar setups will be addressed in this paper. The contribution will present corresponding results and experiences. The performance of the imaging capabilities of the designed radar system will be assessed by reconstruction of complex shaped test objects, which have been placed within the ground. The influence of system parameters of the ground penetrating radar have been varied systematically in order to analyze their effects on the image quality. Among the modified parameters are the step size in transverse plane, height of the antenna over ground, frequency range, frequency points, antennas and varying instrument settings. A signal processing technique based on synthetic aperture radar has been applied on the measured raw data. The focus radius around a specific target has been analyzed concerning the compromise between image quality and processing time. The experiments demonstrate that the designed ground penetrating radar systems are capable for detection of buried objects with high resolution. [C56]

### "Comparison of methods of the resolution increase in GPR for the short range targets"

This paper describes different approaches for high resolution short range 3D imaging with ground penetrating radar (GPR) based on research performed at the Radar R&D (Tomsk). Radar R&D is active in the field of GPR technology and its applications more than 15 years. Ultra-wide operational bandwidth in GPR can be used to obtain high-resolution images of targets. In this paper, different approaches to high-resolution imaging with UWB radars are discussed and compared. As a rule, in existing software of the industrial radar the high-frequency filtration of signals is used that essentially limited efficiency of GPR investigation. It is described that methods of restoration for distorted signals have advantages compare filtration. Possibilities of wavelet transformation for resolution increase of short range targets are discussed. The analysis is carried out on the test images and illustrated by experimental examples. [C57]

### "Radar pulse repetitive patterns detection"

Pulse Repetition Interval (PRI) is an important parameter in the recognition of pulsed radar signals because of its distinctiveness. Pulses time of arrivals (TOA) are PRI sources. Depending on the radar function various PRI modulations are used. So PRI pattern requires the estimation of the numerous calculations to determine its values correctly. PRI complexity makes it as a distinctive parameter for electronic intelligence, under condition that the signal's parameters are estimated ambiguously and repeatedly for different series of measurements. Significant difficulty of analysis is an existence of distortions arising from the propagation properties and signals interference under measurement. In the literature much attention is paid to seeking ways to solve the problem. Proposed, are various algorithms showing good properties for certain types of modulation. They are ineffective for others PRI types. They can be successfully used in ELINT systems, while in the ESM devices, where full automation is required, their usefulness is limited. The paper presents some aspects of PRI analysis on the base of simulated and real signals. Also presented is a modification of the algorithm based on the use of autocorrelation function in the analysis of PRI. The proposed solution allows for more efficient analysis of long sequences of periodic changes in PRI (stagger, complex, dwell and switch) in terms of having a relatively short measurement sequences. [C58]

### "Scenario modeling and simulation for performance prediction of a modern radar in electronics warfare environment"

A Simulation software is presented to evaluate radar performances in EW environments. This Software includes detailed radar and Jammer Models and Scenarios including different signal losses, noise, clutter and Doppler Effect. This software simulates different passive and active jamming techniques and models coherent and no coherent effects and other factors causing losses in jamming to signal ratio (JSR). Required JSR for different techniques to be effective, is output of this simulation software for different radars. This simulation can be used for radar and jammer performance evaluation with changes in input parameters. A sample application for performance evaluation of a UAV based jammer against naval air defense radar is presented. [C59]

### "Weak signal detection using compressive receiver"

Nowadays modern radar uses more and more complex waveforms. Some waveforms are developed intentionally to make their intercept almost impossible. The main distinctive features of modern radar signal are hidden in its time-frequency structure. In the near past the problem of radar signal feature extraction was considered in time or frequency domain separately, because radar waveforms were relatively simple. Today, however, the signals should be observed simultaneously in both domains. Time-frequency distribution concept offers a new approach in radar signals classification/identification. The paper presents some results of weak, pulsed and continuous radar signals detection by the use of compressive receiver. [C60]

### "Classification of LFM radar signals based on the wavelet decomposition and the neural LVQ classifier"

The paper presents a novel approach, based on wavelet decomposition, to automatic classification of signals with the linear frequency modulation (LFM), generated by a radar emitter. The goal of radar transmitter classification is to determine the particular transmitter from which a signal originated, using only the received waveform. To categorise a current signal to the particular transmitter, the discrete wavelet decomposition of the signal is accomplished. The Learning Vector Quantisation (LVQ) algorithm is proposed as the intelligent classification algorithm. [C61]

### "Specified for air safety, monitoring atmospheric phenomena including the volcano dust"

This paper is an overview of methods and means for remote sensing of atmosphere based on backscattering of electromagnetic waves for prediction of dangerous weather phenomena zones along the route of the airplane. In addition to such traditional phenomena as turbulence, hail, icing-in-flight and thunderstorm, the approaches to distinguish areas of volcano dust is also included into consideration. [C62]

#### **"Synthesis planar array and apertures in passive HF phase array radar"**

In this paper we discuss analysis and synthesis techniques for planar arrays usage in passive HF target ranging. Three types of elements geometries are assumed and analyzed for the array. First rectangular element geometry is discussed. Then the analysis method is extended to the case of circular array in which the Fourier function is replaced by the Bessel function. As the last geometry, the non-planar array is discussed briefly. Finally the consideration in applying these arrays in HF passive radar is discussed. [C63]

#### **"Design of RF subsystem for Ku-band radar with synthesized bandwidth of 2GHz by using stepped-frequency chirp signal"**

In this paper we introduce our work on developing a Ku-band 2GHz bandwidth RF subsystem based on Stepped frequency chirp signals (SFCS) including transmitter, receiver and frequency synthesizer, as well as experimental results. Very high resolution radar image for a moving train has been obtained by using the developed RF subsystem. [C64]

#### **"Passive radar: Here comes the new generation VERA-NG"**

Abilities of passive surveillance systems open new applications for military even air traffic control purposes [C65]

#### **"The use of microwave noise from the Sun for on-line verifying azimuth alignment of surveillance radars"**

Radar system cannot operate standalone. Information about detected targets should be send to command and control system. The C2 systems often realize fusion of data coming from bigger number of radars. General problem in data fusion process is quality of received radar data. The radar data quality strongly depends on radar systems calibration and adjustment. One of the source of adjustment errors is azimuth alignment of the radar. In the paper the use of microwave noise from the Sun for on-line verifying azimuth alignment of surveillance radars will be discussed. The real results of radar alignment, advantages and disadvantages will be presented. [C66]

#### **"Incoherent addition of ISAR images from spatially distributed receivers for classification purposes"**

A popular approach for Non-Cooperative Target Identification is the use of 2D Inverse SAR images. To successfully identify a target it is necessary to compare a set of scattering centers in the ISAR image to a data base. In the conventional case of a monostatic radar, however, visibility of scattering centers varies with the target aspect angle. In this paper we show that the visibility of scattering centers can be improved by incoherent addition of images from spatially distributed radars. The main focus lies in the description and relevant results of a multistatic ISAR experiment carried out at Fraunhofer FHR. [C67]

#### **"Parameter estimation from a fraction of the period for a rotating target"**

All the techniques developed for extracting micro-Doppler features for the past decade rely primarily on the assumption that the time series of the signal contains at least one oscillation or more during the coherent integration time or imaging time. However, many applications in real-world scenarios involve short duration signals and often require the detection and the estimation of micro-Doppler characteristics. Short duration signals may contain only a fraction of an oscillation. In this paper, we develop two techniques to estimate the micro-Doppler parameters from a fraction of the period. In these scenarios, the coherent integration will cover only 1/4 and 1/2 of the oscillation. The performance of the proposed methods are evaluated using both synthetic and experimental data. [C68]

#### **"The detection performance of complex cosine CWT and entropy analysis for narrowband signals"**

The problem of detection of narrowband sinusoidal signals buried in additive noise is addressed. Detection is formulated using continuous wavelet transform (CWT) with the custom designed complex cosine wavelet and estimating the presence and frequency of useful signals in the wavelet domain. An adaptive entropy based threshold detector is proposed to detect presence and time localization of useful signal in the transform domain. A simple and pragmatic method of threshold setting as the average of minimum and maximum entropy is

proposed. Application example is focused on detection of useful signal in the harmonic radar system. Simulation results show that the proposed method also allows detection of signals with negative signal-to-noise ratio (SNR). Time-frequency characteristic of the CWT is compared with the short-time Fourier transform (STFT) for the specific mother wavelet. [C69]

#### "A comparison of 1D vertical models of biogenic gas content within a northern peatland from common mid-point and cross-borehole GPR"

Surface-based ground penetrating radar surveys are non-invasive and fast while cross-borehole methods have the potential to be more accurate and repeatable, though time consuming. In order to assess the variation between common mid-point and cross-borehole surveys as a tool for estimating free-phase gas volume in peat soils, we compared the modeled gas content results from surface-based multiple-offset data to down-hole zero-offset profiles. Accuracy of each method was also evaluated using reciprocal measurements and statistical methods. Both common mid-point and cross-borehole methods yielded repeatable measurements and resulted in a similar range of gas content estimates. Variations in gas content estimates ranged from <1%-16%, though the common mid-point measurements underestimated the gas content compared to the cross borehole measurements. [C70]

#### "Qualitative monitoring of the water content evolution in an inhomogeneous soil column"

A microwave imaging problem is considered where a soil column is surrounded by a metallic circular enclosure. This system is presently being developed to demonstrate the potentiality of non-invasive microwave imaging systems for volumetric water content monitoring. The final goal is to retrieve soil moisture information as it is an important parameter for understanding fluid flows in the soil as well as the water uptake by plant roots. Here, we address the qualitative part of the problem with the help of a rapid and rather robust sampling methods: the Linear Sampling Method (LSM) and the MUSIC method. These methods are tested for the following configuration: one water source diffuses in a heterogeneous background. We show that, to a certain extent, the evolution of the soil water content can be qualitatively monitored with the LSM. Moreover, we propose a quick way for detecting the position of the water source inside the soil column. [C71]

#### "Resolution-improved microwave tomography by means of hyperspectral analysis tools"

In microwave tomography, the underlying scattering phenomenon is often linearized to retrieve the associated induced currents maps. These maps are then summed together to provide a good estimation of the target position. This qualitative reconstruction scheme is robust with noise but has a spatial limitation linked to the bandwidth of the radiation operator. We will show that the result of this inverse source problem can be considered in a different way by storing, incidence after incidence, the reconstructed induced current maps. As in hyperspectral imaging, this hypercube can be formalized as several views of the same scene. In hyperspectral imaging, the wavelength is the varying parameter. In harmonic microwave tomography, the incidence angle is the varying parameter. By applying image processing techniques such as principal component analysis, we will show that we can improve the spatial resolution of the qualitative maps. Synthetic results in an aspect-limited configuration will be presented. [C72]

#### "4D GPR tracking of water infiltration in fractured high-porosity limestone"

Three thousand liters of water were infiltrated from a 4 m diameter pond to track flow and transport inside fractured carbonates with 20-40 % porosity. Sixteen time-lapse 3D Ground Penetrating Radar (GPR) surveys with repetition intervals between 2 hrs and 5 days monitored the spreading of the water bulb in the subsurface. Based on local travel time shifts between repeated GPR survey pairs, localized changes of volumetric water content can be related to the processes of wetting, saturation and drainage. Deformation bands consisting of thin subvertical sheets of crushed grains reduce the magnitude of water content changes but enhance flow in sheet parallel direction. This causes an earlier break through across a stratigraphic boundary compared to porous limestone without deformation bands. This experiment shows how time-lapse 3D GPR or 4D GPR can non-invasively track ongoing flow processes in rock-volumes of over 100 m<sup>3</sup>. [C73]

#### "Comparing electromagnetic induction and ground penetrating radar techniques for estimating soil moisture content"

Previous studies have demonstrated the capacity of electromagnetic geophysical methods for estimating soil moisture content. In this study, electromagnetic induction (EMI) and ground-penetrating radar (GPR) measurements were coincidentally collected along a fixed survey line to evaluate temporal changes in apparent electrical conductivity and electromagnetic direct ground wave velocity, respectively; surveys were collected at

three sites (i.e., sand, sandy loam and silt loam) during the course of a complete annual cycle of soil conditions. These two geophysical data sets correlated well during the course of the annual cycle at the silt loam site. Correlation between the two data sets was not as strong at the other two sites, with the sand site showing the lowest correlation values. Further, the geophysical data and gravimetric water content measurements obtained from the upper 0.5 metres indicate higher correlation estimates at the finer grained silt loam site relative to the sand and sandy loam sites. [C74]

### **"Communication in automotive systems: Principles, limits and new trends for vehicles, airplanes and vessels"**

This paper deals mainly with state of the art and next-decade technologies for fiber-optic data buses in automotive applications. Nowadays, fiber-optic data buses in automotive applications are exclusively used in the infotainment domain, MOST (Media Oriented System Transport). Current data rates are in the order of 150 MBit/s. Consequently, the use of LEDs and polymer optical fibers (POF) is sufficient. For higher data rates, also alternative solutions are discussed: The LED as transmitter can be replaced by a vertical surface emitting laser (VCSEL), and the plastic fiber (POF) by a polymer-cladded silica (PCS) fiber. Due to the inherent fact that, as a result, the fiber diameter is reduced, the detector area of the well-known Silicon photo diodes can also be reduced greatly. As a consequence, data rates can be extended into the Gbit/s-region. Furthermore there are different physical layers like optical wireless and radio frequency systems (Radar) to be taken into account. [C75]

### **"LIDAR-based road and road-edge detection"**

In this paper, a LIDAR-based road and road-edge detection method is proposed to identify road regions and road-edges, which is an essential component of autonomous vehicles. LIDAR range data is decomposed into signals in elevation and signals projected on the ground plane. First, the elevation-based signals are processed by filtering techniques to identify the road candidate region, and by pattern recognition techniques to determine whether the candidate region is a road segment. Then, the line representation of the projected signals on the ground plane is identified and compared to a simple road model in the top-down view to determine whether the candidate region is a road segment with its road-edges. The proposed method provides fast processing speed and reliable detection performance of road and road-edge detection. The proposed framework has been verified through the DARPA Urban Challenge to show its robustness and efficiency on the winning entry Boss vehicle. [C76]

### **"3D-segmentation of traffic environments with u/v-disparity supported by radar-given masterpoints"**

3D-segmentation of a traffic scene with two-dimensional row- and column-disparity-histograms, namely u/v-disparities, has become more and more popular for modern stereo-camera-based driver assistance systems due to its fast computation in real-time, few memory requirements and robustness against noisy or intermittent data. In this paper, we present a novel approach to support this pure vision-based method by projecting preprocessed radar-signals directly to u-disparity-space. We called the projection result "masterpoints". This data fusion on low feature-level improved the segmentation process and increased the obstacle detection rate significantly. No assumptions about obstacle-type or -size are needed. Furthermore, the algorithms can be parallelized easily and run in real-time. [C77]

### **"Reliable automotive pre-crash system with out-of-sequence measurement processing"**

In an automotive pre-crash application, it is vital to quickly and accurately estimate the position and velocity of objects in the frontal area of the vehicle. To improve such estimations, several radar sensors are fused to detect objects. Due to their different performance characteristics, their measurements can arrive at the pre-crash processing unit out-of-sequence. This work presents several techniques to integrate measurements into a tracking algorithm that arrive with such an out-of-sequence measurement (OOSM) scenario. A comprehensive complexity analysis of the algorithms is also presented. Most importantly, the algorithms are run on a test vehicle during real crash scenarios. The algorithms' performance is evaluated against reference data from a highly accurate laser scanner. It is shown that using advanced OOSM algorithms in pre-crash systems significantly increases performance and reduces computational cost compared to previous approaches. [C78]

### **"Design of an analog correlator for 22-29GHz UWB vehicular radar system using improved high gain multiplier architecture"**

An analog correlator for ultra-wideband (UWB) vehicular short-range radars (V-SRR) is presented. The correlator is designed for operation at 22-29GHz using the IBM 90nm RFCMOS process. The correlator consists of a multiplier, a Gm-C integrator, and a post amplifier. A novel four-quadrant transconductance multiplier (FQTM) is

proposed to achieve high gain, and a Gm-C integrator is designed to improve the holding time of the correlator. Simulations show that the proposed FQTM has 9.54dB gain increase, and the correlator achieves 2.3ns of holding time and uses 15 mW of power. [C79]

#### "Levy flights for improved Ladar scanning"

A new approach has been used to improve Ladar performance in real time applications based on the use of Levy statistics. This approach speeds up target detection and does not require a full scan of the field of view and the subsequent data processing. This leads to a more efficient Ladar system and opens up the possibility for more real time applications. The approach is to use "Levy flights" instead of traditional techniques, such as Raster and Lissajous scanning, to detect the target in the scene. The performances of these latter techniques and this new approach are compared for a variety of conditions. The simulation results show an enhanced performance when using Levy flights as a scanning technique. [C80]

#### "Evaluation of the influence of a scanning method on the resulting quality of the GPR images"

This paper evaluates the results of experimental 3D Ground Penetrating Radar (GPR) measurements on a physical model with a focus on reinforcement detection. It compares changes in the quality of GPR scans depending on line direction and antenna orientation. This aspect of measurement has an immense effect on the quality of results and on the ability to detect the position of reinforcement inside an investigated concrete structure. [C81]

#### "The use of high speed FIFO chips for implementation of a noise radar"

An ultra wide band spread spectrum radar (a noise radar) can be built using a system that generates two wide band spread spectrum (pseudo-random) waveforms. One waveform is transmitted by the system and one waveform is used to correlate against the received signals. Because of system dispersion, propagation channel dispersion and radar target dispersion, it is often appropriate for the receive correlation waveform to be of a different form than that of the transmitted waveform. Thus a noise radar often needs to be able to generate two different wide band waveforms with controlled differential delay time. This paper will discuss the implementation of such a system using commercially available FIFO microchips. [C82]

#### "Sea-land transitions identification for Coordinate Registration of Over The Horizon Sky-Wave Radar: Numerical model for performance analysis"

We recently proposed a correlation method for the real time Coordinate Registration (CR) of the received echo by Over The Horizon Sky Wave Radar (OTHR-SW) based on a priori knowledge of the positions of the sea-land transitions within the radar coverage area. In this paper we present a simulator that can be used for performance analysis of the proposed CR method in realistic OTHR scenarios. Some simulation result are presented and discussed assuming a single sea-land transition scenario and a geographically invariant vertical electron density profile. [C83]

#### "Detection of subsurface non-metallic objects using stepped frequency continuous wave ground penetrating radar"

In the paper, several aspects of using stepped frequency continuous wave signal in a ground penetrating radar were discussed. Radar was operating in 750-3000 MHz bandwidth, with 563 frequency steps. Test objects included non-metallic object made from wood and plastic, as well as soil with different value of permittivity, all buried at 10-15 cm. [C84]

#### "GPR resolution improvement"

Application of Kirchhoff migration allows to focus images of GPR. Often it is difficult to distinguish close objects. To improve resolution various filtrations can be applied. In this study Inverse filtration with antenna cross talk pulse is used. By this method very close objects can be distinguished. This study shows, that GPR down-range resolution is better, than cross-range resolution. [C85]

#### "A simulation tool for analysis of MTD algorithms employing STAP techniques"

The purpose of this work is development and program realization in MATLAB computational environment of a tool suitable for modeling and evaluating the performance of a pulse doppler MTD (Moving Target Detector) radar with LFM (Linear Frequency Modulated) signals employing STAP (Space Time Adaptive Processing) techniques. It supports numerical design choices with selectable system and signal processing parameters so

that different designs can be traded-off or optimized. This software tool is also able to simulate selectable target, clutter and jamming and thus particular scenarios of interest can be evaluated. The obtained results can be a good base for real time implementation. [C86]

#### "Wind turbines as distorting scattering objects for radar-clutter aspects and visibility"

Wind turbines WT are planned to be constructed often close to radar systems, e.g. air traffic control, air defense, weather radar. The WT are scatterers and may affect the radar operation in-acceptably. The WT are a clutter problem and are not false targets as sometimes treated if the WT are visible to the radar. Clutter characteristics are presented and discussed. [C87]

#### "Effects of iron pipe corrosion on GPR detection"

Many studies into the use of GPR to detect targets assume that the targets are ideal reflectors. In reality most targets have been in the ground for many years and have settled and suffered some contamination or corrosion. Iron pipe in particular can be hard to find with GPR. Some possible corrosion processes suggest that a varying conductivity and permittivity profile may be established around a pipe. The consequences of such corrosion induced profiles are that the radar return may be greatly diminished in the classic look-down GPR mode of operation. The analysis shows that the novel look through GPR mode of operation is affected far less by the corrosion induced profiles. [C88]

#### "Shaping the future of GPR soils research"

Workshops were held at the GPR08 and IWAGPR09 conferences with the intention of developing closer links between GPR users and soil spectroscopy researchers, including developing an improved understanding of the associated research needs. Both workshops were well attended and provided a useful forum that identified elements central to greater interchange of information between the two disciplines. This paper will detail the outcomes of the IWAGPR09 workshop (the GPR08 workshop having been reported on there), providing full information on the perspectives of relevant stakeholders. Included will be details of invited presentation, panel discussion and general discussion sessions. Also, full details of the outcomes of the associated questionnaire, which sought to prioritise the main concerns of stakeholders identified at the GPR08 workshop, will be provided. In conclusion, this paper will consider ways in which those concerns can be addressed, including in terms of standardisation, delivery of research needs, and data sharing. In so doing, the paper is intended to provide GPR and soil spectroscopy stakeholders with an ongoing record of their workshops in order to facilitate debate, discussion and future action. [C89]

#### "Automatic generation of a highly accurate map for driver assistance systems in road construction sites"

Road construction sites often are the reason for traffic jams and accidents due to the reduced road width. Driver assistance systems for these demanding environments highly benefit from a digital representation of the road layout. This digital map includes all important infrastructure elements, such as barriers, temporary road markings and guiding reflector posts. The paper describes the automatic generation of a detailed and highly accurate "Road Work Map" using video camera and laser scanners. [C90]

#### "State estimation of projectiles based on Doppler radar signals using EKF and UKF"

In this paper we compare two methods that lead to distance and velocity estimation of fast moving objects at very close ranges based on Doppler radar signals in real time applications. The first goal of this work has been to find an algorithm and the adjustments to get stable and precise actual state estimations using a low power Doppler radar in field applications. The claim is to reduce the measurement equipment costs. The second step will be an appraisal if this approach can be realized on a real time system. [C91]

#### "Inference of vertical soil moisture distribution using high-frequency CMP and reflection traveltime analysis"

High-frequency ground-penetrating radar (GPR) surveys were used to investigate temporal water content variations in a vertical soil column characterized by stratified clean sand deposits over multiple annual cycles. Reflection profiling and common-midpoint (CMP) soundings were coincidentally performed using 900 MHz antennas across a 2 m intensive monitoring profile. Our ability to identify fixed reflection events along a vertical soil profile permits inference of soil water flux across defined soil intervals in a non-invasive manner. Soil moisture contents were estimated from two-way traveltime measurements between seasonally coherent stratigraphic interfaces in the upper 2-3 m of soil. Interval thicknesses between stratigraphic interfaces were

estimated from normal-moveout velocity analysis of coincidentally collected CMP soundings. Interval traveltimes from reflection profiles were then converted to wave velocity using the interval thickness estimates and a volumetric water content estimate using an appropriate petrophysical relationship. The GPR effectively characterized long (e.g., seasonal trends) and short-period (e.g., distinct wetting events) variations in vertical soil moisture distribution. [C92]

### "Microwave visualization of layered dielectric half-space using range profiling of phase"

A novel method of subsurface radar data processing based on independent determination and representation of amplitude and phase profiles is described. As the phase of the reflected signal depends on dielectric properties of buried target, the proposed technique is suitable for target discrimination. The amplitude and phase information is merged in the common image by governing intensity and color of the image. The amplitude profile of the reflected signal is obtained using a standard inverse Fourier transform of the frequency domain data whereas the phase profile associated with the reflection act at the given depth is derived using a special data processing technique. Some numerical and experimental examples illustrating the method performance are presented. [C93]

### "Motion compensation for landmine detecting vehicle-borne SAR"

In this paper we consider motion compensation of vehicle-borne SAR for landmine detecting, where the motion error is one of the major challenges. Motion compensations algorithms in both azimuth and range direction are discussed. Aiming at vehicle-borne SAR, the motion compensation in range direction utilizes only one 1-axis MEMS accelerometer instead of a 6 Degrees of Freedom inertial sensor, and the motion compensation in azimuth direction can be done only by the knowledge of the vehicle's velocity. The experiment results demonstrate that the motion compensation algorithm together with a standard low-cost accelerometer can yield very useful images for vehicle-borne SAR for landmine detection. [C94]

### "Noise Waveform SAR for 2D and 3D imaging"

Generation of high resolution two-dimensional (2D) and three-dimensional (3D) images in short range applications with the help of coherent radar is the main objective of the paper. Conventional SAR generates 2D image using combination of range compression and 1D aperture synthesis via azimuth (cross-range) compression. The range resolution is limited by the signal spectrum width, while cross-range resolution is defined by the signal wavelength to synthetic aperture length ratio. We suggest applying 2D aperture synthesis that implies cross-range compression technique in both dimensions to generate 2D coherent images. Application of noise waveform with wide enough power spectrum bandwidth enables generation of 3D images of radiotransparent objects, such as trees, bushes, interior of rooms, etc. We present results of modelling of noise waveform radar with 1D and 2D aperture synthesis having various configurations of planar 2D synthetic aperture and results of experiments aimed on SAR imaging with continuous noise waveform and 2D synthetic aperture. [C95]

### "TOA association for handheld UWB radar"

Handheld ultra-wideband radars can be used with advantage during rescue, surveillance or security operations by reason that they enable to track targets moving behind walls. The radar signal processing for that purpose represents a complex process with several processing phases. In this paper, the attention is devoted to the estimation of the correct input data for the localization phase. This is done by applying a new approach that combines the time of arrival (TOA) estimation and the data-association into a single step. The performance of the proposed algorithm is illustrated by processing of real radar signals. Here, the obtained results confirm that the proposed algorithm can provide good, stable and robust TOA estimation including deghosting task solution. [C96]

### "Enhanced monopulse radar tracking using fractional Fourier filtering in the Presence of interference"

Monopulse radars are used to track a target that appears in the look direction beam width. Significant distortion is produced when manmade high power interference (jamming) is introduced to the radar processor through the radar antenna main lobe (main lobe interference) or antenna side lobe (side lobe interference). This leads to errors in the target tracking angles that may cause target mistracking. A new monopulse radar structure is presented in this paper which addresses this problem. This structure is based on the use of optimal Fractional Fourier Transform (FrFT) filtering. The improved performance of the new monopulse radar structure over the traditional monopulse processor is assessed using standard deviation angle estimation error (STDAE) for a range of simulated environments. The proposed system configurations with the optimum FrFT filters is shown to

reduce the interfered signal and to minimize the STDAE for monopulse processors. [C97]

### "Design and implementation of an integrated high resolution imaging ground penetrating radar for water pipeline rehabilitation"

Accurate and timely detection of leaks in water supply pipes is a significant environmental issue. Development of efficient non-invasive methods would lead into significant water saving and prevention of health hazards introduced by water leakage. This paper shows the ability to use a High Resolution Ground Penetrating Imaging Radar (GPIR), to be used as an instrument for water pipeline rehabilitation situations, parallel to the existing industrial equipment. In the framework of the European research initiative WATERPIPE, a Decision Support System (DSS) for the rehabilitation management of the underground water pipelines has been developed, parallel to the implementation of the GPIR. This paper briefly presents the system design, the basic principles of the algorithms' implementation and some indicative results from the initial use of the GPIR system. [C98]

### "UWB radar object recognition for SLAM"

In situations where the environment is filled with dust or smoke, like in many emergency scenarios, UWB Radar is a possible technology to still sense the surrounding and build maps, thus helping firemen and other rescue personal. In this paper, a combination of two algorithms is presented. A basic simultaneous localization and mapping (SLAM) algorithm relying on simple indoor features is used to explore the environment and build a map. This algorithm is augmented by an object-recognition (OR) algorithm that is capable of recognizing and localizing complex shapes. These shapes can be used to improve the map resolution accuracy and resolve ambiguities. First tests using an m-sequence UWB Radar indicate the feasibility of this concept. [C99]

### "Influence of turbulence onto depolarization of signal reflected from hydrometeors"

In this paper the approach to estimate reflected signal depolarization due to turbulence with a single unipolarized antenna is considered. The approach allows to make estimate by character of low frequency envelope change of reflected wave due to changing the depolarization angle of reflected wave. The frequency spectrum of low frequency envelope of reflected wave is also used as a parameter for turbulence intensity estimate. [C100]

### "Simulation of the 24GHz short range, wide band automotive radar"

In this paper we simulated 24 GHz short range, wide band automotive radar. The simulation was done using matlab. The main objective of this work is to reduce traffic accidents and potential danger that faces the driver and the vehicle as a result of the sudden collision. The model consist of six sensors distributed in different sides of the car, these devices provide exact measurement of distance and relative speed of objects in front, beside or behind. Each sensor sends signals to predict, if there is any body around the car to alarm the driver about it. These signals cover distance reach to 30 m. However, if the distance between car & object was less than 2 m the car produce sound like alarm to alert the driver of danger near and the driver can present to take the appropriate decision to avoid collision. [C101]

### "UWB radar for detection and localization of trapped people"

In this paper hardware and software aspects of detection and localization of people by their breathing are discussed. Separately, the problem of non-stationary clutter is considered. All the proposed algorithms are supported by measurement examples. [C102]

### "Quantization effect of the parameter space on the performance of hough detector"

Hough transform is proposed in literature as an effective technique for target detection in search radars. However, this detector has a disadvantage when the received SNR of radar is low. Although the distribution of noise power in the data space is often uniform and all processing cells of this space approximately receive the same power of noise, after transforming these cells to the Hough parameter space, this distribution will not remain uniform. In other words, noise power in some regions of the parameter space is greater than the others. Therefore, false alarm increases in these regions. Selecting a greater threshold to reduce the number of false detections will result a lower probability of detection in lower SNR cases. In this paper, a new quantization method is used for the parameter space which is based on the Maximum Entropy Quantization. It is verified through simulation results that by using this method, the distribution of noise power in this space will become uniform and the average probability of false alarm will be the same for all parameter cells. Also, the performance of Hough detector with a non-uniform quantized parameter space is compared to uniform quantized one through simulation scenarios and it is shown that an improvement of about 2dB results in the required SNR. A method is also introduced to solve the above mentioned problem of the Hough detector for the cases in which the

distribution of noise power in the data space is not known. [C103]

#### "Bistatic Quasi-passive noise SAR experiment"

The paper describes the concept and the preliminary results of bistatic noise SAR experiments carried out at Warsaw University of Technology (WUT). The aim of the experiment was to test the ability of simple system build of Commercial Off-The-Shelf (COTS) components to produce a focused SAR image. The demonstration system is a ground-based one. Instead of using airborne or space-borne antenna system a simple rails wagon with electronically control motor was used to generate the antenna motion. The paper presents the description of the hardware, details of the measurement campaign and the results of signal processing. [C104]

#### "Stepped delay noise radar with high dynamic range"

In the paper we propose and analyze an alternative approach to evaluation of cross correlation function in Noise Radar enabling drastically enhance dynamic range of wideband noise radar with digital signal processing. The approach is based upon digital generation of both sounding and reference signals using fast enough Arbitrary Waveform Generator (AWG) with the required delay and coherent analog reception of the radar returns. Both signals may be up converted to the required carrier frequency. Cross-correlation between the reference and radar returns is to be realized at the carrier frequency using analog mixer and low pass filter. In the paper we describe the new approach and compare it with the conventional one. [C105]

#### "Real-time signal processing in noise radar"

In Noise Radar, coherent reception of scattered signals is performed via estimation of cross-correlation between the sampled reference and radar returns. In the paper we present preliminary results of the design and implementation of FPGA-based correlator for coherent reception of noise radar returns. Parallelization of computations in FPGA gives a hope to realize an algorithm in time domain for evaluation of the cross-correlation function, comparable with the frequency-domain algorithm in efficiency. Moreover, implementation of relay-type correlator algorithm gives a hope to implement evaluation of cross-correlation algorithm which might operate much faster. We present comparison of performance and limitations of different considered designs. [C106]

#### "Analytical sensor data evaluation models for the purpose of evidential inference in electro-magnetic reconnaissance"

This paper describes what particular pieces of information about source should be taken into account to get a reasonable assessment of attribute information based on the sensor data or human originated information. It has been proven that actual sensor weights and hypotheses masses do not change randomly, but they vary in time according to tracked target motion, however not directly to the target position. It is postulated that the knowledge about target position only is insufficient and at least two dynamical coordinates target state vectors are required to reflect the target orientation, which has an influence on actual hypotheses assessment formed, on the basis of the sensor data or visual sightings. [C107]

#### "UWB radar for breath detection"

Using Breath Detection System can be detected breath rate and heart beating rate. System can be used for finding live human being behind nonmetallic obstacles. System was tested and showed good results in Test Polygon. [C108]

#### "94 GHz person scanner with circular aperture as part of a new sensor concept on airports"

In the following paper, a new concept for increasing the airport security is proposed. As a part of this innovative system, a W-band person scanner with a circular aperture for 360° scans has been built up. The usage of the Synthetic Aperture Radar (SAR) principle allows the detection of concealed objects with a resolution of 3mm in azimuth and 3 cm in range direction. [C109]

#### "Using noise modulation in practical radar systems: -Including a comparison with FMCW modulation"

This paper discusses the practical strengths and weaknesses of Noise Radar Techniques when applied to practical radar systems. It will also attempt to distinguish those features which are unique to noise modulation from those which they share with some other modulations. [C110]

### "Development of UWB microwave array radar for concealed weapon detection"

This paper describes two approaches to short-range microwave imaging by means of ultra-wideband (UWB) technology. The first approach deals with synthetic aperture radar (SAR) that employs a transmit-receive antenna pair on mechanical scanner. The second one represents a multiple input multiple output (MIMO) antenna array that scans electronically in the horizontal plane and mechanically, installed on the scanner, in the vertical plane. The mechanical scanning in only one direction reduces significantly the measurement time. Two respective prototypes have been built and compared. Both systems comprise the same 10-18 GHz antennas and multichannel video impulse electronics while the same focusing based on Kirchhoff migration is applied to acquired data for radar imaging. The study has been carried out for an application of concealed weapon detection. [C111]

### "Rank signal detection algorithms based on permutations of partial likelihood ratios"

This paper presents a new approach to design radar signal detection algorithms that are applicable when a priori information is limited. The problem is formulated as testing hypothesis on the kind of density function. A new method that uses ranks of partial likelihood ratios allows to adopt permutation test in a practical algorithm is suggested and researched. This approach gives a possibility to construct the rank detection algorithms, which are sensitive for the signal change for different situations, in the most simple and natural way. The results are useful for applications of signal detection in surveillance and remote sensing radar systems [C112]

### "Designing sparse frequency waveform using iterative algorithm"

Sparse frequency waveform with stopbands sparsely distributed over a larger spectrum band is desired in many radar and communication systems operated in a highly congested spectrum environment. In this paper, a new method for designing sparse frequency waveform with sidelobe constraint is proposed. The basic idea is to construct a penalty function based on both the Power Spectrum Density requirement and the sidelobe requirement and then minimize it through an iterative algorithm. The proposed new method is efficient in computation and can design sparse frequency waveform with large dimensions. Numerical studies with design examples illustrated the efficiency of the proposed method. [C113]

### "On the Range Precision of UWB Radar Sensors"

The precision of radar range measurements depends on certain conditions. For narrow band radar, it is well understood that signal bandwidth and random noise are essential for range resolution and accuracy. The things are more complicated for UWB radar since jitter, antenna behavior, and even the target itself will have influence. This article analyses some aspects distinguishing the UWB radar from the narrowband one with respect to resolution features. [C114]

### "Target localization by the method of joining intersections of the ellipses"

Handheld UWB radar systems used for through wall target localization are usually equipped with one transmitting and two receiving antennas. Sometimes, the radar systems of that kind are not able to localize the target with required accuracy. In order to improve the precision of the target localization, cooperative positioning based on data fusion from two independent radar systems can be used. For this purpose, the novel method of the target localization referred to as the method of joining intersections of the ellipses is introduced in this paper. This method is based on the direct calculation method extended by a decision algorithm. The performance of the proposed method will be compared with the direct calculation method by using real data obtained by measurements by the UWB radar system. [C115]

### "A concept of decentralized fusion of maritime radar targets with multisensor Kalman filter"

The paper presents a concept and an algorithm of multisensor decentralized data fusion for radar tracking of maritime targets. The fusion is performed in the space of Kalman Filter and is done by finding weighted average of single state estimates provided by each of the sensors. The article presents both algorithms-Kalman Filter for tracking objects in single sensor and combining them together to find one fused state vector. Another approach for target tracking, namely neural target tracking is also recalled in the aspect of fusion. Two approaches for data fusion-centralized and decentralized-are stated and the latter is thoroughly examined. The discussion on main problems involved in fusing process in complex radar systems is then presented. This includes coordinates transformation, track association and measurements synchronization. Future plans of including neural tracking in data fusion are presented. The article is ended with summary of the issues pointed out in it. [C116]

### "Tracking of dismounts moving in cross-range using GMTI radar"

The detection of dismounts has a variety of applications, such as tracking remotely for battlefield awareness or at check-points. In this paper we describe the sensitivity of ground moving target indication (GMTI) radar as a dismount moves in cross-range, where the radial velocity is difficult to detect but the micro-Doppler of moving dismounts makes feasible. GMTI target detections are used as a subject moves perpendicular to the beam of the radar. These measurements are compared to vehicular and animal measurements which have minimal micro-Doppler and are much more difficult to detect in their cross-range motion. Ground truth is gathered using video to validate the radar data. We find a detection probability on dismounts in excess of 85% with a low false positive rate of 2%. [C117]

#### "Broadband microwave correlation receiver for noise radar"

The idea of microwave quadrature correlation as well as the block diagram of the microwave broadband correlation receiver are presented in the paper. Measurement results for the function of noise signal correlation are shown. The application of such noise radar solution is presented for precise determination of distance changes and speed of these changes. Conclusions and future plans for the use of presented detection technique in broad-band noise radars close the paper. [C118]

#### "Stepped-frequency noise radar with short switching time and high dynamic range"

Stepped frequency technique is in wide use in radar. Narrow frequency bandwidth of the transmitted signal is an attractive feature of this technique which enables application of rather slow sampling rate. In this case, high-bit and cost effective ADCs are readily availability. However, this technique also has some drawbacks, such as: (a) Ambiguity in range measurements; (b) High level of range side lobes; (c) Low resistance against narrowband coherent interferences. To go around these drawbacks we suggest application of random waveforms with synthesized spectrum. In this case the ensemble of the probing signals realizations can be produced in different ways: (1) Stepped variation of a single frequency signal over a discrete frequency mesh according to a random law, i.e. frequency hopping with random frequency hops; (2) Step-like increase of the central frequency of a narrow band random signal over a discrete mesh of frequencies; (3) Frequency hopping of a narrow band random signal according to a random law, i.e. random frequency hopping of random signals. [C119]

#### "Robust detection in continuous-wave noise radar-experimental results"

In the paper the problem of target detection in continuous-wave noise radar in the presence of impulsive external noise is addressed. If received noise has distribution different than Gaussian, the classical correlation receiver does not provide the optimal results and the performance of the radar is seriously degraded. In order to restore the sensitivity lost due to the impulsive noise a robustification method is proposed. In the method a nonlinear function is applied to the signal in order to remove the outliers. The method is verified on real-life signals. [C120]

#### "Impact of quantization and roundoff errors on the performance of a noise radar correlator"

This paper evaluates the influence of quantization effects on the performance of correlators. The problem is decomposed into two smaller ones, each dealing with difference source of errors (quantization of input signals and finite-precision arithmetics) separately. A discussion of the first type of errors is held on a general level and applicable to any type of correlator. However, roundoff effects depend strongly on details of computations. Therefore, a case study is performed using a fixed-point FFT-based correlator, implemented using LogiCORE IP FFT v. 7.0 engine. [C121]

#### "An application of the content description language XML for modeling of information structures of electronic intelligence system"

XML language is a standard for creating rules of designed data formats. Single documents are mostly defined by XML schemas. As the basis for XML information model one can utilize UML class diagram model. This paper presents an example of application of the content description languages XML and XML Schema standards for modeling of information structures of electronic intelligence system. In particular it is related to transformation UML models to XML schema models using UML Profile and UML mapping rules. [C122]

#### "Comparison of communication signals for passive radar application"

Based on theoretical methods for synthesis of complementary signals briefly below, the authors have developed a new algorithm and software for automated synthesis of Direct sequence complementary codes. The authors propose a numerical method for analysis and comparison of this types synthesize Complementary codes with well-know code sequences like Barker and Z-complementary codes. Build on the autocorrelation and ambiguity

functions of signals, the numerical method estimates the volume of sidelobes separately for each signal. The results are obtained using the specialized software in MATLAB R2007b. [C123]

#### "Higher order statistics sensitivity to radar signal feature"

The paper 1 presents experiments on the use of higher order statistics in the procedures of identification of radar emitters. Studies aimed at testing "sensitivity" of higher order statistics of selected characteristics of the individual sources of emissions. Attention is focused on methods based on analysis of parameters of single-pulse radar emissions. [C124]

#### "Numerical analysis of MIMO radar detection performance under weibull-distributed clutter"

In this paper, the detection performance of a MIMO radar under Weibull distributed clutter is investigated. Numerical results, based on Monte-Carlo simulations, showing the detection performance are provided. The false alarm rate and the detection performance are carried out for different values of the shape parameter of the Weibull distribution and the number of transmit-receive pairs used in the MIMO radar configuration. The obtained results validate the improvements in detection performance available from a MIMO radar against a mono radar. The obtained performances are presented and discussed in this paper. [C125]

#### "Design and implementation of a highly configurable low power robust signal processor for portable ground based "multiple scan rate" surveillance radar"

FPGA based realization of a highly configurable low-power robust signal processor for a portable ground-based multiple scan rates surveillance radar is presented. Portability feature of the radar demands a compact radar system which should be able to detect low flying aerial targets against clutter/interference background. All requirements could be met in a FPGA-based design of a multi-channel signal processor to cater for low peak power large bandwidth waveforms, separate processing for special targets and an embedded softcore processor. Reliable self-test mechanisms-external as well as internal have been built into the signal processor for functional verification of entire radar system. [C126]

#### "Higher order statistics sensitivity to radar signal feature"

The paper 1 presents experiments on the use of higher order statistics in the procedures of identification of radar emitters. Studies aimed at testing "sensitivity" of higher order statistics of selected characteristics of the individual sources of emissions. Attention is focused on methods based on analysis of parameters of single-pulse radar emissions. [C127]

#### "Application of Autoregressive Model for Recognition of Meteorological Objects"

In the paper the results of development of recognition algorithm of meteorological objects by use of autoregressive model with spectrum-correlation signal processing of incoherent radar are presented. The radar hardware and experimental results on estimation of recognition efficiency are described. [C128]

#### "Applying the decision trees to radar targets recognition"

Electronic Support Measure (ESM) systems have been used to passively detect electromagnetic emission from airborne, shipborne, and landborne platforms. The paper describes a method of an automatic radar target recognition based on following principal stages: digital signal processing, feature extraction and selection and applying a combination of decision tree, minimum distance classifier and knowledge base. [C129]

#### "Use of Digital-Television terrestrial (DTV) signals for passive radars"

Purpose of this paper is the description of how to use the Digital-Television terrestrial Video (DTV) stations as a non-cooperative illuminator in bistatic radar. Based on [1] it is shown that the original DTV signal contains random and deterministic components. Analyzing the ambiguity function of the DTV signals, it is found that the deterministic components cause unwanted peaks around the desired peak pertaining to the useful echo thus the target detections is difficult to do and/or false targets can be revealed. In this paper, a new approach to improve the ambiguity function around the useful echo will be proposed. In order to study, evaluate and elaborate the DTV signal, a simulator of the complete signal was performed This paper is organized as follows: next section 1 will describe the obtained outputs of DTV simulator; section (2) will describe the complete block diagram of passive radar using DTV signal, describing the new signal processing approach to improve the ambiguity function; section (3) will describe the obtained results from a realistic scenario; section (4) will present some preliminary results about the multipath effect on the system performance. [C130]

### "Modeled gait variations in human micro-doppler"

Measurement of human motion is important for security applications. One would like to observe humans unobtrusively and without privacy issues, and using radar provides one method to detect abnormal activity without using images. In this paper we focus on modeling the characteristics of human walking parameters in order to determine signature differences that are distinguishable and to determine the variability of normal walking to be compared to armed or loaded walking. We extract micro-Doppler from motion-captured human gait models and verify the models with radar measurements. We then vary the model to determine extent of normal micro-Doppler variation in multiple dimensions of human gait. We also characterize the ability of radar to determine gender and suggest that alternative views to the frontal view may be more discriminative. [C131]

### "Cross ambiguity function analysis of the '8k-mode' DVB-T for passive radar application"

One of non-cooperative illuminators recently considered for passive radar applications is the DVB-T (Digital Video Broadcasting-Terrestrial) station. The thumbtack ambiguity function of the DVB-T signal in addition to being stationary makes such signal a good candidate for such applications. However, certain ambiguities in its ambiguity function necessitates certain issues to be carefully considered when DVB-T signals are to be utilized. In this paper, after studying the origins of these ambiguities, we propose special processing schemes to resolve them. [C132]

### "Data fusion algorithms for sea target tracking using coastal radar model"

The fusion of multiple monitoring systems data is very important, to get a full view of situation in coastal waters. Sea target tracking algorithm is modeled, coast radar system model implemented, multiple ships tracking and detection is tested. [C133]

### "Power analysis of parallel CA-CFAR FPGA design"

We provide a power analysis of a parallel implementation of the Cell Average Constant False Alarm Rate (CA-CFAR) algorithm in reconfigurable hardware, originally proposed by the authors. The design is based on a parallel processing scheme employing extensive data reuse and synchronized sliding windows over the input data sequence. A scalable parallel structure is designed and mapped on Xilinx Virtex II Pro and Altera Stratix I technology. Synthesis and post place and route results from the Xilinx ISE and Quartus II toolset suggest a linear speedup and resource utilization. More specifically, a single CFAR implementation utilizes 1.4% of the VIRTEX II Pro XC2VP30 chip and 2% for Altera EP1S25F780C5 chip, providing a throughput of 974 Mbps. The power consumption of the design is evaluated per technology. The maximum allowed frequencies are determined and compared, as well. [C134]

### "Advantages of the DVB-T signal for passive radar applications"

One of the attractive opportunistic signals for passive radar applications is the DVB-T (Digital Video Broadcasting- Terrestrial) signal. The thumbtack ambiguity function of the DVB-T signal in addition to being stationary makes such signal a good candidate for such applications. In this paper we want to consider its feasibility for this application in more details. So we first examin this signal for the main parts of the the passive radar: Resolving ambiguities before evaluating CAF and direct path intereference rejection, and then consider its processing gain in detecting targets. [C135]

### "SAR image compression based on sparse representation"

The sparse representation based on over-complete dictionary is a new image representation theory. The redundancy of over-complete dictionary can make it effectively to capture the structural characteristics of the image. In this article, we realize SAR image compression based on sparse representation. We only need to store the coefficients of sparse decomposition and the corresponding indices in order to seize the image's information. We adopt a learning method-K-SVD to construct the dictionary. Because the training examples are all from the image itself, the dictionary could be more approximative to the image's structure. The simulation indicates the proposed method is useful for SAR image compression and it outperforms the DCT based JPEG method and the wavelet based EZW and SPIHT method. [C136]

### "K band patch antenna applied in an FMCW radar"

In the paper, a project of a planar patch array antenna in K band intended for application in an FMCW alert radar sensor is shown. The structure of such an antenna consists of 24 Ч 14 patches; the results of simulation and real measurements of the antenna are presented. [C137]

### "Fully solid state radar for vessel traffic services"

A Vessel Traffic Service (VTS) is a maritime traffic monitoring system established by competent authorities. VTS systems use radars to keep track of vessel movements and to assure a safe navigation in the relevant area. For achieving their tasks, these radars must provide high spatial resolution assuring an accurate estimation of the vessel position and the discrimination of close vessels. The traditional VTS radars use magnetron for the final amplification and they are non coherent: high resolution is achieved by short-time high-peak power pulses. The last generation of VTS radars are instead pulse-Doppler and uses fully solid state technology. These new radars can meet the same high resolution with wideband long coded pulses and digital pulse compression; this solution brings to more compact, safe, reliable and flexible radars. In this paper a VTS radar based on a fully solid state architecture -LYRA 50- is presented. This radar is operative and live data can confirm the effectiveness of this solution. [C138]

### "An analysis of through- wall radar based on UWB impulse technique"

Application of through-wall radar requires the ability to detect targets through relatively high-density materials such as concrete, stone and brick. Ultra wideband (UWB) impulse technique is able to penetrate these materials. The capacity to make wall relatively transparent is due to the broad-band nature of the transmitted impulses. First of all, ultra wideband radar system block diagram is depicted. Secondly, the techniques generated UWB impulse and converted from analogue to digital are introduced in detail in the paper. Finally, some simulation results about construction materials such as concrete, stone and brick led to considerable attenuation of electromagnetic waves are analyzed, the analysis presented here can be applied to the implementation of through-wall radar. [C139]

### "Performance analysis in heterogenous environment and implementation on DSP processor of a GOWMAX CFAR detector"

In this paper we present the results of performance analysis of a GOWMAX CFAR detector in non homogenous environment. The study is made for radar targets of Swerling I type embedded in white Gaussian noise. The results are presented in terms of probability of detection and false alarm. Also we expose the algorithm considered and the results obtained for its implementation on DSK 6711 card using a DSP TM320C6711 processor. [C140]

### "One Example of classing and extracting information from GPR images for the archeology"

Ground penetrating radar (GPR) techniques are based on the possibility of sending electromagnetic pulses and registering of the signals back-scattered by the interface between propagation media of different dielectric permittivity. They had been successfully using to examine structures and materials from inside. In the studying, GPR sounding is practically used for detection and reconstruction of the fortification objects. The software for increase of efficiency of archeological researches and reduction of expenses was developed. The GPR method is practically approved for the undersurface environment monitoring for the archeology-interested zones by results of experimental and practical investigations. The estimation of GPR efficiency at monitoring researches, time and expenses on engineering-archeological works were carried out. As a result of researches, contours of fortifications sites are restored. Contours of the stone bases under dwellings are found out and restored. The investigation aims at expounding some preliminary results drawn by specific algorithms for automatically interpreting, classing and extracting explicit information from radar images. [C141]

### "Demonstrator of S band active antenna with T/R modules"

The paper presents realization, mechanical solution and measurements results of transmit and receive systems used in the Demonstrator of S-band Active Antenna. The transmit system contains T/R modules, where individual module supplies half of antenna row of planar array. The 16 antenna rows form in elevation plane cosecant squared type transmit antenna pattern and fin-beam receive antenna pattern. In azimuth plane, pencil-beam radiation pattern is formed. Five elevation positions of the receive beam is electronically set by means of digital phase shifters and attenuators applied in a receive beam forming network. The results of antenna radiation pattern measurements on a tower setup are shown. Additional information about a Control and Diagnostic System is described as well. [C142]

### "Ka-band radar sensor with selection of moving targets for airport surface monitoring"

The paper describes the peculiarities of the technical solutions, operation characteristics and results of the field tests of a prototype of the semiconductor Ka-band radar sensor with a coherent signal processing designed to

be used as a part of the surface monitoring system at airports. The prototype have been developed, fabricated and tested by IRE NASU (Kharkov, Ukraine) and OJSC SPE «Saturn» (Kiev, Ukraine). [C143]

### "Range resolution improvement for low-cost FMCW self-mixing radar"

The principals of range resolution improvement the self-mixing (autodyne) surveillance radar for object detection on distances from ones to hundred meters are considered in this paper. The description of the flow chart, main parameters and results of test bed model examination are given. Application of the self-mixing regime with internal detection allowed to make the construction easier dimensions smaller to increase reliability of the transmitter and the sensor in whole. [C144]

### "Study of double frequency method for remote sensing of liquid precipitations"

The peculiarities of double frequency method for remote sensing liquid precipitation are discussed in monodisperse approximation. The rigorous calculations of electromagnetic waves scattering by dielectric spheres and properties of radar cross section are considered. The limits of method application are discussed as well as results of experiments. [C145]

### "Autodyne system with a single antenna"

A Clapp's single tuned transistor autodyne Oscillator at 1.2 GHz with 12.25 dBm output power is designed and fabricated on a RO4003 substrate with planar capacitors and loop antenna. This small size fuse operates at 7-10 m distance from surface. [C146]

### "Utilizing Adaptive Techniques to Supress Noise In High Frequency Ground Wave Radar"

Reducing noise disturbances in the frequency segment of high frequency (HF) ground wave radar and restraining the sidelobes of strong targets that interfere with the detection of weak targets are the interesting Topic. A new method based on an adaptive techniques that solves these problems is proposed. By changing the working time of the frequency spectrum monitor (FSM), we have shown not only that radar can run in the frequency segments with lower noise disturbances, but also that the noise data produced by FSM can be exploited effectively. There is no correlation between the noise and the useful echo signal, though the correlation between noises over very short time periods is strong, . Exploiting the phenomena, we can adjust system parameters in real-time by adaptive methods to solve the two problems, namely sidelobe disturbance of strong targets and noise distrubance in the frequency segment. [C147]

### "Object recognition in ground surveillance doppler radar by using bispectrum-based time-frequency distributions"

Performance estimation and comparative study of different kinds of time-frequency distributions (TFDs), especially Wigner-Ville distribution (WVD), as well as bispectrum-based distributions: Wigner-bispecrum (WBD), parametric (PBD) and non-parametric (NPBD) obtained by real non-stationary echosignal measuring in ground surveillance Doppler radar are considered for solving moving object recognition and classification problems. Automatic target recognition (ATR) performance has been examined by using information features contained both in the TFDs and cepstral coefficients. Experimental results performed by ground surveillance radar operating in millimeter wavelength for walking human, group of walking humans, bicyclist, vehicles and vegetation clutter show that bispectrum-based approach seems to be attractive tool for ATR systems comparing to the conventional energy-based approaches. [C148]

### "Hydro-meteorological disturbaces influence on radar picture investigation"

Integration and correlation functions used in merchant ship radar nowadays increase radar detection possibility of small objects like recreation and fishery boats. These functions improve safety of maritime navigation considerably. For safety of shipping detection possibility of ship borne radars is important mainly during foggy weather, storm and heavy rain. In the article detection possibilities of FM CW and pulse radars were compared. In order to define them, there were registered, during rain and storm weather, radar video signals of two radars installed in the radar laboratory of Gdynia Maritime University located on shore line near south entrance to the port in Gdynia: pulse radar NSC 34 produced by USA Company Raytheon and CW FM radar CRM-203 produced by Telecommunication Research Institute Ltd. Gdansk Division (PIT Ltd). [C149]

### "Focused algorithms for ground penetrating radar imaging"

The paper describes the simulation results for a ground penetrating SAR radar. As a simulation model of SAR

system the pulse radar with LFM (Linear Frequency Modulation) signal has been applied. The aim of the experiment was to test ability of the SAR system to obtain fully focused image of the underground targets. Simulation results presented in the paper are the first step of realization of the project of GPR (Ground Penetrating Radar) demonstrator which is conducted by Przemysłowy Instytut Telekomunikacji S.A. in cooperation with Warsaw University of Technology. In the next step, the real data measurements are planned to be performed. During measurement campaign the GPR SAR demonstrator mounted on the rails wagon will be used to generate radar motion. [C150]

### "Refraction influence on air target elevation estimation in 3-D radars"

To estimate position of air target the three coordinates are needed: azimuth, range and elevation. The target range and azimuth coordinates errors can be estimated quite precisely. One of source of elevation estimation errors is the refraction of atmosphere (changes of altitude follow changes of refraction index). In results of refraction the false elevation coordinates are obtained. In the paper problem of target elevation estimation using different refraction profiles and usefulness of refraction profiles for medium and long range radar systems, will be also discussed [C151]

### "A novel OFDM based ground penetrating radar"

This paper proposes a novel GPR system based on the Orthogonal Frequency Division Multiplexing (OFDM) technique. The selection of the major system parameters for the OFDM based GPR are considered. An example system configuration is simulated. Target positions can be determined with high accuracy, even when in the presence of noise. Finally, the potential benefits of using OFDM for GPR are presented. [C152]

### "GPR, ERT and CPT data integration for high resolution aquifer modeling"

It is widely accepted that an integrated characterization approach is necessary to define the geometry, internal structure, material distribution and water composition of aquifers. Multiple geophysical and hydrogeological data were measured in the sub-watershed surrounding a former unlined landfill: hydrogeological data in 25 direct push full-screen wells (slug tests, water conductivity, water levels), 21 km of GPR, 5 km of 2D electrical tomography and 30 cone penetration tests (CPT) with soil moisture resistivity (SMR). The 3D data integration in gOcad facilitates data interpretation and provides the basis for a detailed numerical groundwater flow and transport models. [C153]

### "Determination of wall thickness and condition of asbestos cement pipes in sewer rising mains using Surface Penetrating Radar"

Asbestos pipes are commonly used for water and sewage pressure mains. There are very few non-destructive ways of assessing the wall thickness and condition of these Asbestos Cement (AC) pipes. Traditionally, their examination was undertaken by tapping to remove a physical specimen (a 'coupon') of the pipe. This procedure is time consuming, costly and risky. Alternatively, the mains have to be shut down to allow access by CCTV cameras. Advances in Surface Penetrating Radar (SPR) technology in recent years now means that defects in thin walled pipes can now be detected non-destructively from the outside. Selected sewage pipes of different ages, diameters and thicknesses are examined in situ using SPR. In addition, some samples of damaged pipes were examined separately. The main mechanisms for pipe deterioration are from chemical attack at the pipe obvert, and scouring at the pipe invert. The results demonstrate that SPR is an effective method for detecting areas of pipe deterioration and delamination and can detect scour depths as small as 4 mm. The SPR images clearly show a change in the shape and amplitude of the reflected signal from the inner face of the pipe walls and also an apparent increase in material thickness due to retention of water within the pipe wall material in areas affected by chemical attack. Variations are also evident in the signal reflection from the interior of the pipe wall between that at the pipe obvert and that of the side walls. These variations may be attributable to chemical attack and material changes occurring in the AC material. Variations were also observed in the shape and amplitude of reflected signal from the inner face of the pipe invert that are attributed to material loss or scouring at the invert. The SPR image also clearly recorded fluctuating levels of fluid within the pipes during the data collection. Although this makes analysis more of a challenge due to the effect on the reflected signal, this information is very important in locating areas in which pipe failures are more likely to occur through chemical attack and pipe pressure surges. Information on the size of the air pocket present within the pipe and size of the fluctuations can be determined. The signal velocities variations can be detected if the wall thickness is known. Such variations may relate to the moisture content which has been absorbed by the pipe material from the surrounding moist soil and from the pipe contents. The signal velocities determined are less accurate for very thin pipes because of the uncertainty in measuring the thickness interface in the signal. It is evident from the results of cut pipe sections that the SPR provides much better resolution of the inside surface of the pipe when

the pipes are empty. It may be possible to drain the pipes for a short duration to allow the pipes to be scanned in the empty state. This will also eliminate the problem of fluctuating water levels obscuring defects in the pipe obverts. SPR imaging is a quick and effective method which is now available for non-destructively evaluating AC pipes. [C154]

#### "A controlled experiment for water front monitoring using GPR technology"

We use a stepped frequency continuous wave (SFCW) radar and an impulse radar to monitor a water flood experiment in a sand box. The SFCW system operates in the bandwidth from 800 MHz to 2.8 GHz. The impulse radar system is bi-static and works with a central frequency of 1 GHz. The sand box is a meter-scale cylinder partially filled by sand and the water is injected gradually from the bottom of the box. We investigate the ground coupled antenna configuration for both radars. The results demonstrate that the present configuration is useful for monitoring water front movement, but that to have a field application in an oil field environment a quantitative analysis is necessary. This can be done by antenna calibration and inverse modeling. [C155]

#### "Simulation of porosity field using wavelet bayesian inversion of crosswell GPR and log data"

In this paper, we present a novel approach to simulate porosity fields constrained by borehole radar tomography images. The cornerstone of the method is the bayesian analysis of the approximation wavelet coefficients of a petro-physical analogue. The method is tested with a two-dimensional porosity field generated from a digital picture of a real sand deposit. The porosity field is translated into electrical properties and a cross-hole tomography synthetic survey is modeled using a finite-difference modeling algorithm. In parallel, an analogue deposit is created based on the geological knowledge of the area under study. The analogue porosity field is converted into electrical property fields using the same equations as previously. A synthetic GPR tomography is also computed from the latter. Wavelet decomposition of both measured and analogue tomograms and porosity analogue fields is then calculated. Based on the assumption that geophysical data carry only the large-scale information about the geological model, statistical analysis of the approximation coefficients of each variable is carried out. From the measured tomogram approximation coefficients and the cross statistics evaluated on the analogues, the approximation of the real porosity field is inferred using bayesian inference. Finally, based on the geostatistical relationships between wavelet coefficients across the different scales, all the porosity wavelet detail coefficients are simulated using a standard geostatistical simulation algorithm. The wavelet coefficients are then back transformed in the porosity space. The final simulated porosity fields contain the large wavelengths of the measured radar tomogram and the texture of the analogue porosity field. [C156]

#### "GPR of a timber structural element"

GPR of timber structural elements is not yet very common in practise but the technique has the potential for condition evaluation of timber material. In this laboratory investigation, a high frequency (2.3 GHz) radar antenna has been employed for detailed investigation of a historic timber beam from a roof structure. The GPR non-destructive diagnostic of the spruce beam was aimed at obtaining material information with a structural relevance, such as presence of knots, their position and depth, cracks, dimensional variations of geometry and extension of areas of decay. The radar scan was carried out along the beam length. The radargram obtained show very detailed information. [C157]

#### "Detection of granite landmarks in soil with GPR"

In Germany plots of land were often marked with landmarks. They are typically made from granite stones in a defined shape and have been buried closely below the surface. The suitability of GPR for the detection of landmarks has been tested. GPR laboratory experiments in a sandbox under ideal conditions as well as field trials have been carried out. The influence of the water content of soil on the GPR measurements was investigated in laboratory. In these experiments suitable characteristic parameters have been identified to distinguish granite landmarks from other reflectors. [C158]

#### "GPR characterization of rocks buried in the Martian subsoil"

This work presents theoretical and experimental analyses of GPR investigations for the detection of rocks buried in media simulating the Martian soil, in the framework of the "WISDOM" project of ExoMars mission. An experimental set-up has been built consisting in a box filled with a host material and scatterers, scannable with a GPR bistatic antenna. This set-up has also been implemented and studied through an electromagnetic CAD tool. Excellent agreement has been found between the measured and the simulated results on the scattering features, thus providing reliable information on the detectability of rocks in Martian complex subsurface scenarios. [C159]

### "GPR for large-scale estimation of groundwater recharge distribution"

The Gngangara Mound, north of Perth, Western Australia, has been investigated using Ground-Penetrating Radar (GPR). Several hundred line-kilometers of GPR of common offset data have been acquired over an area of approximately 800 km<sup>2</sup>. The acquisition of these datasets was performed at two different center frequencies (50 and 250 MHz) in order to better resolve the complexity of the hydrogeological targets of interest which are water retentive layers found above the water table. These layers impede the recharge of the surficial aquifer and may have important impact on local ecosystems but also on the management of the ground water resource. The data presented here-in demonstrate the successful imaging of the regional water table and of these water retentive layers. For the first time, these data provide insight into the spatial distribution and the continuity of these water retentive layers and provide important information to be included in the flow modeling of the ground water in this region of the world. [C160]

### "GPR reflection and dispersion analysis methods for water content: Multi-year study of GPR estimates and soil core measurements of water content"

A multi-year series of ground penetrating radar (GPR) measurements, complemented by contemporaneous soil cores, were collected at a single location in south-eastern New England, USA. The shallow subsurface is characterized by a 0.9 m thick sandy soil layer which overlies a gravelly-sand layer. Over a number of months, and different soil moisture conditions, 30 common midpoint (CMP) soundings were collected, and on each of the days, co-located soil cores were taken for analysis and comparison with the soil water content from the GPR velocities. GPR velocities were estimated using two independent methods: standard normal moveout (NMO) analysis of reflected traveltimes, and the analysis of frequency-dependent velocity dispersion of shallow GPR waveguide modes. A comparison of GPR estimated water content in the field versus gravimetrically measured water content in the lab provides a site-specific Topp-like empirical basis for predicting soil water conditions from GPR data. Although such site-specific relations may be useful, we find that for our site comparing the results of this study with the conventional Topp relation reconfirms the continuing utility of the latter. [C161]

### "Recent deformation of Quaternary sediments in the northwest Canterbury Plains, New Zealand, as inferred from GPR and seismic data"

A high-resolution seismic reflection survey in the northwest Canterbury Plains, New Zealand, has revealed a network of interconnected faults and folds underneath the seemingly undisturbed flat surface. Known rates of background seismicity in the larger area suggest ongoing deformation in the Plains, despite a lack of convincing surface expression. Ongoing deformation would be seen as disturbance of the uppermost Quaternary sediments. Unfortunately, the resolution of the seismic reflection data falls short in adequately imaging these uppermost sediments. Accordingly, we have collected > 31 kilometers of 50 MHz GPR data to provide complementary images of the uppermost Quaternary sediments. Final images show GPR-facies over the full depth range, indicative of braided river sediments. GPR images together with seismic refraction tomographic images also reveal locations where the youngest Quaternary sediments are deformed. Youngest deformation is observed only where folded Cretaceous-Tertiary and Permian-Triassic units come close to the surface. [C162]

### "Applications of GPR in mineral resource evaluations"

Since the commercialisation of ground penetrating radar (GPR) in the 1970s, radar technology has been employed for niche applications in the mining industry. Although reliant on electrically resistive environments, GPR has gained acceptance in recent years as a standard exploration method for a number of deposit types, ranging from paleochannel delineation to iron ore mapping and kimberlite imaging. Numerous case studies have been published on GPR's applications to specific mineral exploration projects. Provided herein is an overview of commercialised GPR applications for surface mineral resource evaluations, covering examples of alluvial channels, nickel and bauxitic laterites, iron ore deposits, mineral sands, coal, kimberlite and massive sulphide examples. [C163]

### "From Pseudo-3D to full-resolution GPR imaging in archaeology: A complex Roman site in Lugo, Spain"

This case study demonstrates how extra effort on data acquisition can benefit advanced interpretation of 3D GPR data over a complex Roman site situated in a semi-urban area. Two 250 MHz surveys during May 2007 and July 2008 were accomplished after Roman wall remains had been found by chance during soil remove works at Agro da Ponte (Lugo, NW Spain). First campaign covered the whole area by using a pseudo-3D strategy which was only enough for defining the areas of interest and some archaeological features. According to those results, next campaign was focused on a smaller area and based on an ultra-dense grid strategy which eventually revealed full-resolution images of walls, apses and chambers of a Roman villa. [C164]

### "Constructing hydrocarbon reservoir analogues with rapid acquisition long-range GPR"

The bounding surfaces of dunes have long been known to impart significant permeability contrasts to aeolian sequences. The resulting permeability contrasts can affect hydrocarbon flow in subsurface aeolian reservoirs, the impact of which often increases later in the life of a hydrocarbon field. In order to optimally manage petroleum reservoir development, the spatial arrangement of bounding features needs to be incorporated into subsurface models. However, adequate models cannot be obtained directly from the reservoir as no high-resolution imaging techniques exist for the inter-well area. At best, indirect inferences from an ensemble of remote data can be used to broadly constrain major features. However, many spatial parameters remain poorly constrained, particularly in 3D. GPR (Ground Penetrating Radar) has been shown to provide direct 3D imagery of near-surface deposits at a relevant scale and resolution. The resulting models may not be directly transferable to a specific subsurface scenario, but the generic spatial information can be a useful guide to reservoir engineers. Discussed herein is a case study from southern Libya employing the use of a custom long-range rapid-acquisition GPR system to develop 3D volumes over large areas. [C165]

### "Automatic classification of GPR signals"

Ground penetrating radar has been widely used in many areas. However, the processing and interpretation of acquired signals remains a challenging task since it requires experienced users to manage the whole operations. In this paper, we propose an automatic classification system to categorise GPR signals based on magnitude spectrum amplitudes and support vector machines. The system is tested on a real-world GPR data set. The experimental results show that our system can correctly distinguish ground penetrating radar signals reflected by different materials. [C166]

### "Multiscale analysis of 3D GPR data using the continuous wavelet transform"

The main goal of this paper is to extract land topographical information by analyzing the 3D GPR data by the Wavelet Transform Modulus Maxima Lines (WTMM) method. The first objective is to delimitate boundaries of each obstacle, the second is to characterize each one with a special roughness coefficient. Application on real data shows that the proposed tool can enhance the GPR data interpretation. [C167]

### "Georadar Investigation of Graves and Wall Remains in Alacahцык, Central Anatolia"

Archaeological excavations have been conducted in two distinct areas of Alacahцык, located in the northwest of Alaca in the 3orum province and one of the most important Hittite settlements. The subsurface structure of the site was investigated using Ground Penetrating Radar (GPR), which has become widespread in similar studies over the last few years. On the basis of archaeological considerations that graves of princes are thought to be situated in a defined zone (Zone A) and that the possible existence of wall remains are believed to be in another zone (Zone B), we obtained GPR data using the Ramac CU II GPR system with 100 MHz antennae in 2007. In all profiles of the study area, time slices were obtained from the data collected according to the different positions of the transmitter-receiver antennae, some of which were parallel to one another and to the profiles while others were parallel to one another and perpendicular to the profiles. This was performed after the data went through basic processing steps and were mapped to observe what types of structure extensions were involved and to what depths they occurred. The results revealed the presence of strong reflections in GPR sections, which indicated the location of wall remains and some probable princes' graves. Consequently, excavations were recommended where the presence of anomalies was observed. Archaeological finds during the following excavations corroborated the existence of remains where strong reflections were observed in the maps or radargrams. [C168]

### "Different time gain and amplitude-color arranging for ground penetrating radar data: Applied samples"

We introduced a simple time gain approximation with a functioned amplitude-color range to image all amplitudes or only selected amplitudes. First, we reduced ground wave amplitudes near to the maximum reflected / diffracted wave amplitudes of the data. Thus amplitude range of the two dimensional (2D) GPR profile section (radargram) was rescaled by maximum reflected/ diffracted wave amplitude values only for displaying the radargram. Second, we rearranged amplitude-color range with a functional approximation which was very important as well as time gain application to pick events according to the aim of the research. Third, we functioned an opaque range to obtain transparent three dimensional (3D) image of the aligned 2D radargrams. We presented 2D and 3D applications to show our approximations. [C169]

### "Mitigation of RF interference in air-launched 2 GHz GPR antennas"

Air-launched ground penetrating radar (GPR) antennas are useful for analyzing roadway, bridge, and rail-bed construction at very high speeds. The disadvantage of these antennas versus ground-coupled antennas is an increased susceptibility to radio and broadcast interference, predominantly from FM and TV broadcasting as well as cellular telephone base stations. A novel hardware/software interference removal technique has been developed that allows 2 GHz air-launched antennas to operate in the presence of most broadcast interference sources while maintaining data integrity and measurement capability of the interference-free scenario. The performance of the conventional 2 GHz air-launched antenna is compared to the new interference-rejecting system along a 182 km (113 mile) route traversing through the harshest interference-prone highways in the Greater Boston Metropolitan area. It was found that for this data collection route, the amount of unacceptable data was reduced from 18% to 7% with the new technology. It was further found that when only unpredictable interference sources are considered, namely cellular telephones, only 2% of the measurement data is impacted. Finally, a comparison of measurement results during different times of day and antenna polarizations is made, where no improvement was observed in either case. [C170]

### "Localization of buried objects"

The problem of localizing both conductive and dielectric cylinders of arbitrary known radius is dealt with in a two dimensional geometry. A reflection mode multi-frequency multi-monostatic configuration is considered. A linear inversion algorithm for objects embedded into a homogeneous medium is presented, where mutual interaction between the objects is neglected and the problem is formulated in near zone. Here, we examine, by simulated data, the application of the algorithm to subsurface prospection, involving half space geometry, lossy background medium and the presence of multiple scatterers. [C171]

### "A novel detection warning signal creation method for hand-held GPR applications"

In this paper a novel detection warning signal creation method is proposed for pulse Ground Penetrating Radar (GPR) data, especially for small non-metallic targets, in time domain. Background removal is applied to the data through a sliding window scheme and Target Energy Function (TEF) is obtained as correlation summation of consecutive A-scan signals. Then Auxiliary Detection Function (ADF) is defined and a novel automatic Detection Warning Signal (DWS) creation is applied. The proposed method has been tested specifically for a set of small sized dielectric targets which are not easily detectable. The results are promising as full detection performance and zero false alarm rate in original dataset. Moreover, it is obtained that the immunity of the proposed method against noise is very satisfactory. [C172]

### "Textile antenna for the multi-sensor (impulse GPR&EMI) subsurface detection system"

The performance of a planar elliptical dipole textile antenna for the multi-sensor (impulse GPR&EMI) subsurface detection system is investigated. This is a new application of textile antenna. The textile material of antenna does not create an EMI clutter comparing solid Cu material. The antenna characteristics of the proposed antenna in the multi-sensor head are measured and compared with the simulated ones. A buried target into soil, is successfully detected by the multi-sensor system with the usage of the textile antenna in the GPR sensor. [C173]

### "GPR research at the tomb of Zeynel Bey in Hasankeyf ancient city- Southeastern Turkey"

Hasankeyf is a town located along the Tigris River in the Batman Province in Southeastern Turkey. The tomb of Zeynel Bey ruled shortly over Hasankeyf- a rare example of its kind in Anatolia. We measured GPR data inside and around of the tomb of the Zeynel Bey to research buried archaeological remains. We imaged the results with interactive transparent 3D visualization and located archaeological remains with depth range. We determined the base structure and diffraction anomaly groups coming from a cemetery. Excavation in the tomb and around of it encouraged the new 3D image results and found a cemetery in the tomb. [C174]

### "Autonomous FMCW radar survey of Antarctic shear zone"

Radar survey of the Antarctic shear zone was conducted using an ultra-wideband (2-10 GHz) frequency modulated continuous wave (FMCW) radar. The radar was mounted on a sled and pulled by a robot that was specifically designed to operate in a harsh polar environment. Our FMCW radar had good penetration through Antarctic snow and we observed snow stratigraphy to a depth of 20 m. The radar images also revealed multiple crevasses in the shear zone. Our results demonstrate that autonomous survey using high frequency radar is feasible and safe approach for detecting hidden crevasses. [C175]

### "Diagnostic by imaging: 3D GPR investigation of brick masonry and post-tensioned concrete"

In this laboratory study, the comparison of 4 different antenna frequencies (from 1.0 to 2.6 GHz) and radar systems on the same masonry and post-tensioned concrete specimens has served to investigate the precision achievable in imaging cross sections of masonry walls with different brick layouts and of concrete slabs with metal post-tensioning ducts at varying depths. Through high-density 3D data collection and multi-phase post-processing, the work aimed at 2D and 3D data imaging for eased and enhanced diagnosis of structural elements. [C176]

### "Evaluating the practical performance of absorbing boundary conditions (ABC) in higher-order, finite-difference, time-domain (FDTD) GPR modelling"

Finite-difference, time-domain (FDTD) methods are now commonly used for the integrated forward modelling of practical GPR in a wide range of processing, inversion and analysis applications. The wide availability of high-performance computing resources has led to the development of sophisticated, higher-order, 3D models that are able to tackle real-world problems in practical time scales. However, these models are often truncated by computationally inefficient and/or poorly optimised outer absorbing boundary conditions (ABC). In this paper, we evaluate the practical performance of two of the most common techniques; (a) Perfectly Matched Layers (PML) and (b) wave matching boundaries (e.g., Higdon). We show that under certain 3D conditions, the computationally faster, wave matching boundaries can perform as well as the PML techniques and reduce the likelihood of unexpected internal reflections/errors occurring. [C177]

### "TWI in-situ experimental results"

A through-wall imaging problem is tackled by means the linear inverse scattering approach described in. In particular, here, such an approach is validated against experimental data. To this end, a CW-SF ultra-wideband radar system is used to take the measurements and an in situ scattering scenario is considered. [C178]

### "GPR investigation in different archaeological sites in Tuscany. Analysis and comparison of the obtained results"

In the last five years the collaboration between the Laboratory of Landscape Archaeology and Remote Sensing at the University of Siena and the Ground Remote Sensing Lab of the Institute of Technologies Applied to the Cultural Heritage (ITABC-CNR, Rome) produced several site prospection case histories. We focused our attention on a quite limited chronological range between late roman and the early medieval period. Chronology has a direct relationship with material culture and therefore with physical and chemical property of the archaeological stratification and of the context. We should emphasise that most of the site that has been surveyed has been also excavated or at least explored through archaeological sample excavation. The best results has been sistematically achieved through the integration with other methods as magnetic and resistivity systems. The paper will resume our experience, analyzing and comparing the different results, obtained in the sites characterised by late roman and early middle age features. [C179]

### "Mariana (Corsica). Integrating GPR in Roman urban survey"

In 2000 a new phase of archaeological field activities started on the abandoned city site of Mariana, located south of Bastia (NE-Corsica). Within the on-going international research project "Projet Collectif de Recherche: Mariana et la vall e du Golo" a joint team of the Universities of Cassino (I) and Gent (B) studies the topography of the ancient city in a diachronic framework. In this paper we will investigate the crucial role of GPR prospections integrated in a whole set of more traditional methods of non-invasive city survey and stratigraphic excavations. [C180]

### "Integrated geophysical methods for the knowledge of the urban layout of Hierapolis in Phrygia (Turkey)"

The paper concerns the various methods of geophysical prospecting (Ground Penetrating Radar, Magnetometry, Electrical Tomography) applied in Hierapolis of Phrygia, by the Italian Archaeological Mission, during the campaigns of 2007 and 2008. The integration between the different methods (in turn integrated with other exploration methods to the surface, as archaeological surveys and remote sensing from aerial platform and satellite), applied in areas of the city with different geological characteristics, allowed to retrieve important data on the urban layout in areas characterized by thick colluvial and alluvial deposits and in areas where there are extensive limestone formations that have formed recently and have incorporated the ancient remains. [C181]

### "A stepped frequency radar for use on Horizontal Directional Drills"

Horizontal Directional Drills (HDDs) are used to install utilities underground. However, the use of drills in urban environments carries the risk of striking and damaging pre-existing utilities. This paper describes the development and testing of an SFCW radar designed to be installed on the HDD head to determine the presence of obstacles in or nearby the boring path. Transmit and receive antennas are mounted on the drill shaft, behind the drill head spade, and transmit both ahead and to the side of the drill head. Data can be collected at up to 50 traces per second, and all processing and display is done in real time. Special algorithms were developed to enhance the data, and aid in obstacle detection. [C182]

### "Design and full-wave analysis of cavity-backed bow-tie antennas for low-frequency GPR applications"

In this paper, a comprehensive analysis of a novel GPR antenna featuring almost 30: 1 relative bandwidth (55 MHz->1.5GHz), with a maximum antenna size of 40 cm is performed. The antenna transient behavior, near-field radiation properties, and the impact of the ground are analyzed in details. It has been shown that the antenna exhibits reduced and short ringing, low spurious energy emission in the air region, as well as stable circuital and radiation properties over different types of soil. [C183]

### "GPR measurements and FDTD simulations for landmine detection"

Among the technologies used to improve landmine detection, Ground Penetrating Radar (GPR) techniques are being developed and tested jointly by "Sapienza" and "Roma Tre" Universities. Using three-dimensional Finite Difference Time Domain (FDTD) simulations, the electromagnetic field scattered by five different buried objects has been calculated and the solutions have been compared to the measurements obtained by a GPR system on a (1.3 Ч 3.5 Ч 0.5) m3sandbox, located in the Humanitarian Demining Laboratory at Cisterna di Latina, to assess the reliability of the simulations. A combination of pre-calculated FDTD solutions and GPR scans, may make the detection process more accurate. [C184]

### "A GPR imaging algorithm with artifacts suppression"

Based upon an image reconstruction algorithm which has been proposed in medical imaging field, an algorithm termed as Multiply Back Projection (MBP) is firstly used in GPR imaging. This algorithm is similar to the conventional Back Projection (BP) imaging algorithm except for the additional pairing multiplication procedure. In the MBP algorithm, time delays from each synthetic aperture position to a given point in the imaging area are calculated firstly. Then the backscattered signals corresponding to a certain imaging point are searched out through the time delay in each synthetic aperture position. Afterwards, the backscattered signals are multiplied in pair and the products are summed subsequently to form a result point. Experimental results present the superiority of the MBP algorithm over its original counterpart in artifacts suppression, as well as a slightly improvement in image resolution. In the end, theoretic analysis is performed to justify the validity of the MBP algorithm. [C185]

### "EM characterization of resistively loaded printed dipole antennas for GPR applications"

A resistively-loaded printed dipole antenna is modeled and the relevant circuital and radiation properties analyzed thoroughly. The optimal resistive loading is determined in order to achieve a wideband input impedance matching. Then, the electromagnetic characteristics of the individual antenna in terms of radiation efficiency and surface footprint are investigated thoroughly for different types of soil. Emphasis is put on the full-wave analysis of the antenna performance in pair configuration for different Tx-Rx separations and elevations over the ground, as well as on the analysis of the electromagnetic scattering from dielectric and metallic pipes buried at different depths and with different diameters. [C186]

### "Influence of acquisition related uncertainties on ground penetrating radar inversion results"

Ground penetrating radar non-destructive testing requirements become more demanding. In that respect, it is essential to understand how antenna transfer functions and real system dynamic range affect the amount of retrievable information from measurements. This paper examines the confidence level of linear system transfer functions, and practical aspects of noise floor influence on stepped frequency ground penetrating radar. Small inaccuracies in antenna equations directly reflect in Green's function errors. Degradation of the numerical signal resolution was imposed by limiting the data resolution to two-bytes. The capability of the field system to detect thin layering in building materials using numerical modeling studies has been investigated. This would lead to the assumption that the radar model is correct and the only errors are due to inaccuracies in the data and the finite precision determination of the system's linear transfer functions. Systematic errors characterization is partially

possible, limiting uncertainty in the data. A link seems to exist between the data precision and the possibility of information extrapolation for different settings. [C187]

### "Experimental evaluation of the antenna sub-system of the ORFEUS surface GPR"

Within ORFEUS (Optimized Radar for Finding Every Utility in the Street) project a novel antenna system for a SFCW GPR has been developed for detection and location of buried utilities. The antenna system consists of two cavity-backed resistively loaded bow ties and has been designed to cover the frequency range from 100 MHz to 1 GHz with a reasonably high radiation efficiency. The characteristics of the whole system in terms of the impedance matching to the feeding line, radiation level from the individual antenna, parasitic coupling between the transmit and receive antennas and scattering from buried objects have been experimentally investigated in realistic scenarios for different soils. [C188]

### "GPR applications in dense cities: Detection of paleochannels and infilled torrents in Barcelona GPR applications in dense cities"

Barcelona is placed in a basin delimited by the Mediterranean Sea (E), the Collserola Mountains (W) and the rivers Besos (N) and Llobregat (S). The city was built on Quaternary alluvial deposits and on the Tertiary and Palaeozoic materials of the surrounding mountains. The Quaternary materials are preponderant in the plane of the city, presenting a high lateral variability due to the paleochannels and infilled torrents existing between the Sea and the Mountains. The city was built on these heterogeneous materials. In order to prepare a detailed vulnerability map of the Barcelona city, a GPR survey provides information about the position of these geological structures. Results were compared to H/V spectral ratio measurements and soundings. [C189]

### "Monitoring of seasonal influence on spatial distribution of moisture content at a natural Kanto loam site using ground wave of GPR"

Ground penetrating radar (GPR) ground wave was used at a natural Kanto loam (i.e. Andisol) site to examine the influence of seasonal variations on surface soil-moisture content. Kanto loam is a type of volcanic ash soil found widely distributed in Japan. In order to investigate the influence of surface soil conditions on GPR based estimates, the study site was divided in two zones: with and without vegetation. Measurements were conducted at regular intervals during a three month monitoring period. Results indicated that GW was sensitive to the surface soil conditions as well as to seasonal variations. A significant increase in moisture content was observed in the vegetated zone over that of the bare zone during a period of a day after precipitation (i.e. September 1st). It shows that in the vegetated zone moisture in plants themselves, including roots, stems, and leaves, affects GPR measurements, leading to higher moisture content than in the bare zone. However, the influence of vegetation was not found to have a large impact during periods of good weather. The effectiveness of surface soil conditions with seasonal variations on GPR-based moisture content provided a clear insight to agricultural management prospectives. This research confirmed that Kanto loam can be a good GPR site for noninvasive mapping of moisture content regardless of the presence of organic matter, silt, and clay content. [C190]

### "Velocity analysis in the GPR method for loose-zones detection in the river embankments"

Determination of continuous distribution of the loose zones in the river embankment between points of geotechnical investigations is a very important matter for the embankment stability during the flooding. Presently, only non-invasive, geophysical methods can deliver such information. On the basis of numerous tests carried out by the Department of Geophysics at AGH University of Science and Technology in Cracow, the following conclusion may be drawn: zero-offset, reflection GPR profiling very seldom gives positive results at the detection of the loose-zones in the levee. Therefore, another concept of the loose-zones detection, using the GPR method, is presented in the paper. This technique is based on the modified CMP profiling, which allows to prepare a velocity map. Such a map may be used for evaluating of degree of the embankment disintegration. [C191]

### "Petroleum industry techniques yield new insights into 3D GPR data"

We have adapted petroleum industry technologies to 3D GPR datasets from a variety of geological and archaeological settings. Seismic attribute analysis designed for 3D seismic volumes of oil fields has been used to map a 19th century cemetery and to prepare a Roman archaeological site for detailed study by mapping the prior disturbances of the site. Specific seismic attributes that we have successfully applied include connectedness ("geoanomalies"), semblance (or dissimilarity), volume rendering (transparency visualization), and waveform classification. An especially powerful strategy is to use two or more attributes simultaneously via volume rendering that allows multiple visualizations. [C192]

### "Ground penetrating radar (GPR) studies in the Agios Voukolos church, Izmir, Turkey"

The Agios Voukolos church is one of the unique Orthodox constructions in Izmir. Ground penetrating radar (GPR) study was carried out to define the crypts, ossuaries and other subsurface structures under the church. Regular GPR investigations were performed by using a Ramac CU II instrument with 500 MHz center frequency shielded antennae. In addition, two small parts of the Katholikon were measured with 1000 MHz shielded antennas. Data acquired in continuous mode was processed by standard GPR processing steps. The results were given important information about deformation variations (floor cracking and the distortion of architectural elements) and subsurface relics (crypts, ossuaries etc.) inside the church. [C193]

### "Synthetic GPR modelling studies on shallow geological properties and its comparison with the real data"

The synthetic GPR modelling studies are quite important to evaluate the interpretation of shallow geological properties such as faulting, bedding, weathering etc. This study aims to simulate some shallow geological structures by GPR technique. To obtain a successful interpretation, we performed the synthetic modelling studies for paleoseismology, sedimentary and geotechnical problems using different values of electrical properties that affect the radar signals. During the modelling studies, we produced a lot of models for various subsurface conditions. Also, real GPR data was collected on some geological problems. As a result, the combined usage of the real GPR data and synthetic modelling could be contributed the joint interpretation on shallow geological structures. [C194]

### "Analysis of dispersion of pulse signals in underground tunnels using finite-difference time domain and short-time Fourier transform"

The dispersion of pulse signals of a cross borehole radar simulator for tunnel detection was analyzed using FDTD and STFT. Two simulation cases with extremely different dispersion properties were simulated by the FDTD method. In the two cases, the trace path between the transmitter and receiver penetrated an air-filled tunnel perpendicularly and obliquely, respectively. The recorded fields in the cross sectional plane during FDTD computation were decomposed into several frequency components by STFT. By analyzing the propagation behaviors of frequency components, the different dispersion characteristics according to the tunnel's oblique angle variation are visually rendered in detail. [C195]

### "Water table detection by GPR in Sardon, Salamanca, Spain"

GPR was applied in the semi-arid Sardon catchment (Salamanca, Spain) in order to analyze the distribution of the water table depth with a high spatial resolution to serve as input in the parameterization of a hydrological model. We used a pulse radar with a single 200 MHz bowtie antenna combined with a differential GPS and a survey wheel for accurate positioning. Measurements were performed following a series of transects crossing perpendicularly the bed of the Sardon streams, which were dry during that period (September 2009). We measured the depth of the water table in several observation wells to interpret and validate the GPR data. A time domain reflectometry probe was used to estimate the shallow soil dielectric permittivity and corresponding wave propagation velocity along the transects. In general, the water table was visible in the GPR data, with depths ranging from about 2 to 3 meters. [C196]

### "Experimenting with different polarization arrays in a test site"

Four GPR antenna configurations were used to illuminate the subsurface using different polarizations. We conducted field experiments in a test site where different objects were buried at a known depth. Measurements with two co-pole antenna configurations were conducted along crosswise sections. In addition, measurements in a 3D grid were carried out at the top of one of the buried objects using four different antenna configurations. We show preliminary results showing some advantages and limitations of each antenna configuration. [C197]

### "Scattering by a circular cylinder buried beneath a rough surface"

A two-dimensional scattering problem of a circular cylinder buried beneath a rough surface is analyzed through the Cylindrical Wave Approach. The fields scattered by the cylinders are sums of cylindrical waves and the concept of plane-wave spectrum is employed, to take into account reflection and transmission through the interface. The analytical expressions of the fields are derived from the small perturbation method, with a first order approximation for the reflection and transmission coefficients. Results can be obtained both in near-and far-field region, for TE and TM polarization. [C198]

### "A review of geometric issues in GPR prospecting of cylindrical structures in Cultural Heritage applications"

Cultural Heritage diagnostics often involves the application of geophysical methods like ground penetrating radar along non-planar surfaces. Sometimes, as in the investigation of columns with a small radius, the basic assumption underlying the application of conventional processing algorithms (half-space geometry) is strongly violated. Although frequently overlooked, this implies that appropriate algorithms should be developed to take into account the additional data complexity arising from the unusual acquisition setting and exceptional care should be used in interpreting the radargrams. Through numerical and real data examples an in-depth analysis of reflection/diffraction features from buried and above-surface objects is performed in this paper. [C199]

### "GPR resolution in cultural heritage applications"

The non-destructive study of historical buildings, archaeological sites and other Cultural Heritage structures requires high resolution methodologies and a good knowledge of the potential of the different methods. Laboratory measurements provide valuable information about the ability to detect different targets and to determine structural problems, but these data must be compared to the results obtained in real and complex structures. In this work, we present experimental GPR measurements made in order to determine the spatial resolution under laboratory conditions. These results were compared to the data obtained in different GPR surveys applied to Cultural Heritage. The information obtained in drillings, in visual inspections and in old documentation about the historical buildings and archaeological sites is used to determine the resolution in each case. [C200]

### "2D ground-penetrating radar AVO response to a 3D dielectric permittivity anomaly"

To evaluate the amplitude vs offset response of GPR to small distributions of hydrocarbon contamination, I acquired multi-offset 450 MHz GPR data in TE and TM modes over a buried rectangular tank filled with gasoline saturated sand. All dimensions of the tank were less than one wavelength at the characteristic antenna frequency. The permittivity ratio at the moist sand/gasoline sand boundary, estimated by fitting the Fresnel equations to the observed amplitudes and by Brewster's Angle analysis, differed from that obtained through migration velocity analysis by no more than 12%. 2D FDTD modeling reproduced amplitude characteristics for 3 of 4 target/polarization combinations and explained some deviations from the Fresnel curves. Additional deviations may be caused by out-of-plane polarization effects or heterogeneity not included in the 2D model. [C201]

### "Impact of spatial sampling and antenna polarization on 3D GPR fracture detection"

Three-dimensional Ground Penetrating Radar (3D GPR) surveys are needed to reconstruct subsurface fracture networks in terms of strike, dip and interconnectivity. This particular GPR study conducted in the Madonna della Mazza quarry (Italy) compares the impact of a dense acquisition grid versus antenna polarization on the characterization of subvertical fractures. 3D GPR data were acquired using a 250 MHz antenna over a 20 Ч 20 m area with a grid bin size of 5 Ч 5 cm. According to the quarter-wavelength criterion, profile spacing of 5 cm allows to properly sample also the high-frequency content of the signal spectrum. The results demonstrate that, rather than repeated surveys with different antenna orientation but larger profile spacing, a single survey with a regular and highly sampled grid is a preferred approach for high-resolution characterization of three-dimensional fracture networks. [C202]

### "Masonry arch bridges evaluation by means of GPR"

Some masonry arch bridges in Galicia (NW Spain) were surveyed with GPR using 250 and 500 MHz antennas. The main goal of this work was to perform an analysis of historical bridges, obtaining information about filling material homogeneity, detecting inclusions of different materials, defining structural faults -such as internal voids or cracks- and detecting ancient features -as hidden arches or previous profiles of the bridge-. Geometric 3D models of the surveyed bridges obtained with Laser Scanning methods, were used as inputs to create synthetic radargrams through FDTD simulations in order to help GPR data interpretation. [C203]

### "Determination of space behind pre-cast concrete elements in tunnels using GPR"

Many tunnels in Nordic countries are lined with prefabricated concrete elements to protect against frost and leakages. This protective lining is fixed to the rock face in a few points, but when installed renders the rock surface inaccessible, owing to the lack of predesigned inspection hatches. Safety inspections have hitherto consisted of random drilling into the concrete lining. However, such random inspection is both unreliable and expensive. Therefore Ground Penetrating Radar has been introduced in the vault walls to map the contours of

the gap more systematically. Such scanning technology provides satisfactory data, given optimal location of apertures. The scanning technique is therefore extended to the vault roof to pinpoint potential rockfalls. [C204]

#### "Singlehole borehole radar measurement using dipole array antenna fed by coaxial cable"

In this paper, we demonstrate 3-D estimation of reflectors with singlehole borehole radar. We use the dipole array antennas fed by coaxial cables as a directional antenna. Finding the phase shift among the array elements and different depths, we estimate the 3-D positions of the reflector. In the field test site, there is an interface, and we have the preliminary information on the reflector with boring core sampling. The 3-D estimation results with the directional borehole radar were reasonable. [C205]

#### "ORFEUS GPR: a very large bandwidth and high dynamic range CWSF radar"

A very large bandwidth and high dynamic range Continuous Wave Step Frequency (CWSF) Ground Penetrating Radar (GPR) has been developed with the aim to increase the detection capabilities with respect to current systems. In order to achieve this goal, an innovative electronic equipment have been designed and developed. This radar operates with ultra wide bandwidth, ultra fast scan and very high dynamic range capabilities. [C206]

#### "Influence of feed line on DOA estimation with dipole array antenna for directional borehole radar"

In this paper, we investigate the influence of the feed lines on the radar signals in the dipole array antenna fed by coaxial cables for directional borehole radar. In this investigation, we utilize a model of dipole antenna elements in circle near a conducting cylinder in a borehole. The criterion proposed in this paper is calculated, and quantifies the influence of the conducting cylinder. This criterion is tested with the data obtained in experiments in air, and we verified that the criterion represents the influence of the cylinder on the direction estimation. We made the directional borehole radar system with the dipole array antenna, which was fed by semi-rigid cables. With this system, we conducted field experiments in granite. We confirmed that we can estimate direction of arrival after processing the array signals with the band-pass filter, which was designed optimally with the criterion. [C207]

#### "Influence of HE11 mode on direct wave in singlehole borehole radar"

In this paper, we investigate influence of radar sonde eccentricity on a direct wave between a transmitting and a receiving antenna in singlehole borehole radar measurement. According to our calculation, at high frequencies above 200 MHz, guided waves play a vital role in the direct wave. We found that the most important guided wave is HE11mode, which is excited only when the antenna is eccentered in a borehole. We show that this causes artificial noise in the moving average subtraction, which is a common signal processing method used to remove the direct wave. In field experiments in granite, we conducted a special experiment, in which location and rotation of the radar sonde was controlled mechanically. We found the excitation of the HE11mode in high frequencies, when the sonde is eccentered by 1.7 cm in a borehole. These are also predicted in the theoretical analysis. [C208]

#### "Can be GPR technique useful for strength characterization of concrete?"

The possibility of material characterization through the GPR measurements, taking into account the integration with the ultrasonic technique, has been studied and possible relationships between the permittivity of materials and their bulk density are discussed. We present here two different approaches. The first one describes an attempt to correlate the mechanical strength of concrete (as well the ultrasonic velocity) with the permittivity of the material. A series of samples of concrete, characterized by different material properties, were used for georadar and ultrasonic measures, seeking correlations among experimental data. The second approach illustrates the comparison between GPR and ultrasonic techniques to detect anomalies within the concrete. A 3D tomography was performed with ultrasonic and GPR measures on a laboratory model and the data obtained are here compared. [C209]

#### "Imaging for foundation defects using GPR"

During construction of an RCC structure over the reclaimed ground following collapse of old structure, severe difficulties to piling were encountered due to obstruction by debris of previously collapsed RCC structure buried in the foundation regime. Hence GPR profiling along series of lines were carried along several lines at the twin constructions sites. GPR survey revealed presence of RCC debris scattered at a depth of 7-8m along the line of pile foundations. By identifying these scatters, the most likely trouble free locations for piling were demarcated. This facilitated quick solution to foundation obstructions and the erection of new structure was completed without further complications. [C210]

### "Mapping oil leak flow path using Step Frequency Radar: A case study"

Leakage of oil from pipelines in an oil refinery often goes unnoticed until its contamination effect is seen in the polluted ground water. In one such case study in an Indian oil refinery, the oil leak from refinery was traced only when neighbouring villagers complained of contaminated ground water. Since the source of leak was not known nor testing of leaked oil could reveal the source, this oil leak could not be arrested. In order to trace the source of oil leak, the GPR survey was done from the exit point outside the refinery and by following the flow path the survey was progressed inside the refinery campus on different benches. Finally after tracing around 700m long flow path, the particular plant was located from where leakage had originated and it was plugged. This paper describes the intricacies of GPR survey involved in this comprehensive exercise. [C211]

### "Multiple suppression in GPR image for testing back-filled grouting within shield tunnel"

In this study, Ground penetrating radar is used to detect the quality of back-filled grouting in a shield tunnel. A simulated GPR record shows that the steel bars in lining segments usually generate strong scattering and multiples, thereby obscuring the reflections from objects and making it difficult to locate the objects. Various filtering methods for multiple suppression (i.e., predictive deconvolution, f-k multiple attenuation, and Karhunen-Loeve transformation) were applied to the GPR record of a typical grouting defect model. The 'wave field prediction and removal method' is proposed, which involves predicting propagation of the GPR wave field in the lining segment. By subtracting the predicted wave field from the raw GPR record, reflections from objects are precisely abstracted. Application of the method to a synthetic GPR record revealed that the proposed method achieves better results than those obtained using existing methods. [C212]

### "Influence of pipe filling, geometry and antenna polarisation on GPR measurements"

The number of buried cables and pipes in urban areas has increased tremendously over the last decades. As the precise documentation of their layout is often missing, damage occurs frequently during construction work. Consequently there is urgent need for non-destructive methods providing reliable and fast prediction of their location. The Applied Geophysics Section of Frankfurt University takes part in the DETECTINO Project (Hildesheim, Germany) which aims at the development of an all-inclusive utility locating tool. The appraisal of GPR reflection patterns requires profound knowledge of the underlying physical processes. This is best achieved by deploying the locating tool on well defined objects, such as the Frankfurt utility detection test site providing a large variety of pipes and cables in different geotechnical settings. The exact knowledge of the geotechnical data allows the comparison of theoretical and observed data by adequate modelling. In this contribution we present modelled and measured data for pipes with varying depth, diameter and filling, for parallel and perpendicular source polarisation. [C213]

### "A 900MHz shielded bow-tie antenna system for ground penetrating radar"

A back-cavity shielded bow-tie antenna system working at 900MHz center frequency for ground-coupled GPR application is investigated numerically and experimentally in this paper. Bow-tie geometrical structure is modified for a compact design and back-cavity assembly. A layer of absorber is employed to overcome the back reflection by omni-directional radiation pattern of a bow-tie antenna in H-plane, thus increasing the SNR and improve the isolation between T and R antennas as well. The designed antenna system is applied to a prototype GPR system. Tested data shows that the back-cavity shielded antenna works satisfactorily in the 900MHz GPR system. [C214]

### "Processing stepped frequency continuous wave GPR systems to obtain maximum value from archaeological data sets"

Stepped frequency continuous wave ground penetrating radar (GPR) systems allow highly detailed data sets to be collected across a wide bandwidth using multi-element array antenna, such as the 3d-Radar GeoScope system. Although the final presentation of results is similar to time domain systems, the correct processing of the initial frequency domain data acquired in the field is essential to obtain the maximum information from the site. Consideration of the variation of bandwidth with depth, reduction of noise and background subtraction to minimise loss of data quality is required. This paper explores these themes with relation to data from archaeological sites and also considers the data processing challenges presented by high density (e.g. 0.075m Ч 0.075m) multi-hectare surveys. [C215]

### "2D and 3D GPR imaging and characterization of a carbonate hydrocarbon reservoir analogue"

We tested and adapted seismic attributes techniques on a 2-D and 3-D multi frequency GPR dataset to image

the network of stratigraphic joints and fractures, the lithological variations and to characterize the rock mass based on the response to the radar wavefield measured in an abandoned limestone quarry. We applied semi-automatic horizon mapping techniques using manually picked seeds (control points) on selected attributes and automatic extrapolation both on inline and crossline, starting from seed positions. The results were integrated and validated with direct outcrop measures and allowed to image an hydrocarbon reservoir analogue in 3-D up to a depth of over 10m below the topographic surface. [C216]

#### "Disposable stepped-frequency GPR and soil measurement devices"

Some geophysical and geotechnical scientists would wish to non-invasively measure the electromagnetic properties of soils using inexpensive, even disposable, technology. They may even wish to develop inexpensive and compact low-power GPR equipment for such uses as teaching and mitigation of construction risks during excavation. To this end, a heuristic comparison is made between a commercial Vector Network Analyser (VNA) and two very low cost VNAs sourced from the amateur radio community. The results are used to illustrate the potential for technology transfer from amateur communications to the GPR community, in order that a wider range of technologies be available for inexpensive implementation in GPR and soil spectroscopy studies. It will be shown that even very low-cost gain and phase detection semiconductor devices can be used to develop simple GPR and soil measurement systems capable of being used in the field to compliment GPR survey interpretation, as well as for standalone soil monitoring. [C217]

#### "Exploration of geological structures with GPR from helicopter and on the ground in the Letzlinger Heide (Germany)"

Geological structures and the water table were detected by GPR measurements in the sandy area of Letzlinger Heide (Germany). The glacial sediments consist of clayish lenses in sand and the water table is at a depth of more than 40 m. The strong lateral heterogeneity is known from boreholes. Different frequencies from 25 MHz to 200 MHz on the ground were used to detect these structures. The same area was used to test two helicopter-borne GPR systems operating at 30 and 100 MHz center frequency. The results of these measurements are discussed and the capabilities of the methods are shown. [C218]

#### "Sparsity enhanced fast subsurface imaging with GPR"

Sparsity of a signal starts to become very important in many applications. In subsurface imaging, generally potential targets covers a small part of the total subsurface volume to be imaged, thus the targets are spatially sparse. Under this assumption it is shown that the subsurface imaging problem can be formulated as a dictionary selection problem which can be solved quickly using basis pursuit type algorithms compared to previously published convex optimization based methods. Spatial sparsity also indicates that the number of measurements (spatial or time/frequency) that GPR collects can be reduced, decreasing the data acquisition time. Orthogonal matching pursuit algorithm is used for reconstructing sparse subsurface images. Results show that the proposed method reduces time both in data acquisition and processing compared to previous methods with similar performance. [C219]

#### "GPR-PRO: A MATLAB module for GPR data processing"

GPR-Pro, is a flexible and user friendly module developed in MATLAB for processing mainly GPR data. This module can handle the most common GPR data formats. It provides a large number of signal processing algorithms including Principal Component Analysis, FK filtering, data manipulation (matrix algebra), attributes analysis as well as toolboxes for data classification and interpretation. The user can apply different flows on the data keeping always the control of the intermediate and final results. One can easily compare sections and choose the most appropriate flow. [C220]

#### "GPR data time varying deconvolution by kurtosis maximization"

Stochastic and deterministic deconvolution methods encounter difficulties in increasing the temporal resolution of GPR data. Statistical approaches, such as predictive or spiking deconvolution are not effective when the wavelet is non-minimum phase, which is the case for GPR data. Wavelet deconvolution is not successful due to the non-stationarity of the GPR trace. Here, prior deconvolution, we apply a spectral balancing method in t-f domain which efficiently reduces the non-stationarity. The proposed methodology involves correction for phase residuals using the maximum kurtosis method. The effectiveness of this methodology is demonstrated on synthetic and real GPR data. [C221]

#### "Quantitative interpretation of RASCAN holographic radar response from inclined plane reflectors"

### **by a theoretical model"**

Holographic radar of RASCAN type provides an output signal that is amplitude-modulated by the phase variation between transmitted and received signals. In this work RASCAN radar response is compared with a model by several experiments performed in air with a 4GHz probe scanning a planar metallic reflector inclined at different angles. The radar response shows a series of dark and light stripes with spacing dependent on signal frequency and velocity, and reflector inclination angle. The model is used to interpret the amplitude variations as a function of probe position. [C222]

### **"Adaptive linear prediction based buried object detection with varying detector height"**

In the GPR underground inspection problem, received GPR signal is notably dependent on the height of the detector head. A great deal of the former research in this area assumes constant detector height, as absence of this constancy will result in undesired change in the returning signal, which will reduce the success of the detection and identification stages. In this study, we propose a buried object detection method which removes the deforming effect of the variable sensor height. In our approach, adaptive one-sided linear prediction is utilized in a specific manner. The proposed algorithm is causal, which makes it convenient for real time buried object detection applications. [C223]

### **"Modified bowtie antenna for GPR applications"**

This paper presents a novel antenna for Ground Penetrating Radar (GPR) applications. It consists of two crossed bowtie antennas loaded with an annular ring. Numerical and experimental results are reported demonstrating that the proposed antenna exhibits both a broadband impedance bandwidth and very good radiation properties. [C224]

### **"The contribution of GPR analysis to knowledge of the cultural heritage in Apulia (southern Italy)"**

The present article describes two examples of GPR studies addressed to gain a better knowledge of cultural heritage sites in Apulia, southern Italy. [C225]

### **"Freshwater ground penetrating radar the significance of seasonal temperature variation"**

Relatively high temperatures cause an increase in molecular motion as a result of weaker hydrogen bonding and a reduction in the tetrahedral geometry which in turn leads to depolarisation. Therefore a reduction in temperature aids the radar efficiency in several ways, increases the dielectric constant, reduces the velocity of the EM wave and reduces the effect of molecular vibration as a result of stronger bonds causing a reduction in depolarisation i.e. more efficient polarisation. [C226]

### **"Background removal from GPR data using Eigenvalues"**

A GPR radargram of an underground scan has reflections not only from the target but many unwanted objects known as clutters. Additionally, the signal is corrupted by the direct wave and coupling effect of the antennas and background noise. In order to successfully extract the target signature, these extra noise effects need to be eliminated. Though the clutters cannot be totally removed from the data, background removal techniques suppress their effect to quite an extent. Usually mean subtraction is used as a background removal technique but the results are just satisfactory and further improvements can be made. In this paper an Eigenvalue based background removal technique in collaboration with mean subtraction is presented. This proposed method decreases the effect of clutters and the output is much more refined. Even though this method takes slightly more time than the traditional background removal methods, the output eliminates major portion of the clutter therefore the segmentation and classification stages in an automated GPR data processing system would be much more efficient hence reducing the overall time consumption for near real time GPR data processing. The method has been implemented on a number of different data sets and the results indicate that the proposed method gives significant improvement in background removal over the existing background removal methods. [C227]

### **"Subsurface sensing at sub-terahertz and terahertz frequencies"**

Development of millimeter and sub-millimeter wavelengths technologies is of great interest lately, especially for application in terahertz imaging due to bringing high resolution. In our paper we consider a tomography approach for obtaining 3-D imaging in frequency range from 100 GHz up to 325 GHz. We applied the method which we developed earlier for low frequency sub-surface tomography, for extremely high frequencies. The considered method may be used for 3D imaging in non-destructive testing. In the paper we present a theoretical model, experimental method and the comparison of results obtained at terahertz and sub-terahertz frequencies. [C228]

### "Salt dome exploration by directional borehole radar wireline service"

3 D borehole radar, a standard logging method? This was the title of the paper, DMT contributed to the GPR conference 2000. Now this question can be answered. Since more than seven years DMT is applying directional borehole wireline services for salt dome exploration up to depths of 2000 m. The salt dome investigations can be carried out in boreholes or caverns. [C229]

### "An ultrawideband time reversal-based RADAR for microwave-range imaging in cluttered media"

This work presents a new RADAR prototype built for the purpose of imaging targets located in a cluttered environment. The system is capable of performing Phase Conjugation experiments in the ultrawideband [2-4] GHz. In addition, applying the D.O.R.T. method to the inter-element matrix allows us to selectively focus onto targets, hence reducing the clutter contribution. We aim to experimentally explore the use of this focusing wave into an inversion algorithm, in order to improve its robustness against noise. Before testing this idea, we show here the first results validating the prototype separately in the frame of selective focusing via the DORT method and of multistatic-multifrequency inversion. [C230]

### "Novel short-time MUSIC in non-linear FMCW GPR signal analysis"

A novel windowed FFT MUSIC (W-MUSIC) algorithm is presented in the context of using ground penetrating radar (GPR) to detect closely spaced targets under noisy conditions. It is seen to give a better indication of targets than stand-alone FFT and MUSIC algorithms. Distorted signals are analysed, and with the MUSIC algorithm the reported target positions suffer high degrees of error, with the FFT the main lobe broadens making it difficult to recognise closely spaced targets. The use of the Short-Time Frequency-Transform (STFT) algorithm is examined. A novel Short-Time MUSIC approach is presented, it can be used to obtain higher time-frequency resolution than STFT method. [C231]

### "GPR Signal processing in frequency domain using Artificial Neural Network for water content prediction in unsaturated subgrade"

Basing on the recent outcomes of an investigation on the water content evaluation from processing the GPR signal in the frequency domain, an accurate model for the prediction of the frequency spectrum of the reflected GPR signal as the moisture content changes is proposed. This method uses an Artificial Neural Network approach. After the training, the ANN is reasonably able to predict the frequency spectrum for a water content in a specific soil (the error in the spectrum generation computed on a validation set, after 105 training epochs, is about or less than 10% for the same soil, if the ANN is used for all kinds of soil the error increases to about 15-20%). Of course this method can be inverted generating with the trained ANN a catalogue of different spectra for different values of the soil water moisture. Using this inverse approach it is possible to predict the water content of a specific soil just comparing the real current spectrum of the reflected GPR signal with the spectra of the catalogue. This method has been successfully tested on experimental data. [C232]

### "Integrated road pavement survey using GPR and LFWD"

Ground Penetrating Radar is frequently used for inspection the road pavement. Many applications are carried out: from pavement's layer thickness estimation, to damage detection and diagnosis, from the evaluation of geotextile effectiveness to the assessment of the bridge decks. Here we propose to integrate GPR survey with the Light Falling Weight Deflectometer. LFWD is a portable instrument that is used for measuring the Young Modulus through the analysis of the propagation of elastic waves in the pavement structure. The point of strength of this approach is that it is possible to correlate geometrical and some physical characteristics, in this case dielectric constant, of pavement layers, extracted from the GPR maps, to the mechanical properties, such as young modulus, measured using LFWD. It is well known that from a GPR stand alone survey is not possible to have directly any information about the mechanical characteristics of the structure. Otherwise, following this integrated method it is possible to reach a more comprehensive description of the road pavement. This diagnostic tool for pavement damage investigations seems absolutely very promising, cost effective and efficient in its implementation. Finally two case studies are presented: the first over about 3000 m of a real pavement the second over an unpaved airport strip. [C233]

### "Wave parameter analysis of dielectric anisotropy in maritime pine timber using GPR"

The dielectric behaviour of timber in an electrical field depends on many factors, and one of the most important is the direction of the fiber. This work analyses the wave parameter variations of the dielectric response of timber according to the direction of an electrical field applied by ground penetrating radar (GPR) with a 1.6 GHz

antenna. Two types of tests were performed on samples of maritime pine timber (*Pinus pinaster* Ait.). After the acquisition process the propagation velocities, amplitudes, and spectra variations were compared for the studied fiber directions. Interesting differences were found between these parameters when the field was propagated in a parallel direction or perpendicularly to the fiber. [C234]

### "Non-destructive technique to investigate an archaeological structure: A GPR survey in the Domus Aurea (Rome, Italy)"

The discovery and touristic fruition of the Domus Aurea (Latin for "Golden House"), and the heavy rain led to the arrival of moisture, starting the slow and inevitable process of decay and collapse. Furthermore, inside the Domus Aurea, there are a lot of parts not yet excavated, attracting a continuous and archaeological interest. In order to properly plan the restoration of this building and detect buried archaeological features, a non-destructive technique, like Ground Penetrating Radar (GPR), is extensively and profitably used for its rapid data collection and its high resolution images of contrasting subsurface structural or archaeological materials. The results show not only the presence of internal lesions and detachments of the wall and vault structure, but also the existence of buried archaeological targets; these preliminary results allow future restoration plans in order to prevent the rapid degradation of this important building. [C235]

### "Real-time object detection using dynamic principal component analysis"

In this work, we contribute to the real-time detection of buried objects, with special emphasis on explosive ones, using the ground penetrating radar (GPR). When the buried objects have explosive substance, the moment of detection becomes vital. Therefore, we start the detection process right after the very first GPR signals begin to return from the buried objects. For this purpose, we adopted the studies focusing on the online process monitoring methods using principal component analysis (PCA), and adapted them to the dynamic conditions of the ground. Different objects with varying dielectric properties are buried in the test environment and used for the evaluation of the proposed method. With the observed results, it is validated that, the proposed method is employable towards the real-time object detection. [C236]

### "Electromagnetic dispersion estimated from multi-offset, ground-penetrating radar"

Exploiting the dispersion of electromagnetic surface waves as a variational indicator for various physical and hydric states of concretes requires an optimization of its extraction techniques. The validation of these techniques in homogeneous materials is fundamental before data processing of concretes at various water and chloride contents, which is the final aim of our research projects. In the first part, this paper proposes a study of one of the extraction techniques of the direct wave dispersion validated by ground penetrating radar measurements carried out in homogeneous materials such as granite and limestone. The second part is devoted to the study of a physical approach allowing to quantify the evolution of dispersion results between waveguide propagation (multiple reflexions in a slab) and dispersive wave propagation (direct wave in a slab). Finally the last part concerns the dispersion sensitivity to the different parameters related to the experimental device, in particular for the calculation uncertainties in low frequencies. The validation of this parametric study was entirely carried out by finite difference time domain simulations. [C237]

### "The effect of coupling on the determination of time zero for radar antennae"

The a priori knowledge of time zero of radar antennae is essential for an accurate GPR data processing. Indeed, an overevaluation of this parameter can induce inaccuracies in the estimation of the physical and geometrical characteristics of auscultated media from delay picking. This paper proposes experimental methodologies to obtain a stable estimation of Time Zero position through a parametric study based on picking of time signals. The experimental processing results are used to evaluate the effect of antennae coupling and the effect of variations in dielectric parameters on the calculation accuracy of the Time Zero position for various configurations of antennae. [C238]

### "On the variants of Jonscher's model for the electromagnetic characterization of concrete"

The objective of this paper is twofold. Firstly, we carry out a comparison on measurements of the dielectric permittivity of concrete among the different variants of Jonscher's model found in the literature. Each of these variants considers only a limited number of parameters (two or three) based on certain material-dependent and/or bandwidth-related simplifying assumptions. Hence, they affect the inherent "universality" of the model by imposing a tradeoff between representability and practicability. This effect becomes more pronounced for concrete mixtures with high moisture content. Secondly, we propose a computationally efficient, two-step procedure for the estimation of the four model parameters. The proposed procedure filters the linear parameters that contribute to the deviation of the model from the frequency power law by employing the Kramers-Krojnig

relations. Therefore, only two parameters need to be estimated numerically, whereas the filtered parameters are estimated in closed form as the solution of a simple linear least-squares problem. All the variants are applied to various concrete mixtures and evaluated by their goodness of fit. The obtained results show that accounting for the whole parameters of the model via the proposed procedure provides the lowest fitting error, and thus enhances the interpretation of data. [C239]

### "Evaluation of concrete water content and other durability indicators by electromagnetic measurements"

In order to use non destructive techniques (NDT) for the survey of reinforced concrete structures, it is important to show their ability to measure the cover concrete characteristics related to durability, in particular the concrete water and chloride contents. For this purpose, tests with two electromagnetic methods (GPR and capacitive probes) and impact echo method were carried out on 81 slabs of 9 different concrete mixes. Concrete porosity was ranging between 12.5 and 18%. Measurements were carried out at five different water contents. A real structure was also tested in situ. The NDT results are compared to concrete performance indicators such as porosity and water content, as well as chloride profiles. The comparisons show the complementarity of the methods to perform a pertinent diagnosis of concrete structures. [C240]

### "Complex permittivity of common minerals and one soil at low water contents"

The complex permittivity of quartz, feldspars, calcite, and non-crystalline gypsum at 4%-7% volumetric water content shows low conductivity and low-frequency dispersion. At similar water contents, montmorillonite, gypsum crystallites, and a desert soil all show unusually strong and broad low-frequency dispersion, and strong attenuation rates above 100 MHz. The desert soil contained 80% quartz, 10% feldspars, and 10% gypsum, with the gypsum appearing as crystallites and crustations on the quartz particles. Despite insignificant salt or clay mineral content, the dispersion and attenuation rates of the soil exceed those of its constituents and are similar to that of montmorillonite, with a rate exceeding 100 dB m<sup>-1</sup> by 1 GHz. We attribute this to a Maxwell-Wagner type of relaxation, likely caused by polarization resulting from surface charge and from the charge separation caused by dielectric and conductivity contrasts between the gypsum and quartz. The conductivity contrasts were likely enhanced by ions dissolved from the gypsum and feldspars into free water within, and water adsorbed on the quartz surfaces. [C241]

### "Investigation of the frequency dependent antenna transfer functions and phase center position for modeling off-ground GPR"

We compared different methods to estimate the phase center of an ultra wideband ground penetrating radar (GPR) horn antenna operating off-ground, namely, (1) extrapolation of peak-to-peak reflection values in the time domain and assuming a fixed phase center, and (2), frequency-domain full-waveform inversion assuming a frequency dependent phase center. For that purpose, we performed radar measurements at different heights above a perfect electrical conductor (PEC). A double ridged horn antenna operating in the frequency range 0.8-5.2 GHz was used. In the limits of the antenna geometry, we observed that antenna modeling results were not significantly affected by the position of the phase center, even when considering frequency dependence. This implies that the transfer function model used to model the antenna inherently accounts for the phase center position. This analysis showed that the proposed antenna model avoids the need for the frequency dependent phase center determination and is valid for any applications where the field measured by the antenna can be considered as coming from a distance larger than the antenna aperture itself, such as for off-ground GPR or telecommunications. [C242]

### "Uncertainty in ground penetrating radar models"

Uncertainty seems an ignored aspect of everyday life of a geophysicist who uses ground penetrating radar and analyses the data beyond direct interpretation methods. Several causes of uncertainty are discussed that can be classified as belonging to uncertainties in the connection of electromagnetic parameters to desired physical parameters of different application domains, or belonging to uncertainties in the input. The input is either the system transmitter, receiver combination and the antennas, or an incident field. Given the state of the community's ability to model three-dimensional data in complicated subsurface configurations and to estimate electromagnetic parameters or other desired parameters using these models in inverse modeling of measured data, it is advocated that these uncertainties are being considered in the modeling efforts to understand how they propagate through the model into the measured data, and in turn how they affect the parameter estimation results. [C243]

### "Symmetry based 3D GPR feature enhancement and extraction"

The efficient analysis of high-resolution 3D GPR data sets is of increasing importance given today's possibilities to acquire large and dense data volumes. In order to reduce data complexity and enhance the features of interest, attribute based analysis, a well-established field in reflection seismology, has received growing interest also in the GPR community. Here, we present a novel GPR attribute called phase symmetry, which is adapted from image processing. We believe that this attribute is well-suited for analyzing 3D GPR data sets. In this study, we introduce the basic concepts of phase symmetry. Using two synthetic examples and comparing phase symmetry to the well-known Canny edge detector, we illustrate that phase symmetry also provides high quality results in the presence of significant noise and smoothly varying anomalies. Using two 3D GPR field examples collected to detect buried utilities and archaeologically relevant features, respectively, demonstrates the applicability of phase symmetry to real GPR data and illustrates that this attribute is an effective tool in order to extract symmetric features embedded within a heterogeneous background. Additionally, we show that phase symmetry can be combined with the similarity attribute to jointly emphasize event symmetry and waveform similarity. [C244]

#### **"Taper-walled linearly tapered slot antenna: A low direct-coupling antenna for subsurface imaging"**

Ground penetrating radars attract attention of many researchers as a new technique to visualize antipersonnel plastic landmines. Previously we proposed a high-density and wideband array that realizes high-resolution and quick imaging. However, the high-density array sometimes suffers from direct coupling among antenna elements, which decreases the performance of the landmine detection. In this paper, we propose a new antenna element employing open slits and tapered aperture to decrease the direct coupling. [C245]

#### **"Preliminary performance of Sub-Surface Radar for the EJSM/Laplace mission"**

The Sub-Surface Radar (SSR) instrument is a core payload for the Jupiter Ganymede Orbiter (JGO) of the EJSM, which is complementary to the Ice Penetrating Radar on board the Jupiter Europa Orbiter (JEO). These instruments work at low frequency (HF/VHF band) and are designed to penetrate the surfaces of icy moons of Jupiter. The paper will present a preliminary performance model aimed to assess the penetration capability of the instrument in different operative conditions and planet's surface characteristics. [C246]

#### **"Influence of soil inhomogeneity on GPR for landmine detection"**

Landmine detection by ground-penetrating radar (GPR) becomes challenging when soil is inhomogeneous. Soil inhomogeneity causes unwanted reflections (clutter) which disturb reflections from landmines. Thorough investigations on the influence of soil inhomogeneity and clutter on GPR are important for the use in demining to assess the performance and ensure the safety of the operation. In order to observe the influence of soil inhomogeneity an irrigation test was carried out and GPR data were collected after the irrigation while soil water content distribution was changing. Correlation length and variability of soil electric properties are determined by geostatistical analysis from GPR data. The theoretical calculation of Mie scattering using the determined parameters is in good agreement with power of clutter extracted from GPR data. Therefore it is demonstrated that scattering by soil inhomogeneity is governed by Mie scattering. [C247]

#### **"Ultra wide band radar reflectometer for density profile measurement of high temperature plasmas"**

Reflectometry is considered to be one of the key diagnostics to measure density profiles or density fluctuations of fusion oriented plasmas. The electromagnetic wave launched into the plasma is reflected at the cutoff density layer of the ordinary (O) mode or the extraordinary (X) mode. The plasma density profile can be obtained by taking the phase difference between the incident wave and the reflected wave. The high resolution analysis method called signal record analysis (SRA) is utilized to calculate the phase difference. Since wide frequency band is needed for the reflectometry to measure wide density profiles, an ultrashort pulse which includes wide frequency component is utilized as a resource. Also, it is noted that the remote control system using super science information network (super-SINET) has been introduced to the present reflectometry system. [C248]

#### **"Aiding of the GPR method by other measurement techniques for liquid contamination detection"**

In the paper the selected results of measurements carried out for detection of two types of liquid contamination are presented. The authors made detection of contamination, which very often leaks to the ground, i.e. the low-conductivity hydrocarbon contamination and the high-conductivity chemical solution. Depending of the site and the type of contamination different measurement techniques were used: the GPR, the atmogeochemical measurement, the laboratory analysis, the resistivity imaging survey and the conductometry. A brief discussion about possibilities of liquid contamination detection using electrical and electromagnetic techniques is presented in the paper. [C249]

### "Using englacial radar attenuation to better diagnose the subglacial environment: A review"

The magnitude of the radar echo returned from beds underneath ice sheets has been used to identify subglacial lakes based on the prediction that wetter and flatter beds have larger reflectivities than dryer and/or rougher beds. Further quantitative diagnosis of the subglacial environment requires accurate correction for englacial dielectric attenuation, which is primarily a function of ice temperature and secondarily a function of ice chemistry. Models show that the attenuation contribution from chemistry (soluble ions) accounts for about one quarter of the attenuation averaged over the full ice thickness at Siple Dome and Vostok in Antarctica. These predictions suggest that a useful initial attenuation estimate across an ice sheet can be obtained simply with ice-temperature modeling. Methods for estimating attenuation from radar data are also reviewed, with an emphasis on the potential pitfalls of individual methods. Some discrepancies exist between attenuation estimated with ice-core data, temperature models, and radar data. We discuss strategies to improve these attenuation estimates. [C250]

### "Admittance inversion of crosshole radar data"

In this paper, a new inversion approach has been proposed using the ratio of two mutually orthogonal components of recorded electric and magnetic fields: apparent admittance. This study aims at the development of a full waveform inversion algorithm in two-dimension (2D) without the precise knowledge of source functions and without any compensations of 3D nature of radar wave propagation. To alleviate local minima problems, we developed a data weighting method based on the data misfits. The developed inversion approach was firstly demonstrated through inverting 2D FDTD simulation data of crosshole radar survey with false source signatures. Further demonstrated was that the numerical data simulated in the 3D space could be inverted by the proposed 2D algorithm with the 2D FDTD forward modeling. All numerical experiments showed that the material property distribution with remarkably high accuracy can be calculated in spite of the lack of the accurate source information and no compensations of the characteristics of radar wave propagation in 3D space. [C251]

### "Results of an experimental radar survey on the Gornergletscher glacier system (Zwillingsgletscher), Valais, Switzerland"

A 775-m 200-MHz GPR traverse was surveyed in July 2009 over a portion of the Zwillingsgletscher branch of the Gornergletscher System, Valais, Switzerland. The survey line was approximately parallel to the glacial flow direction and situated in an area of prominent wave ogive formation. The traverse shows a well-developed pattern of scattering that is strongly folded into apparent troughs and ridges with the ridges commencing at 10-20 m depth. This pattern mimics the expected ogive structure. The origin of the scattering has not yet been confirmed, but is possibly related to an onset of warmer ice or to variations in rock or sediment content. [C252]

### "Ground-Penetrating Radar reflection data sensitivity to van Genuchten parameter variations GPR reflection data sensitivity to van Genuchten parameters"

We are interested in Ground Penetrating Radar (GPR) as a geophysical tool useful for determining the depth of the ground water table (GWT) and for monitoring shallow water infiltration in sandy soils. At hydrostatic equilibrium, the water content distribution in an homogeneous ground from the vadose zone down to the water saturated zone depends on the medium water retention function. A classical way to model retention curve data is to use a van Genuchten continuous model. Using Finite Difference Time Domain simulations, we study the sensitivity of the GPR signal reflected by a van Genuchten type transition to the hydrostatic parameters. We show a power type relationship between the reflected signal amplitude and the slope of the retention curve. Furthermore, for simulating GPR reflection data acquired above a transition from unsaturated to saturated soil, geophysicists often approximate the soil water retention curve by a piece-wise linear model. We test the validity of such an approximation depending on the frequency of the radar signal and the abruptness of the retention curve. We illustrate our results with high resolution GPR data (1600 MHz) acquired above a fluctuating water table in a sand column at the laboratory scale. [C253]

### "Results of an experimental radar survey on the Gornergletscher glacier system (Zwillingsgletscher), Valais, Switzerland"

A 775-m 200-MHz GPR traverse was surveyed in July 2009 over a portion of the Zwillingsgletscher branch of the Gornergletscher System, Valais, Switzerland. The survey line was approximately parallel to the glacial flow direction and situated in an area of prominent wave ogive formation. The traverse shows a well-developed pattern of scattering that is strongly folded into apparent troughs and ridges with the ridges commencing at 10-20 m depth. This pattern mimics the expected ogive structure. The origin of the scattering has not yet been confirmed, but is possibly related to an onset of warmer ice or to variations in rock or sediment content. [C254]

### "Dynamic monitoring of fracture extension in unconsolidated sand specimen by GPR"

We conducted a GPR monitoring to observe the extension of fractures created by hydraulic fracturing. To achieve this monitoring, a measurement system with higher time accuracy and faster data acquisition rate are needed. We designed a VNA (Vector Network Analyzer) measurement system using a Vivaldi array antenna. The VNA measurement system has the time resolution of 1 ps/sample and the data acquisition rate of 0.78 sec/acquisition, where the system dynamic range is about 100 dB. The Vivaldi array antenna has a wide frequency bandwidth of 0.3 MHz~6 GHz. Comparing the actual formation of the fracture and the infiltrated region with the measurement result, we can verify the extension of the fracture indirectly. Also it may be possible to understand the relation between the pressure of the fracturing fluid and the formation of the fracture in real time. [C255]

### "Sedimentary structure of the Nazar  coastal dunes (Portugal)"

The internal structure of coastal dunes located south of Nazare was analyzed using Ground Penetrating Radar. These coastal dunes comprise stabilized dunes, located in the inner part of the dune field, and foredunes, both separated by a dry dune slack. The radargram analysis allowed the identification of five bounding surfaces that define six main aeolian sand units. The Units I, II, III and IV correspond to the progradation of foredunes seaward (NW), while Units V and VI represent the migration of a parabolic dune and a blowout, respectively, to southeast. A strong reflector separating Units I, II and III from Unit V is interpreted as a paleosol, suggesting a break in aeolian sedimentation of unknown duration, but with sufficient time for soil development. The absence of the paleosol over the Unit IV leaves some doubts in relation to its relative age, although it is indicative of the occurrence of an erosive event. Radar stratigraphic analysis provided a relative chronology of units that will be used as a framework for selecting sampling points for future absolute dating and sedimentological studies. [C256]

### "High power variable nanosecond differential pulses generator design for GPR system"

High power variable nanosecond differential pulses generators based on avalanche transistor and Marx Bank are investigated theoretically and experimentally. The circuit employs six avalanche transistors with charging and discharging circuitry for differential pulses generation and step recovery diode, Schottky diode for pulse shaping. The pulse width can be varied from 1ns to 4ns. The pulse amplitude varies from  $\pm 30V@1ns$  pulse width to  $\pm 58V@2ns$  pulse width. The repetition frequency can reach as high as 500kHz. This variable nanosecond differential pulses generator can be used in pulsed GPR system as transmitter and strobe generator in sequential sampling receiver circuit. [C257]

### "Rebars and defects detection by a GPR survey at a L'Aquila school damaged by the earthquake of April 2009"

After the earthquake of L'Aquila (Abruzzo Region, Italy) occurred on the 6th April 2009, Ground Penetrating Radar investigations of public infrastructures were performed in order to provide an early damage assessment about structural elements such as beams and pillars. In particular, here we present the results of a 1500 MHz GPR survey on a cracked beam of a public building of L'Aquila to verify the goodness of a restoration work by means of epoxy resin injections. First a classical processing routine has been performed in order to focus the rebars hyperbolas and possible reflections coming by the injections; a data volume was built and several depth-slices are here presented. The survey allowed to check the rebars geometry and the reliability of the intervention based on the epoxy resin injections. Limitations of the classical data processing approach are a great complication in imaging the scene also due to the risk of introducing subjectiveness elements in the data by the operator and to the poor resolution achieved for the deeper rebar layer. The possibility of repeating the measurements on the opposite face of the beam in order to detect the second rebar layer was here adopted as a solution of the problem; however this way of operating becomes unacceptable during an earthquake post-crisis phase. The possibility of overcoming these drawbacks was offered by the microwave-tomography (MT) technique. The MT technique was first tested by processing one of the collected profiles acquired on the joist and the result confirmed the ability of the technique to achieve good focusing also of the deeper layer of rebars. [C258]

### "Integrated prospecting in the Crypt of the Holy Spirit in Monopoli (Southern Italy)"

In this contribution we show the results obtained in relationship with GPR and ultrasonic investigations carried out in the Crypt of the Holy Spirit in Monopoli. The exploitation of integrated techniques has allowed to have a meaningful insight of the presence of interesting buried anomalies under the floor and has provided important information about the state of preservation of the columns. [C259]

### "Influence of feed line on DOA estimation with dipole array antenna for directional borehole radar"

In this paper, we investigate the influence of the feed lines on the radar signals in the dipole array antenna fed by coaxial cables for directional borehole radar. In this investigation, we utilize a model of dipole antenna elements in circle near a conducting cylinder in a borehole. The criterion proposed in this paper is calculated, and quantifies the influence of the conducting cylinder. This criterion is tested with the data obtained in experiments in air, and we verified that the criterion represents the influence of the cylinder on the direction estimation. We made the directional borehole radar system with the dipole array antenna, which was fed by semi-rigid cables. With this system, we conducted field experiments in granite. We confirmed that we can estimate direction of arrival after processing the array signals with the band-pass filter, which was designed optimally with the criterion. [C260]

### "Mapping thermal tufa deposits using GPR"

Tufa (freshwater calcareous) deposits can provide excellent targets for GPR exploration due to low clay content and low salinity. Widespread tufa deposits occur at the surface and in the shallow subsurface of Heber Valley, an alluvium-filled basin located in the Rocky Mountains of northern Utah (USA). A set of 200-MHz GPR profiles provides an unprecedented view of the internal structure of a tufa mound and its immediately surrounding platform. Our results indicate that features such as unconformities, caverns, disruptions due to voids, and "seismic" stratigraphic on-lap patterns can be mapped at high resolution. These patterns may be used to constrain interpretations of the episodic growth of a tufa system over geologic time. [C261]

### "Deployment of GPR system ALIS for humanitarian demining in Cambodia"

ALIS is a hand-held dual sensor developed by Tohoku University, Japan since 2002. Dual sensor is a general name of sensor for humanitarian demining, which are equipped with metal detector and GPR. ALIS is only one hand-held dual sensor, which can record the sensor position with sensor signals. Therefore, the data can be processed after data acquisition, and can increase the imaging capability. ALIS has been tested in some mine affected countries including Afghanistan (2004), Egypt(2005), Croatia(2006-) and Cambodia(2007-). Mine fields at each country has different conditions and soil types. Therefore tests at the real mine fields are very important. ALIS has detected more than 30 AP-Mines in evaluation test in Cambodia held in 2009. [C262]

### "GPR as an imaging device: Some problems & potential solutions"

Ground Penetrating Radar (GPR) is an invaluable tool in a wide range of applications. In each sphere of activity to which the technology is applied, however, there is a tension between gaining meaningful information and the time and resources committed to data collection, processing and interpretation. In the light of the current world economic crisis, this is not likely to ease. [C263]

### "High-resolution imaging of a vineyard in south of France using ground penetrating radar and electromagnetic induction"

GPR and EMI surveys were carried out in a vineyard in southern France in order to produce high-resolution maps of soil stratigraphy and to retrieve soil hydrogeophysical properties of the different soil layers. The preliminary results presented in this paper show large spatial variations of the vineyard soil properties, which are in accordance with the distribution of the different soil types within the study area. This is particularly observable from soil electrical conductivity data, which show strong spatial correlation with large areas of comparable values delimited by well-defined discontinuities, revealing sharp variations of soil characteristics over short distances. These discontinuities almost systematically correspond to the limits of the vineyard plots, though areas of contrasted soil electrical conductivity values are also found within some plots. Furthermore, the patterns of soil electrical conductivity are in good agreement with soil stratigraphy observed from GPR measurements. Finally, these results also highlighted compaction as a likely explanation to vine vigour problems observed locally in the vineyard. Future work will focus on the full-waveform inversion of GPR and EMI data to retrieve the properties of the different soil layers and to investigate the spatial variation of soil water availability in the study area, and provide on this basis recommendations for the vineyard management. [C264]

### "Full-waveform modeling of ground-coupled GPR antennas for wave propagation in multilayered media: The problem solved?"

We propose a full-waveform approach for modeling time and frequency domain, off-ground and on-ground radars for wave propagation in multilayered media. The radar antennas are modeled using an equivalent set of infinitesimal electric dipoles placed over the antenna aperture. The linear relations between the fields in the

transmission line, the sources, and the backscattered fields over the antenna aperture are expressed in terms of frequency dependent, global reflection and transmission coefficients, which are characteristic to the antenna. The interactions between the antenna and the layered medium are thereby accounted for. Far-field and near-field measurements are used to determine these antenna coefficients. The fields over the antenna aperture are calculated using three-dimensional Green's functions. We validated the approach using measurements with a 900 MHz centre frequency transmitting and receiving antenna situated at different heights above a copper plane. For heights larger than the antenna, a single point source and receiver was sufficient for accurately modeling the radar data. For smaller distances, using six sources and receivers provided remarkably good results. Although some simplifications were made in this paper, the proposed method shows great promise for characterizing multilayered media using full-waveform inversion, with very limited computation time compared to numerical methods. [C265]

#### **"Inversion and sensitivity analysis of GPR data with waveguide dispersion using Markov Chain Monte Carlo simulation"**

GPR data with waveguide dispersion are known to be very difficult to interpret using traditional inversion methods. Recently, an algorithm was developed that inverts dispersive GPR data using dispersion curves. Here we analyze the sensitivity of this algorithm, and determine posterior probability density functions of the inverted parameters using Markov Chain Monte Carlo simulation. This method is especially designed to work well in the presence of measurement and model error, and is applied to measured CMP data assuming a two layered subsurface. Lower frequencies determine the inverted permittivity of the lower halfspace, whereas higher frequencies contain information about the waveguide height and its permittivity. Removing the beginning or end of the dispersion curve significantly increases parameter uncertainty. [C266]

#### **"Imaging the subsurface structure of Planum Boreum with the Mars Reconnaissance Orbiter Shallow Radar"**

We review prior mapping of the subsurface structure of Planum Boreum that was conducted with 2-D sounding data from the Shallow Radar (SHARAD) instrument onboard the Mars Reconnaissance Orbiter (MRO). Widespread reflections from basal and internal interfaces of the north polar layered deposits (NPLD) occur throughout the 1,000,000-km<sup>2</sup> area. A dome-shaped zone of diffuse reflectivity up to ~1 km thick underlies two-thirds of the NPLD. This zone is associated with a basal unit identified in image data as Amazonian sand-rich layered deposits. In other areas, the NPLD base is remarkably flat-lying and co-planar with the exposed surface of the surrounding Vastitas Borealis materials. Within the NPLD, radar-layer packets that extend throughout the deposits have been mapped as five units with a total volume of 821,000 km<sup>3</sup>, exclusive of the basal unit. Application of a 3-D imaging technique commonly used in processing seismic data to the polar grid of 2-D SHARAD observations is expected to yield an improved representation of the subsurface layering geometry and greatly reduce the effects of surface clutter. [C267]

#### **"Detection and classification of landmines using AR modeling of GPR data"**

In this paper we present some results on detection and classification of low metal content anti personnel (AP) landmines using a modified version of the Auto Regressive (AR) modeling algorithm presented in. A statistical distance is computed between the AR coefficients of the measured GPR time signal and the AR coefficients of a reference database (containing the AR models of the mines of interest) and a detection is declared if this distance is below a given threshold. [C268]

#### **"Rail radar-a fast maturing tool for monitoring trackbed"**

Ground Penetrating Radar ('rail radar') technology has long been a focus for railway trackbed maintenance and renewals planning due to its non-destructive nature and its potential to offer significant efficiency savings in trackbed condition monitoring. This paper provides a brief introduction to the two main interpretation techniques (interface reflection and EM scattering) currently used to monitor railway trackbed and identify the causes of anomalous trackbed conditions. A number of survey examples and scenarios are provided and explained in detail. [C269]

#### **"Radar subsurface sounding over the putative frozen sea in Cerberus Palus, Mars"**

The area of Mars known as Cerberus Palus, suspected of harboring a frozen body of water, has been observed by the two subsurface sounding radar MARSIS and SHARAD. SHARAD data reveal subsurface interfaces at depths ranging from ~50 m to ~150 m which could be interpreted as either the bottom of an ice sheet lying over bedrock, or an interface between two lava flows. Echoes have been analyzed to estimate the dielectric

properties of the surface layer, and results favor the interpretation that no ice is present in the area. [C270]

#### "Broadband stripline to microstrip transition with constant impedance field matching section for applications in multilayer planar technologies"

This paper presents a broadband Stripline-to-Microstrip transition with constant impedance section. In the transition the structural parameters of transmission line have been used to provide smooth electromagnetic field matching together with providing unchanged characteristic impedance along transition section. This solution eliminates the necessity of impedance transformer. The transition enables easy access to stripline circuits situated on the internal layers of multilayer structures by use of typical microstrip terminals. The transition has a simple structure for the ease of fabrication with low cost. The measured performance exhibits flat frequency response over broad bandwidth. The insertion loss is less than 0.5 dB and a return loss is better than 25 dB within frequency range 1 GHz to 10 GHz [C271]

#### "AD-ESPRIT for multi-target localization in bistatic MIMO radar system"

In this paper, an ESPRIT-based approach named as AD-ESPRIT is presented to jointly estimate the directions of arrival (DOAs) and directions of departure (DODs) estimation of interesting multi-targets for bistatic MIMO radar system. The proposed method does not need two-dimensional (2-D) or multiple 1-D spectrum peak searching. Thus, the computational complexity of the proposed algorithm is reduced for the direction finding cross localization in bistatic MIMO radar system. Furthermore, the estimated DODs and DOAs is automatically determined. Simulation results are presented to verify the effectiveness of the proposed method. [C272]

#### "Radar resource management in multifunction radar"

In this paper, a multifunction radar system architecture has been introduced. Multifunction radar is a phased array radar system. A phased array radar system can adapt its parameters on a near-instantaneous basis according to the way in which it perceives its operating environments. This allows the combination of function such as tracking, surveillance, and weapon guidance, which were traditionally performed by dedicated individual radars. Multifunction radar has clear advantages of being able to instantaneously and adaptively position and control the beam, but it also brings a new set of challenges. Radar resource management is the problem of how to allocate finite available resources in an optimal way to carry out a chosen mission. [C273]

#### "X-band coupled cavity slow wave structure of the traveling wave tube for airborne application"

The paper describes the design of the conduction cooling X-band coupled cavity traveling wave tube (CC-TWT) based on the Hughes staggered slots slow wave structure (SWS) which was the first tube of this type made in the Wroclaw Division of PIT. A project of LO-700W traveling wave tube required solving various structural and technological problems e.g. effective termination based on loss ceramic buttons at the sever of RF circuits to minimize reflections and to provide proper attenuation. In this paper an approximate method for calculation of the input antenna of coaxial-line, waveguide transition and output waveguide window is also presented. [C274]

#### "Design of an electronically adaptable low-power reference cell for low-cost CMOS processes"

This paper presents the design of a voltage reference cell suitable for low-voltage and low-power applications without the usage of bipolar structures. The respective reference voltage can be trimmed within a certain range to compensate the unavoidable process variations. The chip is designed based on a 0.13  $\mu\text{m}$  CMOS technology. [C275]

#### "Broadband 444 Butler matrix in microstrip multilayer technology designed with the use of three-section directional couplers and phase correction Networks"

A two-octave 444 Butler matrix has been presented, for the first time in multilayer microstrip asymmetric coupledline technology. To achieve two-octave frequency band in terms of amplitude and phase responses a recently developed approach has been used in which multi-section coupled-line directional couplers and Schiffman C-sections are applied. A highperformance three-section coupled-line 3-dB microstrip directional coupler has been utilized as a basic element of the Butler matrix and two compensated microstripline Schiffman C-sections have been designed to provide appropriate differential phase characteristics. A very good performance has been achieved over two-octave frequency band in terms of amplitude and phase responses. The designed network can be easily applied in large microstrip networks as a surface mount element. [C276]

#### "Performance measures of wavelet families on sar images for compression hypothesis"

Synthetic Aperture Radar (SAR) techniques represent a promising alternative compared to traditional surveillance methods. The capabilities of satellite based SAR systems are confirmed and specific data exploitation methods are still to be developed to provide an efficient automatic interpretation of SAR data. The mean of this paper is to analyze and compare a set of wavelet families on ship SAR images. The outcome of this research is to bring out the important features of wavelet transform in compression of SAR images. The wavelet transform provides efficient performance especially in compression ratios, signal to noise ratio and visual quality. Wavelet Transform decomposes the SAR image into function at different resolution levels. The results provided here is a good reference for SAR application developers to choose the wavelet families. Thus the paper concludes that wavelets transform to be rapid, robust and reliable tool for SAR image compression and able to manage heterogeneous views of SAR images, where the conventional approaches may fail. [C277]

#### **"An algorithm of sorting the phased array radar signal based on RST"**

The aim of This paper is to sorting the phased array radar signal. The method is using the radar beams scanning characters of the phased array radar, then proposes an algorithm based on the rough sets theory to sort the signal of phased array radars. From researching on the characters of the phased array radar's beam scanning manners, we can use the PDW received from the receiving equipments as a set of attributes. Through using RST to reduce the attributes of phased array radar signal, we can get the rule of the attributes' nucleus. So we can sort the phased array radar signal from the electromagnet environment from using the rule. Through experiments showed that this method can get a good result and can efficiently sort the phased array radar signal. [C278]

#### **"An effective virtual ESPRIT algorithm for multi-target localization in bistatic MIMO radar system"**

In a bistatic multiple input multiple output (MIMO) radar system, the location of each interesting target can be determined by the direction finding cross localization with the direction-of-departure (DOD) and direction-of-arrival (DOA). In this paper, an effective virtual ESPRIT algorithm is proposed for jointly DOA and DOD estimation in bistatic MIMO radar system. The pairing problem is addressed as well, for jointly DOA and DOD estimation. Simulation results are presented to verify the effectiveness of the proposed method. [C279]

#### **"Fast automatic target detection of large scene SAR image based on parallel computing"**

An automatic target detection algorithm of SAR image based on parallel computing is presented in this paper. The experimental results based on constant false alarm rate detector verify that the algorithm adapts well to the parallel processing system with high performance and parallel efficiency. That means the algorithm has high real time property. [C280]

#### **"Research on availability simulation of Surface-to-Air missile weapon systems"**

A simulation method that uses discrete event simulation for availability evaluation of Surface-to-Air missile weapon systems is presented. The method uses the R&M&S data at subsystem level and the information about system topology to infer the availability information at system level by modeling the operating process of weapon system. The point and interval estimates for system availability were obtained. The example illuminated that the method is effective for availability evaluation of Surface-to-Air missile weapon systems. [C281]

#### **"Design of remote data acquisition system of passenger flow based on GPRS"**

According to acquisition data of passenger flow relay on artificial and transporting of unreal-time, this paper introduces system of acquisition data of passenger flow base on GPRS by infrared transducer and pressure transducer. Elaborate hardware scheme design of embedded microprocessor in ARM7 core, implement transporting data of passenger flow to data terminal base on GPRS in time and exact, it is provided a reliable basis for real-time scheduling in public transportation. [C282]

#### **"AD-MUSIC for jointly DOA and DOD estimation in bistatic MIMO radar system"**

In this paper, a MUSIC-based approach named as AD-MUSIC is presented to jointly estimate the directions of arrival (DOAs) and directions of departure (DODs) estimation for the direction finding cross localization of multi-targets in bistatic MIMO radar system. The MUSIC algorithm for the DOD estimation is referred to as the D-MUSIC algorithm. On the other hand, the A-MUSIC, which estimates the DOA, is introduced as well. The proposed AD-MUSIC combines two one dimensional (1-D) MUSICs along with the spatial beamforming technique to jointly estimate the DOAs and DODs. At the same time, the estimated DOAs and DODs is automatically determined. Simulation results are presented to verify the effectiveness of the proposed method. [C283]

### "Ultra wide band (UWB) transmitter with configurable design for indoor positioning"

This paper introduces a novel system design for indoor position estimation. The designed indoor positioning system is capable of detecting the coordinates of standalone ultra wide band transmitters in interior environment. An effective, but simple impulse generator has also been developed that can be used in such a positioning system. The simple impulse generator contains only three active elements. The highly configurable design methodology and the easy assembling of UWB transmitter contribute to quick evaluation of localisation algorithms. [C284]

### "Impulse transmitting photonic antenna for ultra-wideband applications"

This paper presents a new transmitting photonic antenna based on pigtailed fiber-optic photodiode module integrated with bow-tie radiator for UWB pulse generation using a gain-switched laser diode module. [C292]

### "Realization of a transmit system using T/R modules applied in the demonstrator of S band active antenna"

The paper presents realization, mechanical solution and measurements results of a transmit system used in the Demonstrator of S-band Active Antenna. The transmit system contains T/R modules, where individual module supplies half of antenna row of planar array. The 16 antenna rows form cosecant squared radiation antenna pattern. Brief description of the whole transmit path with special attention to T/R modules is provided. The results of antenna pattern measurements on a tower setup are shown. Additional information about Power Supply System and Cooling System are described as well. [C293]

### "Red light-emitting diode degradation and low-frequency noise characteristics"

Comprehensive investigation of AlInGaP red light-emitting diodes (red LEDs) radiating at 625 nm characteristics and physical processes that take place in device structure during aging has been carried out. Analysis of noise characteristics (the emitting-light power and the LED voltage fluctuations and their cross-correlation factor) shows that investigated red LEDs degradation is caused by defects that lead to the non-radiating recombination increase in the active region or its interfaces. Our results have shown that noise characteristics are more sensitive to the formation of such defects in the red LED structure, and to its degradation. [C294]

## "2D DOA estimation for coherently distributed source"

In this paper, a novel two-dimensional direction of arrival (2D DOA) estimation method is proposed when coherently distributed source exists. The second-order statistics is formed to estimate the azimuth DOA with integral steering vector expressed as Schur-Hadamard product. And then the elevation DOA is estimated using advantage of the array configuration based on the eigenstructure between the steering matrix and the signal subspace of distributed sources. It has a lower computational complexity without any joint two-dimensional searching. Simulations results are included to demonstrate the performance of the proposed technique. [C298]

## "Based on embedded intelligent vehicle system"

On account of the existing vehicle for using the platform of integration is limited. Besides, computing speed is not fast enough, power-hungry, and the machine's functions are not plentiful. Many of the features which the customer need for the existing car can not be achieved on the basis of machine. With the rapid development of embedded systems applications, this paper designs a chip based on the ARM9 AT91SAM9260 new smart car system. In this design of Intelligent vehicle systems firstly introduces the main features and hardware architecture to achieve, and then analyzes the GPS, GPRS and other modules, the hardware composition and theory, and finally gives the system's software program. [C299]

## "MUSO: An M-learning & University Student Organizer platform"

Mobile devices nowadays are widespread and provide great multimedia capabilities, which make the delivery of mobile learning a more realistic approach since it can provide just in time learning on the move. Currently, students in some universities can watch live lectures or tutorials on their university website after a registration process. Some students who face difficulties in attending their lectures or tutorials due to living in remote areas would like to watch missed lecture/tutorial by downloading lecture/tutorial videos for their mobiles. This paper describes an M-learning and University Student Organizer (MUSO) application which offers solutions to these problems. MUSO is developed using Java 2 Micro Edition (J2ME) which is supported by most available mobile handsets. This application uses the internet through GPRS or WiFi connections. MUSO uses the concept of client-server architecture which gives the ability to have large data sets and decreases the computation processes on the mobile phones. This paper presents a test case for MUSO on a real university. [C300]

## "Intelligent Traffic Management system base on WSN and RFID"

With wireless communication and the speedy development of micro-electro-mechanical system (MEMS), the wireless sensor network (WSN) has aroused enthusiasm in the world. The research of intelligent transportation system base on WSN is a hotspot to solve the traffic problems in recent years. This paper first introduces intelligent transportation system base on RFID and WSN, then discusses the hardware and software design principles of the system. It has produced the wireless long-distance automatic monitor sensor network design realization plan, finally it forecasts the development of intelligent transportation system. Practice shows that the system is characterized by low cost, economic and pragmatic and high reliability. [C301]

## "Comparisons of speckle noise filtering methods on high resolution SAR image"

Numerous image processing methods to suppress the speckle noise in synthetic aperture radar (SAR) have been proposed. There is always a tradeoff between smoothing out speckle and preserving the useful spatial information (i.e. edge, texture). This paper proposed a novel index by integrating the evaluation of both speckle and edge preservation to evaluate the balance of the aforementioned two criteria. Some of the well-known adaptive speckle suppression filters are then compared and evaluated using two high resolution SAR datasets on heterogeneous areas. Experimental result shows that Kuan filter performance better in preserving image sharpness and detail while suppressing noise. [C302]

## "SAR and Landsat ETM+ image fusion using variational model"

Multispectral and synthetic aperture radar (SAR) image fusion is one of the most complex tasks to perform integration of multi-source remotely sensed imagery. Fusion of SAR and optical remote sensing image, with highly complementary characteristics, may contribute to a better understanding of the objects with the imaged scene and finally benefit to application such as precision farming/ agricultural. In this paper, we adopt a variational model to fuse SAR imagery and multispectral imagery. Experimental results on Cosmo-SkyMed SAR and Landsat-7 Enhanced Thematic Mapper Plus (ETM+) satellite images of an urban area, demonstrate accurate spectral preservation, which is indicated by high correlation between original multispectral and fused bands. [C303]

#### **"The realization of precision agriculture monitoring system based on wireless sensor network"**

Based on the analysis of the development of agricultural mechanization, the trend of agricultural service system reform, agricultural environment protection and the development of information technology, it is possible to realize the precision agriculture. This paper designs the agricultural environmental monitoring system based on the wireless sensor network (WSN). The system can real-timely monitor agriculture environmental information, such as the temperature, humidity, and light intensity. This paper introduces the theory of the monitoring system, and discusses the aspect of hardware and software design of the composed modules, network topology, network communication protocol and the present challenges. Experiments show that the node can achieve agricultural environmental information collection and transmission. The system has the feature of compact in frame, light in weight, steady in performance and facilitated in operation. It greatly improves the agricultural production efficiency and automatic level drastically. [C304]

#### **"Decision to avoid ships collision in fog and application"**

Ships officers can't look out by eyes efficiently in dense fog, and radar observing becomes only systemic and efficient aid-navigation method. This thesis analyses ships collision avoidance theory in fog according to radar plotting diagram and relative collision avoidance rules and good seamen skill custom, brings out conclusion of decision to avoid ships collision in fog, supplies reasonable support for auto Avoiding Collision. [C305]

#### **"Extraction of gap and canopy properties using LiDAR and multispectral data for forest microclimate modelling"**

The creation of gaps in forest canopies can dramatically change the microclimate and soil water balance which strongly influences the process of regeneration and biodiversity within forest ecosystems. Hence, understanding the microclimatic conditions in canopy gaps is a prerequisite in developing and improving techniques for forest management and conservation practices. However, information is scarce on how the size and shape of gaps and their spatial distribution affects the microclimate and soil water balance across forest stands. In the present study we investigated the potential for retrieving forest gap and canopy attributes from LiDAR and multispectral sensors in order to provide new opportunities for modelling forest microclimates. A spatially explicit microclimate model (FORGAP-BD) was developed which could be driven using inputs from remote sensing. The model was implemented for a study site in the broadleaved deciduous forest, Eaves Wood, UK in order to quantify the spatio-temporal dynamics of microclimates over an entire forest stand. [C306]

#### **"Characterising Reedbed habitat quality using Leaf-off LiDAR Data"**

The aim of this paper was to investigate the potential of using leaf-off LiDAR data to characterise the quality of reedbed habitats in Leighton moss, North west UK. The correlation between LiDAR derived and ground-measured heights were determined using six selected spatial buffers and the most significant selected. The results indicated that accurate estimates of canopy height were derivable from the first return data, a valuable indicator of reedbed habitat quality. However, the lack of any subsequent returns from reedbeds prevented the extraction of any further biophysical variables. This paper outlines the methodology of deriving suitable height estimates of reeds and the limitations of using leaf-off LiDAR data. [C307]

#### **"Ocean-land segmentation based on active contour model for SAR imagery"**

Ocean-land segmentation is a basis for oceanic targets detection for SAR imagery. The traditional manual segmentation method can acquire a fairly good result, while it is unable to achieve a satisfying efficiency. Thus the manual method is unsuitable for batch processing. Ocean map based land masking method requires a priori information, which restricts its application. This paper presents an automatic active contour model based ocean-land segmentation method for SAR imagery. This method forces the active contour to the real coastline by variation level set. Under the restriction of minimizing a given energy function, the method obtains the final segmentation result when the active contour is overlapped on the coastline. In addition, an optimizing method is proposed to improve its computation efficiency, which makes our segmentation method more applicable. [C308]

### "Research on the spaceborne SAR image processing and feature extraction for ocean fronts detection"

This paper discusses the interaction of short surface waves with shearing and converging current. On the basis of the spectral perturbations caused by the interaction, the influences of the interaction on the ocean surface wave spectral density and gradients are analyzed. A two-scale electromagnetic scattering model explains not only the interaction between short-wave and radar backscatter, but also the interaction between long-wave and radar backscattering. Then SAR imaging mechanism of ocean fronts is derived. In SAR images, the scale of ocean fronts is 2-3 orders larger than that of sea waves. Most of wave information is filtered out by the 2-D spatial spectrum analytics. Then the characteristic information of ocean fronts is extracted by digital image processing technology. Thus, information processing means by which characteristic information of ocean fronts can be extracted from SAR images is constructed. [C309]

### "GISTDA EOC synthetic aperture radar data processing system"

Located in Ladkrabang, Bangkok, The Earth Observation Center (EOC) of the Geo-Informatics and Space Technology Development Agency (GISTDA) is a ground station for receiving, managing, processing and archiving the Earth observation satellites data. The GISTDA EOC has two SAR data processing systems (SDPS) to support data processing from two SAR satellite constellations: RADARSAT and ALOS. This paper provides the overview of both SAR data processing systems including descriptions of the systems, data processing algorithms, architectures and functionality. The paper finally verifies the image quality characteristics of the example SAR data products generated by the two SDPS by comparing with the satellite operating agency's specifications. [C310]

### "Comparison of classical and orthogonal UWB waveforms for radar applications"

In this paper, classical UltraWideband (UWB) waveforms and orthogonal functions (Hermite and Gegenbauer) for radar applications are proposed. The use of this emergent technology in radar applications domains allows the development of compact and low-cost radars with multiple fields of application in daily life. In many classical UWB radar systems, only Gaussian and monocycle pulses are used. UWB waveforms based on orthogonal functions (Hermite and Gegenbauer) are proposed for their good resolution adapted more to radar detection function. Their multiple access capacity due to their orthogonality presents an important advantage of these waveforms. This study proposes to compare these waveforms to Gaussian and monocycle pulses with simulations for short range avoidance collision radar application. [C311]

### "A new SAR image segmentation method based on fusion"

In this paper, a new synthetic aperture radar(SAR) image segmentation approach based on fusion is proposed. The wavelet transform algorithm and morphology reconstruction algorithm fusion technique can preserve more spatial feature and more functional information content, respectively. The new fusion method are adopted 2 SAR images of the same area taken with overexposure and under exposure are used for image processing. Compared with other methods, the experimental results of the proposed method based on image fusion using real SAR images are much better in reservation of information and boundary as well as correctness of original region. [C312]

### "A novel distance-assisted localization algorithm in wireless sensor networks"

In wireless sensor networks, calculation and management of node position is a subject which has a profound theoretical basis and wide range of application. Due to the randomness of sensor network nodes and the dynamic variability of network topology, lots of algorithms can not meet the requirements of positioning accuracy. For this reason, a DV-DScale localization algorithm is proposed in this paper based on distance-assisted and hop quantization. In the algorithm, cumulative distance value is no longer directly used for maximum likelihood estimation to localization, but as scale to amend the straight-line distance between nodes and estimate the position information of nodes. Because of the low resolution of hops, the traditional localization algorithm which is based on hop can only adapt to the isotropic dense networks. The simulation results show that the proposed algorithm effectively ameliorate the positioning accuracy. Even in the case of random distribution of nodes, the algorithm can also get a higher positioning accuracy. [C313]

### "An impact point of shipboard artillery shell calculating system based on DSP and matlab-simulink simulation"

This paper introduces an impact point of shipboard artillery projectile calculating system based on DSP, and

expatiate the system model, mathematical model, working principle and matlab simulation models. Because radar having detected the trajectory of flying artillery projectile, the system calculate the whole trajectory and impact point coordinates, using DSP techniques. The simulation experiment indicate that the feasibility and practicality of the system. [C314]

#### **"Fault diagnosis expert system of artillery radar based on neural network"**

The fault of new type artillery radar is highly complex and correlative. The neural network technology was incorporated into the radar fault diagnosis after the fault features of new type artillery radar and the shortage of the expert diagnosis system were analyzed. There are many difficulties in the process of the servicing for the artillery radar, such as technology level is low, fault diagnosis is difficult. To resolve the problem, a fault diagnosis expert system was realized based on RBF(Radial Basis Function) neural network. The collectivity structure of expert system, structure and function of software were discussed. Accordingly, several key techniques such as the fault diagnosis principle of RBF neural network, knowledge database, reasoning engine were also given in detail. The application results showed that the expert system proved its feasibility and practical, the servicing efficiency and fault diagnosis ability are improved. [C315]

#### **"A despeckling algorithm combining curvelet and wavelet transforms of high resolution SAR images"**

SAR images despeckling is one of the most important research subjects in SAR images processing. Following discussion on the advantage and disadvantage of curvelet and wavelet transforms based SAR images despeckling, an algorithm which combined curvelet and wavelet transforms was proposed for despeckling of high resolution SAR images. Firstly, the curvelet and wavelet were used to denoise the original SAR image, then the related residual image between their results was acquired, which was then denoised through the curvelet transform. Finally the denoised residual image was added to the curvelet denoised image. Experimental results of TerraSAR-X high resolution images indicated that, compared with the Enhanced Lee filter, the Enhanced Frost filter, the wavelet transform based and curvelet transform based methods, the algorithm presented here had well despeckling effect, as well as fine edge-preserving ability. [C316]

#### **"Realization of position selection simulation evaluation system for artillery reconnaissance radar"**

Aiming at improving the position selection limitation of artillery reconnaissance radar by map work and field reconnaissance, Multigen Creator and Vega were adopted as the development platform of visual simulation software, the position selection simulation evaluation system of artillery reconnaissance radar was realized. The structure and function of system, three dimension scene modeling and terrain selection evaluation were discussed. Several key techniques such as improved terrain building algorithm, position evaluation algorithm were given in detail. The results show that the simulation system simulates the position selection operation process of artillery reconnaissance radar livingly and can meet the requirement of real time simulation. [C317]

#### **"A novel design of water environment monitoring system based on WSN"**

The importance of maintaining good water environment highlights the increasing need for advanced technologies. This paper proposes a novel design of water environment monitoring system based on wireless sensor networks (WSN). The system consists of three parts: sensor nodes; sink nodes and data monitoring center. The sensor nodes can be constructed with arbitrary parameter or multi-parameter sensor modules such as PH, dissolved oxygen (DO), conductivity and temperature. The measurement capacity ranges from 0 to 14 on PH value; from 0~20 mg/L on DO; from 0~2 S/cm on conductivity. The sink nodes communicate with the local or remote data monitoring center by RS232 or 3 G/GPRS. The performance shows the system can be effectively applied to some water area such as aquiculture, lake and river for distributed water environment automatic monitoring. [C318]

#### **"Simulation study of noise convolution jamming countering to SAR"**

A new active jamming technique to synthetic aperture radar (SAR) is analyzed, which is called noise convolution jamming technique, or smart noise jamming technique. This technique can receive part of the SAR's process gains, so it is superior to current noise blanketing styles. It can reduce the jamming energy and improve the utility of jamming power greatly. By selecting the noise signal's initial time and terminal time, we can control the position and width of the jamming region in order to suppress distributed targets. Theoretical analysis and computer simulation justify the validity and efficiency of the new jamming technique. [C319]

#### **"A method for specific emitter identification based on empirical mode decomposition"**

Real radio and radar signals turn out to be non-stationary and nonlinear time series, and estimating instantaneous parameters of such signals in time domain will benefit detecting and identifying specific emitters, such as civil or military radios. However, conventional methods such as Wavelet and Wigner-Ville distribution (WVD) methods are difficult to deal with these transient signals when the signal is non-stationary. To provide more efficient approach for estimating instantaneous parameters of non-stationary and identifying specific emitter with high accuracy, a new method based on empirical mode decomposition (EMD) for analyze non-stationary signal is proposed in this paper. The results show that the instantaneous frequency estimates generated by the EMD method are more accurate than those obtained by the Wavelet technique. [C320]

#### "Improved pattern synthesis method with linearly constraint minimum variance criterion"

For the pattern synthesis method of the arbitrary array antenna with the linearly constraint minimum variance criterion (LCMV-PS), the primary disadvantage is its poor adaptability, namely its performance is determined by the iterative coefficient. In order to improve its performance, the effect of the relative amplitude between synthesis pattern and its reference upon the pattern synthesis is considered adequately, via adding a proportion constant to the iterative formula, not only the pattern synthesis efficiency is improved, but also the adaptability is extended. By the novel improvement for its iterative coefficient, the application area and adaptability of the pattern synthesis method are enhanced. The last simulation attests its correctness and effectiveness. [C321]

#### "Scheduling of tasks with fuzzy dwell times in a multifunction radar"

This paper proposes an algorithm for scheduling tasks in a multifunction radar. A greedy algorithm designed for tasks with crisp dwell times is extended to situations where the dwell time is allowed to be fuzzy. The greedy scheduling algorithm attempts to schedule as many tasks as possible while maintaining temporal regularity between the task update intervals. Tasks that cannot be scheduled by the greedy algorithm are then input to the fuzzy scheduling algorithm, which adjusts the dwell time of the tasks according to their membership function until they can be scheduled. An example scheduling scenario is provided to demonstrate the behavior of the proposed algorithm. [C322]

#### "A reduced-rank STAP method based on solution of linear equations"

STAP is an effective method for clutter suppressing and Reduced-rank STAP can reduce the calculation quantity as well as memory capacity. The connection between the eigenvectors of the clutter covariance matrix and the reduced-rank subspace is analyzed. A method based on the solution of linear equations which can get the whole eigenvectors of the minimum eigenvalues is proposed. By the method, the reduced-rank STAP can be done in the noise subspace without eigen-decomposition. Analysis is made about the distribution of SINR metric in the eigen-space and the solution space. Finally, simulations via real data proved the validity and correctness of the method. [C323]

#### "Research on autocorrelation of chaotic sequence by phase space method"

Chaotic sequences have been widely used as pseudorandom sequences. But the problem of how to judge their autocorrelation function's performances are good or not, up to now, have not been solved. In the paper, by method of phase space, we studied the autocorrelation function of chaotic sequence and discovered that their performance is determined by whether its phase space trajectory is axis symmetrical. This paper deduced theorems to describe and solve these problems, and presented a simple and effective method to judge autocorrelation performance of chaotic sequences, and a method to improve their autocorrelation performance was presented, too. Many simulations were presented to verify the theorems and methods. [C324]

#### "Remove multifrequency mixture noise in processing of Wireless Communication wave/radar reflect signal by method of ICA"

The ICA technique is used to remove multifrequency mixture noise in Wireless Communication wave/radar reflects signal processing. The characteristics of Wireless Communication wave/radar reflect signals are analyzed, build up models of expectation signal and consociation mixture noise and a constituted method of the independence prognosticate machine is discussed. Use the improved algorithmic of FastICA to simulate it. From simulation results, a well effect is acquired by method of the mixture signals separate above-mentioned. Via this, it can gain source signals almost pure furthermore wider the range ratio scope of each signal channel and type of signal. The method in the text possesses very good anti-jamming ability and it is can be expand other related signal processing, so the method is widely accepted. [C325]

#### "Session C6: Radar technique"

{no data available} [C326]

### "Analysis of mode-hopping effect in fabry-perot laser diodes"

Mode-hopping effect in Fabry-Perot laser diode (LD) operation was investigated. Radiation spectra and noise characteristics (optical and electrical fluctuations and their simultaneous cross-correlation factor) are measured under stable and mode-hopping operation of the LD. At mode-hopping point LD radiation spectrum is unstable, highly correlated intensive Lorentzian-type optical and electrical fluctuations are observed. Different cross-correlation factor value and sign (positive or negative) is observed for mode-hopping noise peaks at different LD operation conditions. Origin of the intensive Lorentzian-type fluctuations during mode hopping is caused due to generation-recombination processes in defects in barrier layers. [C327]

### "Ka-band FMCW radar sensor for remote control of presence and speed of railroad-cars and trains in territory of grading belts"

The results of development of low cost radar sensors for remote control of track occupancy and railway cars speed over the territory of hump yards under heavy weather conditions are presented. The radar sensor feature is application of Ka-band FMCW autodyne (self-mixing) transmitter and digital systems for forming sounding signal and spectral processing of received signals. Sensor is equipped with the systems of remote control and transmission of radar and service information to the control point. [C328]

### "Complex radar signal source for radar receivers testing"

This paper presents a design of a Radar Signal Generator (RSG) for radar receivers testing and development (i.e. receiver dynamic measurement, pulse compression modules). RSG is a multifunction flexible radar signal source generating multichannel coherent signals with reference signal for radar station and the other auxiliary signals and noise signal. The presented design is based on digital synthesizers with high flexibility in radar signal intrapulse modulation schemes. The architecture of RSG allows complex signals generating with bandwidth up to 150MHz (the frequency range is limited with proper filters due to most used frequency ranges). Phase stability of the output signal is less 1e deviation RMS and phase noise performance of reference signals is - 134dBc/Hz@1kHz for 10MHz. [C329]

### "Opening session"

{no data available} [C330]

### "Session A1: Antenna design"

{no data available} [C331]

### "A marine testing's result of experimental radar with 64-channels digital antenna array"

In this article are analyzed a results of experimental radar with digital antenna array full-scale test against above-water targets. [C332]

### "Experimental pulse reaction estimation of the centimeter wave channel"

We solve the problem of experimental estimation of the cm wave channel pulse response. Give an estimation of the pulse response for different paths at different angular positions of the transmitting antenna. [C333]

### "Multi-radar system database integration using metrized small world technology"

The present article describes the possibility of integrating the data from several radars with shared radiolocation areas in order to acquire precise information about the targets by means of analyzing the events in neighboring spatiotemporal resolution elements. The paper suggests an algorithm for integrating the data based on creating the graph which possesses the characteristics of the "Metrized Small World". A possibility of processing the integrated data in real time is analyzed. The article describes efficient metrics for integrating multi-radar data into a single Metrized Small World graph. Examples of such algorithms are given. [C334]

### "Collapse of nonlinear spin dipole wave pulses of millimeter wave range in YIG films"

Spatiotemporal collapse of spin-dipole wave (SDW) pulses of millimeter wave range is investigated theoretically. The dispersion and diffraction coefficients of SDW have been calculated, when the retardation has been taken into account. It is demonstrated that YIG films are suitable for observing the collapse in millimeter wave range,

due to low dissipation and quite high values of dispersion and diffraction coefficients. Numerical simulations have been confirmed this result. [C335]

#### "Moving multy-scatterer target parametric identification using radar image"

The wideband coherent pulse radar provides high resolution image of the target. A model of this image is composed of the complex envelope superposition of signals diffracted by the point scatterers. The values of complex envelope are distributed over the radar image coordinate plane in accordance with the point scatterer's positions and their reflection coefficients. The radar image model is combining of the range and Doppler profiles. The parameters of the target point scatterers are processed using one dimensional data extracted from the complex discrete Fourier transform of the radar image. The Matrix Pencil algorithm is used for the parametrical target identification. [C336]

#### "Ground target position estimation in passive location"

Ground target tracking is difficult and actual problem. Because of the high target density and maneuverability, high clutter, low visibility due to terrain masking, etc., ground target tracking presents unique challenges that does not present in tracking of other targets types. But many tracking approaches have been developed for air targets and they work poorly for ground targets tracking. This article includes research work results in radar position estimation for passive range-difference location. Radio source is stationary and performs circular scan. Transmitted signal is received in three points. But beside true measurements of time difference of arrival (TDOA) there are false measurements originated by clutter. Usually clutter measurements are modeled as independent identically distributed. But real experimental data processing shows that in crosscountry its distribution may be multimodal. Therefore standard tracking algorithms are not efficient in this situation. Multimodal distribution is caused by re-reflected signal from underlying terrain. Some ground objects re-reflect signal and imitate additional (false) targets. We propose special approach to decide position estimation problem in such high clutter environment and verify it on experimental data [C337]

#### "Terahertz and sub-terahertz subsurface tomography"

Development of millimeter and sub-millimeter wavelengths technologies is of great interest lately, especially for application in so called terahertz imaging. As a rule, two main approaches are used for this purpose based on employment of active and passive methods of visualization. In our paper we consider a tomography approach for obtaining 3-D imaging in frequency range from 100 GHz up to 325 GHz. We applied the method which we developed earlier for low frequency sub-surface tomography for extremely high frequencies. The considered method may be used for nondestructive testing. In the paper we present a theoretical model, experimental method and the results obtained. [C338]

#### "Modulators of THz range based on integrated silicon P-I-N-structures in dielectric waveguides"

Modulators of terahertz (THz) range on the base of silicon integrated p-i-n-structures in the isolated silicon dielectric waveguide are investigated. For the double injection problem, the generalized boundary conditions at the injecting electrodes have been used in the case of highly doped p++, n++ regions. The silicon dielectric waveguides possess low losses in the regime without injection. The investigations of modulation properties of integrated p-i-n-structures in dielectric waveguides of THz range have demonstrated a possibility to use these structures up to the frequencies  $\ll 8$  THz. #### "Receive system of S band active antenna demonstrator"

The paper presents realization, mechanical solution and measurements results of a receive system used in the Demonstrator of an S-band Active Antenna. The receive system employs 16 antenna rows of planar array to form fan-beam receive antenna pattern in elevation plane and pencil-beam in azimuth. Five elevation positions of a pencil receive beam is electronically set by means of digital phase shifters and attenuators applied in receive beam forming network. The receive system realizes sum and difference beam signals for both azimuth and elevation planes at beam former outputs. Brief description of the whole receive path with main blocks is presented. The results of antenna pattern measurements on a tower setup are shown. [C354]

#### "Phase drift versus temperature measurements of coaxial cables"

Radio frequency systems developed for large scientific experiments have become increasingly sensitive to phase changes in their subcomponents. Amongst the most important subassemblies there are definitely coaxial cables that provide interconnections between experiment subsystems. It is commonly known that the most important source of phase drifts in coaxial cables is their sensitivity to temperature changes. The phenomenon of phase drifts in cables is discussed in this paper. A phase drift measurement setup is described. Samples of cables of various types used in RF system installations have been measured. Measurement results are presented. [C355]

#### "X-band pulsed measurement system of transmittance changes of power amplifiers"

The paper presents a system designed for measurements of transmittance changes of amplifiers and other active N-ports. This system is especially developed for measuring the transmittance variation of X-band T/R modules used in Active Phased-Array Radars (APAR). The measurements are automatically performed with the controlled sampling period  $0.2\mu\text{s}$ – $2\mu\text{s}$  for RF pulse of  $5\mu\text{s}$ – $300\mu\text{s}$  duration and 20Hz–2kHz repetition frequency

over an 8.8GHz to 9.5GHz frequency range. The system is capable of achieving the transmittance changes with accuracy of 0.2ofor phase and 0.05dB for amplitude. [C356]

### "An integrated SiGe HBT bandpass-pulse length modulator for switch mode power amplifiers in the SHF range"

The need for efficiency improvement of conventional class-AB-amplifiers when used with non-constant envelope modulations has set up interest in introducing switch mode amplifiers in the GHz operating frequency range. In order to be suitable for the amplification of arbitrarily modulated signals, a one-bit modulator is required at the input of the switch mode amplifier. Beside bandpass delta sigma modulation (BDSM), bandpass pulse length modulation (BP-PLM) seems to be a promising approach for this task. Here, the modulator output signal switches with the cycle of the RF-carrier signal frequency itself so that no oversampling is required, thus reducing switching losses in the amplifier. The length of each pulse is varied according to the envelope signal while the phase information is contained in the position of the pulses within the carrier period. We present here the design of a bandpass pulse length modulator circuit, capable of operating at microwave carrier frequencies above 3GHz. Measurement results for a QPSK-test signal show minimum error vector magnitudes of about 1.4 %. The modulator was manufactured in a 250nm SiGe:C-BiCMOS technology at IHP GmbH, Frankfurt (Oder), Germany. [C357]

### "Analysis of helical systems containing periodical inhomogeneities"

Properties of helical systems containing periodical inhomogeneities are considered. The multiconductor line method is applied for modeling of the systems and calculations of retardation factor and input impedance. ABCD matrices are used to reveal rejection properties of lines containing periodical inhomogeneities. The method based on multiple reflection diagrams is used to determine transient responses. Possibilities to improve characteristics of helical systems containing periodical inhomogeneities are discovered. [C358]

### "Measurement of thickness and electrophysical parameters of nanometer films by means of optical and microwave methods"

The possibility to determine the thickness and electrophysical parameters of thin nanometer dielectric and metal films in sandwich-like structures using the results of measurement of reflection and transmission spectra in microwave and optical band has been shown. The results of measurement of refractive index of SnO<sub>2</sub> in the thicknesses range from 40 nm to 2.8 mkm and the results of measurement of conductivity of Cr-films applied to ceramic substrates are presented. [C359]

### "Millimeter waves controlled elements on the basis of disk dielectric resonators"

The results of experimental study of spectral, power and field characteristics of single, half-disk, spiral resonators and also coupled disk dielectric resonators (DDR) with whispering gallery modes (WGM) in millimeter wave band by means of the computerized measuring stand are presented. The possibility of design of controlled EHF elements on the basis of coupled DDRs for the probable application in terahertz and optical frequency ranges is discussed. [C360]

### "Measurement of antenna characteristics by near-and far-field techniques within time domain"

The conventional method developed over a long period in the antenna measurement technique is application of monochrome measuring signals. Measurements performed with the use of monochrome signals are named frequency-domain measurements. [C361]

### "Synthesis of microstrip multiconductor lines, operating in normal mode"

Microstrip multiconductor lines (MMCL) are broadly used in microwave areas as transmission lines, or as physical models for developing various devices: couplers, filters etc. In general case, separate waves propagate along every conductor, and interference takes place in N-conductor MMCL. Transmitted signals are not distorted if structure of propagating wave remains unchanged, i.e. normal mode wave propagates; therefore it is necessary to restrict wave propagation to normal mode in MMCL, in order to minimize signal distortion. Synthesis technique of four-conductor symmetrically coupled MMCL, operating in normal mode, is presented in this article. [C362]

### "Wavelet packet based de-noising algorithm for UWB GPR data"

For subsurface detection by UWB GPR, one of the big challenge is to eliminate background clutters. In this

paper, a wavelet packet based de-noising algorithm driven by best-tree for UWB GPR data is developed. We introduce the procedure of the de-noising algorithm, and present the experiment result of iron pipe B-scan de-noising. Later, provide the suggestion for future work. [C363]

#### "Session C5: Millimeter technology"

{no data available} [C364]

#### "Cost-effective millimeter wave-to-optical conversion with patch antenna and MMIC chipset for RoF's uplink"

A cost-effective circuitry for the RoF's base station uplink channel including millimeter-wave microstrip antenna, down-converting MMIC chipset and low-cost Fabri-Perot laser diode is proposed and simulated in detail. [C365]

#### "UWB CPW-fed monopole antenna with a band-notch function"

In this paper a CPW-fed monopole antenna with a size of (24 Ч 24 Ч 1.6 mm<sup>3</sup>) and a staircase feed line is presented. The antenna is designed for operation across the entire UWB from 3.1 to 10.6 GHz with band-notch in 5-6 GHz, by inserting a H-shape slot on the proposed CPW feeder. By changing in width and length of H-shape slot, the operation on notch-band becomes different. The proposed antenna has a reflection coefficient below -10 dB through the band frequency and reasonable gain values over the same frequency band. [C366]

#### "On the issue of the construction of wideband measuring antennae 0, 85 to 37, 5 Ghz"

Analysis of parameters of different types of measuring antennae has been conducted, the reasonability and possibility of the realization of a number of superwideband horn-lens antennae with coaxial input has been done. Presented are the results of the designing of the horn-lens antennae within the range f 0.85 to 37.5 GHz. The range is overlapped by three models of antennae: -П6-23М for 0, 85 to 17.44 GHz; -П6-65 of 2.0 to 25.95 GHz; -П6-66 of 12.05 to 37.5 GHz. Measuring antennae parameters ensure the realization of a big number of requirements of different modern devices with which these antennae work (spectrum analyzers, receivers, signal monitoring systems, etc) The wide range of frequencies, high performance and the possibility of operation under severe climatic conditions (from minus 50°C to plus 60°C) make the these antennae one of the best devices of their class. [C367]

#### "Estimation of capacity bounds of free space optical channels under strong turbulence conditions"

The last few years, the free space optical communication systems attracting research and commercial interest due to their capability of transferring data, over short distances, with high rate and security, with low cost demands and without licensing fees. The main disadvantage of these systems is that their performance depends strongly on the atmospheric conditions in the link's area. In this work, we investigate the influence of the turbulence on both the average and the outage capacity of such a system for strong turbulence channels modeled by the K-distribution. We present a novel closed-form expression for the estimation of outage capacity of the channel and we determine the practical bounds of wireless optical channels' capacity. [C368]

#### "Testing of telecom and datacom signals with a wide-bandwidth sampling oscilloscopes"

The article will discuss main procedures and best practices for testing a wide-bandwidth signals by using USB sampling oscilloscopes. The article reviews the performance parameters that are used to specify the quality of the signals and networks, and examines how they can be effectively tested and assessed. All tests for both electrical and optical signals are made with the PicoScope 9200 USB sampling oscilloscopes. [C369]

#### "Pattern matching localization in ZigBee wireless sensor networks"

This paper focuses on the results of localization based on ZigBee wireless network. Different methods of localization are discussed, and pattern matching method is selected for tests. It presents the way to adapt ZigBee network to work with localization algorithm. [C370]

#### "An optimal scheduling algorithm in spatial TDMA mobile ad hoc network"

Spatial TDMA (STDMA) is a "conflict-free" MAC protocol so that concurrent communication among the connected nodes. Therefore it can enable high spectral utilization, if optimal scheduling algorithm is achieved. As directional antenna technology developed, point to point transmission to other node could generate higher data transmission rate at the same time, lower interference with other nodes than omnidirectional antenna. Therefore

an optimal scheduling algorithm needs to design to allocate the right slot to the right node in order to achieve high efficiency spatial reuse. To achieve this aim, we propose a new optimal scheduling algorithm: Max Spatial Reuse Scheduling Algorithm (MARSA). By using of directional antenna, it allows 1-hop distance neighbor node communication with other node in same slot unless one node connect to two node. Thus this concurrent scheduling algorithm allows more node communication with other nodes in one slot. Our method based on communication graph can be achieved with low complexity. [C371]

#### **"Towards establishing traceable coaxial Type-N scattering-parameter measurements at NIT"**

We present results of our work aimed at establishing traceable coaxial type-N vector-network-analyzer scattering-parameter measurements at the National Institute of Telecommunications, Poland. To this end, we employed a set of high-grade coaxial air-dielectric transmission lines as the primary calibration standards and a calibration procedure based on the multilane through-reflect-line method. In order to verify our procedure, we compared it with the calibration procedure implemented in the vector-network-analyzer and based on an electronic calibrator. Preliminary experimental results show very good agreement between the two procedures. [C372]

#### **"High power S band T/R module"**

The paper describes S-band T/R Modules designed for use in an Active Phased Array. Brief principles of its operation are described and electrical and mechanical information are presented. Main parameters of T/R Modules are shown in the form of characteristics. Results of measurements in wide range of the ambient temperature are presented as well. Basing on the obtained results, conditions of Transmit Modules operation are defined. [C373]

#### **"Adaptive potential of spatial transmission processing techniques"**

In this paper we evaluate the adaptive potential of multi-antenna transmission systems employing precoded spacetime block codes. Based on the transmit parameters that are intended to be efficiently use, the most appropriate precoded transmission is evaluated. Several performance criteria were considered: bit error rate, capacity, spectral efficiency and link throughput. [C374]

#### **"Determination of radio refractivity using meteorological data"**

Seasonal and daily variations of radio refractivity have been analyzed in the localities of Lithuania. The method proposed in the Recommendation of International Telecommunication Union (ITU) has been used. The local meteorological data have been used in calculation of radio refractivity. The values of radio refractivity have been determined in Vilnius, Kaunas, Klaipėda, and Mažeikiai. The meteorological data collected in February, April, July and October have been used. The highest values of the radio refractivity have been observed in Klaipėda in the year 2009. In July 2009, the values of the radio refractivity were highest in all localities investigated here and over all the time of the day. [C375]

#### **"Reduced complexity schemes to greedy power allocation for multicarrier systems"**

Discrete bit loading for multicarrier systems based on the greedy power allocation (GPA) algorithm is considered in this paper. A new suboptimal scheme that independently performs GPA on groups of subcarriers and therefore can significantly reduce complexity compared to the standard GPA is proposed. These groups are formed in an initial step of a uniform power allocation (UPA) algorithm. In order to more efficiently allocate the available transmit power, two power re-distribution algorithms are further introduced by including a transfer of residual power between groups. Simulation results show that the two proposed algorithms can achieve near optimal performance in two separate and distinctive SNR regions. We demonstrate by analysis how these methods can greatly simplify the computational complexity of the GPA algorithm. [C376]

#### **"Electromagnetic study of planar pre-fractal structures using the scale changing technique"**

In this paper, the scale-changing method is used to compute the surface impedance of pre-fractal structures characterized by the coexistence of metallic patterns at multiple scale levels. The multi-scale nature of these structures is used to split them into sub-structures enclosed by appropriate boundaries. The calculation starts from the elementary substructure:  $N$  active modes excite the considered sub-structure in order to compute the corresponding surface impedance matrix useful for the transition from a scale toward another. The choice of active modes is important in order to ensure the coupling between two consecutive scales and to have a correct description of the electromagnetic state within discontinuities. Consequently, the local modal basis is divided into two parts: -Higher-order modes: localized modes essentially useful for the local electromagnetic description within

discontinuities. -Lower-order modes or active modes: travelling modes useful for the coupling between sub-structures. When localized modes are used as active, we show that the electromagnetic description within discontinuities is not correct. The surface impedance obtained by the multi-scale method is compared to the surface impedance computed by the MoM method. The error variation with the number of active modes is presented. It converges with an error less than 0.3% when a sufficient Number of active modes are used. [C377]

#### "Variable microwave time delay by utilizing optical approaches"

A new method is presented for establishing variable microwave time delay utilizing optical approaches. In many applications there is a need for a significant time delay which cannot be established by microwave methods. The optical fiber can offer a substantial time delay which can be utilized by converting the microwave signal into the optical domain and after the proper delay it is converted back to microwave. By choosing the fiber length the necessary microwave delay can be adjusted. The main contribution is the variation of the delay. That is achieved by applying a dispersive fiber and a tunable laser. When the laser wavelength is changed the delay is varied due to the fiber dispersion. That new approach is very advantageous for beam steering of phased array antennas. [C378]

#### "Using space time coding MIMO system for software-defined radio to improve BER"

The demand for mobile communication systems with global coverage, interfacing with various standards and protocols, high data rates and improved link quality for a variety of applications has dramatically increased in recent years. The Software-Defined Radio (SDR) is the recent proposal to achieve these. In SDR, new concepts and methods, which can optimally exploit the limited resources, are necessary. Multiple antenna system is one of those, which resort to transmit strategies, referred to as Space-Time Codes (STCs). It gives high quality error performance by incorporating spatial and temporal redundancy. The paper discusses the space-time block codes and highlights the trade-off between the number of transmitter and receiver antennas and the bit error rate. We simulate MIMO systems using M-ary Phase Shift Keying (PSK) and compare the results with Single Input Single Output (SISO) systems. This analysis can be helpful in choosing the desired modulation scheme depending upon the Bit error rate (BER) and Signal to noise ratio (SNR) requirements of the service. [C379]

#### "EXIT chart analysis of iteratively detected and SVD-assisted broadband MIMO-BICM schemes"

In this contribution the number of activated MIMO layers and the number of bits per symbol are jointly optimized under the constraint of a given fixed data throughput and integrity. In general, non-frequency selective MIMO links have attracted a lot of research and have reached a state of maturity. By contrast, frequency selective MIMO links require substantial further research, where spatio-temporal vector coding (STVC) introduced by Raleigh seems to be an appropriate candidate for broadband transmission channels. In analogy to bit-interleaved coded irregular modulation, a broadband MIMO-BICM scheme is introduced, where different signal constellations and mappings are used within a single codeword. Extrinsic Information Transfer (EXIT) charts are used for analyzing and optimizing the convergence behaviour of the iterative demapping and decoding. Our results show that in order to achieve the best bit-error rate, not necessarily all MIMO layers have to be activated. [C380]

#### "PER-based analysis of a mobile WiMAX system"

Among the 4G technologies that managed to impose is the IEEE 802.16e Mobile WiMAX technology. Mobile WiMAX promises to deliver high data rates over wide areas and at vehicular speeds of up to 120 km/h. The performance of such a system is greatly influenced by the type of application desired to be supported, either TCP-based (FTP, web browsing) or UDP-based (video streaming). The current paper proposes to analyze and compare the performance of a fully compliant Mobile WiMAX system operating at 2.3 GHz in a vehicular multipath fading channel (ITU M.1225 Veh.A). The results are generated on a link speed basis and are expressed in terms of the adaptive modulation and coding (AMC) switching points as well as the maximum achievable throughput and operating range. Different physical packet error rate (PER) requirements are considered, based on the quality of service (QoS) level imposed. [C381]

#### "Reference signal extraction for GSM passive coherent location"

This paper investigates two equalization methods enabling the passive coherent location (PCL) system using GSM as illuminator of opportunity to eliminate the distortion of the reference signal. The first one is the Constant Modulus Algorithm (CMA) based on a blind method. The second one using the Viterbi Algorithm to decode the transmitted bits and to regenerate the reference signal. [C382]

#### "Decoding and reconstruction of reference DVB-T signal in passive radar systems"

The paper presents a method for reception, decoding and reconstruction of DVB-T signal for the purpose of using it in passive coherent location (PCL) as a reference. The signal is received using universal COTS components not dedicated for DVB-T, contrary to common television receivers. The proposed algorithm is tested on real-life signals. [C383]

#### **"Impact of synchronization on the ambiguity function shape for PBR based on DVB-T signals"**

In this paper the use of Digital Video Broadcasting Terrestrial (DVB-T) signals is addressed for Passive Bistatic Radar (PBR). The impact of the synchronization accuracy is analyzed on the PBR Ambiguity Function (AF) shape in term of Peak to Side Lobe Ratio (PSLR), there including timing synchronization, frequency offset synchronization and frequency sampling offset synchronization. Different approaches proposed in the past are considered for the removal of the side peaks of the AF of DVB-T-based PBR. Their performance in the presence of synchronization errors are evaluated both by simulation and against a real data set collected by a PBR prototype developed and fielded at the INFOCOM Dept. of the University of Rome "La Sapienza". [C384]

#### **"SETHI flying lab: A tool for remote sensing applications"**

This paper presents the new-generation test bench SETHI, developed by ONERA, the French Aerospace Lab. SETHI is a medium range platform dedicated to environmental, scientific and security applications. This paper presents the system architecture, the development state and the future capabilities planned. Before concluding, this paper displays a set of recent significant results covering three major applications: high spatial resolution image, change detection between two acquisitions, bio mass measurement in the tropical forest. [C385]

#### **"A software defined UMTS passive radar demonstrator"**

Passive radar systems, also referred to as Passive Coherent Location systems (PCL), exploit non-cooperative illuminators of opportunity (IO) in order to detect and track targets. Some of the main advantages of such systems with respect to conventional radars include low cost architectures, low energy requirements, the capability of operating without any spectrum resource allocation and a potentially null probability of intercept. In this paper, we introduce a passive radar demonstrator based on the use of UMTS (Universal Mobile Telecommunications System) signals as a source of opportunity. An overview of the UMTS standard and some preliminary measurements are firstly presented in order to verify the suitability of the UMTS waveform for radar applications. Secondly, a low cost software defined experimental radar system is introduced together with a measurement scenario. Finally, some live data detection results are presented and discussed in order to demonstrate the capability of this passive radar system. [C386]

#### **"Signal reconstruction as an effective means of detecting targets in a DAB-based PBR"**

This paper aims to validate the method of target detection by correlating a surveillance (target) signal with a reconstructed reference signal in DAB-based Passive Bistatic Radar (PBR). Whereas most conventional PBRs condition the surveillance signal by suppressing Direct Signal Interference (DSI) and then correlate this with a similarly measured reference signal to reveal targets, the approach adopted at FHR is to correlate the surveillance signal with a perfectly reconstructed, error-free, copy to the transmitted signal. [C387]

#### **"Fusion of SAR and optical images as a method for improving target recognition on the earth surface"**

The paper presents the real-life data results of SAR and optical images data fusion. The fusion has been carried out for SAR images obtained in classical SAR, multilook SAR and multilook color mapping SAR modes. The aim of the presented images fusion was to enhance the target recognition capabilities on the Earth surface for a simple single-channel SAR receiver. [C388]

#### **"Extending range coverage with GSM passive localization by sensor fusion"**

Among the available illuminators for passive localization GSM base stations enjoy the advantage of global availability and frequency diversity. However, the low transmit power limits the achievable range. This paper studies the possibilities of range coverage extension by fusion of bistatic systems with multiple transmitters. [C389]

#### **"Deghosting in passive air surveillance systems"**

Digital Audio/Video Broadcasting (DAB/DVB-T) is already available in a large area of Europe. The advantage of using these signals for passive air surveillance is the disposability of a large range of illuminators sending an

easily decodeable digital broadcast signal. In the considered multi-static scenario, one observer provides bistatic Time Difference of Arrival (TDoA), Doppler and (with limited quality) also azimuth measurements. The main task of target tracking is to handle ghosts that arise due to problems of association between illuminators, targets and measurements. To prevent enumeration and maintaining of all association possibilities, a decision criteria needs to be found to discriminate ghosts quickly and efficiently. In this paper we try to give a general understanding of the characteristics of ghosts; we derive two different Deghosting criteria and compare their performance with respect to Monte-Carlo simulations. [C390]

### "FM based passive bistatic radar target range improvement-Part II"

The bistatic radar has been revitalized over the last few years through the rapid development of the passive bistatic radar technology. Passive bistatic radar systems have unique properties, especially is time on target high compared to traditional radar systems, as well as the freedom in choosing from the available transmitters of opportunity. This paper will focus on how to take advantage of the latter of these two special properties in order to achieve better range resolution. [C391]

### "High performance reflector-based Synthetic Aperture Radar: -A system performance analysis -"

The success of current spaceborne Synthetic Aperture Radar (SAR) is boosting the performance requirement of next generation systems. In order to cope with the evolution of SAR the design of the new systems will need to meet higher requirements for spacial and radiometric resolutions together with an increased availability. This tendency is recognized nearly independently of the application area and manifests itself through several study programs initiated by space agencies aiming at the design of future SAR systems. In this context the use of large reflectors combined with digital feed arrays for SAR has not always received adequate attention. This paper suggests an X-band spaceborne SAR system utilizing a deployable reflector together with a digital feed array, analyzes its performance and highlights its advantages compared to other systems based on direct radiating arrays. [C392]

### "Nonuniform spatial sampling in a noise SAR"

The paper presents an idea of nonuniform spatial sampling applied to a noise synthetic aperture radar. Lowering number of spatial (along-track) domain samples taken in a SAR radar may lead to spatial aliasing and incorrect reconstruction of the image. Nonuniform sampling allows to reduce the aliasing effect and reconstruct the image better. This technique may be useful when the overall number of samples or the spatial sampling frequency is limited by external constraints. The idea will be verified with an experimental noise SAR built at ISE PW. [C393]

### "Principles of the electromagnetic modelling of som microwave components, based on the circular waveguides with azimuthally magnetized ferrite"

The principles of electrodynamic analysis of the characteristics of the ferrite control components (nonreciprocal digital phase shifters, cut-off switches and isolators) which use circular waveguides, entirely filled with azimuthally magnetized ferrite or containing a coaxial disc- or ring-shaped area of the medium alluded to and a dielectric one, surrounding it or taking up its hollow, resp., and work in the normal TE<sub>01</sub> mode, are enunciated: i) employment of complex confluent hypergeometric and eventually also of real cylindrical functions; ii) indispensability of inventing of numerical methods for evaluation of some special functions of the mathematical physics: the Euler gamma function, its logarithmic derivative and the confluent functions in the complex field, as well as of the cylindrical ones in the real domain; iii) elaboration of techniques for numerical solution of complicated transcendental equations, involving complex confluent and possibly real cylindrical functions, too; iv) introduction of a new class of real numbers, called L numbers, connected with the purely imaginary roots of the equations mentioned; v) development of numerical schemes for computation of the phase curves of geometries regarded and of iterative procedures for finding the differential phase shift provided by them; vi) laying down of criteria for the operation of configurations as phase shifters, magnetically controlled cut-off switches and isolators. Each of the maxims pointed out is elucidated in detail. [C394]

### "Range Doppler SAR processing using the Fractional Fourier Transform"

The Fractional Fourier transform (FrFT), which is a generalized form of the well-known Fourier transform, has opened up the possibility of a new range of potentially promising and useful applications including radar involving the use and detection of chirp signals, pattern recognition and Synthetic Aperture Radar (SAR) image processing. In this paper the Fractional Fourier transform is applied to the Range Doppler Algorithm in order to obtain a better result in terms of resolution. The proposed technique takes advantage from the property of the FrFT to resolve with high precision chirp signals. Preliminary results are encouraging and confirms that the FrFT can be useful to perform high resolution SAR processing. [C395]

### "Fusion of data received FM-CW radar and AIS-analysis of functionality: Topic 3. Radar application"

Development of Frequency Modulated Continuous Wave (FM-CW) radars and universal shipborne Automatic Identification System (AIS) creates new questions in practical application of these technologies for purposes of ships traffic monitoring and control. Accuracy of FM-CW radar distance measurement, not achievable for pulse radars, causes questions of correctness of charted data presented by ECDIS and information about ship's position transmitted by AIS. Paper presents some questions connected with comparison of electronic chart data and FM-CW measurement accuracies and fusion of data received from AIS and radar tracking system. Described researches were conducted in the scope of research work financed by the Polish Ministry of Science and Higher Education as developmental project from the means for science in 2008-2010 years. [C396]

### "Short-range Ku-band hybrid-mode CW-LFM radar"

Short-range CW-LFM radar design is discussed. Hybrid mode operation consisting of pure CW and CW-LFM periods is implemented. Such algorithm allows sufficiently simplify the processing and reduce the false alarm probability. [C401]

### "Copyright page"

{no data available} [C402]

### "On the resolution performance of passive radar using DVB-T illuminations"

DVB-T signals used as illumination for passive radar offer advantageous radar signal processing properties and promise sufficiently high range resolution. Passive DVB-T radar performance assessment is based on a signal processing model including reference signal reconstruction, the influence of bit-error rates on range performance and the application of error corrections. A verification of the estimated range resolution performance is attempted using the experimental passive radar system PETRA of FHR to discriminate small civilian aircraft in close flight under realistic measurement conditions. The results encourage utilising DVB-T signals as trend-setting non-cooperative illuminations in future passive radar systems, not only in central Europe. [C403]

### "Correction of radiometric errors by multi-look processing with extended number of looks"

The application of the clutter-lock technique in case of fast and significant instabilities of the antenna orientation leads to strong geometric distortions in SAR images. In the paper we propose a radiometric correction approach which could be used with SAR processing algorithms without clutter-lock. The technique has been tested by using a Ku-band airborne SAR system, installed on a light-weight aircraft. [C404]

### "Multi-look stripmap SAR processing with built-in geometric correction"

Small airborne SAR systems suffer from trajectory deviations and instabilities of antenna orientation. These kinds of motion errors lead to significant geometric distortions in SAR images. In the paper, we describe a time-domain multi-look stripmap SAR processing algorithm with built-in geometric correction. In the algorithm, the azimuth reference functions and range migration curves are designed to produce SAR images directly on a correct rectangular grid on the ground plane. The proposed technique has been successfully tested by using a Ku-band airborne SAR system, installed on a light-weight aircraft. [C405]

### "New challenges for PCL system: 3D requirements and "Optimal" resources management for PCL air traffic survey"

For more than 15 years, the interest for PCL (Passive Coherent Location) system has been growing. It began with the analog waveforms like TV [1] and FM [2, 3], nevertheless it quickly appears that the recent digital waveforms (using COFDM modulation) could offer new interesting capabilities especially for range resolution. Despite the interesting recent progress related to these digital waveforms like the compulsory development of a specific zero-Doppler path cancellation filter [2, 4] especially for SFN mode, some new additional requirements mentioned by several potential users [5, 6] of such PCL system have appeared: • Such PCL systems are generally considered as complementary sensors for low altitude coverage. As a consequence, these systems should provide an altitude estimation and especially for these low altitude targets. • On other hand, it is also important to manage and chose the most suitable donors in a given area in order to "optimise" the system definition according to our objectives. This paper will illustrate some experimental results for site estimation using DVB-T transmitters in SFN mode. The signals are received on a 2D array. Then a brief comparison of the mutual and specific benefits expected for the main civilian broadcasters (FM, DAB, DVB-T) will be provided.

[C406]

### "Exploiting polarimetric diversity to mitigate the effect of interferences in FM-based passive radar"

In this paper the effect of interfering sources is characterized on the performance of a passive bistatic radar exploiting a FM radio broadcast transmitter. The signals emitted on same/adjacent frequency channels by other potential transmitters located in the surveillance area are shown to significantly affect the performance of the considered system in terms of both disturbance cancellation and target detection capability. To mitigate the effect of such interferences, the exploitation of different polarizations is considered for the surveillance antenna. A preliminary approach is proposed to jointly exploit the diversity of information conveyed by different polarizations. The results are shown against a real data set collected by an experimental multi-channel passive radar prototype developed and fielded at the Infocom Dept. of the University of Rome "La Sapienza" (Italy).

[C407]

### "Multiband experimental PCL system: Concept and measurement results"

Over recent years, interest in passive radar systems using non-cooperative analogue and digital broadcast transmitters as illuminators has been growing significantly. They are being considered as possible future stand-alone systems or as gap fillers for existing air surveillance systems [1]. Recently passive radar is also discussed for the deployment in border surveillance as well as for detection of land and sea targets. The technical maturity and detection performance of experimental and prototype system implementations has been steadily improving. Starting from early FM-broadcast-based systems, the evolution to DAB-based and DVB-T-based digital systems is currently ongoing. In this paper, a multiband experimental passive radar system exploiting FM, DAB and DVB-T transmitters is presented. The hybrid system concept is described and the results of various measurements with different types of aerial and sea targets are shown.

[C408]

### "Mutual coupling compensation applied to a uniform circular array"

In this paper, two approaches for compensation of mutual coupling and phase shifts in a passive radar system based on a circular array are compared. The first method is based on the measurement of the antenna scattering parameters and of further relative phase and amplitude variations between the channels introduced by the receiver analog front-end and by the analog-to-digital converter. The second method derives a total coupling matrix, which contains both the antenna and the front-end contributions, by measuring the signals transmitted from known positions. The two procedures have been applied to an FM-based passive radar that uses an 8-element circular array. It appears that for the considered geometry the antenna mutual coupling does not significantly affect the radiation pattern, while the major contribution is due to phase shifts introduced by the receiver front-end.

[C409]

### "Cargo ship RCS estimation based on HF radar measurements"

High-Frequency (HF) radars are operated in the 3-30 MHz frequency band. For oceanographic applications low transmit power HF radar systems have been developed, which use surface electromagnetic wave propagation along the salty ocean surface. The WERA HF radar system transmits a power of 30 Watts but achieves detection ranges up to 200 km. Hence the radar system can be used for many applications in coastal monitoring. The measured radar data were analyzed together with simultaneously available Automatic Identification System (AIS) information, which shows current ship position, speed, course and type. This paper presents the target reflectivity measurements as signal-to-noise ratio (SNR) to estimate the radar cross section (RCS) of cargo ships.

[C410]

### **"Reflector-based digital beam-forming radar system for space debris detection"**

The paper considers a novel radar system concept for space debris detection based on a reflector antenna and utilizing digital beam-forming techniques. The main operational principles of the system are discussed. First, a classical radar system and its performance aspects are considered. Then in terms of the considered aspects, the performance enhancements of the novel digital beam-forming radar are demonstrated. [C411]

### **"A subspace-based technique for joint DOA-DOD estimation in bistatic MIMO radar"**

In this paper, we propose a new subspace-based approach for joint DOA-DOD estimation in the bistatic MIMO radar. This method use a polynomial root findings for determining jointly the DOA-DOD directions. This algorithm allows an efficient estimation of the target DOA and DOD with automatic pairing. The simulation results of the proposed algorithms are presented and the performances are investigated and discussed. [C412]

### **"Analysis of ATR features for non-cooperative ground-based classification of ships"**

Measurements were taken at 17 GHz of a ship that was first approaching the coast-based radar and then followed a circular course between 6km and 7km distance. It is demonstrated how the high range resolution profile of the ship and consequently any ATR (automatic target recognition) classification features derived therefrom are modified by multipath as a function of range and aspect angle. For comparison, the TERPEM software is used to simulate the effect and analyse it in a more controlled way. [C413]

### **"Technological challenges of a multifunction active phased array radar for weather, air traffic control and security applications"**

By means of Active Phased Array techniques, an integrated target/weather surveillance at medium range, i.e. for Terminal Manoeuvre Area in the frame of ATC and regional weather monitoring, is possible and affordable provided that cost reduction for Transmit/Receive modules makes phased array radar affordable to civilian users. The MPAR (Multifunction Phased Array Radar) architecture allows a single equipment to satisfy different requirements for Air Traffic Control, Weather monitoring and analysis, and Security applications. The key techniques needed to achieve the required performance are (a) interleaving of functions by careful scheduling, (b) digital beam forming for target surveillance and (c) fast (electronic) scanning for the weather surveillance. The core technologies are of course those needed to implement at low cost the Transmit/Receive module (TRM), that in the proposed architecture may transmit a low peak power (order of one Watt), compatible with the low-cost requirement. [C414]

### **"Solid state C band radar for detection of hovering helicopter"**

A technical data and a project of the structure the radar detected hovering helicopters is shown in the paper. The results of research simulation and range tests of prototype are presented also. They indicate that this solution of radar was properly chosen. [C415]

### **"Energy allocation for correlated MIMO radar antennas with ricean targets"**

MIMO (multiple-input multiple-output) radar systems with widely separated transmitters and receivers have capacity to considerably improve the performance of radar systems. This is accomplished by utilizing the notion of spatial diversity as receivers can observe incoming echos originating off various aspect angles. This work attempts to alleviate the performance of MIMO systems in the existence of correlation and Ricean scattering models by proposing a power allocation scheme. The scheme adjusts weights at the antennas proportionally by taking account of any correlation and line-of-sight information present at the transmitters. Antennas who are correlated or perceive low line-of-sight reflectivity are allocated less power so that the total available energy is spread across diversity branches and strong reflectors more accordingly. Simulations are used to validate the results. [C416]

### **"An investigation of signal synthesis for radar applications"**

A method of signal synthesis is presented. After theoretical introduction an algorithm of frequency modulated (FM) signal synthesis is presented. Simulation results made in Matlab are presented in the last chapter. [C417]

### **"Classification of air targets including a rejection stage for unknown targets"**

In this paper an algorithm for Non-Cooperative Target Identification (NCTI) of airplanes is presented. The

advantage of NCTI over Identification Friend-Foe-systems (IFF-systems) is its ability to identify positively not only friendly airplanes but also neutral or hostiles ones. The approach described here uses one-dimensional radar images, so-called High Range Resolution profiles (HRR-profiles) for NCTI. However only the locations of the local maxima of the HRR-profiles were used for classification instead of using the whole HRR-profiles. Furthermore a statistical test procedure is presented that is carried out prior to the classification procedure to determine if an airplane belongs to a known or to an unknown class of airplanes without distinguishing the known classes of airplanes. [C418]

#### "Optimal sampling rate for short chirp signals"

Short broadband signals with the use of linear modulation of frequency LMF (so-called chirp signals) are widely used in locations. The aim of this paper is to study an influence of a sampling rate on single LMF signals with  $BT < 100$  compression when initial phases and shapes of the signal and IR amplitude spectra are optimized at using nonlinear operations on convolutions in the time domain. [C419]

#### "Multipath exploitation in an urban environment using a MIMO surveillance radar"

Surveillance in an urban environment under all atmospheric conditions and situations can be performed by means of radars. The multipath created by buildings and moving targets can be exploited, for example in order to increase SNR. In this paper we present the initial results of the measurements of a moving target in a roadblock scenario in non line of sight (NLOS). The results suggest that MIMO systems are suitable for urban environment surveillance. [C420]

#### "A MIMO radar for Sense and Avoid function: A fully static solution for UAV"

Up to now, UAV are employed in crisis or war times. For training purposes, some areas are especially attributed for UAV deployment in a limited space area and in a limited time slot. In the future, both for emerging civilian applications and for training purpose, these limitations will no longer be acceptable and UAV will have to be inserted in the general air traffic. Thus, "Sense and Avoid" systems will be mandatory. The radar is the most pertinent non-cooperative "all-weather" sensor because it provides, by essence, accurate ranging, direction and closing speed. In this paper, we propose a low cost radar solution based on the coherent "MIMO" principles. This design allows the implementation of the radar within the UAV airframe without any moving part. [C421]

#### "Moving target estimation using distributed MIMO radar in non-homogeneous clutter"

In this paper, we consider parameter estimation for moving target detection using a distributed MIMO radar, where the multi-static transmit-receive configuration causes non-homogeneous clutter. Specifically, the clutter power for the same resolution cell may vary significantly from one transmit-receive pair to another, due to azimuth-selective backscattering. Moreover, the clutter power may also vary across resolution cells in the neighborhood of the test cell. In this work, the non-homogeneous clutter is modeled using a subspace approach, whereby the subspace is spanned by a few Fourier bases and the non-homogeneity of the clutter is captured by coefficients that vary with different transmit-receive pairs and/or different resolution cells. The choice of the Fourier bases is based the fact that the clutter Doppler spectrum is bandlimited. We develop a maximum likelihood (ML) estimator for the parameters associated with the target and clutter. The Cramer-Rao bound (CRB) for velocity estimation is also derived. Numerical results show that the proposed estimator outperforms an alternative solution that ignores the non-homogeneous nature of the clutter. [C422]

#### "Adaptive hough detector threshold analysis in presence of randomly arriving impulse interference"

In this paper a technique of Hough detector threshold procedure for moving target detection in conditions of randomly arriving impulse interference with Poisson distributed flow and Raleigh amplitude distribution is proposed. The expressions of detection and false alarm probability are derived for a highly fluctuating Swerling II target. A comparative analysis of the performance of a Hough detector with fixed threshold and other five Hough detection structures keeping constant false alarm rates is done. These are CA CFAR (Cell Averaging Constant False Alarm Rate), EXC CFAR (Excision Constant False Alarm Rate), CFAR BI (Constant False Alarm Rate with Binary Integration), EXC CFAR BI (Excision Constant False Alarm Rate with Binary Integration) and API CFAR (Adaptive censoring Post detection Integration Constant False Alarm Rate). A method for losses estimation, which allows choosing of optimal detector parameters, is developed. Obtained are estimates of the effectiveness of Hough detector in presence of randomly arriving impulse interference and they are compared to patterns researched from other authors. The achieved results can be successfully applied for radar target detection and in the existing communication network receivers that use pulse signals. [C423]

### "Pedestrian recognition based on 24 GHz radar sensors"

Some 24GHz radar signal features are introduced in this paper for a reliable recognition of pedestrians and vehicles in an arbitrary traffic situation. It examines in particular the Doppler spectrum and the range profile.

[C424]

### "Milestones in radar and the success story of automotive radar systems"

Radio Detection and Ranging (RADAR) is a world wide well-known technique since more than 100 years, which is originally based on the invention of the German engineer Christian Hulsmeier, who applied his patent at the Kaiserliche Patentamt in Berlin on April the 30th, 1904. He called his invention Telemobiloskop in a good tradition of using Latin terms for technical subjects. The radar story started with the theoretical work of James Clerk Maxwell, followed by Heinrich Hertz, born in Hamburg, who did all the experimental work to understand the nature of electromagnetic waves. Collision avoidance between ships was the first application for this new technique. Today we come back to the collision avoidance application however now between cars. This is just the beginning of the automotive radar systems success story. [C425]

### "Ultra-wideband sensing: The road to new radar applications"

Research on ultra-wideband topics started about 50 to 60 years ago driven by needs in radar and communication technology as well as to emulate EMPs of nuclear explosions. Meanwhile, ultra-wideband sensing opens new perspectives for radar applications. Small and cost effective devices, high resolution and sensitivity, as well as low exposition by radio waves will give this radar technology access to new applications in industry, non-destructive testing, medical engineering and health care, surveillance, search and rescue, and many others more. High peak power devices will be limited to special applications and a low number of devices due to their radio interference and mostly only military interest. Therefore, this paper only deals with some aspects of high-resolution short-range sensing giving new perspectives for a wider community. [C426]

### "Increasing vehicular safety at intersections by using LFMSK modulated radar sensors"

This paper deals with environment perception for automotive application especially in intersection-related scenarios. The recognition of relevant objects within intersection-related scenarios is performed not at least with high performance 24 GHz radar sensors. These sensors are dedicated to detect objects in the surroundings of the equipped demonstrator vehicle. The modulation of the transmit signal plays an important role for precise measurements. In this paper a linear frequency modulated shift keying (LFMSK) measurement principle is proposed. [C427]

### "Angular measurement with lens based automotive radar sensors"

77 GHz automotive radar sensors based on lens antennas have a high market penetration in the field of driver assistance systems due to their compact and cost effective concept. These kinds of sensors need not only a good field of view but also the possibility to measure angles. In this paper the parameters amplitude and phase in the focal region are discussed for a diffraction dominated system. Special attention is paid to phase differences between the received signals from antennas mounted in the focal region. [C428]

### "Development milestones in 24 GHz automotive radar systems"

Driving a car means a dangerous task! There are about 5000 fatalities on German streets every year, which are absolutely too many. Drivers have strong limitations in the ability to measure precisely the distance and the speed difference between cars, which is the reason for several accidents. Therefore some assistance is needed. There is large progress in waveform and system design as well as in MMIC chip development for 24 GHz radar sensor technology [4]. [C429]

### "Passive radar from history to future"

The history of passive radar dates back to the early days of radar in 1935 when the Daventry experiment was conducted in the UK. It continues in WW II with the German Klein Heidelberg passive radar and receives new interest today, as passive covert radar (PCR) systems like Silent Sentry and Homeland Alerter 100 are ready for operation. The future of PCR will strongly depend on the availability of transmitters of opportunity such as FM-radio and digital broadcast networks. [C430]

### "A dual-use system for radar and communication with complete complementary codes"

A dual-use architecture is proposed for both radar and communication. The proposed method uses complete

complementary codes for both radar and communication signals, whose outputs almost become zero sidelobe. In this paper, the principle of the proposed method and simulation results are described. [C431]

#### "MVDR radar signal processing approach for jamming suppression in satellite navigation receivers"

The Minimum Variance Distortionless Response (MVDR) technique, which is well-known in radar signal processing, will be applied in this paper for jamming suppression in a satellite navigation receiver. Two different beamforming schemes, conventional and MVDR are applied to a satellite navigation receiver for mitigation of strong jamming before acquisition of the C/A code. The effect of beamforming on the cross-correlation performance is evaluated in terms of two quality factors: the signal-to-interference-plus-noise ratio (SINR) improvement factor estimated at the beamformer output and the post correlation signal-to-noise ratio (SNR) which will be estimated at the cross-correlator output. The simulation results demonstrate that the more effective jamming protection and as a consequence the improved performance of the C/A code acquisition are achieved using the MVDR beamformer procedure compared to the conventional one. [C432]

#### "Stabilisation of false alarm in the signal detection tasks"

The task of the known form signal detection on background of non-correlated normal interference with unknown variance is considered. The invariant to shift and scale parameters algorithm based on order statistics is suggested. The analysis of quality characteristics of the algorithm has been carried out [C433]

#### "A history of oscilloscope development in Lithuania and neighbor countries"

This article describes a history of oscilloscope development in Lithuania and neighbor countries during fifty years. Oscilloscope, general-purpose oscilloscope, digital storage oscilloscope, "traveling wave" CRT, sampling oscilloscope, service oscilloscope, oscilloscope calibrator. [C434]

#### "Fifty years of noise radar"

The talk provides a historical account of noise radar from 1959 to 2009, describe notable results from world-wide R&D activities in noise radar, and predict possible developments over the next fifty years. [C435]

#### "Radar target detection and Doppler ambiguity resolution"

A Continuous Wave (CW) radar with a linear Frequency Modulation (FM) and a very short chirp duration is considered in this paper. A single target range and Doppler frequency measurement consists of a sequence of L chirp signals with the same chirp duration. The maximum unambiguously measurable radial velocity in this case is limited by a minimum chirp duration. Therefore fast moving targets will cause ambiguous measurement results, that have to be resolved. The technique of resolving ambiguities on the basis of several subsequent measurements with different ambiguity interval lengths is well known as Chinese Remainder Theorem (CRT). It has been extensively described in literature [2]. Two different signal processing approaches to apply this technique for the resolution of ambiguities are compared in this paper. These do not differ in terms of the ambiguity resolution itself, because they are based on the same principle. The detection performance however is different. [C436]

#### "Session 9b: Electronic warfare"

{no data available} [C437]

#### "Multifrequency radar images of electrodynamics objects located behind dielectric layer in millimeter wave range"

The problem of measurements of reflectivity of different structures situated behind a dielectric slab is rather general problem, which is induced by requirements of technological radar, non-destructive testing of industrial products, building materials, underground probing. The implementation of multifrequency method for measuring microwave reflectivity in the free space allowed testing various numbers of objects with the purpose of estimating their parameters such as width, length, the form and reflecting ability. The purpose of the paper is present some results for simple objects which located behind the radiotransparent barrier. [C438]

#### "GPR signal phase structure application for estimation of distribution of soil electrical properties on depth"

The mathematical algorithms for reconstruction of the soil layers electrical characteristics using the estimated

dependency of radio waves attenuation per unit length on frequency or similar dependency on phase velocity are described in [1, 2]. To perform this reconstruction we used a well known Kramer-Kronig equation, which is then lead to a nonlinear singular integral equation for the unknown functional dependence of the soil conductivity on the frequency. Then the equation is solved by a numerical iterative method, with evaluated dependencies of conductivity and permittivity on the frequency in a range of probing signal carrier frequency as a result. The main difficulty here is an attempt to assess the functional dependence of attenuation per unit length or the phase velocity on frequency. The first method uses filtering of signal that corresponds to specific soil layer on the output of georadar receiver phase detector. Then the frequency dependence of the phase velocity of radio waves in this layer is estimated using the displacement of the object image in depth when using low-frequency and high frequency parts of the probe signal spectrum. Both the first and second algorithms do not allow obtaining highly accurately estimated electrical characteristics, so it is impossible to estimate accurately the frequency dependence of attenuation per unit length or the phase velocity of radio waves propagation in the layers of the soil. [C439]

#### "Radar identification of clouds"

In the present paper the algorithm of meteorological objects recognition is studied on the base of autoregressive (AR) model of signals reflected from the output of incoherent pulse radar, the experimental; is carried out and analysis of meteorological objects correct recognition is performed using examples of highaltitude cumulus clouds, cumulonimbus clouds and "angel-echoes" in the form of Braggs reflections from inhomogeneities in surface layer of clear atmosphere. [C440]

#### "The longitudinal slot characteristics in waveguide with dielectric layer, situated parallel to its broad walls"

Waveguide slot arrays (WSA) are widely used in ground and onboard radar-tracking, radiorelay, radionavigating systems. There is a danger of occurrence interference maxima of the higher orders in WSA on a hollow waveguides. To avoid occurrence of these maxima, distances between radiators are reduced using different ways. One of them is the use of waveguides of the  $\Pi$ -shaped form, another one consists in reduction of a waveguide width. To pull together radiators within the limits of one linear array and to reduce distances between radiators in the neighboring linear arrays it is possible to use slowing down a wave in a waveguide by insertion a dielectric layer. The purpose of the present work is to research WSA characteristics at partial overlapping along z axis of regions of the neighboring slot arrangements when the slots are cut in a wide wall of the rectangular waveguide with dielectric layer located parallel to its broad walls. [C441]

#### "Time-domain simulation of trains of oscillation pulses in a Gunn diode system with a remote resonator"

We present self-consistent time-domain simulation of trains of short oscillation pulses in a time-delay transmission-line circuit of active devices with a remote resonator for emerging radar applications. Inherent instability and essential nonlinearity of active devices makes many simulation tools inadequate for rigorous modeling of active systems with complicated dynamics of generated fields. Conventional software (e.g., SPICE) cannot easily cope with active distributed systems where the wave propagation between devices is an important part of system operation. A promising approach is the hybrid method that combines both the frequency-domain and the time-domain computations, though it suffers from various limitations (narrow-band approximation etc). For these reasons, the design of active structures is usually split in two stages dealing with either linear or nonlinear parts of the system. In this method, the attention is focused on passive components whose design is carried out in much detail. As a compromise, some assumptions have to be met in this approach such as the operation in the narrow band or in a given set of a few narrow bands, etc. In our work, we develop an alternative approach and focus attention on the nonlinear part of problem, while the linear part is chosen to be relatively simple. In this approach, the aim is the accurate self-consistent modeling of nonlinear effects through rigorous solutions of governing equations and, specifically, accurate time-domain simulations of nonlinear oscillations and non-conventional dynamics (chaos, pulses) emerging in various conditions. In addition, nonlinear power combining is investigated in a self-consistent manner. [C442]

#### "Improvement of range resolution of FMCW autodyne radar"

The principals of range resolution improvement the self-mixing FMCW radar based on analysis of the spectrum of high-order harmonics of intermediate frequency is proposed. Developed the scheme and investigated the model of Ka-band surveillance self-mixing FMCW radar with digital control and spectral processing of receiving signal. Advantages of this radar are small size, low power consumption and use of scanning antenna. [C443]

### "Measurement of intensity of liquid precipitation using double frequency radar"

The rain intensity is very important characteristic of precipitation which is useful for many fields of people activity especially for such areas as agriculture and municipal services. That is why it is of big interest now to develop new approaches to measure precipitation intensity the most popular of which is radar methods permitted to obtain data distantly and promptly for large territories. Now it is known some radar approaches for measurement of rain precipitation. But the method grounded on measurement of radar reflectance  $Z$  mm6/m3 is the most widespread. It is based on use of dependence  $Z=x^y$ , where  $x$  and  $y$  some constants, depended on climatic, geographic conditions and mechanism of precipitation formation. The main disadvantage of such approach is absence of universal correlation between radar reflectance and rain intensity. Accordingly data of different authors [1,2] the values of parameter  $x$  can be varied from 50 to 2000,  $y$  from 1 to 2,87. Such variation of parameters  $x$  and  $y$  strongly influences on accuracy of intensity measurement. [C444]

### "Diagnostics of refraction coefficient on results of meteorological parameters measurement in arbitrary points of area"

It is known the operating efficiency of radio technical systems of different function (navigation, radar, communication), to a great extent depend on condition of propagation of radio-waves is conditioned on atmosphere refraction state. It for one's turn is conditioned on spatial-temporal distribution of refraction coefficient  $n$ . And variation of mean refraction and numerous cases of so called anomalous propagation of radio-waves could lead to considerable increasing of signal level over the horizon or signal fading in the radio optical line of distance and influence on accuracy of radar and navigation measurements. At present for location the systems of global navigation is in wide application. The completely deployed GPS system of USA exists today. Russia realizes intense work on unwrapping of complete constellation of GLONAS satellites. In the Europe the development of Galileo system is finishes. To the utmost the troposphere influences on results of coordinate measurements. Ignoring of this fact leads to error of measuring of pseudo-range from 2,5 m. (in zenith) to 25 m. (while satellite elevation about 5 degrees). The possible way to decreasing of location error is taking into account troposphere influence while processing of information in the Ukrainian system of cosmic navigation provision (USCNP) [1, 2]. There are two main modes of correction: real-time and post session. For real-time processing we propose to use the data of meteorological stations are in the set of controlling-correcting stations (CCS) USCNP. At that have to be provided accuracies of coordinates determination not worth of some meters. While post session processing corrections are forming on the base of phase observations by stations of USCNP net. The obtained errors of measurement are about some centimeters. Troposphere delays in the realtime the meteorological parameters are obtained in series of points of space are used for approximation. The meteorological parameters of functions approximating dependence of temperature, pressure and humidity on latitude and longitude in the range of Ukraine are forming and giving for users on the base of these delays. Besides the parameters of functions approximating dependence of zenith troposphere delay on latitude and longitude in the range of Ukraine are forming and giving for users. Both these approaches are on the base of troposphere delays calculation using data of meteorological stations to the sea level. Truncation error of estimation is about 2.5%. The analyses is carried out [2] and shows the order of approximating model practically not influences on error of troposphere delay measurement and so we conclude about possibility of usage of zero order model, i.e. the mean data for Ukraine. We seem the bases for such conclusion is small accuracies of measurement of meteorological parameters. [C445]

### "Adaptive phase synchronization in distributed digital arrays"

Self-synchronizing distributed arrays have been investigated for a number of sensor applications such as radar. This paper discusses several methods for phase synchronizing a distributed array so that coherent processing can be performed. One of the concepts involves transmission of a beacon that is used directly as the frequency reference. After a phase synchronization process is performed sequentially across the array, measured phase differences are obtained that can be used in the digital processing to compensate for hardware and propagation channel differences. The concept was demonstrated for a two element array using commercial hardware at 2.45 GHz. Leakage cancellation techniques were employed to achieve phase accuracies of approximately 20 degrees. [C446]

### "iBoard: A highly-capable, high-performance, reconfigurable FPGA-based building block for flight instrument digital electronics"

iBoard is a highly capable, highly reusable, and modular FPGA-based common building block for instrument digital electronics. It is targeted to those space-borne instruments that require high-performance on-board processing capabilities. The paper explains the design methodology, describes requirements of flight instrument digital electronics, presents implementation of the first prototype, iBoard 2. [C447]

### "Potentialities of the Doppler spectrum of backscattered microwave signal in the problem of remote sensing of the sea surface"

Information about sea waves and the near surface wind speed is very important for meteorology. It is well-known that this information, in principle, can be obtained from a backscattered microwave signal. Evidently, the sea state determines both spectral and power characteristics of backscattered microwave signal. However, usually only a radar cross section is used for retrieval of the near surface wind speed. Considering only a radar cross section we lose the important information about the movement of sea surface that can be used for retrieval of key sea state parameters. In this paper the new description of a sea state is suggested and basic features of the microwave Doppler spectrum are discussed. We consider some features of various sea states and analyze their manifestation in the Doppler spectrum. [C448]

### "Application of double frequency radar for measurement of parameters of solid polydisperse aerosols"

In this paper the possibilities of application for double frequency remote sensing of solid aerosols are considered in the case of polydisperse medium. Use of double frequency sounding permits to evaluate effective aerosols parameters with satisfactory accuracy for "narrow"  $\Delta r \leq 0.3$  and "wide"  $\Delta r \geq 4$  distribution law. The experiments with calibrated sand particles with "narrow" distribution law (as aerosols model) confirm the possibility of satisfactory evaluation of aerosol parameters. [C449]

### "Robust DFT-based signal processing in Micro-Doppler radars"

Micro-Doppler (mD) radar is an efficient tool for surveillance systems and they are rapidly developing now. One reason for this is the potential ability of mD radars to provide additional information (features) useful for recognition of objects extracted from short-time spectral or higher-order estimates. In particular, it is known that a signal reflected from a walking human represents a set of harmonics reflected by different parts of a human body. These harmonics have amplitudes and frequencies changing in time. Joint analysis of these frequencies and their evolution in time serve as aforementioned features that are to be retrieved. [C450]

### "Doppler radar method for gas-discharge plasma research"

The aim of the paper is development and describing of remote method for low-ionized plasma characteristics research by means of homodyne two frequency Doppler radar. Gas-discharge plasma sources such as so called noise oscillators (NO) in millimeter (mm) and centimeter (cm) range (ГПП-5, ГПП-10, ГПП-11) which are widely used in microwave radio equipment for mm and cm range receiving apparatus calibration and tuning have been objects of our research. [C451]

### "Kravchenko weight functions in problems of restoration radar images at the modified synthesizing aperture"

The modified algorithms of optimum space-time signal processing (STSP) in the synthetic-aperture radar (SAR) are synthesized. They provide improvement of significant are support significant rise above the radar images (RI) resolution in comparison with classical SAR. It is earlier shown, compression system ambiguity function (AmF) on range and an azimuth is accompanied by growth of AmF sidelobe which soften contrast RI area and deform the real form of the sounded objects. The simple solution of such problems can be received by application weight processing sounding signals and amplitude-phase distribution (APD) in the antenna array aperture. As weight functions (windows, distributions) of any classical functions (Hamming, Gaus, ...) can be use. In [3-4] weight windows on the basis atomic functions Kravchenko windows. In the work are developed influence of Kravchenko windows on quality of RI formation in SAR with modified algorithms STSP are researched. In work the algorithm modified STSP in SAR is synthesized. It provides possibility of formation RI with more higher resolution, than it is possible at use of classical algorithm. The kind modified AmF depends on relation  $\sigma^\circ(F) / N_0 = 20$  (at unlimited increase of this relation the kind of AF aspires to delta-function). Thus the sizes of pixel decreases, and generated RI is characterised by bigger resolution. On such image the speckle dispersion increases also it demands the further processing. Its can be made both at a stage primary, and at a stage of secondary processing. Influence of weight windows on quality of formation RI with use classical windows, and Kravchenko new weight functions is analysed. The expediency use weight functions of Kravchenko, in specifically, window  $[h_2(x, \Delta = 0,001)]^{0,5}$ , as  $V(t)$  and  $V(r)$  is proved. [C452]

### "Optimization of statistical processing radar-tracking signals with use Kravchenko'S weight windows"

In the report on the basis of a method the peak credibility algorithms optimum processing existential signals are synthesised. The attention is converted that in these algorithms naturally arises beamforming. Necessity of introduction weight windows for these algorithms is shown. It is proved expediency of carrying out joint optimisation processing existential signals on a method of the peak credibility and weight processing signals and peak-phase allocations a field in the antenna aperture. It is shown, that use weight windows of Kravchenko allows to provide the solution tasks in view with demanded exponents quality. [C453]

#### **"Aggregated convex regularization and variational analysis technique for enhancement of mm waveband remote sensing imagery"**

In this paper, the statistical Bayesian and descriptive regularization approaches for high resolution radar image formation is detailed in many works, where such approach is adapted to the sm and mm waveband remote sensing (RS) applications considered. [C454]

#### **"Fifty years of noise radar"**

The talk provides a historical account of noise radar from 1959 to 2009, describe notable results from world-wide R&D activities in noise radar, and predict possible developments over the next years. [C455]

#### **"Sources of intense impulse microwave emission"**

Impulse electromagnetic fields of large intensity in combination with ultra-short pulse (USP) duration are widely used for modification a property of materials, creation special types of radars and test facilities at studies of electromagnetic compatibility/strength (EMC/S). Long-term experience of NSC KIPT in the area of highpower impulse radiation sources used for tests of radioand electronic equipment and components to impact of USP microwaves with narrowband (NB) and ultra-wideband (UWB) frequency ranges. [C456]

#### **"System aspects of a low-cost coherent radar system with AESA antenna for maritime applications"**

Motivated by new performance requirements and technological progress Fraunhofer FHR has initiated the development of a low-cost coherent radar system demonstrator with AESA antenna for maritime applications. The proposed system is expected to exhibit smaller operational costs and better performance than conventional shipborne navigation radar systems. In this contribution an overview of the total system was given. Emphasis was placed on the overall system design and the verification of the feasibility resorting to commercial low-cost components (COTS). The antenna front-end and the custom-designed mixed-signal integrated circuits which are the core components of the T/R-modules were presented. In the near future, a demonstrator of the antenna front-end will be completed enabling representative performance measurements. [C457]

#### **"Experiment design framework for super-high resolution imaging with the geostar configured sensor array data"**

In this work, we intend to address a novel look at the enhanced RS imaging with the mm-band array radar/SAR that employ the GeoSTAR sensor array geometry pursuing new descriptive experiment design regularization (DEDR) methodology that aggregates the concept of sensor array design with different methods for sensor system and reconstructive imaging method fusion, and report the simulation results of different DEDR-related GeoSTAR-adapted imaging techniques using the specialized elaborated software that we refer to as "Virtual Remote Sensing Laboratory" (VRSL). [C458]

#### **"Comparative analysis of regression line fitting algorithms in blind method of mixed noise variance evaluation in radar images"**

Radar images obtained by remote sensing systems as a rule are corrupted by mixed additive and multiplicative noise. To carry out high-efficiency filtering, the information about noise statistics in these images is required. However, in many practical situations such information is a priori unknown. Therefore methods able to evaluate variances simultaneously for both noise components are necessary. [C459]

#### **"Signal processing algorithms in stepped frequency continues wave ground penetrating radar"**

Broad use of underground sensing led to development of a new signal processing algorithms which can extract much more information about soil and underground objects physical characteristics. These algorithms require information about how specific attenuation is dependent upon frequency, about phase velocity of radio waves in soil or about signals phase structure in cases when underground objects are present or absent. This kind of

information can be easily obtained when using probing signal with stepped change of a carrier frequency. Radar systems with this kind of sensing signals are called Stepped Frequency Continuous Wave (SFCW) GPR.

[C460]

### "Compact millimeter-wave distance and speed measurement sensor for railway applications"

Radar sensor for use in automatic shunting system which executes remote control of track occupancy on hump yards and railroad switches and cut speed control passing along retarder position is developed. The sensors are equipped by systems of remote control and internal parameters diagnostics transmitting the radar and service information to the control point. The sensors could be applicable for use in the data nets. The main feature of the developed radar is the use of FMCW self-mixing transceiver with internal detection and digital control and spectral processing of the signal. [C461]

### "Communication of characteristics of radiation and dispersion of a lattice of flat wave guides"

As now in a radar of modern carriers the phased antenna lattice is a principal view of aerials working out of methods of the analysis and research of characteristics of dispersion of antenna lattices as the most perspective is an actual problem. Antenna lattices find wide application in quality and highly effective radar-tracking reflectors. They are applied in various areas of technics: in a radar-location, navigation, meteorology, etc. Therefore the interrelation of characteristics of radiation and dispersion is important. [C462]

### "Double frequency sounding of liquid precipitation"

Measurement of microstructure characteristics of precipitation is very important for study of process of their formation and progress. Use of the remote sensing methods is also quite interesting especially for measurement of particle size of liquid precipitation. That is why the double frequency method for measurement of particle dimensions is quite relevant. Peculiarity of liquid precipitation is dependence of their permittivity on temperature and operating wavelength. This fact essentially complicates application of double frequency method. So the goal of this paper is analysis of the method facilities in the frequency band, which is traditionally used for radio meteorology (8 mm and 3 cm). Experimental study of proposed approach was performed for single water drop by means of Doppler double frequency radar ( $\lambda_1=8$  mm and  $\lambda_2=3,2$  cm). The special measuring bench was developed for formation of drops with different sizes. The experimental data have good repeatability  $\leq 1\%$  and measurement error is about 30 %. Thereby performed experiments confirm possibility of use of double frequency method for estimation of effective drop size of liquid precipitation and their integral characteristics water content and intensity. [C463]

### "Algorithm of data processing in GPR"

Special algorithms and methods of data processing have built into the software are usually used to increase the efficiency of subsurface radar sounding with a ground penetrating radar (GPR). They are intended to improve SNR and to present results of a survey of the subsurface in a convenient for operator form. A number of different signal processing algorithms for subsurface probing are developed. Basic attention of this article is concentrated on the algorithm of automatic search for local objects using the Hough transform. Hough transform allows finding defined analytically plane curves, for example, straight lines, circles, ellipses, etc. in the monochrome image. The monochrome image is the image consisting of points of two types which are background points and points of interest. The task of Hough transform is separation the curves formed by points of interest. An example of algorithm of search for hyperbole in GPR image is discussed in the work. [C464]

### "Cooperation in distributed surveillance"

This paper discusses distributed surveillance problems, where a set of sensors, of different modalities, can sense collaboratively and continuously a certain volume of interest. Surveillance operations in complex environments, such as littoral regions, are introduced and their main features and challenges are presented. Effective cooperation among the sensors can synergistically improve the performance of these systems and can endow them with higher-level faculties, such as dynamic task allocation, communication relaying, and cooperative target search and tracking. Different forms of cooperation in distributed surveillance systems are mentioned. The paper focuses on intra-and inter-platform target cueing and handoff as augmentative forms of cooperation in distributed surveillance. [C465]

"A frequency selective magnetodielectric layer in polarimetric radar antenna track"

A periodically stratified medium consisting of alternating layers of two magnetodielectric media is considered. In the long wavelength limit such a medium might be treated as uniaxial effective substrate. For oblique incidence of TE and TM type electromagnetic waves, the reflection and transmission coefficients are found. On the basis of numerical solution of associated periodic boundary-value problem, finite scale homogenization model is discussed. Prospective applications of the slab treated for designing frequency selective structure situated in the track of polarimetric radar antenna is pointed out. [C480]

## "Design of prospective spaceborne multi-aperture UWB polarimetric high performance SAR system"

Multi-aperture synthetic aperture radar (SAR) systems ensure high performance SAR imaging that is unachievable for conventional SAR. Application of modern technological capabilities in ultra-wide-band radar signals digital forming and processing (including optional modulation modes) enables realizing high performance characteristics and using operational flexibility of the SAR system. This report presents technical pattern and characteristics of the SAR, that is based on segmented polarimetric wide-band active phased array and multichannel digital subsystem for signal parameters control. The system uses technologies of 'multidimensional waveform encoding' for transmitted signal and 'digital beam forming' (DBF) for echoed signal receiving. The design main qualitative characteristics are estimated for multichannel remote sensing modes. [C482]

## "The "COMPACT" family of the small-sized airborne synthetic aperture radars (design philosophy and practical experience)"

Basic functionality and design features of the "COMPACT" family of the small-sized airborne synthetic aperture radarr(SAR) are described. Main technical characteristics of the SAR realisations in the X-, L-, P- and VHF - frequency bands are shown together with features of these application on various types of flying vehicles. Several examples of practical processing and thematic decoding of the radar data are listed that were obtained at the time of real observations in the interests of the various customers. [C483]

## "Numerical implementation of continuous-discrete IMM state estimators"

This paper deals with the problem of numerical implementation of adaptive tracking filters based on continuous-time dynamic models of target motion and on discrete-time models of radar measurement process. The particular problem considered is characterised by: non-linear and non-stationary dynamic models of target movement, uncertain parameters and relatively low data rate due to a rotating antenna. The proposed tracking filter relies basically on the continuous-discrete variant of the extended Kalman filter (EKF), the probabilistic data association (PDA) technique and the interacting multiple-model (IMM) state estimation scheme. [C484]

## "A kind of MIMO ground penetrating radar plane antenna array and corresponding imaging"

#### method"

Antenna array is widely used in real time imaging of ground penetrating radar (GPR). With circumstance restricting, the number and interval of antenna elements are difficult to fit the need of high imaging resolution. In this paper, a kind of 4-transmitter and N-receiver MIMO GPR plane antenna array is proposed. Based on phase center approximation (PCA) theory, its equivalent antenna array is a uniform square antenna array with  $4N$  T/R antenna elements, and the interval of equivalent elements is half of that of the real receiving elements. The equivalent uniform square antenna array has two synthetic apertures and can obtain the 2D information of target. So, the 2D image of the target can be derived by using narrowband transmitting signals and the 3D image can be derived by using wideband transmitting signals. Corresponding imaging method and procedure are also given in this paper. [C493]

#### "Study on Digital Management of Industrial Water System in Steel Industry"

At present, the shortage of water resources has restricted the development of steel industry. Industrial water minimization is the inevitable choice that break through the bottleneck and reduce energy consumption in enterprises. To solve problems of more extensive operating mode, lower water recycle rate and higher wastewater discharge, life cycle and digital management is very important to joint enterprises. Firstly, the accurate base data was accessed by water balance testing. Then, online monitoring, diagnosis, early warning and the use of dynamic cascade control system was established. This system can realize dosing process control and the reasonable dynamic cascade of wastewater. The model of intensive and digital management would tap maximum energy saving, water-saving potential. [C494]

#### "An improved IMM algorithm with variable structure"

In this paper, an IMM algorithm with variable structure is proposed aiming at the large amount and low efficiency of computation, which is inherent weakness of standard IMM algorithm. Based on standard IMM algorithm, the new method obtains state information of targets, and establishes rules on entrance and exit of models, with which the algorithm adjusts the model set to motion of targets. Results of simulation show that the new algorithm leads to fewer models and higher computation efficiency without lowering the tracking performance. [C495]

#### "Remote sensing retrieval of soil moisture using ENVISAT-ASAR images: A case study in suburban region of Peking, China"

Soil moisture is a highly variable component of soil, and plays an important role in materials and energy exchanges between earth and atmosphere. It is also the basic parameter of crop growing and crop yield forecast. With the features of observing large area synchronously, timely, and economically, remote sensing technique makes dynamic soil moisture monitoring possible. Soil moisture remote sensing monitoring has 30 years history and many researches have been done home and abroad in this field, including visible and infrared remote sensing based NDVI methods, hyper spectral remote sensing based algorithm, and microwave remote sensing orientated methodology and so on. Among these methods, microwave has great advantage in retrieval soil moisture because of the characteristics of all-weather, penetrability and not affected by the cloud. Through study people found that microwave is one of the most effective methods in retrieval soil moisture in various technologies. This paper summarizes the major microwave sensors and the principle of microwave remote sensing, and introduces the microwave model and soil moisture algorithm. Based on ENVISAT Radar data, with suburban farmland (wheat and corn as the main crop) of Peking as the study area, we established the microwave scattering characteristics database of local exposed surface. We used the selected model to simulate the response characteristics of backscattering coefficient influenced by a variety of parameters, such as soil moisture, surface roughness, incidence angle, polarization, etc. Then we got the updated inversion empirical model of the exposed surface, and evaluated the accuracy of model with the actually surveyed data in the field. This article makes certain contributions to the active microwave soil moisture retrieval methods study, and provide a viable model for water resources decision-making support to the Peking municipal government. [C496]

#### "Design and Practice of GPS Inspection Data Acquisition System to Telecom Pipeline Network"

Pipeline network is an important component of the telecommunications system, effective management of pipeline networks, pipeline networks and equipment to ensure safety and efficient utilization of a basic work. The network GPS inspection data collection system was designed based on unistrong expansion product in this paper. the advantages of the system was analyzed based on briefly described the overall design of the system, and principles of data acquisition and data processing methods were described, and finally system application practice was detailedly explicated, and made a detailed analysis. The actual application shows that the program can effectively meet the telecommunication resource management pipeline fast, efficient, timely, and with the original data and GIS platform for seamless docking of the job requirements. [C497]

### "The Research in New Architecture of Petroleum Drilling Instrument System"

Drilling technology in petroleum exploration and development has developed, which follows the development of sensor technologies, electronic measurement and computer network technology, more and more assistant methods are used in the course of drilling, and more information about drilling project and underground to be detected. They direct the driller to operate. At the same time they also allow the decision-makers at the base of oil field and technicians in first time to understand the progress of drilling with the schedule. And we can also receive the regional geological parameters to do other applications and decision-making. This article presents a drilling instrumentation system. It is able well site connect to the base of oil field as a whole by wireless network. They can collect and storage the state of drilling on-site and the geological data and transfer to the base quickly. This system could get the new detecting signal in drilling process, and incorporate in to our instrumentation system signal. Just because the high cost of oil professionals and the volatile political situation of oil-production region, it is the most urgent desire of many oil companies to reduce the number of technical staff in site. This paper discusses the system which could enable multiple drilling well field to share professionals and technical experts in the base, so we could achieve remote operation, remote control in this way. [C498]

### "Chinese AIS Network and Impact on the Maritime Management"

AIS (Automatic Identification System) has more and more been used on a ship to identify a target and improve the navigation safety at sea as a new type of radio navaid system. AIS network has also been constructed at the main harbor in many countries to enhance the traffic safety and the maritime management. In the paper, AIS system is briefly described. It stresses on Chinese AIS network frame. The applications and traffic management are discussed. It is analyzed that AIS network brings to the benefits and the influences on the traffic safety and the maritime management in China. Expectation of application prospect of the network is conducted. [C499]

### "Estimation of forest height, biomass and volume using support vector regression and segmentation from lidar transects and Quickbird imagery"

Lidar (light detection and ranging) remote sensing can accurately characterize forest vertical structure, such as canopy height, above-ground biomass (AGB) and timber volume; however, data acquisition is expensive. To reduce costs, one potential method is to integrate (small area) lidar transects and (large extent) optical imagery to estimate forest characteristics. Typically, multiple regression is used to link variables extracted from lidar transect data and optical imagery. Height information is then generalized from the area covered by lidar transects to other areas without lidar coverage. However, multiple regression models may not fully capture the complex relationship between variables. Fortunately, Support vector regression (SVR) provides a solution to deal with such complex nonlinear problems. Using a case study in Vancouver Island, Canada, SVR was applied to generalize canopy height from lidar transect(s) to the entire study area (2601 ha) based on a segmented Quickbird image. Results show that: (i) compared to typical multiple regression models, the SVR models provided better results for estimating canopy height; (ii) by using only one lidar transect (i.e., 8.8% cover), the SVR model generates an average canopy height estimation error of 6.2 m-which is less than a British Columbia forest inventory height class (9.0 m); and (iii) the final model estimates have relatively high correlations with field data for forest canopy height ( $R^2$ : 0.81), AGB ( $R^2$ : 0.76) and volume ( $R^2$ : 0.64), while representing dramatically reduced acquisition costs. [C500]

### "InSAR analysis over Yellow River Delta for mapping water-level changes over wetland"

Wetlands cover more than 4% of the Earth's land surface and include hydrologic and other process that are fundamental to understanding ecologic and climatic changes. It is very important for wetlands protection and re-construction to measure water level changes and consequently water-storage capacity changes in wetlands. Using VV polarization C-band and HH polarization L-band SAR data, combined with synchronous field measurement and investigation, this paper analyzes the difference of backscattering and interferometric coherence characteristics of different types of wetlands. After evaluating factors that influence interferometric coherence, the framework, for measuring water level changes using InSAR phase information, is presented in this paper. With obtained SAR data, this paper studies the InSAR-derived water level changes in Yellow-River Delta wetlands. The results show that the InSAR technology has a great potential in mapping water level changes in coastal wetlands, and InSAR-derived water level changes can supply unprecedented spatial details. [C501]

### "Multitemporal polarimetric SAR data fusion for land cover mapping"

With the development of the polarimetric Synthetic Aperture Radar (SAR), the research on the land cover classification using SAR data has developed rapidly. But the classification accuracy is serious affected by the

speckle noises on the SAR image. A new method which combines the advantages of multi temporal SAR data and quad-polarization SAR data was presented in this paper. A method of multitemporal SAR data fusion was used to eliminate the effect of the speckle noises on the SAR image. An area of 12 Ч 17 km was selected as test area. 6 multi temporal RADARSAT-2 images were used in this study to contact the land cover classification. The results show that different land cover type denote different backscattering mechanism and the backscattering coefficient value of different land cover type varies as function of time. Based on the fusion result of multi temporal polarimetric SAR data, the land cover classification was fulfilled and the results show this method can effectively distinguish the man-made buildings, forest, farm land and water. The speckle noise was obviously reduced and the visual appearance of the SAR fusion image well improved. [C502]

#### **"A study of PS-InSAR method for small area urban land subsidence"**

Persistent Scatterers for SAR Interferometry (PS-InSAR) technique allows monitoring the temporal evolution of a deformation phenomenon at millimeter level, via the generation of mean deformation velocity maps and displacement time series from a data set of acquired SAR images. However, the serious noises of multi-temporal SAR images make the selection of permanent scatters (PSs) difficult. In this paper, we propose a novel PS-InSAR method based on wavelet phase analysis to solve this problem by improving the quality of interferograms. Firstly, both the real parts and the imaginary parts of SAR interferograms are processed by wavelet decomposition. Secondly, the interferograms on every level are filtered by grads dependent adaptive filter and reconstructed. Finally, interferograms are processed to identify PSs by using two indices namely, amplitude disperse index and spatial correlation index, followed by an unwrap process to extract land subsidence information. We then use this method to process 12 ENVISAT SAR imgs covering Jiaxing city in Zhejiang province, China. The experimental results show its effectiveness in residuals and PSs identification and land subsidence extraction for plain urban area. [C503]

#### **"Estimation of wetland aboveground biomass based on SAR image: A case study of Honghe National Natural Reserve in Heilongjiang, China"**

Wetland is a significant component of the land ecosystems to discover the characteristics and ecological laws. Presently, a common method to estimate a regional wetland biomass is normally based on optical remote sensing images. The estimation of wetland biomass by Synthesize Aperture Radar (SAR) is a novel subject. As a new type sensor, SAR has advantages for wetland applications, therefore, it can be apply for generating some important information about wetland ecology and hydrology, especially with the complex ecological habitat of the transitional place between land and water, radar images can be significant tool for wetland biomass estimation. In this paper, as a case study of SAR application on Honghe National Natural Reserve (HNNR), the wet weight and dry weight field data of 28 quadrats of diverse vegetation in a growing season from the study area in 2009 were gathered, the ASAR image was acquired at the same time with field work. The backscattering coefficient of polarimetric radar and wet weight and dry weight data was taken as correlation variable, the fitting equations of regression models and water cloud model were built to estimate the wet weight and dry weight, a validation was made from 9 measured plots. The research shows the estimation of the wetland biomass by SAR image can be a supplement to optical image with a scientific significance in ecology studying. [C504]

#### **"Wetland mapping by using multi-band and multitemporal SAR images: A case study of Hong he National Natural Reserve"**

Wetland ecosystems have many important functions as the regional environment stabilization, natural species protection and ecological resources facility. Investigation and monitoring on wetland urgently need the application of remote sensing. The optional remote sensing technology is sometimes difficult to receive the data due to the bad weather, or in specific light conditions. However, radar remote sensing has a great potential for technical application in wetland mapping with its all-weather, all-time capabilities. And SAR scattering intensity is sensitive to the soil moisture of land cover and land change, therefore it is also helpful to the wetland research. In this paper, multi-band, multi-temporal SAR technique was used for wetland mapping. Unifies the SAR polarization characteristic, the backscattering characteristic of multi-temporal ENVISAT ASAR HH, HV, VV polarization data and ALOS PALSAR HH polarization data of different land use type and different vegetation type in Honghe National Natural Reserve (HNNR) were analyzed. The multi-temporal SAR data was used for vegetation classification research in decision tree classification method. And the authors use actual samples to do accuracy assessment in the way of computing confusion matrix. The result from this study shows that the improvement of water and marsh classification accuracy owes to the summer data, and the classification accuracy can be improved when we used the multitemporal data, HV polarization data in winter is more advantageous for forest map. The recognition rate of water, marsh and forest was relatively high. The classification of grass and bush had confusion. The classification accuracy of multitemporal SAR reached 79.55%. [C505]

### "Vulnerability assessment of combined impacts of sea level rise and coastal flooding for China's coastal region using remote sensing and GIS"

China's coastal region is physically and socio-economically vulnerable to accelerated sea-level rise and associated coastal flooding because of its low topography, highly developed economy and highly-dense population. In this study, we present a scenario of sea level rise and storm surge flooding along the China's coastal region over the next century and apply them to a digital elevation model (DEM) which acquired by the shuttle radar topography mission (SRTM) to illustrate the extent and spatial distribution to which coastal areas are susceptible to permanent inundation and episodic flooding due to storm events. To perform flood scenario analysis and vulnerability assessment, a method for producing several sets of data was implemented by combining remote sensing processing, the use of grid-based socio-economic data, and subsequent analysis using Geographical Information Systems (GIS). This analysis shows that inundation and coastal flooding will mainly occur in the major delta without the protection of dike systems. However, due to the concentration of population and economic activities in China's coastal region, societal and economic consequences of continued sea-level rise would be substantial. Finally, some suggestions are presented for decision-makers, and other concerned stakeholders to develop appropriate public policies and mitigation measures. [C506]

### "The Internet of Things Based on Embedded Mode Design"

This article describes a composition by the sensor and the embedded system host, and it is the internet of thing technology which collect data on the material and sent to the Internet .The system uses the ARM7 microprocessor as a core processing unit, and it will receive the temperature and humidity sensors which send real-time temperature and humidity data by TCP / IP protocol sent by the GPRS module to the GPRS public networks. Socket programming technology used to establish TCP/IP server, the host sends the data to receive the embedded information, and the data uploaded to the Internet with a rich client (Rich internet application, RIA) model for dynamic call. [C507]

### "Spatial-harmonic magnetrons with cold secondary-emission cathode: Towards unlimited lifetime"

Spatial-harmonic magnetrons with cold secondary-emission cathode are efficient high-power millimeter-wavelength oscillators. Advances in the design, realizations, and investigation of such magnetrons are reviewed. Potentials for further increasing of the lifetime of the spatial -harmonic magnetrons are considered in more details. [C508]

### "Developments in marine radar magnetrons"

Magnetrons for civil marine radar applications have been manufactured on the e2v Chelmsford site since 1947. The earliest production was of the original S band wartime designs developed by the Radiation Laboratory at MIT but it was not long before engineers at the then English Electric Valve Company began making improvements. This paper traces the development of magnetrons for marine radar from the first glass envelope "Gen 1" devices to the current state of the art in 4th generation magnetrons. Each generation of magnetrons introduced significant design innovations and the designers also took advantage of technological developments in both materials and production techniques. The key changes are described and illustrated together with some of the technological improvements that have resulted in today's highly reliable devices. These latest devices embody novel techniques for internal suppression of unwanted oscillatory modes and also use novel processing techniques to achieve unprecedented levels of performance and reliability. [C509]

### "Cavity magnetron in Russia"

The first domestic researches of the cavity magnetron in Russia were in the thirties of the XX century. In the paper it is told about destinies of the first researchers (including D. Malyarov and N. Alekseev). The Second World War not only has changed the approach to cavity magnetron development and to their practical application, but also has caused a set of transformations to the industries. There were new state decisions, enterprises, names. The further evolution of magnetron development occurred within a restriction of access to the information which has become partially excellent only in recent years. In the paper a short characteristic of history and development of the magnetron tendencies on the basis of the domestic industry is presented. [C510]

### "The study on extracting of vessels information from the SAR satellite data"

The paper introduces satellite remote sensing technology used into marine traffic investigation, to detect and analyze actual marine traffic situation on a large scale. The paper introduces characteristics of SAR image and the procedure for extracting information of vessels based on the SAR Remote Sensing image. Vessel Detection Technology is studied based on multi-source space borne SAR data, after analyzing the characteristics of

various types of vessels detection algorithm and combining with the needs of marine vessel detection and traffic investigation. According to the characteristics of SAR images, four methods of extracting ship information have been developed, including gravitational field, CFAR detection, PNN and adaptive algorithm. Taking the ERS-2 images as an example, the reliability and limitations of vessel information extracting from the satellite image is discussed. The study shows that satellite remote sensing provides a new and feasible method for marine vessel traffic investigation. At present, the technology has been developed and some tests have been carried out. However, some limitations in the system need further study, especially the impact of the sea state. [C511]

#### "Developments of radar and magnetrons in the Netherlands after 1945"

This paper covers developments and applications of radar and magnetrons in The Netherlands after 1945. The paper describes: 1. The most important participants, 2. The rapid expansion of the radar installed base, 3. A couple of magnetron-related research projects, 4. Some magnetron applications-in the M20 series radar-in (industrial) heating applications, CW magnetrons. [C512]

#### "In the labor people's name: Development of 60-kW magnetrons in the artificial famine plagued Ukraine in the early 1930's"

The emergence and formation of microwave, electronics and radar community in Ukraine had been closely tied to the invention and development of original high-power decimeter-wave split-anode magnetrons in Kharkov in the 1920-30's. Navigating their lives and research between the deadly Orwellian torrents of the early USSR, the scientists had to close their eyes on the politically motivated famine, which was devastating Ukrainian countryside. Both microwave research and development and food confiscations were done in the name of labor people. [C513]

#### "Frequency bandwidth narrowing technology for cavity magnetrons installing cavity magnetrons into commercial marine radar"

The unmodulated pulse magnetrons design and technology has advanced over the last seven years at New Japan Radio Co., Ltd. (New JRC). These developments have resulted in a dramatic reduction in the unwanted emission levels produced by magnetron devices. This was necessary to meet the increasing global demand for a more efficient use of the radio frequency spectrum, which is seen as a limited and scarce resource. These magnetrons utilise new techniques to reduce the unwanted emissions, while also improving the spectrum in the utilised frequency bandwidth. This paper explains in detail the processes and methodology used to reduce the unwanted emission levels for unmodulated pulse magnetron devices. In addition, this paper will describe Japan Radio's (JRC) commercial marine radar systems, operating in the S and X bands. [C514]

#### "Tracing systems for user&Control-Plan traffic of Packet Core of GPRS-UMTS networks"

The resources of actual tracing tools for Control-Plane and User-Plan traffic are limited and most of them are crashing under the task of tracing 100% User-Plan traffic. This paper proposes a new tracing system for UP&CP traffic of Packet Core networks, like GPRS-UMTS networks, in order to verify their functionality. [C515]

#### "Research on Improved Quality Measures for the Fuzzy Association Rules of One Airborne Radar Intelligence Database"

To address the problems of the rule redundancy and the long algorithm execution time in the process of mining one airborne radar intelligence database by the fuzzy association rules algorithm, this paper define a new QL-implicator based fuzzy support measure in order to enhance the recognition probability of the positive association rules and introduce the fuzzy conditional entropy measure (CE-measure) based on information theory to find the negative association rules, and then pruning the generated rules to shorten the run time of the algorithm. The experimental results show that the proposed method is effective, and the accuracy and efficiency for generating rules have improved significantly by comparing with the traditional fuzzy association rules algorithm. [C516]

#### "Remote Monitoring System of the Motor in GPRS Based on LabVIEW and Embedded TCP/IP"

According to the demand of actual application for motors, the software and hardware structure of remote wireless monitoring and control system for the motor based on LabVIEW and GPRS were designed. The paper presented the design principles of the motor's speed measurement system based on the singlechip, studied the communication protocol of the serial interface between singlechip and GPRS module. The remote computer monitoring platform was established with network communication technology of LabVIEW and database technology. The system was not affected by geographic location restrictions and it was suitable for the remote

monitoring and control system of the motor in different districts. [C517]

### "Early magnetron development especially in Germany"

Magnetic control was a very early form of controlling electrons. The original Braun tube was magnetically controlled, and so was the first telephone relay of Robert von Lieben. Even the first successful attempt to obtain oscillations from a (mercury cathode) tube by Frederick Vreeland in 1908 was equipped with magnetic coils. Descriptions of magnetically controlled tubes were given by several authors, e.g. in 1910 by H. Gerdien of the Siemens Co. and, two years later, a theory of electron motion in a coaxial diode, accompanied by measured results, was given by H. Greinacher. In 1918, A.W. Hull described the use of a coaxial magnetic field with a dynatron, and later he discussed the motion of electrons in a coaxial diode and gave the characteristic of plate current as a function of magnetic field strength. He also proposed an oscillator using feedback via the magnetic coil. In 1924, E. Habann published a paper on the split-anode magnetron, which can be looked at as the first 'real' magnetron oscillator. Presumably, because of the lack of application of very high frequencies at that time, the German literature of the late 1920s seems to have forgotten about the Habann generator. The (at that time) famous books, e.g. of Barkhausen or Strecker, mention for the key-word 'magnetron' the Hull tube, and for highest frequency oscillators the retarding field tube following Barkhausen-Kurz. The work on split-anode magnetrons during the later 1920s was mainly done in Japan by Okabe and in the beginning of the 1930s by Megaw in England. Starting about 1933, the interest in high frequency oscillators, and thus in magnetrons too, arose again. The main interest of application, however, lay in the field of high frequency telephone links rather than in the beginning radar developments. A special problem was the modulation of magnetrons. One method was to install a control grid for amplitude modulation. Also discussed was 'Zeitmodulation', that is pulse modulation. But the problems of modulation remained severe: e.g. the commercial telephone link coded 'Rudolf', which first appeared in 1941, was initially equipped with a magnetron, but later redesigned for a triode transmitter. Technological development led, on one hand, to high-power, water-cooled, split-anode magnetrons. On the other hand, there was the attempt to include the high frequency resonant elements into the vacuum vessel. In most cases these were Lecher type wires. The coupling to the outside was either capacitive or the Lecher wires were led through the envelope. To the author's knowledge, cavities were used only in Barkhausen type tubes called 'Resotank'. When in 1943 the magnetron type CV 64 was found in a crashed British aircraft, the political restrictions for the development of cm-wave tubes vanished in Germany. [C518]

### "Maurice Ponte and Henri Gutton, pioneers of early French studies on resonant magnetron (1932-1940)"

After a quick reminder of French scientists who pioneered the UHF domain in the 20's, emphasis is put on the decisive role of Maurice Ponte at SFR/CSF, who revived Okabe's magnetron concept in 1932 and built up a lot of high efficiency oscillating valves working within the range 3 m-70 cm. Two years later H. Gutton succeeded him and began to work on multi-segment, resonating anode design. Between 1934 to 1938 he tested a large variety of anode architectures, resulting finally in the 8-segment anode and oxide-coated cathode M-16 which in late 1939 delivered a peak power record of 1 kW at  $\lambda = 16$  cm. The M-16 found immediate applications in radio-link communications, particularly in a naval obstacle detector (a very early decimetric radar) tested on board the liner "Normandie" from mid-1935. It was improved in a dedicated laboratory established in 1936 at Le Havre. But its military adaptation had to be destroyed in June 1940 to escape the German invasion. The legacy of these works survived through the scientific exchanges established throughout this time between Dr. Ponte/Gutton at SFR and Dr. Megaw at GEC UK. They had a noticeable influence on the emergence of the British multi-cavity anode invention. In May 1940 the oxide-coated and indirectly heated cathode brought to Wembley by Ponte was the final touch. Promptly inserted in the new E-1189 GEC prototype, it proved to be an essential part of "the most valuable cargo" sent by the Tizard mission to the US a few months later. [C519]

### "From \$10,000 magetee to \$7 magetee and \$10 transmitter and receiver (T/R) on single chip"

The paper reviews the developments in microwave devices for radar applications. It starts with the development of high power magetee and magnetron to solid-state microwave devices and integrated circuits. It also covered recent development and breakthroughs in active electronically scanned arrays (AESA). [C520]

### "Integration of LIDAR data and geological maps for landslide hazard assessment in the Three Gorges Reservoir area, China"

The water storage and millions of immigrants work have a great impact on engineering geological condition which may cause slope instability in the Three Gorges Reservoir area, China. This paper presents regional assessment of landslide hazard from Zigui to Badong based on Light Detection and Ranging (LIDAR) data in combination with geological maps and landslides information of this area. Four essential parameters, including

engineering rocks, slope, slope structure and water impact, are extracted from this data. The informative model is employed to create landslide hazard map. The result shows that informative model successfully identified the stable regions as well as instable reservoir banks. Reservoir water and engineering rocks are principle control on slope stability in this area. We also divided the study area into fourteen sections according to the landslide hazard map. [C521]

### "SAR satellite image interpretation based on the multilayer level set approach"

Synthetic aperture radar, SAR, is a remote sensing way to explore the ground truth in day and night. How to interpret the given SAR images provides an import clue to study the characteristics of the imaged areas. However, the image interpretations for SAR images are difficult because of the effects of speckle signals shown in the images. In order to solve the problem, several algorithms have been proposed. The processed results show the proposed algorithms still have their own limits on reducing the effect of speckle signals. In this paper, the multilayer level set approach is employed to have the SAR images be grouped into several sub-regions such that the segmented regions are homogeneous. Based on this minimization of the energy, the multilayer level set method implicitly presents the regional boundaries as several nested level lines. By increasing iterations and preselected level values, these lines evolve close to the level boundaries based on the energy minimization. This method provides numerical stability and quick convergence. In order to implement the multilayer level set approach, several level values need to be established firstly. Those level values are determined with calculating the average values from the classified groups with applying K-means method. Based on the four-color theory, the multilayer level set method is able to generate an optimal piecewise continuous approximation for the SAR image such that each approximation sub-region is homogeneous. From the processed results, the multilayer level set approach can efficiently reduce the effect of the speckle signals, and quickly segment SAR images for further image interpretation. [C522]

### "Assessment of ASTER GDEM performance by comparing with SRTM and ICESat/GLAS data in Central China"

Recently, a new Global Digital Elevation Model (GDEM) from optical stereo data acquired by the Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) was released with the resolution of 1 arc sec. In this study, the performance of the new ASTER GDEM is assessed by comparing with SRTM (the Shuttle Radar Topography Mission) and point data from ICESat/GLAS (Ice, Cloud, and land Elevation Satellite/ Geoscience Laser Altimeter System). A 5°45' area (30°-35°N, 110°-115°E) with varied terrain was chosen as the study area. Standard DEM-to-DEM comparison, DEM-to-control-point comparison and visual analysis were used to evaluate the ASTER GDEM quality. The results show that the ASTER GDEM has much fewer voids than SRTM V2 (the version 2 SRTM). The ASTER GDEM has lower elevations (approximately -5m) compared with SRTM, whereas the ASTER GDEM has higher elevations (approximately 15m) compared with ICESat/GLAS points. To the vertical accuracy, the results of the ASTER GDEM compared with SRTM V4 (the version 4 SRTM), SRTM V2 and ICESat/GLAS points are 39.55m, 25.99m, 33.99m at 95% confidence respectively, exceeding 20m estimated prior to the ASTER GDEM production. The poor accuracy may be related to the high terrain relief and high ratio of lower stack number of the ASTER GDEM in the study area. The ASTER GDEM shows better performance in the flat areas than that in the mountainous areas, and the accuracy improves with the increasing stack number. The ASTER GDEM has many artifacts including inland water noises and straight lines related to the irregular stack number boundaries, which are caused by the methodology to produce the ASTER GDEM. [C523]

### "Study of the airborne LIDAR data filtering methods"

Filter of airborne LIDAR data is a primary step of data processing. This paper reviews the literature of filter algorithms from aspects of theory and performance. The methods of filtering usually are slope-based surface-based and clustering/segmentation-based. In this paper the filtering methods of Lidar data are studied and summarized especially, the advantages and shortages of the present means are discussed. In addition, prospect is also given to provide references for future research. [C524]

### "An image segmentation algorithm for SAR images based on wavelet packets frame transformation"

SAR (synthetic aperture radar) images are strongly disturbed by speckle noises, which brings difficulty to the segmentation of the SAR images. Some model-based SAR image segmentation approaches (such as the Markov random field model, fractal model) are too complex and time consuming. We propose an new method to segment the SAR images fast in this paper. First we transform the original SAR intensity image into some subimages using the wavelet packets frame transformation. Then we analyze the energy distribution in the

transformed subimages and find that the energy of the speckle noise is mainly concentrated in the high frequency subimages. So we segment the SAR image based on the gray level of the low frequency subimages using a threshold classifying method. The result shows that this method can get a satisfying segmentation result and time saving. [C525]

#### "Geodesics-based topographical feature extraction from airborne Lidar data for disaster management"

Hundreds of thousands of lives were lost in the natural disasters such as geological earthquakes, floods, landslides and mud-rock flow in every year. Nowadays, with the rapid development in airborne LiDAR techniques, extraction of the multi-scale topographical features from high-resolution topographic data acquired via airborne LiDAR would lead to fundamentally new understandings of earth essential to mapping flood, landslide and mud-rock flow hazards for decision makers. In this paper, we define topographic features in a multi-scale manner using a center-surround operator on Gaussian-weighted mean curvatures. These multi-scale topographical features would allow improved detecting, understanding and prediction of flood inundation, landslide and mud-rock flow likelihood. For example, experimental results identify that proposed method can be employed for detecting landslide. [C526]

#### "The atmosphere correction in SBAS D-InSAR land subsidence monitoring application: A case study in Jiaxing-Huzhou plain, China"

It is well known that atmospheric phase screen (APS) effect in Small Baseline Subset (SBAS) D-InSAR processing to obtain ground deformation in long time series leads to additional interferometry phase and the unreliable result. To solve the problem above, MODIS product provides a mean to stimulate atmospheric field of SAR data for reducing the APS effect in D-InSAR processing. In this paper, 12 ENVISAT ASAR images are used to process SBAS method and 6 MODIS MOD05\_L2 products are used to process atmosphere correction. A case study in the Jiaxing-Huzhou plain in Zhejiang province, China shows successfully stimulate the atmospheric field of SAR data and analysis its effect on SBAS application. [C527]

#### "Building extraction using dual-aspect high resolution SAR images"

Interpretation of SAR image in urban area is far from solved with the increase of spatial resolution, and building extraction in SAR image has remained as a tough work. Typically, the outlines of buildings are usually not complete, and the geometric distortions further complicate the appearances of buildings in high resolution SAR images. Thus, in this paper, a strategy based on dual-aspect high resolution SAR images was proposed to extract complete footprint of buildings in urban area. Experiments prove that dual-aspect SAR images, especially with high resolution, are very useful for building extraction in urban areas. [C528]

#### "Study on MIMO radar velocity resolution"

Multiple Input Multiple Output (MIMO) radar is a novel radar technique developed recently. It has many advantages over conventional phased radar in many ways such as anti-intercept of radar signal, low velocity target detection, and resolution. In this paper, the signal model and signal processing for MIMO radar is studied. And then, a simulation platform is established with Matlab. Using this platform, the advantage of velocity resolution of the MIMO radar over conventional phased array is researched. [C529]

#### "Wavelet based signal for MIMO radar"

Multiple Input Multiple Output (MIMO) radar can effectively improve radar performance by transmitting specially designed orthogonal signals. In this paper, the orthogonal wavelet division multiplexing is used because of their prominent properties such as favorable ambiguity function and high bandwidth efficiency. The signal design flow is presented in this paper. [C530]

#### "The chaotic signal design for MIMO radar"

The study of multiple-input multiple-output (MIMO) radar has received much attention from researchers in recent years. It has many advantages over conventional phased radar in many ways such as anti-intercept of radar signal, low velocity target detection, and resolution. The signal design is an important problem for radar which decides the performance of radar. In this paper, the chaotic signal is employed to the MIMO radar application. Some preprocessed method is employed to make the signal has small Crest Factor (CF), large bandwidth. Some simulation is presented to show efficiency of proposed method. [C531]

### "Multi-resolution 3D reconstruction of city statue based on laser scanning and photogrammetric concept"

In order to improve the visualization effects of some areas in cyber city, it's often required to reconstruct 3D model of city statues. In this paper, we present a pipeline to build 3D city statue model of high fidelity that fusing multi-resolution LIDAR data and high-resolution digital images. Firstly, the classic ICP algorithm is used to register multi-resolution LIDAR data. Secondly, the geometric seams between multi-resolution LIDAR data are fused by a progressive fusion strategy. Finally, a virtual camera based on basic Photogrammetry concept is proposed to do the texture mapping. Combining all kinds of automatic and semi-automatic methods, the pipeline works well for 3D reconstruction with multi-resolution laser scanning data and high-resolution digital images.

[C532]

### "Ortho-rectification of high-resolution SAR image in mountain area by DEM"

Because of the side-looking imaging characteristics, the quality of Synthetic Aperture Radar (SAR) image is badly affected by variable terrain. Such terrain can introduce large displacements in the SAR image geometry that inhibits the collocation of SAR-derived quantities with geographically referenced information acquired from other sources. So it is necessary to eliminate such inherent geometric distortions by generating a radar ortho-imagery that corresponds to a well defined map projection. In this paper, aiming at the newest high-resolution SAR data-RADARSAT-2 and TerraSAR-X, an effective ortho-rectification method was studied in detail and the result showed this method could achieve high geo-location accuracy. [C533]

### "The application of IMM in MIMO radar"

Multiple Input Multiple Output (MIMO) radar has drawn much attention from researcher. It can effectively improve radar performance by transmitting specially designed orthogonal signals. In this paper, interacting Multiple Model(IMM) estimator is applied to MIMO radar. The detection flow based on IMM is presented in this paper.

[C534]

### "Identification of inclined buildings from aerial LIDAR Data for disaster management"

Airborne laser scanning has demonstrated a strong ability to obtain the location of collapsed buildings and the dimension and characteristic of their damage. This paper focuses on the identification of inclined buildings from aerial LIDAR Data which contains amount of noise and small details. To achieve the goal, several steps were carried out in the approach: Firstly, the building's roof was classified and majority of roof types were taken into account in our research; Secondly, a chosen algorithm was used to extract the roof facets of building and also the foundation, and it was proved to be robust to eliminate the noise and give a good result; Thirdly, the geometric axis line of a building was extracted; fourthly, a method was proposed to determining whether buildings are inclined. Finally, an experimental study was made to demonstrate the feasibility of the proposed solution on disaster management. [C535]

### "A case study on co-seismic ground deformation of the Wenchuan earthquake using L-band and C-band SAR interferometry"

Synthetic aperture radar interferometry (InSAR) has been widely used for the co-seismic ground deformation monitoring. In this paper, The L-band SAR datasets acquired by ALOS PALSAR and C-band acquired by Envisat ASAR are tested respectively for monitoring the co-seismic ground deformation in the area of Dujiangyan, where the Wenchuan Ms8.0 earthquake occurred on May 12, 2008. The displacement on line of sight has been acquired with two-pass DInSAR processing. It is also found that the C-band SAR data results generally have lower coherence over high vegetated and rugged areas, while the L-band SAR with comparatively longer wavelength is more suitable for monitoring the deformation where large displacement over a small spatial extent occurs and the mountainous terrain. However, current satellite radar interferometry, because of its single-frequency signal structure, is hard to measure ground deformation with large gradients as it produce very dense fringe patterns, which cause that the ground displacement deformed in the faults cannot be measured. Although the longer wavelength of the radar signal is less susceptible to high deformation gradients, loss of correlation often still occurs in the faults caused by earthquake. So it is necessary to propose techniques which can monitor large-gradient deformation and the data fusion methods of multi-source satellite SAR images. [C536]

### "Study on accurate estimation of baseline parameters of space-borne InSAR based on GCPs"

The estimation of baseline parameters is an important step in SAR interferometry (InSAR) processing and applications, because its accuracy influences directly the quality of the final DEM generated from interferogram. In this paper, some classical methods of baseline parameters estimation, based respectively on precise orbit

data, interferogram and Ground Control Points(GCPs), are summarized and compared. For it is recognized that the baseline parameters estimation based on GCPs is the most reliable method at present, this paper concentrate on researching optimizing model of several correction algorithms based on GCPs for baseline parameters. The approach is tested with ENVISAT ASAR data over the Dujiangyan region of Sichuan Province of China. Finally, the feasibility and rationality of the proposed method is showed by comparing the quality of DEM generated from interferogram with SRTM DEM. [C537]

### "An improved filtering method for digital elevation models construction based on LiDAR"

LiDAR (Light Detection and Ranging) is a positive remote sensing technology. In this paper, with analyzed the characteristic of LiDAR data and discussed the advantages of LiDAR data, we present an improved data filtering algorithm for LiDAR data. It is basing on the last return laser pulses and tries to design an fast pre-processing LiDAR point data with the purpose of DEM Modeling from LiDAR based point cloud data. The algorithm contains two times of filtering with different aims and data process strategies. Experiments of real terrain area are presented for testing efficiency and accuracy of this filtering method. [C538]

### "Precise SAR satellite orbit parameters determination based on Ground Control Points"

Aim to solve the georeferencing problem of spaceborne SAR imagery, accounting for the orbit physics model and the impact of the earth perturbations, some description models such as four parameters model and polynomial model could be applied to determine the satellite orbit parameters. However the orbit state vectors solved by 5 satellite state vectors supplied by header file in SAR data files could hardly acquire precise orbit parameters, which would greatly effect on the accuracy of co-registration, phase unwrapping, baseline estimation and the generation of Interferogram and DEM (Digital Elevation Model). In this paper, combined with R-D (Range-Doppler) conformation equation and earth ellipsoid equation, which explicitly describe the relationship of corresponding pixel between the 2D image coordinate and the 3D cartographic coordinate of ground targets, an advanced orbit model algorithm by adding few GCPs (Ground Control Points) to improve satellite state vectors is presented. All the correlative formulas are deduced and the orbit parameters can then be iteratively determined through solving a linear equation set consisting of the error equations from all GCPs under Recursive Least Square (RLS) algorithm. The algorithm is tested on an ERS SCL (Single Complex Looked) scene with a series of simulation experiments and the improved orbit parameters and contrasted with accurate SAR orbit data supplied by DEOS institution of Delft University in Holland, which could be demonstrated of validity and stability. [C539]

### "Determination of sedimentation rate of tidal flats at the Yangtze estuary, China, using multi-temporal Landsat TM images"

Remote sensing, combined with in situ surveying, is an effective tool for monitoring the tidal flats. Airborne light detection and ranging (LIDAR) or radar interferometry can be utilized to measure precisely the surface topographic change. However, neither the satellite-borne synthetic aperture radar (SAR) nor LIDAR is an effective way to obtain appropriate data on tidal flats, mainly because of the little opportunity of finding favorable tidal conditions. Therefore, the waterline method is, so far, the only useful approach to the practical application of satellite remote sensing to monitor the tidal flat environment. The 'waterline' is defined as the boundary between a water body and an exposed land mass in a remotely sensed image. Waterline method has been applied in analyzing the horizontal evolution of tidal flat, but such approach has seldom been used for vertical development. Sedimentation rate is an important factor describing the dynamic nature of tidal flat, so waterline method to determine multi-year mean sedimentation rate was reported at Chongming Dongtan Nature Preserve in Shanghai, China in this paper. The waterlines were extracted from multi-temporal Landsat TM images by unsupervised classification method and region growing algorithm. The mean sedimentation rates were calculated at four transects according to corresponding elevation measurements and waterlines with heights assigned by hydrodynamic model. The results showed that the evolution of the bed level was changed spatially in the cross-shore profiles. The peak of accretion rate occurred at different elevations of the four profiles. Sediment surface of all profiles showed a shoreward reduction from the maximum site to the high marsh, likely due to the shoreward decrease in water energy and submergence time as well as the protective effect of marsh vegetation. The offshore decrease may be related to hydrodynamic attenuation by vegetation and settling lag. A positive relationship was demonstrated--between the mean accretion rates and surface elevation of low marsh and mudflat ( $R^2=0.8106$ ). Spatial changes in sedimentation rate were also striking at the same elevations of different profiles, which could be attributed to differences in sediment distribution and hydrodynamics. The effects of tidal marshes on hydrodynamics and sedimentation were also related to the degree of shelter from water energy. The relationship between sedimentation rate and vegetation distribution was also discussed. [C540]

### "Multi-spectral and SAR images fusion via Mallat and A trous wavelet transform"

The information which is contained in the multi-spectral and SAR images have different characteristic. Multi-spectral images contain a great deal of spectral information, whereas SAR images contain rich texture information, such as buildings and road network. SAR and TM images fusion based on the wavelet transform ensure the fusion image showing more spatial detail, not only conserving the spectral information of the multi-spectral images and reducing the distortions as well, but also highlighting the texture information of the SAR image. In this paper, the wavelet transform-based image fusion methods by using SAR and TM multi-spectral images are implemented by Mallat and a trous algorithms separately. Before the image fusion, both of the SAR and TM images have to be geographic coordinate registered in order to they having the same pixel size. In wavelet decomposition, the decomposition level is determined by statistical of entropy value. According to SAR and TM image fusion based on wavelet transform, it can be seen that the fusion image is greatly improved and both of spectral and textural information are enhanced. The value of entropy, variance, average gradient and correlation coefficients of the fusion image are analyzed for two different algorithms evaluation. By analyzing the results, It can be concluded that the image fusion by a trous wavelet transform has a good effect in experiment. [C541]

#### **"Regional aboveground forest biomass estimation using airborne and spaceborne LiDAR fusion with optical data in the Southwest of China"**

Laser altimeter systems provide an accurate measurement of canopy height, the vertical structure of vegetation and the aboveground biomass (AGB). Airborne discrete return LiDAR (Light Detection and Ranging) was used operationally in many cases and some regions; spaceborne large footprint LiDAR (ICESat GLAS) has acquired over 250 million LiDAR observations over forest regions globally. The ICESat GLAS data have been used successfully for forest height and biomass in various sites. To estimate aboveground forest biomass in the Southwest of China, products from EOS MODIS and ENVISAT MERIS were used to expand the estimation from GLAS data. Airborne LiDAR data were collected along GLAS orbit to estimate forest height and biomass for each GLAS footprint after training with 81 field measured plots. The  $R^2$  are 0.68 and 0.91 for field measured biomass and mean height estimation using airborne LiDAR data. Then the aboveground biomass was estimated from ICESat GLAS data using the equation trained by field data ( $R^2 = 0.47$ ,  $n = 185$ ). EOS MODIS Vegetation Continuous Fields (VCF) product, enhanced vegetation index (EVI) product and ENVISAT MERIS Regional Land Cover product were used to generate 175 forest classes, which included five forest canopy density classes, five vegetation index classes, and seven forest cover types. Then we combined forest aboveground biomass derived from GLAS pulses footprint with 175 forest classes to generate a continuous aboveground forest biomass map of study area. Forest aboveground biomass was minimal at 43 Mg/ha, maximal at 133 Mg/ha, averaged at 78.9 Mg/ha in the study area. The results of predicted aboveground biomass were in agreement on the amount and distribution after comparison with reference data, which showed that the predict model for GLAS successfully captured the distribution of aboveground biomass. [C542]

#### **"Large-scale, rapid detection method of surface subsidence in western mining area"**

In view of the character of mining disaster and the limitation of traditional methods of earth surface deformation monitoring in western mining area, an attempt at adopting InSAR techniques in dynamic deformation monitoring in west mining area has been developed. This paper takes Shaanxi Province Binchang mining area as study area, processes the SAR image by differential interference, obtains the deformation image of Binchang Coal Mining Area, This shows that the InSAR can rapid detect the surface subsidence areas in a large area (100 km<sup>2</sup>~100 km). InSAR technology will be widely used in mining damage dynamic monitoring in western mining area. [C543]

#### **"SAR and multi-spectral image fusion based on feature additive integration"**

Fusion of SAR image and multi-spectral (MS) image can provide complementary information about the ground observed objects. This paper presents an fusion method of SAR and multi-spectral images based on the IHS transformation and phase congruence feature extraction. The IHS transform is firstly made to MS image to separate the intensity from the hue and saturation components. Then the phase congruence is calculated from intensity component of MS image and SAR image, which can provide an absolute measure of image features that is viewing-condition-independent and is invariant to change in illumination and magnification. According to both phase congruence values, the feature of SAR image is integrated into MS image. The experiments show that the fusion method proposed has a good performance. [C544]

#### **"Production and accuracy analysis of high quality TerraSAR-X DOM"**

The production and accuracy analysis of high quality TerraSAR-X DOM are presented. The main focus is given to how to control the accuracy of ortho-rectification framework. Two SpotLight scenes of 1 meter resolution

images and two ScanSAR scenes of 3 meter resolution images in China are used as the experimental data. Based on the proposal ortho-rectification framework, the absolute accuracy of TerraSAR-X DOM can reach to less than three pixels. [C545]

#### **"A solution for the data collection in the field survey based on Mobile and Wireless GIS"**

Traditional data collection methods for geological investigation, profile measurement, and other field survey in the research community of geosciences are generally based on the manual measuring and recording by the investigators. The most popular "instruments" used in the traditional survey are pencils as well as printed hard copy charts. The methods are obviously complicated and inefficient, at the same time the collected data are always inaccurate and not compatible with the digital process in computer. For these reasons, a solution for the data collection in the field survey based on Mobile and Wireless GIS is proposed in this study. Key technologies involved in the solution are reviewed at first. Then, a prototype of mobile GIS with basic GIS functions is designed and implemented based on independent development. Important technologies of implementation some basic GIS services for data collection in mobile environment introduced and many key challenges related, which are overcome in the process of the system development, are studied in detail. [C546]

#### **"Extraction of features from airborne Lidar and onboard image data for future driver assistance systems"**

Driver assistance system is currently an active research and development field for the general goal to provide useful information to drivers in order to reduce the number of injuries and fatalities in traffic. One important component of future systems will be an accurate and reliable positioning, which can be realized by relative measurement, using onboard sensors and maps of the environment. However, a prerequisite will be that such maps can be produced fully automatically. This paper explores the use of dense laser scan data from airborne LiDAR scanning systems for the production of such 3D navigation maps, extracting features from airborne LiDAR data and onboard image data, so as to simultaneous matching and positioning based on overlapping the LiDAR data and onboard images. [C547]

#### **"Digital terrain model extraction from airborne LiDAR data in complex mining area"**

Airborne light detection and ranging (LiDAR) proved to be an adequate technique to deliver highly accurate 3D mass points of the surface. However, the surface of mining area is complex with steep slope, dense vegetation, artificial mining facilities and buildings, which is different from the flat surface of city. The main processing workflow for DTM generation from LiDAR includes points filtering and DEM interpolation. In this article, five methods for removing object points from LiDAR data in mining area were compared. These methods, including Adaptive TIN (ATIN), Elevation Threshold with Expand Window (ETEW), Maximum Local Slope (MLS), Mathematical morphology (MM), Iterative Polynomial Fitting (IPF), analyze data points based on variations of local slope, elevation and height difference between points and the interpolated surfaces. Complex mining area data set with various cliffs of quarry, trees, houses, roads and small reliefs were selected to test the filtering methods. The results show that all methods can effectively remove most object points in complex mining areas. The ATIN and MM filter generated the best result in sharp cliff area of a quarry, whereas the other algorithms tended to remove the steep edge of quarry and roads. Depending on the filtering parameters, each method experienced various omission or commission errors. Quantitative assessment shows the ATIN and IPF based on the height difference between points and surface perform better. DEM interpolation assessment experiments indicate that interpolation biases were minute. Global statistics show that Modified Shepard's method, Spline and Radial basis function interpolation methods have the lowest errors in the study area. [C548]

#### **"Elevation-map based regional hazard detection for planetary landing"**

Future planetary exploration missions will aim at landing a spacecraft in hazardous or unknown regions of a distant planet, thereby requiring an ability to autonomously detect and avoid surface hazards and land at an affirmed safe site. Descent stage is typically subdivided into several stages to detect different hazards of varying styles and sizes. This paper focuses on those large surface features that could be detected at a high altitude and we present an elevation-map based regional hazard detection algorithm using image segmentation techniques. The algorithm is tested using Martian elevation maps and testing results show that the proposed algorithm is effective at detecting typical regional hazards such as craters, ravines and ridges, and reliable in selecting a safe and cheap landing window. [C549]

#### **"A system demonstrator for the performance evaluation of a 24 GHz ISM band radar operating with OFDM waveforms"**

OFDM signals possess a high flexibility, which, besides their typical employment for wireless digital communications, makes them also suitable for radar applications. In this paper an OFDM system will be presented that offers communication and radar functions in parallel based on one joint transmit signal. A typical application area would be intelligent transportation systems, which require the ability for vehicle-to-vehicle communication as well as the need for reliable environment sensing. A system demonstrator based on commercial equipment has been set up that allows for the transmission of an OFDM signal carrying arbitrary user information. From the reflected signal radar images resolving the distances of multiple reflecting objects can be calculated. In this paper, first the employed waveform and the detailed system setup will be discussed. Then, measurement results will be shown that prove the operability of the developed system concept and its performance. [C550]

#### "Underwater FDTD ELF simulation using dedicated hardware"

The 1-core CPU, 32-core CPU and Acceleware calculations were performed for the comparison. The results show that Acceleware approach is faster than the 1-core CPU calculation and twice as fast as the 32-core CPU calculation. [C551]

#### "Substrate integrate waveguide quasi Yagi antenna using SIW-to-CPS transition for low mutual coupling"

In this paper, the substrate integrated waveguide (SIW) quasi-Yagi antenna is proposed to enhance the low mutual coupling characteristics by using the SIW-to-CPS transition. The proposed design is based on impedance and mode matching method between the antenna components, such as quasi-Yagi antenna, the CPS feed, and the SIW-to-CPS transition. Moreover, the mutual coupling between neighboring elements of a quasi-Yagi antenna array is lower than the microstrip quasi-Yagi antenna with a measured level of  $< -29$  dB for a 2element structure with  $\lambda_0/2$  (where  $\lambda_0$  is a free-space wavelength at the center frequency of 9.5 GHz) separation. The phased array system using the proposed work can be applied with low mutual coupling characteristics can be applied to various applications in modern communications and radar systems as well as millimeter wave imaging arrays. [C552]

#### "Numerical vibration analysis of a SAR antenna"

Advanced military aircrafts and modern Medium/High Altitude Long Endurance aircraft or unmanned aerial vehicles will be equipped with structurally integrated array antennas for radar applications. The inertial forces and the aerodynamic loads will cause deformations and vibrations of the total antenna. The influence of deformations and vibrations will be most significant on array antennas, which are large in terms of wavelength (high gain antennas). An example of such an antenna is an array antenna for side-looking Synthetic Aperture Radar (SAR) mounted on the aircraft. ASELN SAR applications require highly directional antennas with a narrow beam and low side-lobe levels. In order to design a light and minimally vibrating SAR antenna, modal design is applied to virtual model of the preliminary design. Then, the physical model development tests and integration verification tests will be applied on the later design steps. [C553]

#### "UWB radar target sensing and imaging for granular materials research applications"

In this paper, we investigate a first-generation prototype of a radar system that will provide a minimally invasive fully automated measurement of individual and bulk particle movement in a 3D volume. The radar system comprises inexpensive tracer particles as targets, a test signal generation and measurement unit, and a post-processing unit for imaging. The proposed target is a square retroreflector, which is made up of three orthogonal square metal plates. An array of wideband antennas surrounding the testbed is operated in monostatic mode using swept-frequency VNA measurements that are processed to mimic an ultrawideband (UWB) bandpass pulse. In our first-generation prototype, we synthesize a linear array by moving the testbed relative to a single antenna. The testbed contains one or more targets deployed in a free-space (rather than granular material) volume. We perform delay-and-sum beamforming to reconstruct an image of the testbed. Images are generated for the retroreflector at two distinct orientations (normal and oblique) relative to the array. [C554]

#### "A novel passive ultrasensitive RF temperature transducer for remote sensing and identification utilizing radar cross sections variability"

In this paper, a prototype of the novel SRR temperature sensor integrated into the passive multi-sensor identification sensing system is demonstrated as well as RCS measurements. [C555]

#### "EM techniques for the detection of breast cancer"

Radar based microwave imaging technique has great potential for breast cancer detection. It has been demonstrated by recent experiments that the data adaptive radar microwave imaging reveals good image resolution. However, purely scattered energy based image reconstruction methods can face major challenges in differentiation since the fibroconnective and glandular tissues which could have similar dielectric properties as that of malignant tissues. It has been proposed that the morphological features of the tissue can differentiate the benign from malignant tissues due to their irregular, spiculated shapes. Thus to efficiently differentiate the healthy, benign and breast tissues, this paper proposes a method that combines a novel data-independent beamformer called MWDAS method with Matrix Pencil (MP) method to first localize the suspicious region and then extract the resonant frequency and damping factor of complex natural resonance (CNR) of the malignant tissues. We employ FD-TD based computational 2D and 3D breast models for testing our method. [C556]

#### **"Design and analysis of wideband antennas for borehole and surface ground penetrating radars: Application to soil moisture content measurements"**

In this paper, we have presented original wide band antenna design associated with a crosshole and a surface GPR configuration dedicated to the dielectric characterization of the subsurface. The antenna geometries defined, usually used for UWB applications at frequencies higher than 3 GHz, have been adapted to work at lower frequencies around 500 MHz to obtain a sufficient penetration depth. Moreover, size constraints have led us to design compact geometries. The overall links in both configurations have been modeled using FDTD simulations and detailed parametric studies have been made to optimize the antenna geometries for our application. First measurements associated with the crosshole radar have allowed to validate the two types of antenna designs proposed. Concerning the surface radar the experimental validation of the antennas developed on a test site is under way. [C557]

#### **"Performance evaluation of Null-Steering Bistatic MIMO Radar"**

They propose completely opposite radar system against conventional beam-steering radars. NBMR does not need the process to form omnidirectional beam to reestimate target position when target escapes null of beam. It is shown in Fig. 2. Moreover NBMR with autocorrelation involving weighting factor never lose target because it keeps almost a same resolution for target angle from transmitter, even if target escapes null of beam. It is shown in Fig. 3. With NBMR, we can realize efficient target tracking without being detected from airplanes. [C558]

#### **"Applying non-iterative phase errors compensation method to restore radar subsurface image"**

In this paper we describe a non iterative approach to evaluate and compensate the phase errors of radar subsurface image, and implement the approach to the images based on the MARSIS (Mars Advance Radar for Subsurface and Ionosphere Sounding) data. The main idea of the approach is to build the relationship by phase error vector between the unknown perfect image and a given phase-corrupted image, use the no return area in the perfect image as the constraint condition or known condition to solve out the phase errors vector directly. [C559]

#### **"Directional coupled sectorial loops antenna for Ground Penetrating Radars applications"**

In this paper, a directional UWB antenna based on the concept of coupled sectorial loops antenna (CSLA) is presented [2] [3]. The proposed antenna uses CSLA backed by a short cylindrical cavity with a modal suppressing septum to accomplish unidirectional radiation pattern. Bandwidth enhancement is accomplished by a pair of peripheral slots and a stacked CSLA configuration. sensitivity study is carried out to optimize the geometrical parameters of the antenna in order to achieve the maximum bandwidth and uniform radiation pattern. Through this optimization, this antenna has a VSWR lower than 2.5 across a 2.7:1 frequency range without the use of absorbing foams or lossy elements. The dimension of this antenna is approximately  $0.5 \lambda_0$  at the lowest frequency of operation. [C560]

#### **"Radon transform interpretation of the Physical Optics integral and application to near and far field acoustic scattering problems"**

Radon transform(RT) interpretation of the physical optics integral and application to near and far field acoustic scattering problems are reported. Closed-form expression of the radiation integral will be found for both acoustically soft and hard surfaces, and it will be shown that as a consequence of the RT interpretation of PO integral, the surface integral reduces to a line integral over the intersection curve. The line integral will be evaluated and analytical formulae for the scattered field will be developed for the triangular patches. [C561]

### "3D imaging of passive objects using dual-sided phase conjugating sequentially switched lens"

In this paper we introduce a new concept of a dual sided phase conjugating lens operating as an imaging sensor for continuous wave or pulsed signals for passive target 3D localization. We describe the principle of operation and demonstrate the core resolution properties for single and multiple objects by the way of numerical simulation. Particularly it is shown that the characteristic resolution of a single target by the lens operating under Gaussian pulse excitation is approximately the same as that obtained using UWB synthetic aperture radar techniques. The present concept offers major advantages with respect to existing time reversal techniques which involve computationally expensive high speed digital signal processing of the scattered field. The lens only requires hardware to collect the field scattered from the target(s) and to refocus it onto these target(s). This property should be of high potential for imaging applications where refocusing has to be accomplished in a real time i.e. when high speed target acquisition is necessary. Alternatively the lens can be operated in conjunction with a conventional imaging regime, i.e. to collect the scattered field data, send it to a post processing unit for mathematical image localization. [C562]

### "Research on vibration control and structure integration of antennas in NATO/RTO/SET-131"

Integration of antennas into ground, air or water vehicles is a critical task due to the increasing number of RF and microwave systems used for communication, radar or ESM. Structural aspects such as mechanical or thermal stability, aerodynamics or outer appearance are of great importance. Methods and technology for the integration of single antennas or antenna arrays into structures of different type (e.g. glass or carbon fibre composite materials) are currently being developed at different companies and research institutes and are scope of research work in the NATO task group SET-131. The performance of a system should not be affected by the influence of the carrier platform or by electromagnetic interaction between different systems. Another important aspect are variations of the shape of a vehicle or its parts which may also degrade the overall system performance. There are different reasons for these changes, e.g. vehicle motion, moving parts such as rudders or turbines, or the impact of a projectile or collision. [C563]

### "Double-sided parallel-strip line-fed circular monopole antenna"

This work presents a double-sided parallel-strip line fed ultra-wideband circular monopole antenna. This antenna exhibits a periodic 2:1 VSWR bandwidth from 1.0-9.0 GHz and a continuous 2:1 VSWR bandwidth from 9.5-14.0 GHz. Above 14.0 GHz, the antenna exhibits a mixture of continuous and periodic 2:1 VSWR bandwidths. At 5.0 GHz the antenna radiates an omni-directional beam with a maximum gain of 5.5 dBi, and at 10.0 GHz the antenna radiates a monopulse beam in the end-fire direction with a maximum gain of 6.7 dBi. These measured results confirm the expected values from simulation. [C564]

### "Three-dimensional through wall imaging using an UWB SAR"

A 3-D UWB SAR has been designed to detect the positions of the targets behind the wall and identify them as well. The beam scanning is based on the mechanical movement of the wideband Tx/Rx Vivaldi array. The system transceiver and 3-D microwave beamforming algorithm are introduced in details. An experiment is performed to recover the 3-D images of a human mock-up. The demonstrated 3-D imaging results have indicated the capability of accurately locating, tracking and identifying human beings behind the wall. [C565]

### "Time-Reversal Processing and Autofocus of Targets Behind Complex Wall"

Through-the-wall radar imaging (TWRI) beyond a single wall is a growing area of study. A novel near-field time-reversal match filter deconvolution procedure was proposed to improve imaging behind complex periodic walls. Promising results with improved target resolution were shown. Future work will leverage such technique to tolerate errors in wall parameters leading to an autofocus approach. [C566]

### "Miniature double-ridged horn antennas composed of solid high-permittivity sintered ceramics for biomedical ultra-wideband radar applications"

Ultra-wideband (UWB) radar sensors are attracting more and more attention, e.g., for biomedical applications. In contrast to established techniques like X-ray tomography or invasive diagnostic approaches, UWB radar offers the potential for remote access and ultra-low power signal intensities. Inspired by promising studies of breast tumor imaging, we are continuing and extending our previous work on biomedical M-sequence radar and antenna techniques. We describe the development and the potential of innovative double-ridged horn antennas, based on high-permittivity sintered ceramics, which have been adapted to the envisaged biomedical applications. In this context, the miniaturization of UWB antennas, due to the restriction to small examination areas, without compromising the electromagnetic fidelity is the overall challenge. For the dielectric scaling of antennas with the

potential to operate over wide bandwidths, we focus on nearly frequency independent, high-permittivity and low-loss materials. In what follows, we describe the arduous path from the first idea to functional laboratory versions of double-ridged horn antennas based on solid sintered ceramics. In this way, the paper illustrates the successful interdependence between microwave engineering and mechanical and material engineering. [C567]

#### "Compact reflectarray antenna element using split ring resonator"

This paper presents a compact reflectarray element using split ring resonators (SRRs) for small size and high gain reflectarray design. The proposed element is constructed of dual concentric split rings and a metal line on different layers. Several design parameters of the unit cell are studied for obtaining better phase response. The proposed unit cell achieves a good phase response of 700 degrees at X-band. The unit cell size is 14 mm Ч 14 mm ( $0.36 \lambda_0 \times 0.36 \lambda_0$ ). Due to the small unit cell size, the reflectarray with the proposed element can be expected to achieve high gain. [C568]

#### "Detecting flaws in buried pipes under rough surface using the natural frequency technique"

The matrix pencil method is a MatLab friendly algorithm that generates results in real time. The technique was able to detect cracks in pipes whether they were on top of the pipe or on the bottom up to a SNR = 10dB. Also cracks in hidden and buried pipes were detected using the same technique. [C569]

#### "Radar imaging of a large building based on near-field Xpatch model"

The U.S. Army Research Laboratory's ultra-wideband (UWB) radar was used in field experiments for through-the-wall imaging of an abandoned Army barrack with an approximate 33 m by 27 m footprint. In a previous paper, we used a Physical Optics (PO) based ray tracing code simulating a far-field spotlight configuration in order to explain some scattering features observed in the experimental image (obtained via near-field strip-map configuration). In this paper, we use the same code and model for a data collection geometry that closely matches the experimental setup, and the backprojection algorithm (BPA) for image formation. The new simulated image shows an improved correlation with the measured image, further confirming the applicability of ray tracing codes for UWB imaging in a realistic environment. [C570]

#### "DFT-UTD based MoM approach for an efficient analysis of scattering from large, finite arrays in the vicinity of scattering objects"

This paper presents an efficient hybrid method for analyzing scattering/radiation from electrically large arrays in the vicinity of nearby obstacles. Electrically large arrays are widely used in several applications such as radars, remote sensing systems, and modern communication systems. In general, these arrays radiate in the presence of nearby obstacles, such as an array on a mast. The proposed approach is based on the combination of a ray-field representation of the field radiated by electrically large arrays and a DFT (Discrete Fourier Transform) representation of nonuniform array current distribution. Realistic array current distributions are nonuniform even if the array is excited uniformly due to coupling among the array elements and coupling between array and scattering objects. DFT employment for expressing nonuniform array current distribution is a robust approach, since, for practical array current distributions most of the DFT coefficients are close to zero, except for a few significant terms. [C571]

#### "Effect of primary feed polarization on phase centre location of parabolic reflector antennas"

Knowledge of the phase centre location of the antenna is of great importance in various applications, such as global positioning system (GPS), remote sensing, radars, and virtual arrays. In parabolic reflectors, the phase centre is located at the center of the aperture plane when it is illuminated by a prime-focus point source feed having an axially symmetric pattern. It is clear that if one displaces the antenna phase centre, the apparent location of the antenna will move resulting in a virtual antenna. The virtual array antenna can be thought of as an antenna having multiple identical beams, with multiple displaced phase centre locations. Such a property is desirable in remote sensing applications, to allow multiple antenna representations. Multiple phase centre reflector antennas were studied in using a dual-mode feed horn as a primary feed. In this paper, the impact of the feed polarization on the phase centre location of offset reflector antennas will be addressed. The feed is a dual mode circular waveguide antenna operating at its fundamental mode,  $TE_n$ , and the higher order mode  $TE_{21}$ . It will be shown that the phase centre displacement can be controlled by simply changing the excitation amplitude and phase of each mode, as well as employing different mode orientations. In particular, the direction of the phase centre movement will depend on the polarization of each mode. [C572]

#### "A printed extremely wideband antenna for multi-band wireless systems"

In this paper, a printed elliptical monopole antenna, which is fed by a modified, tapered microstrip feed is presented. The measurements indicate it has an extremely wide impedance bandwidth of 1.08-27.4 GHz. The antenna can support many communication and wireless other services, such as GPS, GSM1800, WLAN, UWB communication systems (3.1-10.6 GHz) and part of the UWB vehicle radar systems (22-29GHz). It is also suitable for extremely wideband spectrum monitoring, interference characterisation and similar EMC/EMI applications, as well as extremely broadband RF energy scavenging. The proposed antenna design and results are discussed. [C573]

#### "Low frequency imaging of separated objects using the ramp response technique"

In this paper, the authors have presented new results of separated objects reconstruction with the ramp response technique. With the canonical example of 2 separated spheres, we have shown that the limit of separation between these objects is given by the spatial limit of resolution, which is inversely proportional to the frequency band. Indeed, the spread in the shadow region does not impact this limit of separation, but it only affects the shape of objects; this must be compensated in the reconstruction process. [C574]

#### "Advanced through-the-wall radar imaging using spectral and wall estimation techniques"

Two techniques are introduced and combined to improve SAR imaging of TWR scenarios, namely wall estimation and spectral estimation imaging using MUSIC. It was shown that homogeneous walls can be eliminated from SAR images although a significant amount of clutter remains if the wall shows inhomogeneities. Furthermore, applying the MUSIC algorithm can significantly clear up the image and make the targets behind the wall more visible. In conclusion, both the described wall estimation technique and MUSIC imaging can enhance TWR images, allowing a clearer interpretation or building a more reliable basis for further processing like target detection. [C575]

#### "Circularly polarized supershaped dielectric resonator antennas for indoor ultra wide band applications"

A recent paper [1] has introduced a new class of dielectric resonator antennas (DRAs), the so-called supershaped DRAs (S-DRAs). This class of radiators took its name from the mathematical formula, known in literature as superformula (see [1] and references therein), that defines the geometry of the base of the dielectric prism acting as dielectric resonator (DR). S-DRAs feature wideband matching characteristics (with relative bandwidths exceeding 50%) and broadside radiation. Moreover, the radiation pattern of this family of DRAs can be varied by changing the DR shape such to become broad and rather stable over large frequency ranges. All these features, combined with the possibility of manufacturing S-DRAs in an inexpensive manner, suggest a possible application of these components in the realm of indoor communication. More specifically, such antennas could be used as access points for wireless local area networks supporting ultra wide band application. However, a closer look at the radiation properties of the S-DRAs has put in evidence the fact that some components of the radiated fields experience sharp notches along specific directions. This could cause severe fading effects in the radio channel in the case of using inexpensive receiving devices (e.g. mobile hand-held terminals). To mitigate this problem an improved version of a specific sub-set of S-DRAs is hereafter presented. The selection of DR cross-shapes having two symmetry planes allows for the excitation of two orthogonal and degenerate radiation modes that, combined, ensure circularly polarized radiated fields. A dual-point feed strategy (see [2], Ch. 7) is adopted to ensure broadband operation. Naturally, as means to ensure circularly polarized radiation, the two degenerate and orthogonal radiating modes are fed with synchronous time-harmonic signals of equal amplitude having an initial phase difference of 90°. [C576]

#### "UWB antenna array for real beam radar imaging"

The four element ultra-wideband (UWB) comb taper slot antenna array with 18 cm element spacing is used for receiving the wideband scattering signal. A double ridge wideband antenna is used as the transmitting antenna and the above developed large aperture UWB array is used as the receiving antenna. The transmitting antenna and the receiving antenna are placed close to each other for quasi monostatic radar imaging. The total linear scan length of target is 200 cm. The receiving impulse signal is achieved not only by the measurement but also by the simulation tool of GEMS. The receiving impulse signals at various positions are processed by the delay and sum algorithm. The results of real beam radar imaging from both simulation and experiment are well agreed. [C577]

#### "Application of the SHGA basing on the CFPM to hypersonic vehicle wing-body location design optimization"

The Genetic Algorithms (GA) is a kind of modern intellectual global optimization algorithm, but there are many shortcomings in some idiographic questions, and its local searching ability is worse. In this paper, aiming at the wing-body joint location of quasi-waverider hypersonic vehicle, improving on the Simple Genetic Algorithms (SGA), inducing the Constrained Flexible Polyhedron Method (CFPM), the Serial Hybrid Genetic Algorithm (SHGA) is presented. Optimizing the wing-body location with the SHGA, getting the Pareto optimal solution of the multi-objective optimization question, the best configuration is recommended. Comparing with the basic model configuration, the recommended configuration improves in the balancing, maneuverability and stability, hiding ability. The SHGA and results of this paper are valuable for hypersonic vehicle design. [C578]

#### "Simulation of UWB echoes from ground based on CPML-FDTD"

In designing some UWB-IR (ultra-wideband impulse radio) devices, the effects of ground echoes must be taken into consideration. The dispersion of soil and roughness of ground surface are significant factors in ground echoes calculation. FDTD (finite difference of time domain) algorithms applied in ground echo simulation at present have the problems of slow speed or large errors. By using multi-pole Debye model as soil dielectric coefficients, and CPML (convolutional perfectly matched layer) as absorption boundary condition, a CPML-FDTD algorithm is derived in multi-pole Debye media. Simulations are carried out under different conditions, and comparison with non-PML FDTD algorithm proves the validity and efficiency of the proposed algorithm. [C579]

#### "Feature extraction and selection for landmine detection using textures of Time-Frequency Representation"

Ground Penetrating Radar (GPR) is widely used in the probe of subsurface targets, in which the Time-Frequency Representation (TFR) approaches have been proved effective for GPR signatures. Since we can treat TFR results as 2-D images, texture analysis is an applicable way for image discrimination. In this study, we propose a target detection method based on TFR textures of GPR A-scans and then select 20 descriptors to interpret TFR image into texture features for decision. The mutual correlation and discrimination ability of the descriptors are studied based on the comparative experiment. According to the results, it is clear that the twenty descriptors are redundant and can be grouped into three weak-correlated classes: 11 descriptors of the first class and 2 of the second one are helpful and recommended to use in texture discrimination while the rest can be discarded. [C580]

#### "Radar jamming resources assignment algorithm for EW real-time decision support system of multi-platforms"

Modern naval battle forces generally include many different platforms, e.g., ships, planes, helicopters, etc. The optimal assignment of radar jamming resources distributed over these platforms is an important research aspect of EW real-time decision support system. This paper presents the mathematical model of the radar jamming resources assignment of multi-platforms and proposes the assignment algorithm based on multi-agents distributed cooperative auction. The algorithm is proved to be feasible by an example. [C581]

#### "Analysis and pattern recognition of blast furnace burden surface based on multi-radar data"

Iron making is the first stage and also an important part in steel making process, which will bring the problem of energy efficiency and economic benefits. In this process, the distribution of the blast burden impacts greatly on the production of BF (blast furnace). Therefore, the prediction of furnace burden distribution in furnace throat will play an important role in the control strategy of furnace burden. Based on the data from the multi-radar, the blast burden curve can be formed. Feature extraction and classification based on different curves (i.e. different pattern) can be made by using BP neural networks. The work proposed in this paper will be a guidance for the future research of burden surface based on the data of phased-array radar. [C582]

#### "Research on the model of Target's trail and the detection simulation of air-defense radar"

In the trace fusion system, it is the unitary way and high cost to get the data sources of air-defense radar. Aiming at those shortcomings, this paper gives a method to generate data based on the model of target's trail and the detection simulation of air radar. The emphasis is placed on the model of target's trail and the process of air-defense radar detection. First of all, the trail model is built up on the flight plane, and then converted into rectangular coordinates system. The radar detection model simulates the detection process to estimate whether the target can be found. The real-time trace data is obtained if the target is found. The experiments validated the models and algorithms. [C583]

#### "Research on modeling and simulation of cruise missile interception system based on Object-

### **Oriented Petri net"**

Petri net is a tool suited for describing system with the feature of concurrence, asynchronization, distribution and undecision. This paper studied and realized a modelling method based on Petri net which integrated Object-Oriented approach and Petri net method, calling Timed Object-Oriented Petri net. It's more powerful to describe complex system but with less complex Petri net structure. We researched how to realize this method in computer simulation and applied this theory to the confrontation simulation of cruise missile interception system, which is a very complex system. [C584]

### **"Design and realization of virtual simulation training system for certain type artillery radar"**

There are many difficulties in the process of the training for the artillery radar's position selection, such as training field is limited, the evaluation method for training is laggard. To resolve the problem, a virtual simulation and training system was designed based on Virtual Reality technology. This system developed with tools of OpenGL, Multigen-Creator, VC++6.0, and created a 3D scene with the DEM data of digital map. The system simulated virtual equipment of artillery radar, special effects of rain, snow, and fog based on collision detection technology and particle system technologies, and formed a realistic virtual battlefield environment, and composition structure, function module and key technologies of the system were discussed. Accordingly, the system implemented all the functions of scenario edit, scene display, position selection training and training evaluation. [C585]

### **"A high-performance heterogeneous embedded signal processing system based on serial RapidIO interconnection"**

The demand for high-performance embedded signal processing systems has expanded rapidly in recent years. As applications requiring faster computation capability, higher throughput bandwidth and more flexible interconnection, traditional embedded signal processing systems could not meet the demand of ever-increasing performance. The paper designs a high-performance heterogeneous embedded signal processing system based on the serial RapidIO interconnection to fulfill the next generation radar system. The system is designed based from aspects of computation capability of single processor, scale of parallelism in system, arrangement of memory architecture, interconnection topology and bandwidth. The system consists of three modules which are high-speed AD module, heterogeneous processing module including FPGA and CPU and RapidIO switch module. The system conform to Advanced Mezzanine Card (AMC) Standard and AdvancedTCA Standard and all modules aggregated by serial RapidIO. The system can perform up to 2 Gsps sampling rate, up to 550MHz processing capability on FPGA and 1.5 GHz on CPU and up to 80 Gbits/s aggregate bandwidth. And finally applications such as system dataflow and control are presented. [C586]

### **"Wide band noise interference suppression for SAR with dechirping and eigensubspace filtering"**

It is necessary to enhance the anti-jamming capability of Synthetic Aperture Radar (SAR) for ensuring its imaging performance. A new approach to suppress wide band noise interference (WBNI) based on dechirping and eigensubspace filtering was proposed in this essay, and computer simulations were performed. All results prove that this approach can effectively suppress WBNI with negligible signal distortion under the condition that the Jamming-to-Signal Ratio (JSR) is 5dB smaller than pulse compression gain. [C587]

### **"Design and realization of virtual scene explore system for artillery reconnaissance radar"**

Virtual Scene Technology is one of the important parts of VR systems. It takes charge of Vision issue in VR systems, and is the most important fact to affect the immersive of the system. There are many problems in training simulation of artillery reconnaissance radar, such as the battlefield environment isn't living, the load of assemble and disassemble is large, the training cost is high. The virtual scene explore system was developed. The general structure of VS Explore System is analyzed and demonstrated, and connection between different parts of VS explore system in system construction process is explained. Several key techniques such as the building of virtual topography based on Delaunay triangle through Delaunay arithmetic, the building of radar, virtual scene explore, etc, are also given in detail. [C588]

### **"The research of interaction management based on the IPv6 wireless mobile terminals"**

The packet switching service of the third-generation mobile communication network (3G) has provide a broader range of services, while wireless local area network (WLAN) has a faster speed in information transmission, thus making these two complementary functionally. However, with the improvement of technology and increasing of mobile users, it has a significant impact on network communication when switching the networks which result in handover latency, although the different networks allow mobile users roaming between different IP networks;

furthermore, it will lead to care-of-address of mobile users error caused by the failure of agent information return if the users move too fast. This thesis basically studies on mobile terminals in the WLAN and 3GPP, two different networks using a wireless IPv6, aiming at proposing a to reduce switching delay and position error.

[C589]

### "A target selection method for ASM based on ICP algorithm"

It's a hard task for anti-ship missile (ASM) to select the target ship from multi-objects acquired by terminal guidance radar. In this paper, a method to select the target in a ship formation is presented based on iterated closet point (ICP) algorithm. The principle of this method is described as follows: (1) a ship formation is independently detected by fire-control radar and terminal guidance radar, and the detected ships by each sensor are separately described with two point sets in a plane; (2) the target selection is realized by matching this two point sets based on ICP algorithm, i.e. finding the correspondences of points in the two point sets; (3) the correspondence of the designated ship in the point set detected by fire-control radar is the target ship to be selected. Compared with former MPR (mutual Position Relationship) method, the performance of the method in this paper is hardly influenced while the ship formation changes the course during the self-control phase of ASM. This superiority is validated by simulation results. [C590]

### "An improved particle filter based on 4D discontinuous measurements"

During the target detection of the airborne pulse Doppler (PD) radar, a 4D measurement comprised of range, azimuth, elevation and radial velocity can be obtained to track the target exactly. But the factors including the Doppler blind zone (DBZ) would result in discontinuous measurements which breaks the continuity of the target track. To be consistent with the practice, we constitute the 3D relative motion model between the airborne radar and the target based on moving platform, and deduce the character of the relative radial velocity in DBZ. According to this, an improved particle filter with relative maneuver detection is proposed. This algorithm is able to adjust the moving direction of the particles according to the type of maneuver, and maintain the tracking by predicting the possible region where the target reappear from the DBZ. The simulation results indicate the validity and feasibility of this method. [C591]

### "UWB cylindrical microwave imaging system with novel image reconstruction algorithm"

In this paper, we apply an ultra wideband radar technique to detect and locate small cylindrical objects in a dielectric cylindrical body emulating the woman's breast. We propose a new image reconstruction algorithm which exploits the monopulse radar principle involving a 2-element array antenna. Using the difference of two signals received by the elements of this array, the part of the signal due to a background being symmetric with respect to the axis of the array is removed. The remaining part is the signal which is due to a scattering object located in the off-axis position of the array. The acquired set of difference signals obtained for various locations of the probing antenna is suitably scaled and mapped to show an internal image of the scanned body. The operation of this system including the new image reconstruction algorithm is demonstrated via full EM simulations and experiment. The proposed imaging approach should be of considerable interest to researchers working in the field of microwave techniques for breast cancer detection and location. [C592]

### "Project management and data quality control"

The Building Sustainability Index (BASIX) is a government initiative at the New South Wales (NSW) Australia to assess the potential performance of new homes against a range of sustainability indices. Over the past 5 years, BASIX has grown into one of the largest environmental sustainability projects in the world and all the houses built and renovated since 2004 have to comply with the BASIX requirement. As a, a large amount of data has been collected and the data sets are grown at a daily basis. Data quality monitoring (DQM), control and the development of a standard for data quality metrics have become a business-critical issue.. In this paper, the authors, based on the BASIX development experience accumulated over the past 6 years, look into the issue of data management, data quality control and recent work carried out at the NSW Department of Planning. [C593]

### "Application of compressed sensing theory to radar signal processing"

Compressed sensing theory is a newly developed theory which unites the signal sampling and compression, based on the sparsity characteristic of signal. The union can reduce sampling rate, and then reduce computational complexity of the system without the loss of the performance of the system. The paper describes the theoretical frame and some key technical, and then illustrates the application of compressed sensing theory to radar signal processing. [C594]

### "High resolution radar imaging utilizing a portable opportunistic sensing platform"

In this paper, high resolution 3-D images generated via a portable wideband RF imaging system are presented. In contrast to traditional SAR processing, this system is able to construct high quality composite images by incorporating a handful of individual coherent radar "snapshots". In the pursuing paragraphs, system functionality and hardware integration are briefly described followed by a 3-D imaging example to display system capabilities. [C595]

### "Y-band phenomenology of indoor environment"

Characteristics of indoor environment at Y-band frequencies have been investigated. Radar measurements of hallways were carried for both vertical and horizontal polarizations. Measurement results show that horizontal polarization gives a more accurate mapping of the indoor obstacles. [C596]

### "Design of two-element probe antenna for UWB near-field imaging"

This paper has reported a microwave imaging system employing a monopulse radar technique to eliminate adverse effects of strong reflection from the air-imaged body interface. This technique is realized using a newly constructed ultra wideband twoelement probe antenna fed by a 180° hybrid. The validity of the proposed system has been verified via full-wave EM simulations. Using the signal data obtained from the outof-phase fed UWB probe and by applying a confocal image reconstruction algorithm, the presence of a 9mm-diameter cylindrical target inside the 100mm diameter container filled with vegetable oil has been detected by just visual inspection of the produced image. [C597]

### "A novel method for limiting the amplitude of SAR images with the principal axis detection"

Amplitude limiting of SAR target is one important preprocessing procedure in SAR target recognition. Traditional amplitude limiting adopted simple threshold value and is usually sensitive to noise. In this paper, a novel method for limiting amplitude is proposed, which is based on the priori knowledge that normally the strong scatter points are nearby target's principal axis. First, target's principal axis and its center is detected with the strong scatter points, then the target area is estimated and the strong scatter points' amplitude are limited by a simple smooth process. Experiments on SAR image show that the proposed method can limit the amplitude of the strong scatter points and enlarge that of the weak scattering points well. [C598]

### "On orthogonal waveform design for MIMO sonar"

MIMO sonar that transmits orthogonal waveforms via transmitter sensors is an emerging technology that has significant application potential. Compared to standard phased array sonar, orthogonal transform waveform can bring many advantages including improved angular resolution and multi-target detection ability. We derive in this paper a novel binary-phase waveform design coded by Gold sequences. This phase code is computationally efficient compared to other codes previously proposed in the literature. We provide some numerical examples to demonstrate the performances of the new code sequence. [C599]

### "A multi-sensors data fusion method based on the augmented support degree"

Due to data fusion with a large number of data on some characteristic index, an improved online data fusion method is proposed. At first, it used a fuzzy-index function to measure the mutual support degree of the observation values. Then an augmented matrix was defined as the criterion for integrated support degree of data from various sensors. According to this augmented matrix's maximum modulus eigenvectors, corresponding weight coefficients of all the observation values were allocated, hence, the final expression of data fusion and estimation was obtained. Finally, an experiment and a simulation were used to compare the proposed method with other two similar fusion methods. Simulation shows that this method is likely have higher precision and strong ability of stableness, and can be employed in uncertain environment with variable sensors. [C600]

### "Application of fuzzy pattern recognition in burden surface identification"

A kind of pattern recognition method with Fuzzy clustering is applied to identify the burden surface of blast furnace. According to the information of burden surface distribution, the target clustering analysis is used to set up a standard model database. Based on the character of distribution, each target burden surface is matched into different standard model database by using fuzzy pattern recognition method. Maximal minimal similarity method is adapted in the course of fuzzy pattern recognition. The simulation results show the effectiveness of the proposed method. [C601]

### "An adaptive modulation method based on bit preassign for HF OFDM systems"

Adaptive HF OFDM system can improve the transmission performance by bit and power loading based on the characteristic of subchannel. Greedy algorithm is the optimal method for finite granularity bit allocation, but it has high computational complexity. A new improved bit and power loading algorithm is proposed for HF OFDM systems in this paper, some bits is pre-allocated to some subchannels based on SNR, the spare bits are allocated by greedy algorithm in new method. The results of simulation reveal that the BER performance of the new method approaches to greedy algorithm when the adjustable coefficient is 0.5, and the computational complexity is lower than greedy algorithm. [C602]

### "Research on design process for complex product"

The workflow is playing a more and more important role in collaborative design due to inherent complexity of the design process. The characteristics of the development for the complex product are studied and a multi-level, modular, integrated workflow is put forward. The functions which should be provided by the workflow is discussed and based on the function the framework of workflow is set up. Then the execution pattern which takes input/output template as the drive is studied. At last, a workflow management system (WFMS) for the development of radar is illustrated. [C603]

### "Neural based optimization analysis of distributed MEMS transmission line phase shifters"

RF MEMS (Radio Frequency Micro Electro Mechanical System) technology is a key innovation for building low-loss phase shifters and other control circuits at millimeter-wave frequencies. The developments of electronic phase shifters with high insertion loss have been used in phased array radar and in wide range of systems including communications and measurement instrumentation. In this paper we propose an efficient approach based on Artificial Neural Network (ANN) for optimization of Distributed MEMS Transmission Line (DMTL) to obtain the maximum amount of phase shift with minimum insertion loss. Based on the work of Rodwell et al for analysis of loss in distributed non linear Coplanar Waveguide (CPW) line, we extend the work for optimization for best phase shift. A stand-alone model for optimization of DMTL phase shift is derived efficiently using ANN. The results from the neural models trained by Levenberg-Marquardt algorithm are in very good agreement with the theoretical results available in the literature. [C604]

### "Mitigation of radar interference with WiMAX systems"

In this paper, the effect of radar-induced electromagnetic interference (EMI) on a WiMAX base station receiver is investigated through the use of MATLAB models. The three types of radar pulses investigated include: a short, wideband, chirp pulse; a long, narrowband, chirp pulse; and a long, sinusoidal pulse. The benefits of superimposing these pulses in the guard interval and/or guard band of the WiMAX waveform are explored. [C605]

### "An MIMO-MTI approach for through-the-wall radar imaging applications"

In this paper, we apply Multiple-Input Multiple-Output (MIMO) configurations to Moving Target Identification (MTI) for urban sensing using radars. In particular, we consider MIMO-MTI formulations for detecting slow-moving personnel inside enclosed structures and behind walls. Using signal multiplexing from two transmitters and several receiver positions, it is shown that the virtual array (co-array) implementing MIMO schemes, applied to stepped-frequency radars, permit improvement in image resolution of moving targets. Laboratory experiments are conducted to validate the proposed approach with targets walking behind walls. [C606]

### "SMSE-based DSA radar waveforms"

Previous communications systems research has demonstrated that the Spectrally Modulated, Spectrally Encoded (SMSE) framework is well suited to SDR platforms and operation in both contiguous and non-contiguous spectrum given its ability to generate a wide variety of multicarrier waveforms such as OFDM, NC-OFDM, MC-CDMA, NC-MC-CDMA, CI/MC-CDMA, NCCI/MC-CDMA, and TDCS. In this paper, SMSE waveforms are extended for use in sparse frequency radar systems. Sparse frequency radar can be capable of dynamically sensing available spectrum, and tailoring the transmitted waveforms to suit the instantaneous RF environment conditions, simultaneously transmitting energy in multiple noncontiguous spectrum bands. Conventional radar performance metrics are reviewed, and a new metric is introduced which specifically addresses performance of noncontiguous spectrum waveforms through comparison to contiguous spectrum waveforms. Through simulation, various examples are shown to illustrate and characterize the impairments that are introduced in processing these classes of non-contiguous spectrum waveform returns, specifically the generation of large range sidelobes. [C607]

### "Using time reversal of multipath for intra-pulse radar-embedded communications"

This paper considers the problem of embedding a covert communication waveform into the backscatter from an illuminating radar by an RF tag/transponder within a multipath environment. We propose to exploit the multipath via time reversal, which is ideally suited for backscatter communications. Multipath time reversal induces a spatio-temporal focusing of the embedded communication waveform at the desired receiver while distorting it at all other locations thus further reducing the probability of intercept. Specifically, the paper addresses the case where the radar waveform is known to the tag/transponder thus allowing for estimation of the multipath via coherent processing (i.e. pulse compression). Within the radar-embedded communications context the use of the estimated multipath is compared with the case when no multipath knowledge is employed. [C608]

### "The impact of internal clutter motion on a sample matrix inversion space-time adaptive processing algorithm and the GMTI minimum detectable velocity"

A MATLAB simulation was constructed to better study the effects of internal clutter motion on a notional X band monostatic airborne radar employing a ground moving target indicator (GMTI) algorithm to detect slow velocity targets of low radar cross section. A sample matrix inversion (SMI) fully adapted post-Doppler space-time processor (tapered and untapered) was utilized and the internal clutter motion model of Ward [1] was applied to the overall simulation. As one would expect, the untapered version yielded slightly better results but in all cases final minimum detectable velocities of about 1.0 meter/second were obtained. By judicious choice and implementation of a reduced rank/dimension algorithm, it should be possible to obtain similar MDV results.

[C609]

### "Target RCS exploitations in compressive sensing for through wall imaging"

In this paper, target radar cross-section (RCS) is utilized to improve the performance of compressive sensing (CS) when applied to sensing through wall based on RF modality. Using step-frequency SAR imaging, it is shown that the selection of frequencies emitted at each antenna position of the SAR system can benefit from a priori knowledge of the target RCS. Frequencies with high target response allow the CS performance to be more robust to noise and are able to reveal target presence in noisy and cluttered environments. [C610]

### "Embedding information into radar emissions via waveform implementation"

In this paper an approach for the joint design of multiple receive filters is described that enables the use of different waveforms during a radar CPI while minimizing the attendant Doppler coherency degradation due to range sidelobe clutter modulation. This capability allows for a set of unique radar waveforms to serve the dual purpose of acting as communication symbols while acceptable radar performance is maintained. The receive filter design approach is based upon the well-known Least-Squares (LS) mismatch filter formulation. The novel modification is the iterative adaptation of the desired response such that all the waveform/filter pair responses are driven to be identical. [C611]

### "ISAR imaging in sea clutter via compressive sensing"

We investigate the application of compressive sensing (CS) to inverse synthetic aperture radar (ISAR) imaging of moving targets. We present our results for a simulated target immersed in different levels of sea clutter. Comparison between traditional and CS approaches to ISAR imaging reveal that our based CS algorithm offers some advantages compared to traditional ISAR imaging under certain limited operating conditions that are nevertheless of practical interest. We conclude by pointing out directions for future work in extending the results of this paper. [C612]

### "Pareto-optimal radar waveform design"

This paper deals with the problem of Pareto-optimal waveform design in the presence of colored Gaussian noise, under a similarity and an energy constraint. At the design stage, we determine the optimal radar code according to the following criterion: joint constrained maximization of the detection probability and constrained minimization of the Cramer Rao Lower Bound (CRLB) on the Doppler estimation accuracy. This is tantamount to jointly maximizing two quadratic forms under two quadratic constraints, so that the problem can be formulated in terms of a non-convex multi-objective optimization problem. In order to solve it, we resort to the scalarization technique, which reduces the vectorial problem into a scalar one using a Pareto weight defining the relative importance of the two objective functions. At the analysis stage, we assess the performance of the proposed waveform design scheme in terms of detection performance and region of achievable Doppler estimation accuracy. In particular, we analyze the role of the Pareto weight in the optimization process. [C613]

### "Waveform design for low frequency tomography"

There are multiple applications that would benefit from the ability to produce three dimensional, high resolution, imagery collected at low operating frequency; among them remote archeological survey of ruins through foliage, and searching for voids in collapsed structures and underground. High vertical resolution circular SAR requires the use of wide-to-ultra wideband waveforms, a problematic aspect in the modern RF spectral environment, particularly at lower frequencies. RF tomography offers the potential to yield high, 3-dimensional resolution using spectrally sparse, narrowband waveforms simultaneously with operation at frequencies that have demonstrated favorable penetration through intervening dielectric media. In this paper we explore this potential by evaluating minimal spatial support tomographic apertures combining diverse narrowband signals with the form (trajectory) of the monostatic collection aperture. Results are presented in terms of image quality metrics: those frequency combinations that jointly minimize peak and rms voxel sidelobe level, cardinal axis resolution length and voxel volume. It is shown that, generally, the frequency selection is a soft constraint in terms of the achievable resolution and image sidelobe levels; that the tomographic aperture with spatial sampling that is linearly continuous and substantially less than hemispherical yields high spatial resolution, and that there is interaction between the form/shape of the tomographic and the waveform set. [C614]

### "Channel probability ensemble update for multiplatform radar systems"

Cognitive radar (CR) is a recently proposed concept that depicts the radar channel in a probabilistic manner. In a multiplatform or networked radar system, some parameters or dimensions of interest are visible (i.e., resolvable) to one radar and not to others depending on the geometry of the scenario. For a radar with new measurements, Bayesian methods to update the cell ensemble probabilities in the non-visible parameters are needed. Here, we show how the overall probabilistic understanding of the channel can be updated despite the fact that some cells are non-visible or "ambiguous". Unfortunately, the number of calculations needed to accomplish a full update is exponentially related to the number of cells. As such, we also introduce a technique that reduces the calculations immensely. Finally, we apply both update techniques to a two-platform radar system trying to form a two-dimensional probability ensemble of the channel. [C615]

### "Target localization in multipath environment through the exploitation of multi-frequency array"

In this paper, we propose a multi-frequency array structure that achieves accurate target localization in a multipath environment. The use of multi-frequencies enables decorrelation in the array to operate direction-of-arrival (DOA) estimation for coherent arrival paths, whereas the spatial filtering of the signals makes the paths separable for robust range estimation. Multi-frequency radar techniques are then applied for range estimation of each path. The target position is identified by the shortest range coupled with its DOA. [C616]

### "Frequency diverse waveforms for compressive radar sensing"

High range resolution radar systems use wideband frequency modulated waveforms to estimate the spatial distribution of the scatterers in the scene. Estimation of range profiles from backscatter energy is a linear inverse problem. The emerging field of compressive sensing has provided provable performance guarantees and signal recovery algorithms for random sub-sampling of sparse or compressible signals. In this paper a novel compressive sensing strategy for radar is introduced which relies on using waveforms with frequency diversity on transmit and random aliasing on receive, that shifts the burden of the sampling operator from the receiver to the transmitter. The transmitter and receiver structure for compressive sensing is described and the sensing matrix for the proposed compressive sensing strategy is derived for use in compressive sensing recovery algorithms based on sparsity regularized inversion. A preliminary experimental demonstration of the compressive sensing strategy is given through sampling of staggered multifrequency linear FM signals through a single low rate A/D. [C617]

### "Optimal mismatched filter bank design for MIMO radar via convex optimization"

In this paper, a mismatched filter bank is designed for suppressing the autocorrelation peak sidelobe level (PSL) and the peak cross-correlation level (PCCL) of an orthogonal polyphase sequence set applied in a multiple-input multiple-output (MIMO) radar system. The mismatched filter bank is obtained by minimizing a weighted maximum of the PSL and PCCL on the basis of the convex optimization. Compared with the iteratively reweighted least squares (IRLS) method, the proposed convex method can get the optimal mismatched filter bank with the minimum PSL and PCCL, and can also control the system signal-to-noise ratio loss (SNRL). Numerical examples show that the optimal mismatched filter bank at the cost of a slight SNRL can achieve a good improvement of the PSL and a moderate improvement of the PCCL, if the filter length  $P$  and the weighting factor  $w$  between the PSL and PCCL are appropriately chosen. [C618]

### "Reduced rank detection algorithms for distributed array sensors"

Distributed sensing systems provide an inherent spatial diversity by viewing a potential target from different aspect angles. Even though the centralized fully adapted processing scheme provides optimum performance, it is impractical for reasons of computational complexity and the sample support required for weight training. This paper presents two decentralized reduced rank STAP algorithms to overcome the drawbacks of centralized fully adapted processing. [C619]

### "Compressive radar imaging using white stochastic waveforms"

In this paper, we apply the principles of compressive sampling to ultra-wideband (UWB) stochastic waveform radar. The theory of compressive sampling says that it is possible to recover a signal that is parsimonious when represented in a particular basis, by acquiring few projections on to an appropriate basis set. Drawing on literature in compressive sampling, we develop the theory behind stochastic waveform-based compressive imaging. We show that using stochastic waveforms for radar imaging, it is possible to estimate target parameters and detect targets by sampling at a rate that is considerably slower than the Nyquist rate and recovering using compressive sensing algorithms. Thus, it is theoretically possible to increase the bandwidth (and hence the spatial resolution) of an ultra-wideband radar system using stochastic waveforms, without significant additions to the data acquisition system. Further, there is virtually no degradation in the performance of a UWB stochastic waveform radar system that employs compressive sampling. We present numerical simulations to show that the performance guarantees provided by theoretical results are achieved in realistic scenarios. [C620]

### "Phase-modulated waveform design for the target detection in the presence of signal-dependent clutter"

The problem to be considered is a phase-modulated waveform design for detection of extended targets contaminated by signal-dependent clutter returns and additive channel noise in practical radar systems. We first introduce an optimal waveform design algorithm for extended target detection in a band-limited radar system by maximizing the signal-to-clutter-and-noise ratio (SCNR) at the output of the receiver, and give the analytical solution of the optimal signal energy spectral density (ESD). In order to make full use of the transmission power, a phase iterative algorithm to design the phase-modulated waveform with constant envelope is proposed, which is proven to be able to achieve a small SCNR loss by minimizing the mean-square spectral distance between the optimal waveform and the designed one. The results of extensive simulations illustrate that our approach provides less than 1 dB SCNR loss when the signal duration is greater than 1  $\mu$ s. [C621]

### "Waveform-diverse moving-target spotlight SAR"

This paper develops the theory for waveform-diverse moving-target synthetic-aperture radar. We assume that the targets are moving linearly, but we allow an arbitrary flight path and (almost) arbitrary waveforms. We consider the monostatic case, in which a single antenna phase center is used for both transmitting and receiving. We include the case of waveforms whose duration is sufficiently long that the targets and/or platform move appreciably while the data is being collected. [C622]

### "Design of an optimal radar signal waveform for a range-doppler spreading channel"

This paper deals with the optimal radar waveform design problem using the quadratically constraint quadratic programming (QCQP) in the narrowband signal echo to range-doppler extended target regime. The solution is obtained in the sense of signal to interference plus noise ratio (SINR) maximization with resolution and fixed transmit power constraints. The performance is compared with other conventional waveforms such as continuous wave (CW) pulse and linearly frequency modulated (LFM) pulse, in terms of resolution through ambiguity function. [C623]

### "The metrication of low probability of intercept waveforms"

In recent years, military radar operators have been concerned that the transmitted radar signals will beacon the presence of the radar to an enemy. If intercepted, the radar signals alert a target to an attack which could prompt evasive measures or countermeasures to be taken by the target including the possibility of a reprisal attack using an antiradiation missile. Furthermore, intercepted signals can divulge operating parameters of the radar to the enemy. In response to this low probability of intercept (LPI) requirement, waveforms have been designed to minimize the probability of intercept by an enemy receiver. These are largely based on the use of low peak powers and spread spectrum waveforms offering large processing gains. The interception of signals is a function of both the transmitted radar waveform and the intercept receiver. The aim of this work is to deduce a metric which may be used to quantify and hence compare how "discrete" many of the commonly used LPI radar

waveforms actually are. This study considers the following LPI waveforms: Linear Frequency Modulation (LFM), Sinusoidal Frequency Modulation (Sin FM), PolyPhase Shift Keying (PPSK) techniques including Frank, P1, P2, P3, and P4 codes Costas code Frequency Shift Keying (FSK), and Costas-Barker Hybrid (FSK/PSK). This work represents the first attempt to be published in the open literature to quantify the LPI properties of transmitted radar waveforms. Secure waveform coding strategies to minimize the risk of divulging radar capabilities is known as low probability of exploitation (LPE) and is not considered here. [C624]

### "Bat-inspired multi-harmonic waveforms"

Bats achieve remarkable target detection and selection performance in the most challenging environments. These activities are carried out mainly by echolocation, i.e. by transmitting pulses at ultrasound frequencies and processing the echoes from targets. Because they have relied on high level performance for survival, as a consequence of natural selection, it is believed that they have evolved in order to optimise these capabilities. Echolocation calls are very sophisticated, diverse, and commonly composed of a number of harmonic components. If evolution has resulted in multi-harmonic waveforms there might be advantages deriving by doing so. In this paper we simulate multi-harmonics waveforms and exploit advantages or disadvantages by a range analysis of their ambiguity functions. Results are discussed in relation to the radar and sonar case. [C625]

### "A multi-target detector using mutual information for noise radar systems in low SNR regimes"

Target detection is one of important roles of radar systems. In this paper, we present a detection method using total correlation based on information theory for noise radar systems which enables a system detects multiple targets at low signal to noise ratio regimes. The proposed method utilizes the largest eigenvalue of the sample covariance matrix to extract information from replica of the transmitted signal, and can perform better than the conventional total correlation detector when reflected signals have intermediate or low signal to noise ratio. In addition, in order to avoid ambiguous target detection, we find thresholds to guarantee the detection performance with the same receiving antenna elements for a given false alarm probability. The threshold is computed from the largest and smallest eigenvalue distributions based on random matrix theory. Simulations show the proposed detection method can be used for intermediate and low signal to noise ratio environments, and the thresholds provides exact target detection. [C626]

### "Time-Range Adaptive Processing for pulse agile radar"

Some radar systems utilize pulse agility to mitigate interference or synthesize bandwidth. Transmitting different waveforms on a pulse-to-pulse basis can have deleterious effects when traditional pulse-Doppler processing is employed. In this paper a recursive MMSE-based receiver design, denoted as Time-Range Adaptive Processing, is presented. The new method jointly adapts in range and Doppler, thus yielding enhanced sensitivity when compared to adaptation in each dimension separately. [C627]

### "Analysis of the performance of a multiband passive bistatic radar processing scheme"

The bistatic radar has been revitalized over the last few years through the rapid development of the passive bistatic radar technology. Passive bistatic radar systems have unique properties, especially is time on target high compared to traditional radar systems, as well as the freedom in choosing from the available transmitters of opportunity. This paper will focus on how to take advantage of the latter of these two special properties in order to achieve better range resolution while maintaining the high coherent processing interval. [C628]

### "Cognitive radar for target tracking in multipath scenarios"

In this paper, we propose a cognitive radar system for target tracking in the presence of multipath reflections. We exploit the inherent spatial diversity offered by the multipath environment by constructing a new measurement vector, which we refer to as a virtual measurement vector. We employ broadband Orthogonal Frequency Division Multiplexing (OFDM) signalling at the transmitter and implement adaptive waveform design by minimizing the posterior Cramer Rao bound (PCRB) on the target state estimates to find the optimal weights to be transmitted on each subcarrier bin of the OFDM signal. We demonstrate with numerical simulations that the mean square error in the case of a cognitive radar is significantly lower than the mean square error in the case of a standard radar. [C629]

### "An adaptive multimodal radar system with progressive resolution enhancement"

This paper describes the architecture for an adaptive multimodal RF sensor that is capable of both a wide and narrow field of view. The architecture consists of a test-bed that will enable the generation of linear frequency modulation waveforms of various bandwidths. This paper discusses the proposed architecture, multimodal

algorithm and simulation results. [C630]

### "Radar transmit waveform design for lossy propagation channels"

This paper proposes that radar transmit codes can be tailored to a specific target scene through the use of Marginal Fisher Information (MFI). Where peak sidelobe level (PSL) and Total Integrated Sidelobe Level (TISL) are metrics frequently used in determining the quality of radar transmit codes, well performing free-space waveforms with low PSL and TISL may not be optimal for lossy propagation channels. When some knowledge is available regarding the propagation characteristics of the scene, MFI can be used to develop transmit codes with significantly increased estimation accuracy over codes designed to be optimal for free-space cases. [C631]

### "Designing for spectral conformity: Issues in power amplifier design"

Spectral constraints placed upon radar systems by regulatory agencies require the design of highly linear amplifiers. Spectral spreading in power amplifiers is a result of transistors operated in the nonlinear regime to optimize efficiency. Several different methods are employed by power amplifier designers to maximize both linearity and efficiency. The methods of predistortion, feedforward, envelope tracking, Doherty, and "Linear Amplification Using Nonlinear Components" (LINC) are discussed in this paper. Tradeoffs and challenges inherent in these design approaches are surveyed. [C632]

### "Design, simulation and analysis of neural controller based Series resonant converter"

The Objective of this paper is to design Series resonant converter with 200W, 250 KHz switching frequency which is used for radar power supply and to verify the results using PSPICE. The properties of the energy feedback control, and particularly the optimal trajectory control law, are analyzed. As a result, the state space is considered to be divided into two sub-spaces that correspond to different states of the switches in the converter. An analog neural network learns to classify these two classes by means of a learning algorithm. A simple electronic implementation of this controller is proposed and applied to a series resonant converter (SRC). Results based on prototype measurements show a good improvement in the SRC response versus classical control methods based on the linearization of the state variable equations around a working point and confirm the validity of the neural approach. [C633]

### "Velocity evaluating of the moving objects"

The paper deals with methods of contactless tachometry by radar sensors. The radar sensors are characterized by a good reliability and relatively high accuracy of measurements. The goal of the paper is to propose and realize the system which would manage to measure moving objects with a pulse radar and the Matlab software. Measuring of moving objects has been realized through the radar sensor which operates in an X-frequency band. The audio output of the radar sensor has been used for the velocity measurement and for the signal processing, a PC sound card and Matlab DAQ libraries have been used. [C634]

### "Improvement of bearing-only tracking fusion strategy based on bionics with infrared sensor"

This paper\* mainly studies some improvements of bearing-only data association with a single passive sensor to overcome the existing problems in the applications of JPDA approaches for bearing-only target locating and tracking. First, some adaptive modified rules are presented by deep analysis of JPDA application. This bearing-only association approach reduces computational complexity clearly under the premise of better tracking precision. Then, an effective track management strategy is designed. This strategy helps to set up a clear tracking level and manage historical the information of the target. The application of the proposed approach in a simulation and engineering system proves its effectiveness and practicability. [C635]

### "Tracking People with a 360-Degree Lidar"

Advances in lidar technology, in particular 360-degree lidar sensors, create new opportunities to augment and improve traditional surveillance systems. This paper describes an initial challenge to use a single stationary 360-degree lidar sensor to detect and track people moving throughout a scene in real-time. The depicted approach focuses on overcoming three primary challenges inherent in any lidar tracker: classification and matching errors between multiple human targets, segmentation errors between humans and fixed objects in the scene, and segmentation errors between targets that are very close together. [C636]

### "Human Localization in a Cluttered Space Using Multiple Cameras"

The use of single and dual-camera approaches to locating a subject in a 3-D cluttered space is investigated.

Specifically, we investigate the case where the lower portion of the body may be occluded, e.g., by a chair on a bus. Experiments were conducted involving eleven subjects moving along a pre-designated route within a cluttered space. For each time instant the position of each subject was manually estimated and compared to that produced automatically. The dual camera approach was found to give significantly better performance than the single camera approach. It was found that inaccurate bounding of the lowest part of the subject, due to occlusion, led to localisation errors in range as large as 10m for the latter. Using the side bounds of the detected object, which were found to be robust, accurate azimuth estimates can be obtained for a single camera. The dual-camera approach exploits the greater degree of accuracy in azimuth to estimate the range through triangulation, giving average localisation errors of 40cm over the space of interest. [C637]

#### "Embedded control of LCC resonant converter analysis, design, simulation and experimental results"

The Objective of this paper is to design LCC resonant converter with 200W, 250 KHz switching frequency which is used for radar power supply and to verify the results using PSPICE Simulation for wide variation in loading conditions. We have used motor load (R-L-E) and embedded based triggering circuit. The embedded 'C' Program is checked in Keil Software and also triggering circuit is simulated in PSPICE Software. In this paper analysis, simulation and experimental results were presented and compared with theoretical results. [C638]

#### "Partner Selection Strategy in Cooperative Diversity Systems"

In this paper, a novel strategy for partner selection in cooperative communication system is proposed. The system model is constructed based on the user distribution in the circular area. And then the performance of the present selection method is investigated under the constraint of cooperative gain. The simulation results show that the frame error rate of the method is superior to the random selection in the cooperative area. [C639]

#### "Joint Angle Estimation for Bistatic MIMO Radar"

A new joint direction of arrivals (DOAs) and direction of departures (DODs) estimation algorithm for bistatic multiple-input multiple-output (MIMO) radar is proposed. Instead of two-dimensional nonlinear search or iterative computation, the algorithm uses a one-dimensional search to estimate the DOAs, and then the DODs can be obtained; therefore they can be paired automatically. Furthermore, the algorithm can solve the problem of joint angle estimation when angle ambiguity of DODs occurs. The performance of the proposed algorithm is validated by the simulation results. [C640]

#### "A New Improved Particle Filter Algorithm Based on UKF and GASA"

The degeneracy is the critical problem existed in particle filter (PF). In order to solve this problem, we propose a new algorithm combined PF with unscented Kalman filter algorithm (UKF) and genetic simulated annealing algorithm (GASA) in this paper. In the new algorithm, UKF is used to generate the importance proposal distribution which can match the true posterior distribution more closely, and GASA based on the survival-of-the-fitness principle is applied to enhance the diversity of samples. As a result, the simulation results indicate that the new algorithm can resolve the problem of sample degeneracy successfully and outperform other particle filter algorithms in terms of accuracy and suppression the noise. [C641]

#### "The Application of Poly-Phase Filter in Radar Signal Processing"

A multi-channel structure using half-band filter is presented as poly-phase filter to divide the wide frequency band of the Doppler radar echo into 1-1 pairs. In most of the traditional system, this filter adopts FIR (Finite Impulses Respond) structure to get linear phase and simplify the design ignoring resource consumption. Here a four-channel half-band filter based on poly-phase IIR (Infinite Impulse Respond) structure is carried out. This IIR structure can also get linear phase but need less resources. This design is simulated using Simulink in MATLAB followed by prototype C code generation and performing on the target hardware platform. The results show the correctness of this method. [C642]

#### "A New Adaptive Algorithm for Passive Multi-Sensor Maneuvering Target Tracking"

When tracking maneuvering targets, the sudden changes of target states and nonlinear problems in passive tracking cause serious decline and even divergence in the performance of some conventional algorithms. Taking this into account, a novel adaptive tracking algorithm for maneuvering targets is proposed in this paper. First, a new weighed factor could adaptively adjust the filter gain is introduced in Modified Input Estimation (MIE) algorithm to improve its tracking performance. Then, the least squares technique is combined for tracking passive multi-sensor maneuvering targets in high accuracy without any priori information of maneuver.

Simulation results show the effectiveness of the proposed algorithm. Compared with the traditional MIE and fuzzy MIE algorithm, this algorithm has a better tracking performance. [C643]

#### "A Frequency Estimation Algorithm for Pulsed Magnetron Radar Transmitter Sample Signal"

The pulsed magnetron Cloud sounding radar is one of non-coherent radar, a magnetron has a random starting phase and its frequency chirps during the transmit pulse. This paper presents a frequency estimation algorithm for pulsed magnetron radar transmitter sample signal, based on the modified Wigner-Ville time-frequency analysis. From the three groups' data of compared simulation experiment, at any condition, this paper method can get higher performance than FFT method, and can get measurement mean error less than 0.105% at low algorithm complexity. The method can be used as frequency discriminator in pulsed magnetron Cloud sounding radar AFC real-time hardware system. [C644]

#### "A Novel Spectral Parameters Estimation Approach for Weather Echoes Based on Fitting"

White noise pollution mainly reduce the precision of spectral moments estimation for weather echoes, this paper presents a novel spectral estimation method based on fitting to decrease the impact of white noise on spectral parameters estimation. Fitting polynomial is firstly formed by analyzing the spectral characteristics of weather echoes, and then calibrates the received fitted spectrum by triangle. The simulation results show that the method can successfully reduce the impact of white noise on the spectral moments estimation, and can get higher performance than FFT method with a measurement mean error less than 0.4%. So the proposed method can be applied in weather radar. [C645]

#### "Probabilistic robust hyperbola mixture model for interpreting ground penetrating radar data"

This paper proposes a probabilistic robust hyperbola mixture model based on a classification expectation maximization algorithm and applies this algorithm to Ground Penetrating Radar (GPR) spatial data interpretation. Previous work tackling this problem using the Hough transform or neural networks for identifying GPR hyperbolae are unsuitable for on-site applications owing to their computational demands and the difficulties of getting sufficient appropriate training data for neural network based approaches. By incorporating a robust hyperbola fitting algorithm based on orthogonal distance into the probabilistic mixture model, the proposed algorithm can identify the hyperbolae in GPR data in real time and also calculate the depth and the size of the buried utility pipes. The number of the hyperbolae can be determined by conducting model selection using a Bayesian information criterion. The experimental results on both the synthetic/simulated and real GPR data show the effectiveness of this algorithm. [C646]

#### "Golay waveforms and adaptive estimation"

An iterative range profile estimation process is derived for Golay waveforms. The Re-Iterative Super Resolution (RISR) algorithm is used in conjunction with Golay waveforms and processing for radar range-Doppler estimation. Various additional range-Doppler estimation methods that use RISR and Golay waveforms and processing are simulated for the sake of comparison. Range and Doppler sidelobes are seen in simulation to be mitigated to a significant extent by using RISR in conjunction with Golay waveforms and processing. [C647]

#### "Waveform diversity and advanced signaling strategies for the Hybrid MIMO Phased Array Radar"

The Hybrid MIMO Phased Array Radar, or HMPAR, is a notional concept for a multisensor radar architecture that combines elements of traditional phased-array radar with the emerging technology of Multiple-Input Multiple Output (MIMO) radar. A HMPAR comprises a large number,  $MP$ , of T/R elements, organized into  $M$  subarrays of  $P$  elements each. Within each subarray, passive element-level phase shifting is used to steer transmit and receive beams in some desired fashion. Each of the  $M$  subarrays are in turn driven by independently amplified phase-coded signals. This paper proposes new transmit signal selection strategies based on the observation that some MIMO signal sets, such as those proposed by us previously, cause a very rapid sequential or raster scan across some field of view. Exploiting this property allows one to create and process multiple beams simultaneously. Furthermore, there exists a range-angle coupling in the transmit and receive signals that may lead to high-resolution target localization. [C648]

#### "A Novel Range Detection Method for 60GHz LFM CW Radar"

The linear frequency-modulated continuous-wave (LFMCW) millimeter-wave radar has been widely used in automotive industry applications. The motivation of this paper is to propose a segmented range detection (SRD) method on the foundation of plentiful mature research on the target detection of LFM CW radar. According to the SRD method, the detection range (about 150m in the scene of vehicular collision warning) is divided into several

segments and triangular modulation waveform which consists of several different frequencies is designed. Compared with typical digital signal processing method, the SRD method can available decrease the bandwidth of the IF signal, therefore the in-band noise will be significantly reduced and the signal to noise ratio (SNR) improved. Additionally, different range resolutions can be achieved and average range resolution improved. The SRD method is also validated through multiple outdoor experiments with the use of 60 GHz LFMCW millimeter-wave radar system designed by our research group. The efficiency of the SRD method is demonstrated in terms of ranging accuracy and range resolution after the analysis of experiment results. [C649]

#### "Wireless tomography, Part I: A novel approach to remote sensing"

Wireless tomography, a novel approach to remote sensing, is proposed in Part I of this series. The methodology, literature review, related work, and system engineering are presented. Concrete algorithms and hardware platforms are implemented to demonstrate this concept. Self-cohering tomography is studied in depth. More research will be reported, following this initiative. [C650]

#### "Geometric diversity versus frequency diversity an imaging example"

In classical radar, frequency diversity offers one method of obtaining additional information about targets. With the most basic form of frequency diversity, namely increased bandwidth, high range resolution is afforded to the user. Geometric diversity can also offer the potential for increased resolution, and is the multi-static dual to frequency diversity (increased bandwidth) in classical mono-static radar. In the extreme case, 360 degrees of geometric diversity (tomography) offers sub-wavelength resolution, even under the monochromatic assumption. Operational constraints can limit the system performance. Frequency diversity and geometric diversity can be used in various combinations to obtain the best image under these constraints. For example, frequency allocation can limit the available bandwidth. Geometric diversity with a single or multiple narrowband signals can provide the required system performance. Imaging performance can be evaluated using two factors: resolution and target dynamic range. Resolution is the ability to distinguish two closely separated targets and dynamic range is the ability to determine the presence of a 'weak' target in the presence of a 'strong' target. [C651]

#### "Thinned spectrum radar waveforms"

Small phase perturbations applied to a stepped-frequency or linear-frequency-modulated radar waveform have been proposed as a means to generate frequency nulls in the spectrum of the transmitted waveform. By nulling selected frequencies (or thinning) in the spectrum of transmitted pulses, the interference between the transmitted and received signals is reduced, which facilitates the spectral cohabitation of multiple RF users. Preliminary experimental results of two methods of spectral nulling are presented with consideration to in-band and out-of-band interference. Range processing is examined to determine the effects of the phase perturbation on radar operations. [C652]

#### "Two-Step Moving Target Detection Algorithm for Automotive 77 GHz FMCW Radar"

Today, 77GHz FMCW (Frequency Modulation Continuous Wave) radar sensors are used for automotive applications. In typical automotive radar, the target of interest is a moving target. Thus, to improve the detection probability and reduce the false alarm rate, an MTD(Moving Target Detection) algorithm should be required. This paper describes the proposed two-step MTD algorithm. The 1st MTD processing consists of a clutter cancellation step and a noise cancellation step. The two steps can cancel almost all clutter including stationary targets. However, clutter still remains among the interest beat frequencies detected during the 1st MTD and CFAR (Constant False Alarm) processing. Thus, in the 2nd MTD step, we remove the rest of the clutter with zero phase variation. [C653]

#### "Thermal infrared radiosity and heat diffusion model verification and validation"

A radiosity model used for predicting effective hyperspectral emissivity spectra and radiant temperatures for rough surfaces has been developed. Here we compare the computer model results to analytic model results in order to verify that the computer model is working properly, and validate the model results by comparison to spectra measured in the field by an hyperspectral imaging spectrometer. We measured a cm-scale DEM of the test scene using a tripod-based LiDAR. The discrepancies between analytical and modeled values are less than 0.01%. Modeled emissivity spectra deviate from the measured by no more than 0.015 emissivity units. [C654]

#### "Canopy vertical structure using MODIS Bidirectional Reflectance data"

Canopy spectral invariant variables, escape probability and recollision probability, are wavelength independent and intrinsic canopy structure properties. They provide a physical interpretation of the correlation between canopy

architecture and multi-angle spectral data. The 500m Moderate resolution Imaging Spectrodiometer (MODIS) Bidirectional Reflectance Distribution Function (BRDF) product from study sites at Howland Forest, Maine are used to develop multivariate linear regression models to estimate canopy vertical structure using both escape probabilities and directional reflectance. These are compared with canopy height information which has been retrieved from the airborne Laser Vegetation Imaging Sensor (LVIS) at a finer scale spatial resolution. Both the escape probability and the directional reflectance approaches achieve similar results with correlation coefficients of 0.63-0.66. This suggests that the MODIS 500m BRDF data can be useful in extrapolating limited lidar information on canopy vertical structure to larger regional areas. [C655]

#### "A wideband variable gain amplifier with feedback DC-offset correction in 0.13 $\mu$ m CMOS technology"

A low power and area optimized wideband variable gain amplifier (VGA) has been designed in 0.13  $\mu$ m CMOS technology for an integrated Synthetic Aperture Radar (SAR) receiver. The VGA consists of three gain stages. The first stage is a resistively loaded, fixed gain source coupled pair, while the other two are variable gain degenerated differential pairs. Each stage also utilizes negative Miller capacitance to extend the bandwidth, resulting in a VGA configuration with -3 dB bandwidth of 1 GHz. The gain of the VGA can be continuously varied from 10 dB to 30 dB. The input-referred noise density is 2.8 nV/ $\sqrt{\text{Hz}}$  and the out-of-band IIP3 is -1 dBm. The circuit consumes only 5.25 mW from a 1.2 V supply (excluding the output buffer) and occupies 0.037 mm<sup>2</sup> die area. [C656]

#### "Active hyperspectral LIDAR methods for object classification"

We have studied the fusion of active hyperspectral and range (LIDAR) data to investigate the concept of an active hyperspectral LIDAR and its potential applications in the remote sensing of vegetation. We have built two prototype instruments using the newly developed supercontinuum laser technique providing a continuous spectrum, which has then been used both for combined hyperspectral and LIDAR or time-of-flight measurement. The preliminary results point out the potential of active hyperspectral methods in laser-based remote sensing applications: the combined topographic and spectral information, such as the normalized difference vegetation index (NDVI), can be used efficiently in automatic target identification and classification. [C657]

#### "Fusion of hyperspectral images and LiDAR data for civil engineering structure monitoring"

Investigation of civil engineering materials includes a wide range of applications that requires three-dimensional (3D) information. Complex structures shapes and formations within heterogeneous artificial/natural land covers under varying environmental conditions requires knowledge on the 3D status of the urban materials for better (visual) interpretation of polluted sources. Obtaining 3D information and merge them with aerial photography is not a trivial task. It is thus, strongly needed to develop new approaches for near real time analysis of the urban environment with natural 3D visualization of extensive coverage. The hyperspectral remote sensing (HRS) technology is a promising and powerful tool to assess degradation of urban materials in artificial structures by exploring possible chemical physical changes using spectral information across the VIS-NIR-SWIR spectral region (400-2500nm). This technique provides the ability for easy, rapid and accurate in situ assessment of many materials on a spatial domain within near real time condition and high temporal resolution. LiDAR technology, on the other hand, offers precise information about the geometrical properties of the surfaces within the study areas and can reflect different shapes and formations of the complex urban environment. Generating a monitoring system that is based on the integrative fusion between HRS and LiDAR data may enlarge the application envelop of each technology separately and contribute valuable information on urban runoff and planning. The aim of the presented research is to implement this direction and define set of rules for practical integration between the two datasets. A fusion process defined by integrative decision tree analysis includes spectral/spatial and 3D information is developed and presented. [C658]

#### "Vegetation management of utility corridors using high-resolution hyperspectral imaging and LiDAR"

This study examines the use of high spatial resolution hyperspectral imagery in combination with light detection and ranging (LiDAR) data and digital aerial imagery for vegetation management of utility corridors. Two different classification methods, i.e. the support vector machines (SVM) and the spectral angle mapper (SAM) were applied on the datasets to test their ability for discrimination of various vegetation species. The SVM classifier performed best with an overall accuracy of 83% applied on the hyperspectral imagery. With inclusion of the LiDAR data the accuracy could be increased to 92%. Power lines were extracted from the LiDAR data and the conductor clearance was calculated. The results were merged with the SVM classification and a species map of vegetation that could cause potential damage to the power lines was generated. The results of this study show

that an improved approach for vegetation management of utility corridors can be achieved by combining the spatial and spectral information of multi-source datasets. [C659]

#### "Mismatched filtering of chaotic codes"

Low Probability of Intercept (LPI) pulse compression waveforms find applications in secure communications. Conventional waveforms with good correlation properties fail to satisfy requirements in presence of unintentional interference. Chaotic pulse compression codes combined with mismatched sidelobe suppression filters are proposed to simultaneously improve LPI performance and meet low sidelobe level requirements of secure communications. [C660]

#### "Development of a wireless communication and localization system for VRU eSafety"

Based on the experience from two predecessor projects, a novel architecture for the detection of vulnerable road users (VRU) is developed. It combines communication and localization, following the function principles of a secondary radar. Challenges are in the accuracy, the scalability, the bandwidth availability and the limited cost and complexity of the devices. This paper describes the objective of the overall project, the architectural approach of the wireless protocol and the design flow, which has been chosen for the development, which is still in progress. [C661]

#### "Membership service specifications for safety-critical geocast in vehicular networks"

Geographic group communication is a promising technique for collaborative driving applications. While one-way, geographic broadcast (geocast) is well-studied in vehicular networks, there has been little work to address the challenging reliability problems that arise. Not only do vehicular networks experience highly variable packet loss, but communication failures are difficult to detect. The presence of vehicles in an area and thus the set of vehicles that is supposed to receive a geocast, changes continuously. Without an expectation of the vehicles that should respond to queries, communication failure cannot easily be distinguished from absence. This requires a cross-layer approach, exploiting communication, sensing and driving rules. In this paper, we propose a membership service that provides group views for geographic areas as a building block to reliable geocast. We specify the semantics of the service and discuss different ways of implementing it. Finally, we show how it can be used for safe, collaborative driving. [C662]

#### "Performance analysis of sequential detection in early warning radar applications"

In early-warning radar surveillance environment, sequential procedures are preferred to detect the targets, for they promise a reduction in the time needed to take a decision. In this paper, a sequential detection algorithm is concerned and the interplay between the parameter  $dsnr$  and the system performance is mainly discussed. Numerical results have shown that sequential detector can lead a great reduction in the average-sample-number (ASN) especially in high SNR. In order to get a proper system performance, a trade off should be made between the ASN and detection performance when choosing the parameter  $dsnr$ . [C663]

#### "The real-time gpr signals preprocessing algorithm based on LWT in high scan rate"

In this work, we use DSP mechanism for real-time Ground Penetrating Radar (GPR) data preprocessing assess in high scan-rate scenarios. The lifting wavelet transform-based algorithm takes the advantages of efficient computation and memory reduction and is a suitable solution for DSP real-time implementation. In addition, the parallel operations technique on DSP memory is applied to enhance the system efficiency. Such that we realize a 3-level pipeline data structure which can significantly release the signal preprocessing time from the data collecting and data display time etc. The experimental results demonstrate the effectiveness of the developed scheme for real-time GPR data processing. [C664]

#### "On the propagation characteristics of ultra-wideband signal in aluminum"

The UWB reflected signal at 4.7 GHz is characterized and measured for the application of short-circuited reflection material analysis with aluminum backing the sample. The sub-pulse with 120-ps pulse width is used to characterize the UWB reflected wave propagation phenomenon in some aluminum plates with different thickness. It was found the normalized amplitude of principal sub-pulse that is generated by 24th derivative of a Gaussian pulse yields a linear relation with the thickness of aluminum ranged from 1 to 10 mm. The amplitude of these high order pulses shows that there is destructive interference when combining waves reflected from front and rear interfaces of aluminum. The pulse width of these sub-pulses is insensitive to the aluminum's thickness change in the experiment. [C665]

### "A height-measuring algorithm applied to TERCOM radar altimeter"

Radar altimeter is applied to measure the height of an aircraft above the ground in terrain contour matching system (TERCOM). The total performance of the TERCOM is almost determined by the height-measuring algorithms embedded in the radar altimeter. When facing a complex terrain area with a large degree of fluctuation, the traditional radar altimetry height-measuring algorithm performance will be greatly affected, for the reason that wide-beam pulse radar altimeter illuminates widely. In order to solve the problem, this paper proposes a new algorithm named average-height algorithm, and the detailed derivation is carried out. Simulation and flying test has shown that it has good performance and can be applied to any kind of terrain. [C666]

### "An algorithm of resolving the range ambiguity using a single PRF"

A new algorithm of range ambiguity resolution is presented which is substantially different from previously proposed algorithms. The algorithm utilizes a constant pulse repetition frequency (PRF). Firstly, a merit function is designed according to the moving characteristics of the targets. Secondly, range ambiguity resolution is achieved by minimizing the merit function. Numerical simulation results indicate that the proposed algorithm can resolve the range ambiguity efficiently using a single constant PRF. [C667]

### "An inverse model for coastal acoustic tomography and its application to Chinese coastal sea"

An inverse model for coastal acoustic tomography (CAT) to reconstruct the tidal current distributions was built and applied to the Zhitouyang Bay near the Zhoushan Island, China. The range-averaged current (post-inversion result) obtained along the transmission lines by the inverse model showed a prominent semidiurnal oscillation and was in good agreement with that (pre-inversion result) obtained from the travel time difference data, producing a root-mean-square (rms) difference of 0.036 m/s. Also both the range-averaged currents agreed with the ADCP results, and their rms differences were 0.097 m/s for the post-inversion result and 0.042 m/s for the pre-inversion result. The horizontal distributions of tidal current obtained from the inverse model were in rough agreement with that of the shipboard acoustic Doppler current profiler velocity. The rms differences for the eastward and northward currents were 11.70 cm/s and 16.50 cm/s, respectively. The above results indicate that the inverse model worked well, and could be used for mapping tidal current fields in Chinese coastal region. [C668]

### "Target recognition for marine search and rescue radar"

The key point of marine search and rescue is to find out and recognize the distress objects. At present, the visual search method is usually adopted to detect the ships in distress, and this method can only be used at good sea condition and visibility. In this paper, a new target detection and recognition system is proposed. The parameters of radar transmitter and echo graphics and the invariant moments of radar images are extracted as the system's recognition features, and the system's target classifier is based on BP neural networks. The developed recognition classifier has been tested using three kinds of target images, the target's features are used as the inputs of trained BP neural networks and the outputs of networks are target classification. Sea experimental results show that the proposed method is well-clustering and with high classified accuracy. [C669]

### "A fuzzy pattern recognition method of radar signal based on neural network"

Radar signal recognition is an important step of radar countermeasure processing. The classical recognition method is called weight distance, in which the feature parameter weights are obtained by expert and then the weight distance of unknown radar signal and signal template in database is computed. For its existing subjectivity in setting of feature parameter weights with classical recognition method, and the computing method of recognition is too simple, all of which make recognition result can't reflect the true fact objectively. Considering this point, a fuzzy pattern recognition method based on neural network getting weights to radar signal recognition is studied in this paper, the feature parameter weights in this method are fixed on by neural network and then the unknown radar signal is recognized by fuzzy pattern recognition method. Simulation experiment and its result show the method in this paper is practicable and more reliable compared with classical method. [C670]

### "A novel detection scheme to mitigate the TD-LTE interference"

In this article, a novel detection scheme will be introduced into the CR system based on the Time Duplex-Long Term Evolution (TD-LTE) scheme, in which radar system is the primary user. If the CR nodes carry on the on-line energy detection to the radar signal, it will be subject to the interference originated from the TD-LTE system's Base Station (BS). We propose a new detection program employed only in the TD-LTE uplink timeslots. In this program, the interference, which is coming from the TD-LTE system's User Equipment (UE), may be weaker than it originated from BS. At the same time, the performance will be enhanced by accumulating multiple

coherent detecting results. Through theoretical analysis and simulation, the feasibility of the new program has been verified. [C671]

#### **"Coexistence studies for TD-LTE with radar system in the band 2300-2400 MHz"**

Because of the lack of dedicated frequency bands, the TD-LTE system is possibly deployed in the same band with other existed mobile systems. In this paper, the coexistence studies for the TD-LTE system with the radar system which has been widely deployed in the band 2300-2400 MHz, is presented. The dynamical system simulation methodology is utilized in the coexistence studies, and simulation results of the impacts on the system performance with different isolation distance and frequency spacing are given. The feasibility of the coexistence between TD-LTE and the radar systems is investigated and some useful conclusions are also presented. [C672]

#### **"Design and implementation of marine dumping area's monitoring system based on GPS/GPRS"**

In this paper, it advances the reasonable development programs of the waste dumping in the dumping areas and achieve the position, navigation and monitoring of the ship-borne navigation monitoring system which based on the GPS/ GPRS wireless remote monitoring technology on the embedded SPCE3200 platform. The software and the hardware which are consisted of a ship-borne information processing termination are introduced. Our work provides a low cost scheme for realizing the information-based management of the ship and the safety of the shipping and the effective management of the dumping areas. [C673]

#### **"Clutter classification in heterogeneous environments"**

In this paper, we present a preprocessing method for classification of environmental clutter surrounding in radar application. This method is developed based on Generalized Likelihood Ratio (GLR) hypotheses test, employing observed data vectors from cells surrounding each radar cell. These tests attempt to recognize the equality or inequality of clutter Covariance Matrix (CM) of radar cells. Using these tests, an algorithm is presented which classifies the clutter. Simulation results show that detectors and classifiers achieve satisfactory performance under several simulated situations of known spectral clutter models. [C674]

#### **"The fuzzy targets setting and comprehensive evaluation of the vehicle comfort"**

To vehicle development problem, setting development targets is mainly based on the benchmark test data of competitors. Usually, the target setting is subjective and ambiguous. To reform the method, fuzzy decision-making matrices were established based on Analytic Hierarchy Process (AHP), hence, the comfort targets were set quantitatively. Then, the improved radar chart was used to make comprehensive evaluation on the developing model and the competitors'. The results show that, for the fuzzy comparative problem, AHP could set the targets reasonably and quantitatively. [C675]

#### **"Experimental analysis of ground speed measuring systems for the intelligent agricultural machinery"**

Measuring machine's speed precisely is quite critical for intelligent agricultural machinery. With Advanced RISC Machines (ARM) as the speed measurement terminal, speed measurement precision was tested and studied when the sensor was served by the encoder, inductance near-switch, doppler-radar and Global Positioning System (GPS) in the Autumn-ploughed farmland. In a 40m-long testing distance, the measurement precision of the above sensors was tested when the tractor driving at 4.0km/h, 5.0km/h and 6.0km/h. After the measured speed data were contrasted to the theoretical data, the result proves that the coefficient of variation (CV) of GPS is the highest; the data from the radar is most close to the theoretical data with the error of 2.03%; the biggest error of the inductance near-switch is 2.82%; the biggest error of the encoder is 2.85%. The performance price ratio of the inductance near-switch is the highest among the four, and it can meet the requirement of intelligent agricultural machinery. [C676]

#### **"Design of target data fusion algorithm for passive radar based-on dual GSM base stations"**

The ambiguity of GSM signals transmitted by GSM base stations has a pushpin-type and low side lobe, and it's no ambiguity at distance and Doppler-axis. It's very suitable as a illuminator source of passive radar. This paper presented a mathematical model of passive radar using two GSM base stations as the illumination source, simulated with extended Kalman filter algorithm and verified the feasibility and effectiveness of the algorithm. The results shows that it can effectively overcome the defects such as low tracking accuracy and long time of target dynamic process when adopting single GSM base station to building passive radar. This system can be used as supplementary to urban low-altitude defense system so as to effectively respond to low-altitude invading enemy weapons. [C677]

### **"A new ground penetrating radar signal analysis method based on S transform"**

The paper discussed the characteristics of GPR signals of one object and two objects respectively, and studied the rule of extracting twin-peak attribute when the size of object or the distance of two objects was changing through GST. For one object, the two reflections can't be resolved in time when the diameter of object is less than or equal to  $1/3$  dominant wavelength within object medium, but the twin-peak attribute can resolve the reflections when the diameter is as small as  $1/7$  dominant wavelength, so the size can be estimated combining the attribute with time-domain waveform and the definition of a small object can be given. For two objects that each is a small object in time-frequency domain, we considered the situations where the permittivity were same or different, and it is pointed out that the attribute can improve the resolution of two objects and can estimate the distance combined with time-domain waveform. The selection rule of parameter and frequency point of twin-peak attribute was given as well so the unsystematic problem was solved. [C678]

### **"Simulation of algorithm for relief profile measurement and recognition of objects in on-board scanning pulsed laser rangefinders"**

This paper proposes the algorithm and presents the preliminary results obtained from the simulation of three-dimensional images for scanning pulsed laser rangefinders with nanosecond probe pulses. The prospects for construction of high-speed on-board devices intended for recognition of ground (above-water) objects by geometric features are demonstrated. [C679]

### **"Mining environmental data in hydrological scenarios"**

We present data mining methods which are used in a hydro-meteorological scenarios within the FP7 project ADMIRE1. The scenarios uses data mining techniques instead of more common physical models in order to predict phenomena which are not being ordinarily solved in Slovakia-water temperature, discharge wave propagation downstream of a major water reservoir and short-term rainfall prediction by analyzing radar imagery. These scenarios are one of a set of use cases, which form the Flood Forecasting Simulation Cascade-a pilot application of ADMIRE project. We describe the variables used in data mining training of these scenarios and also an introduction to the data integration methodology approach we have devised. [C680]

### **"The design and implementation of domain-specific text summarization system based on co-reference resolution algorithm"**

In order to benefit from the vast amounts of information quickly and accurately, topics on automatic abstracting have become more and more popular. Compared with the traditional automatic abstracting methods, we adopted the statistic methods and word list in domain-specific field to develop domain-specific text summarization system. Referring is a common phenomenon in the real life. In the process of text handling, referring often leads to inaccurate results. To solve the problem caused by the referring, combined with the current studies, this paper introduced co-reference resolution algorithm and the implementation of domain-specific text summarization system based on resolution algorithm. By analyzing the referring phenomenon in the original text, term frequency and sentence importance are recalculated to obtain new abstracting results. [C681]

### **"A Parallel Centralized Multi-sensor General Association Algorithm"**

This paper has researched on the problem of centralized multi-sensor multi-target tracking against a background, which has a high demand of real-time and a relative demand of tracking precision, and analyzed the advantages and disadvantages of the existent classical algorithms theoretically in this environment. Based on the research and the analysis, general association algorithm has been extended into multi-sensor system through the parallel structure and a new algorithm named parallel centralized multi-sensor general association algorithm has been proposed. In this algorithm, a lot of hypotheses are built with the measurements of each sensor and the track of each target, the score of every hypothesis could be obtained with the formula of the score function in multi-sensor general association algorithm, and the state estimation of the fusion center is gained finally. The simulation results show that this algorithm could track the targets effectively with the high density clutter and the general performance of this algorithm is better than that of sequential centralized multi-sensor joint probabilistic data association algorithm and parallel centralized multi-sensor probabilistic nearest neighbor standard function. [C682]

### **"Novel Architecture for Highly Hardware Efficient Implementation of Real Time Matrix Inversion Using Gauss Jordan Technique"**

Advent of Matrix Theory has greatly aided and simplified the analysis for variety of signal processing algorithms.

It has been proven that matrix notation is convenient for representation of signals and to perform operations on them. Many problems such as signal modeling, Wiener filtering and spectrum estimation require finding the solution or solutions to a set of linear equations. Some of the common matrix related operations include transpose, triangularization, determinant calculation, eigen value decomposition and matrix inversion. Most of these operations are computationally intensive and have been difficult to implement on real time systems and therefore are not pursued much in VLSI design. In this paper we present a highly hardware efficient and simple memory based novel architecture implementing widely established Gauss Jordan technique for finding matrix inverse. First triangularization of the matrix is done which on further processing calculates the inverse matrix.

[C683]

#### **"Blind channel estimation for MRC systems with maneuvering transmit/receive terminals"**

This paper presents a new blind channel estimation technique for maximum-ratio combining systems where the relative speed of the transmit/receive terminals may change. This changing speed is called maneuvering. The proposed blind system has a hard decision switching block which selects between different speed modes of a maneuvering terminal. The speed can be therefore tracked in a mobile data communication link. This is accomplished based on only the received data information signal, i.e., no other information (for example from a speed sensor or radar, etc.) is required. The performance of the proposed technique is evaluated by simulation and comparison is made with optimal coherent detection. The importance of introducing the switching block can be demonstrated by disabling it in the algorithm, and this results in a large degradation in performance. To assess the direct impact of the proposed blind channel estimation on the error performance, a fair comparison with a known, blind technique based on Kalman filtering is also made, with the assumption of non-maneuvering terminals. Here, improved performance is observed. [C684]

#### **"FCM-based radar target detection in medium frequency signal of radar"**

In radar target detection application fields, rich of information of targets may be included in medium frequency. Doppler shift caused by moving target is one of them. In this paper, Doppler shift and its Short Time Fourier Transform-STFT is analyzed and discussed. Since it is difficult to distinguish the Doppler shift of moving target even in frequency domain with STFF method, fuzzy C means clustering method is introduced to seek the two centers of the mixed signals in a radar scanning period. Using multiple radar scanning period, several centers can be determined by a center function using arithmetic mean filter. Finally the targets can be detected by threshold decision and calculated the detection probability. This algorithm is simple, easily to realize, with small computation burden and good target detection probability. [C685]

#### **"Hailstone detection based on time series association rules"**

Hailstone is one of main meteorological disasters and it is difficult to forecast effectively. In this paper, a new hail echo detection method based on time series association rules was proposed and a hail echo automatic detection system was built. Compared to the existing methods, the test results have shown that this method eliminated hail alert failure completely and also reduced the proportion of false alarm, raising the accuracy of hail forecast. The system was able to assist forecasters to make correct hail forecasts and provide reference to other disastrous weather forecast. [C686]

#### **"Real-time data acquisition system for pulse laser radar based on clock distribution technology"**

A high-bandwidth data acquisition system for pulse laser radar is developed. Four 250MHz of AD collecting chips are used for data acquisition under clock distribution chip, and then put together for a 1GHz Sps data sample rates. The USB protocol is used for data transmission between system and computer, the AD9520 is used for clock distribution, the FPGA is used for data acquisition, down-conversion, caching and transmission control chip, and the LVPECL and LVDS bus is used to ensure the stability of high-speed data transmission and signal process. The experimental results show that the system can satisfy the data acquisition tasks of the pulse laser radar. [C687]

#### **"Evolutionary global attitude planning for satellite signature suppression shield"**

This paper explores the global attitude planning for satellite signature suppression shields with limited attitude control abilities. Space surveillance radar and high energy laser are the main threats to on-orbit satellite. The radar detection probability and laser irradiation power are coupled with the satellite's radar cross section (RCS) and laser cross section (LCS) respectively, which are determined by the shield's attitude. This paper presents an evolutionary global attitude planning algorithm for low observable satellites, to reduce their RCS and LCS in threat directions by limited shield attitude control. A novel evolutionary strategy is developed. The strategy has problem-specific individual structure and evolutionary methods, and is able to find a near-optimal global attitude

solution with limited iterative steps. At the same time, a novel planning mathematical model and a relative evolutionary evaluation function are defined to reduce the planning's computational complexity. According to the simulation results, the algorithm is proved to be efficient. [C688]

#### **"Intrusion detection using software defined noise radar"**

The need for reliable systems for detecting intrusions into a given area has given rise to the research and use of random noise radars. This paper deals with the issues regarding the use of such systems. The advantages of the use of such radar are illustrated followed by the actual mode of implementing the system itself. The novelty in this approach is the use a software defined radio as the platform for the system as it has a number of added advantages as have been detailed Subsequently, the intrusion detection can be viewed as a classification problem and solved using any machine learning algorithm. The paper also investigates the use of support vector machines (SVM) for the above said problem and derives a suitable model for classification. The training and testing of SVM model is in progress. [C689]

#### **"A cue line based method for building modeling from LiDAR and satellite imagery"**

Building modeling in an urban environment is a challenging task yet has many applications such as urban planning, simulation of disaster scenarios, cartography, wireless network planning, line-of-sight analysis, virtual tours, and many others. This paper presents a cue line based method for residential building modeling in urban areas using airborne light detection and ranging (LiDAR) data and satellite imagery. The main contribution is the automatic isolation of building roofs and roof reconstruction based on the fusion of LiDAR data and satellite imagery. By using cue lines which are generated from satellite imagery to separate buildings from other objects (including other buildings), we are able to automatically identify individual buildings from residential clutter and re-create a virtual representation with improved accuracy and reasonable computation time. We applied the method to urban sites in the city of New Orleans and demonstrated that it identified building measurements successfully and rendered 3D models effectively. Our experiments show that our method can successfully reconstruct small buildings with relatively sparse LiDAR sampling and in the presence of noise. [C690]

#### **"Copyright page"**

The following topics are dealt with: MIMO, radar, imaging techniques, spectral cohabitation, adaptive waveforms, modulation techniques, and spectrum management. [C691]

#### **"A practical ground penetrating radar signal processing method based on wavelet transform"**

Wavelet transform is a new applied signal processing technique in recent years, its time-frequency multi-resolution and signal processing performance are analyzed in the paper. A practical ground penetrating radar signal processing method based on wavelet transform is proposed; it contrast with continuous wavelet transform, the experiments indicate that it improves the processing performance of underground target detecting. [C692]

#### **"Semi-supervised remote sensing image classification via maximum entropy"**

Remote sensing image segmentation requires multi-category classification typically with limited number of labeled training samples. While semi-supervised learning (SSL) has emerged as a sub-field of machine learning to tackle the scarcity of labeled samples, most SSL algorithms to date have had trade-offs in terms of scalability and/or applicability to multi-categorical data. In this paper, we evaluate semi-supervised logistic regression (SLR), a recent information theoretic semi-supervised algorithm, for remote sensing image classification problems. SLR is a probabilistic discriminative classifier and a specific instance of the generalized maximum entropy framework with a convex loss function. Moreover, the method is inherently multi-class and easy to implement. These characteristics make SLR a strong alternative to the widely used semi-supervised variants of SVM for the segmentation of remote sensing images. We demonstrate the competitiveness of SLR in multispectral, hyperspectral and radar image classification. [C693]

#### **"Implementation of a low cost synthetic aperture radar using Software Defined Radio"**

GNU radio is a free open-source software toolkit for building software radios, in which software defines the transmitted waveforms and demodulates the received waveforms. In this paper an attempt has been made to explore the means to use a Software Defined Radio (SDR) to implement a basic radar system and then synthetic aperture radar. An experiment where in readings at two different scenarios (free environment and metal object) are taken into account and their plots are also given. This has been attempted keeping in mind the exponential increase in chip computing power and the ability to upgrade a radio transceiver via software updates with a marginal investment, the two features which makes such a foray attractive, technology wise and cost

wise. This attempt also takes us a step closer to establishing the concept of a Cognitive radar which is software signal processing intensive. [C694]

### "Pulse Doppler radar waveforms"

Modern military airborne radars are highly sophisticated, multi-mode systems which are required to detect difficult targets in all aspects and over a large range/velocity detection space. There are particular difficulties associated with the airborne case such as the limited antenna aperture, high platform velocity and severe clutter levels which present difficult waveform design challenges. This tutorial will consider the design parameters of high pulse repetition frequency (PRF) and medium PRF waveforms commonly used in airborne pulse Doppler radar modes. The majority of this tutorial will be devoted to the issues concerning the selection of the number of PRFs and of the PRF values used in the medium PRF mode. PRF optimisation methods using evolutionary algorithms used by the author and his colleagues in a number of recent studies will be described. Examples will be given of airborne fire control radars, airborne early warning systems and active radar seekers used in anti-aircraft missiles. [C695]

### "OFDM radar waveform design for sparsity-based multi-target tracking"

We propose a sparsity-based approach to track multiple targets using an orthogonal frequency division multiplexing (OFDM) radar. The use of an OFDM signal increases the frequency diversity of our system as different scattering centers of a target resonate variably at different frequencies. We observe that in a particular pulse interval the targets lie at a few points on the delay-Doppler plane. Hence, we exploit that inherent sparsity to develop a tracking procedure. The nonzero entries of the sparse vector in our model correspond to the target scattering coefficients at different OFDM subcarriers. Therefore, the sparse vector and associated sparse measurement model exhibit block-sparsity property. We design the spectral weights of the transmitting OFDM waveform to minimize the block-coherence measure of the sparse model. In the tracking filter, we develop a block version of the compressive sampling matching pursuit (CoSaMP) algorithm. We present numerical examples to show the performance of our sparsity-based tracking approach and compare with that of a particle filter (PF). The proposed sparsity-based tracking algorithm takes significantly less computational time and provides equivalent, and sometimes better, tracking performance in comparison with the PF-based tracking. [C696]

### "Design of look-up table based architecture for wideband beamforming"

Wideband beamforming with a real-time array testbed will be studied in this paper. The algorithm and implementation architecture on wideband beamforming will be the main focus. The contribution of this paper can be summarized in the following three aspects. First, the channel imbalances among different RF chains will be taken into account. The equivalent complex baseband impulse responses of RF chains are measured from the AFRL TELA testbed. The second contribution is that the novel architecture of wideband beamforming is proposed. Look-up table (LUT) based architecture is exploited to replace the pre-steering delay component to avoid fractional delay-one implementation bottleneck. In addition, the general optimization issue for wideband beamforming is formulated as semi-definite programming (SDP), which can be efficiently solved by the convex optimization tool, e.g. CVX. [C697]

### "Adaptive design for distributed MIMO radar using sparse modeling"

Multiple Input Multiple Output (MIMO) radar systems with widely separated antennas provide spatial diversity gain by viewing the targets from different angles. In this paper, we propose an approach to accurately estimate the properties (position, velocity) of multiple targets using such systems by employing sparse modeling. We also propose a new metric to analyze the performance of the radar system. We develop an adaptive mechanism for optimal energy allocation at different transmitters. We show that this adaptive mechanism outperforms MIMO radar systems that transmit fixed equal energy across all the antennas. [C698]

### "Waveform diversity & knowledge based systems"

Summary form only given. Waveform diversity is an emerging technology that has dramatically altered the development of futuristic radar systems, as has knowledge based processing and control. With increasing numbers of radio frequency sensors and communications systems, battlefield scenarios have become more complex and continuously redefined. Our challenge will be to effectively use this technology to enhance overall performance of advanced radar systems operating within available spectrum in these battlefield environments. Technologies essential to this goal include cognition and knowledge based systems for waveform generation timing and control, and intelligent radar signal/data processing for detection, parameter estimation and track processing. Cognition is defined as the act or process of knowing, including both awareness and judgment.

Awareness of the dynamically changing spectral environment and judgment for the selection of optimal waveform parameters and sensor placement will enable dramatically improved performance for target surveillance/reconnaissance in addition to enhanced interference mitigation. A confluence of factors and technologies now makes waveform diverse knowledge based systems a logical and affordable alternative to classically designed radars. [C699]

### "Coherent MIMO radar"

Multiple-input multiple-output (MIMO) extensions to radar systems enable a number of advantages compared to traditional approaches. These advantages include improved angle estimation and target detection. In this tutorial, an overview of MIMO radar is provided, and the concept of coherent MIMO radar is defined. In addition, two topics are addressed more thoroughly: MIMO waveform/array geometry optimization for target tracking, and MIMO ground moving target indication (GMTI). [C700]

### "Wideband MIMO waveform design for transmit beampattern synthesis"

The usage of multi-input-multi-output (MIMO) systems such as a MIMO radar allows the array elements to transmit different waveforms freely. This waveform diversity can lead to flexible transmit beampattern synthesis, which is useful in many applications such as radar/sonar and biomedical imaging. In the past literature most attention was paid to receive beampattern design due to the stringent constraints on waveforms in the transmit beampattern case. Recently progress has been made on MIMO transmit beampattern synthesis but mainly only for narrowband signals. In this paper we propose a new approach that can be used to efficiently synthesize MIMO waveforms in order to match a given wideband transmit beampattern, i.e. to match a transmit energy distribution in both space and frequency. The synthesized waveforms satisfy the unit-modulus or low peak-to-average power ratio (PAR) constraints that are highly desirable in practice. Several examples are provided to investigate the performance of the proposed approach. [C701]

### "An IMM-UF algorithm for tracking highly maneuvering target"

Tracking of highly maneuvering targets with unknown behavior is a difficult problem in state estimation. This paper presents an adaptive interacting multiple model algorithm (IMM) utilizing adaptive turn rate models to track a maneuvering target. The turn rate is calculated at each step from the estimator of velocity and the radius of curvature of the trajectory of the target by using Least Square (LS) and curve fitting theory. Simulation in different scenario proves that the turn-rate estimation techniques in this adaptive framework can significantly solve the problem of tracking maneuvering targets. [C702]

### "Quantum-inspired immune clonal clustering algorithm based on watershed"

Based on the concepts and principles of quantum computing, a novel clustering algorithm, called a quantum-inspired immune clonal clustering algorithm based on watershed (QICW), is proposed to deal with the problem of image segmentation. In QICW, antibody is proliferated and divided into a set of subpopulation groups. Antibodies in a subpopulation group are represented by multi-state gene quantum bits. In the antibody's updating, the quantum mutation operator is applied to accelerate convergence. The quantum recombination realizes the information communication between the subpopulation groups so as to avoid premature convergences. In this paper, the segmentation problem is viewed as a combinatorial optimization problem, the original image is partitioned into small blocks by watershed algorithm, and the quantum-inspired immune clonal algorithm is used to search the optimal clustering centre, and make the sequence of maximum affinity function as clustering result, and finally obtain the segmentation result. Experimental results show that the proposed method is effective for texture image and SAR image segmentation, compared with the genetic clustering algorithm based on watershed (W-GAC), and the k-means algorithm based on watershed (W-KM). [C703]

### "Detecting potential human activities using coherent change detection"

This paper describes detection and interpretation of temporal changes in an area of interest using coherent change detection in repeat-pass Synthetic Aperture Radar imagery, with the main goal of detecting subtle scene changes such as potential human activities. Possibilities of introducing knowledge sources in order to improve the final result are also presented. [C704]

### "Support vector machine fusion of multisensor imagery in tropical ecosystems"

One of the major stakeholders of image fusion is being able to process the most complex images at the finest possible integration level and with the most reliable accuracy. The use of support vector machine (SVM) fusion for the classification of multisensors images representing a complex tropical ecosystem is investigated. First,

SVM are trained individually on a set of complementary sources: multispectral, synthetic aperture radar (SAR) images and a digital elevation model (DEM). Then a SVM-based decision fusion is performed on the three sources. SVM fusion outperforms all monosource classifications outputting results with the same accuracy as the majority of other comparable studies on cultural landscapes. SVM-based hybrid consensus classification does not only balance successful and misclassified results, it also uses misclassification patterns as information. Such a successful approach is partially due to the integration of DEM-extracted indices which are relevant to land cover mapping in non-cultural and topographically complex landscapes. [C705]

#### **"The lake water bloom intelligent prediction method and water quality remote monitoring system"**

According to the lagging state of water quality monitoring and problems of difficulty to predict water bloom, one water bloom prediction method based on grey-BP neural network is proposed and a system on water environmental remote monitoring and water bloom early warning based on GPRS wireless communication technology is built, which can obtain the automatic real-time monitoring information for the change of water quality and occurrence of water bloom, then provide a kind of efficient and practical system for water environment control. [C706]

#### **"The application of perceptual weighting on millimeter wave conducted speech enhancement"**

A new non-air conducted speech detecting method is developed in our laboratory by means of millimeter wave (MMW) radar. However, the resulting radar speech is of less intelligible and poor audibility since the present of the combined and colored additive noise. This paper, therefore, investigates the problem of the MMW radar speech enhancement by taking into account the frequency-domain masking properties of the human auditory system and reduces the perceptual effect of the residual noise. The results from both acoustic and listening evaluation suggest that the background noise can be reduced efficiently while the distortion of MMW radar speech remains acceptable, suggesting that the proposed algorithm achieved a better performances of noise reduction over traditional subtractive-type algorithms. [C707]

#### **"Enhancing the MIMO-OFDM Radar systems performance using GA"**

This paper proposes a new peak-to-average power ratio (PAPR) reduction method for a multiple-input multiple-output (MIMO)-orthogonal frequency division multiplexing (OFDM) systems based on a genetic algorithm (GA). It has been introduced to be compatible with Radar systems, where the GA was used to optimize the MIMO-OFDM symbols in such way that could improve the system's performance. During this work, there was a comparison that has been stated among three systems; original radar system, radar system-based MIMO-OFDM and radar system-based MIMO-OFDM uses GA. Finally, a range of simulation results are provided to demonstrate the superiority of the proposed scheme, since it is showed an enhancement in the coverage distance besides reducing the PAPR effects. [C708]

#### **"On mean revisit frequency of non-repeating satellite orbits with finite sensor range"**

The length and the frequency of the visibility times during which a fixed ground station sees a non-geosynchronous satellite is a function of the parameters of a fixed ground station and a function of the orbital parameters of the satellite. The focus, in this paper, is on the mean revisit frequency of a non-geosynchronous satellite with non-repeating ground track as seen by a fixed ground station with a finite sensor range. A mathematical analysis is provided for the calculation of the mean revisit frequency. There are several possible application areas of such visibility statistics, like optimizing a gateway's latitude to maximize the mean revisit frequency of a satellite, thus maximizing the communication possibilities. The analytical solution provides a good match with simulation results at all latitudes and the mathematical background of the analytical solution is foreseen to be useful for the analysis and design of satellite constellations. [C709]

#### **"Improvement on obstacle avoiding ability based on laser range finder"**

Mobile robot works in complicated environment have to deal with all kinds of obstacles, some obstacles may leave only a narrow way, and some obstacles moves quickly or arbitrarily, such as a child. The robot must improve its ability to quickly sensing the obstacles and tracking their state, and then avoid these obstacle and move to the original goal at the same time by motion planning. To improve the obstacle avoiding ability, a three layers obstacle avoiding policy is adopted to deal with the obstacle in different range. The dangerous obstacles are determined and the sub-goal based avoiding policy is presented. To improve the responding ability to moving object, a tracking model is set up, which takes into account the influence of moving platform. The robot may anticipate the collision possibility, collision time and position from tracking algorithm, and then three obstacle avoiding policy is presented according to the collision estimation. The experiment shows good moving object avoiding result. [C710]

### "SNR-dependent filtering for Time Of Arrival estimation in high noise"

Time of Arrival (ToA) estimation is a cornerstone of many of the remote sensing applications including radar, sonar, and reflective seismology. The conventional Matched Filter Maximum Likelihood (MFML) ToA estimator suffers from rapid deterioration in the accuracy as Signal to Noise Ratio (SNR) falls below certain threshold value. In this paper we suggest an alternative method for ToA estimation based on the fusion of measurements from biased estimators which are obtained using a pair of unmatched filters. Suboptimal but not perfectly correlated estimators are combined together to produce a robust estimator for ToA estimation in high noise. The unmatched filters pair is parameterized by a single parameter (phase shift) which is selected based on estimated SNR level. [C711]

### "The wireless extension of CAN-bus based on GPRS"

CAN-bus is applied widely in many industrial systems and vehicles. Nevertheless, in some cases, two or more distant CAN-bus segments are needed to transfer data. If the distance is too long, utilizing twisted wire pairs are impossible. In wireless method, GPRS is so far the reliable style. In this paper, a kind of CAN/GPRS gateway is designed to achieve the function of the wireless extension of CAN-bus. [C712]

### "Portable satellite backhauling solution for emergency communications"

This paper describes the portable satellite backhauling solution for emergency communications used in the e-Triage Project. The main objective of e-Triage is the efficient electronic on-site registration of the victims in Mass Casualty Incidents (MCIs) to enable a fast distribution of the information to hospitals for a better handling of victims. To achieve this, e-Triage designs the end device used to register the victims, the database where the information of the victims is saved, and the communications infrastructure necessary to transmit the data, as after a disaster event the terrestrial networks are likely to be overloaded, damaged or not operative, if they ever existed. This paper focuses on the design aspects of a hand-luggage-size suitcase that offers GSM/GPRS and WLAN to rescue teams and victims in the disaster area and connects them over satellite to the disaster-safe area. [C713]

### "Ultra-wideband transmitters based on M-sequences for high resolution radar and sensing applications"

In this paper we present a novel ultra-wideband transmitter architecture for high resolution radar and sensing applications up to 30GHz. The concept for pulse compression is based on maximal-length sequences to reduce the peak-to-average power ratio. The proposed transmitter consists of a 29-1 linear feedback shift register (LFSR) to generate the radar signal and a fully differential broadband amplifier. A variable gain control has been implemented to provide high sensitivity and decrease the dynamic range. The presented circuit architecture permits the possibility of upconversion, which drastically increases the operational flexibility of the radar system. [C714]

### "Co-construction of ontology-based knowledge base through the Web: Theory and practice"

Ontology-based knowledge base plays an increasingly important role in improving the precision and recall rate of a retrieval system. Based on Distributed Learning theory, a novel approach for the co-construction of ontology-based knowledge base is explored. Making use of the platform set up for the co-construction and sharing of domain-specific knowledge through the Web, we constructed an ontology-based knowledge base of airborne radar field. This study is expected to contribute to the effective improvement of precision and recall rate of information retrieval in the airborne radar field. Hopefully, the mode we designed and adopted for the co-construction and sharing of domain-specific knowledge base could be enlightening for other similar studies. [C715]

### "High resolution two-dimensional imaging of spinning space debris"

A high resolution two-dimensional imaging algorithm of spinning space debris is proposed in this paper. It incorporates the characteristic that the space debris rotates around its principal axis at a certain angular speed and it is applicable to various kinds of signals, such as LFM signal, random noise signal. The corresponding compensation terms are constructed by searching for matched two-dimensional parameters and the position information of scattering points is obtained by energy accumulation using FFT. CLEAN method is combined to enlarge target dynamic range. Imaging of spinning debris by noise frequency modulated continuous wave (FMCW) signal is taken as an example to be analyzed and simulated. The simulations confirm the validity of the proposed algorithm. [C716]

### "Pulse emitter identification by the use of higher order statistics"

The paper presents experiments on the use of higher order statistics in the procedures of identification of radar emitters. Studies aimed at testing "sensitivity" of higher order statistics of selected characteristics of the individual sources of emissions. Attention is focused on methods based on analysis of parameters of single-pulse radar emissions. [C717]

### "A general two-dimensional spectrum based on polynomial range model for medium-earth-orbit Synthetic Aperture Radar signal processing"

The  $k$ th-order polynomial range model (PRM) for Medium-Earth-Orbit (MEO) Synthetic Aperture Radar (SAR) signal processing is proposed, analyzed, and verified in this paper. The coefficients of the PRM are calculated according to the relative state vectors between the satellite and the given target on earth, which implies power series expansion around the beam center crossing time. In addition, the relevant two-dimensional spectrum is deduced out as well by using the principle of stationary phase (POSP) and the series reversion approximation. The accuracy of this spectrum is flexible and limited both by the order of the PRM and the order of the spectrum in an expanded form. Therefore, the PRM-based spectrum is general for MEO SAR with any azimuth resolution at any orbit height. [C718]

### "Frequency broadband signal MVDR adaptive beamforming method and application"

In this paper, frequency broadband signal beamforming methods of digital array radar (DAR) are researched and broadband signal adaptive beamforming is realized through MVDR rule. Simulation and comparison show that blocked DFT beamforming method has advantage of little calculating quantity. For non-superposition of each block destroy the relativity of signal, blocked DFT make aberrance to pulse compression and take bad influence in succedent processing. Sliding-window DFT beamforming can achieve good performance of pulse compression, but it has large calculating quantity. Improved DFT beamforming method has the same calculating quantity with blocked DFT method, and it doesn't destroy the relativity of signal so that it can achieve good performance of pulse compression and in succedent processing. Improved DFT beamforming method is fit for used in engineering. The result of its application in DAR has been given. [C719]

### "A fast range migration compensation method"

Coherent integration is usually used in matched filter radar signal processing to improve target signal to noise ratio (SNR), but the accumulation time is restrained by target's motion according to the conventional radar design principle. Keystone transform can correct range migration without the exact value of target velocity and as a result, the SNR is improved through coherently accumulating all pulses. But the usually used interpolation method has very huge calculation burden. In this paper, a fast range migration compensation method without interpolation based on keystone transform is proposed, which greatly reduce the computational cost, and is more suitable for real-time processing. The simulation results verify its effectiveness. [C720]

### "Jamming research to SAR based on frequency characteristic"

This work is concerned with developing the blanket jamming technology against SAR based on frequency characteristic. Firstly, the SAR imaging output of the shift frequency jamming style is deduced and analyzed. Then a modified shift frequency jamming to SAR, random Shift frequency jamming (RSFJ), is presented and discussed. The theoretic research and simulation show that the RSFJ is an effective blanket jamming style to SAR with the less jamming power requirement than noise jamming. [C721]

### "A novel three-dimensional data association algorithm for 2D radars and sensors"

Fast and precise data association methods are very important in heterogeneous sensor information fusion system. In order to solve the typical problem of three-dimensional data association in heterogeneous sensor system which is composed with 2D radar and IRST, a new algorithm is presented. Firstly, the precise azimuth and elevation of IRST and radial distance of 2D radar are used to obtain the possible position of target in two-dimensional coordinate, and angle statistics is constructed to eliminate most false points. Then, the two-dimensional assignment algorithm is used to achieve the optimum assignment solution. Simulation results show that the proposed method is an effective data association method, and the probability of right association is improved obviously. [C722]

### "MIMO antenna array design for airborne down-looking 3D imaging SAR"

Airborne down-looking three dimensional imaging SAR (ADL-3D-SAR) is a new radar system developed in recent years, which overcomes the shadowing effects and can gather more information compared to the conventional side looking SAR systems. However, it still has many constraints, e.g. antenna array configuration designing, cross-track resolution and vibration errors. In this paper, we focus on the designing of antenna configuration and propose several new multiple-input-multiple-output (MIMO) antenna array models which can provide more reasonable properties for 3D SAR system's stability, applicability, and vibration errors reduction. The validity of these models is discussed in the end. [C723]

#### **"System performance simulation of electronic surveillance receiver for spaceborne SAR"**

Reconnaissance equation for SAR side lobe detection is derived based on SAR movement and antenna pattern. The surveillance scene model as well as algorithm flow is also established. Requirements are given for ground electronic surveillance (ES) receiver to conduct SAR signal surveillance under given tracking time occasions. [C724]

#### **"Design and implementation of a dual-interface radar data recorder"**

This paper analyses the design and implementation of a small-scale dual-interface radar data recorder based on DSP+FPGA. It has two types of interfaces: solid-state IDE hard disk and RJ45. The recorder can save sampling data of original radar waveforms in real time for further analysis and validation. It adapts to a variety of application environments and has a high storage speed and reliable operation performance. It can be widely used in radar testing and flight experiments. [C725]

#### **"A temperature remote monitoring system of cable joint"**

In order to monitor the temperature of cable joint, this paper designed a cable joint real-time temperature monitoring system based on GPRS which is integrated of computer technology, microcomputer control technology and digital sensor technology. It described the whole structure diagram of the system, and presented the hardware circuit and software design in detail. The system takes SCM as main control chip, adopts DS18B20 to build up the temperature measurement terminals, and uses the GPRS network as a wireless transmission network to realize wireless data transmission through the TCP/IP protocol management. Experimental results show that: the system have high accuracy, it is able to identify a variety of cable faults caused from overheating effectively and can meet the needs of cable temperature monitoring. [C726]

#### **"A frequency-based inter/intra partly coherent jamming style to SAR"**

This work is concerned with developing the frequency-based jamming technology against SAR. Firstly, the shift frequency jamming to LFM radar and SAR is analyzed. Then a modified shift frequency jamming to SAR, stepped shift frequency jamming (SSFJ), is presented and discussed. The theoretic research and simulation show that the SSFJ is inter/intra partly coherent with the SAR system and has a region imaging output for protecting the distributed targets. Its jamming power is much less than other jamming styles such as noise jamming, random shift frequency jamming and etc. [C727]

#### **"A radar emitter identification method based on pulse match template sequence"**

In the dense emitter environment, the existing radar emitter identification methods can not effectively and rapidly give the class of radars with complex modulation signal. So this paper proposes a new radar emitter identification method based on pulse match template sequence and gives the structure and algorithm of this method. Through computer simulation, this method can rapidly and effectively identify the class of radar emitter. [C728]

#### **"A design of efficient transport layer protocol for wireless sensor network gateway"**

It is necessary that in the small-or-medium-size wireless sensor networks, the networking information of network and monitoring data of sensors should be sent to the remote computers through the gateway to achieve remote monitoring for the target area. Wireless sensor network data characterize strong bursts, instability of traffic and small amount of data in a single packet. Considering these features as well as the bandwidth of wireless network, the paper proposes a Transport Control Protocol (TCP) with an improved Nagle algorithm. The experiments prove that the improved algorithm obviously enhances the utilization of wireless channel and reduces system energy consumption, while it ensures transmission reliability. [C729]

#### **"Wireless video monitoring system based on image restoration technology"**

A video monitoring system based on GPRS wireless transmission technology is introduced. The system mainly consists of video monitoring modules, MCU, GPRS communication system and monitoring computer. It can use GPRS network and the Internet instead of traditional wired video system to monitor the remote targets in the environments of not suitable for cable transmission. For video degradation during the image formation and transmission process, a method of image restoration based on Hopfield neural network is introduced. Simulation results show that this method can restore the vague image effectively. [C730]

#### "High resolution radar range imaging method using bandwidth extrapolation"

The high resolution radar demands transmitting ultra wide bandwidth chirp signals, which consequently leads to increasing the system complexity and expenses. The frequency domain AR model for radar chirp signals was presented in the paper based on the bandwidth extrapolation technique together with linear prediction algorithm to broaden the effective bandwidth of the signal. The performance estimation function, namely the prediction error as a function of the linear error prediction filter length, was derived through analyzing large numbers of computer simulation experiment results. It is of considerable importance to determine the linear error prediction filter length for optimizing the bandwidth extrapolation parameters. It is demonstrated by the theoretical analysis and simulation results that the bandwidth extrapolation method is feasible and effective for increasing bandwidth of the radar signal to obtain higher range resolution. [C731]

#### "A two-stage hybrid space-time adaptive processing approach"

This paper presents a new two stage hybrid space-time adaptive processing (STAP) algorithm, which combine space-time multiple-beam (STMB) architecture and direct data domain (DDD) approach. The proposed two stage hybrid algorithm use the direct data domain approach as the first stage to suppress discrete interference in the range cell under test and use STMB method as the second stage to suppress the residue correlated interference. Therefore this approach takes advantage of the DDD and STMB method and alleviates their drawback, so it can suppress discrete interference and correlated interference simultaneously. [C732]

#### "Design of a light-weight digital beam forming antenna for future sar applications"

The CSA has been working actively during the past decade on developing various technologies for improving the capabilities of SAR antennas. Various techniques have been investigated for decreasing the mass per unit of area as well as improving the electronic capabilities of the radar. These efforts were combined to form a new concept that is presented here. The concept was defined for C-band applications but could also be applied at lower frequency. The radar antenna has a total area of 38 m<sup>2</sup>. The central aperture (~10 m<sup>2</sup>) is used on transmit and receive while the wings are receive only phased arrays spanning a total area of 28 m<sup>2</sup>. The central aperture transmits a large beam and the receive aperture captures the echo simultaneously from various directions through a digital beam synthesis. [C733]

#### "Remote control software development for a small airborne electronic support payload"

An unmanned aerial vehicle (UAV) electronic support payload (ESP) has been developed for the purpose of detecting and analyzing radar signals. The airborne payload control system (PCS) must be controlled from a ground control station (GCS) remotely through a wireless link. For the purpose, a control program, called Radar Signal Acquisition System (RSAS), has been designed, implemented and integrated with ESP. This paper introduces the ESP system, provides an overview of the general acquisition process, gives details on the RSAS and wireless link implementation using the Matlab scripting language, and finally presents some test results. [C734]

#### "Application of passive acoustic radar to automatic localization, tracking and classification of sound sources"

A concept, a practical realization and applications of a passive acoustic radar for automatic localization, tracking and classification of sound sources were presented in the paper. The device consists of a new kind of multichannel miniature sound intensity sensors and a group of digital signal processing algorithms. Contrary to active radars, it does not emit a scanning beam but after receiving surrounding sounds it provides an information about the directions of incoming acoustical signals. The acoustic sound pressure of a given event should be greater than the noise background. The practical examinations of the sensitivity and accuracy of the developed passive acoustic radar were also presented and discussed. The recognized sound events were divided into several types such as: explosion, shot, breaking glass, human scream. The information about the sound event direction can be used to the automatic and remote control of a Pan Tilt Zoom (PTZ) camera. The automatic and continuous tracking of a selected sound source movement is also possible. The proposed device can significantly improve the functionality of traditional surveillance monitoring systems. [C735]

### "An overview of range detection techniques for wireless sensor networks"

Range detection is a key problem in wireless sensor networks (WSN). In this paper, a brief overview is provided for basic techniques for this problem. The fundamental principles for range detection are inherited from RADAR systems, but careful designs need to be made to balance the expected accuracy and the device complexity, considering the limited resources of a WSN. We will introduce some basic measurement principles of range detection for WSN and some available range detection systems. We will also discuss several signal processing algorithms used for range detection. [C736]

### "Inverse synthetic aperture 3-D imaging laser radar"

Three-dimensional (3-D) Image can represent target's physical characteristic well and improve target recognition capability, however, conventional optical imaging radar which is limited by the array units or scan system cannot realize the high resolution imaging for moving targets. This paper combines the inverse synthetic aperture technology, laser signal and interferometric technique to suggest a new radar system which is called Inverse Synthetic Aperture 3-D Imaging Laser Radar, describes initial design project of this radar system, analyzes the imaging theory and implement method, and finishes the imaging simulation. The simulation shows the feasibility of this radar system and advantages of the image obtained from this radar. [C737]

### "Three-dimensional micro-doppler signature extraction in MIMO radar"

In traditional monostatic radar, only the micromotion signatures projected in line-of-sight (LOS) could be extracted from the target's echoes, which are insufficient for accurate target recognition due to the target-aspect sensitivity. In this paper, we propose an algorithm for the three-dimensional micro-Doppler signature extraction using the multi-input multi-output (MIMO) radar technique. The micro-Doppler effect in MIMO radar induced by rotation is analyzed. Profited from the multi-view of MIMO radar, the three-dimensional micro-motion features, which are not sensitive to the target's aspect anymore, are obtained by solving nonlinear multivariable equation systems. Simulations are given to validate the effectiveness of the proposed algorithm. [C738]

### "Simultaneous registration and fusion of radar and ESM by EM-EKS"

In this paper, we present an approach for radar and electronic support measure (ESM) simultaneous registration and fusion. An expectation-maximization based extended Kalman smoother (EM-EKS) is developed here to perform fusing of the system states and to simultaneously estimate the sensor biases. Computer simulations are carried out to validate the efficiencies and robustness of the proposed algorithm. [C740]

### "Radar velocity-measuring system design and computation algorithm based on ARM processor"

The real-time monitoring of vehicles velocity has become essential for traffic safety. Therefore, in order to improve the method of monitoring the velocity of vehicles on road, this paper has designed a new radar velocity-measuring system which is based on ARM processor. This system is based on Doppler principle and spectral estimation algorithm, in its hardware design part, and it takes full use of the underlying resources of ARM processor, to achieve sample, digital signal processing and peripheral control in the separate ARM core. In the software design part, it analyses the main program flow, at the same time, since the ARM processor does not support hardware floating-point operations, it puts forward the usage of fixed-point numbers to store and calculate floating-point numbers, which makes the data loading and storage minimization; And it uses ARM assembly language to write the core algorithm and takes full advantage of the 5-stage pipeline of ARM processor, to achieve the right register allocation and instruction scheduling for fine-grained control, and also to avoid the pipeline interlocks. Experimental results indicate that the accuracy of this velocity measurement system can reach  $\pm 1\text{km/h}$ . It not only can be used in traffic enforcement agencies, but also has low cost, low power consumption advantages. [C741]

### "VLSI signal processing system employing six phase codes for spread spectrum applications"

Spread Spectrum applications require a set of sequences with individually peaky auto-correlation and pair-wise cross-correlation. Obtaining such sequences is a combinatorial problem. If the auto-correlation and cross-correlation are taken in the aperiodic sense then there are hardly any theoretical aids available. Thus the problem of signal design referred to above is a challenging problem for which many global optimization algorithms like

Genetic Algorithm, Simulated Annealing and Tunneling Algorithm were reported in the literature. Recently an efficient VLSI architecture for Generation of the Six phase codes was proposed. Integrating this generation architecture with the currently proposed identification architecture provides an efficient Real-Time Hardware solution for identification and generation of the Six phase codes. The paper aims at an efficient hardware implementation of the Modified Genetic Algorithm (MGA) for the synthesis of optimal Six-Phase codes useful for Spread Spectrum applications. The VLSI System is implemented on the Field Programmable Gate Array (FPGA) as it provides the flexibility of Reconfigurability and Reprogramability. [C742]

#### "Space-time adaptive processing for sea clutter and jamming suppression in radar seekers"

When radar seeker searches and tracks moving target on sea surface, sea clutter spectra severely spread out due to the strong effect of sea conditions. Conventional methods for suppressing sea clutter have achieved poor performance. This paper mainly analyzes the sea clutter characteristics in azimuth-Doppler domain and clutter spectra with different scanning angles. Then space-time adaptive processing (STAP) technique is applied to suppress sea clutter. Research results indicate that sea clutter spectra have some special characteristics in space-time distribution, and the proposed STAP algorithm can detect slow moving targets effectively as it can suppress sea clutter and strong jamming. [C743]

#### "A new waveform for range-velocity decoupling in automotive radar"

Radar sensors for automotive applications require extremely high performance figures in terms of measurement accuracy and time. LFM CW radar sensors have the advantages of high range resolution, but it will bring out ghost targets and missed targets in multi-target detection. This paper describes a new waveform combining LFM CW with SFCW pairing is proposed and discusses in detail to demonstrate the technical differences and advantages. [C744]

#### "High-efficiency and well-integrity method for dynamic acquisition of GNSS location information"

Location-based services play an ever increasingly important role in modern society. The high efficiency and well integrity of GNSS location information is required in these services. For well integrity, a new dynamic transmission processing method named Transmission Intelligent Selecting Mechanism (TISM) is presented in this paper. Based on the detection of communication signal, different methods for information processing are selected for different signal intensity. For high efficiency, a new dynamic compression method named Time-Interval Alternated with Distance-Interval Intelligent Judging Method (TAD) is presented based on traditional compression methods Single Time-Interval method (STI) and Single Distance-Interval method (SDI). There are three different modes, high speed mode, medium speed mode and low speed mode in TAD. For different modes, different compression styles are selected. Experimental results show that TISM has made location information acquired successfully in some areas where the GPRS signal is very weak. TAD has reduced more than 75% of data and 50% of deviation comparing with STI. Thus, more than 75% of communication cost has been reserved. [C745]

#### "Compressive sensing radar imaging based on smoothed l0 norm"

Compressive sensing techniques have been shown to reduce the number of data samples beyond the Nyquist theorem, achieving perfect reconstruction of the original signal. In this paper, we propose a compressive sensing radar imaging arithmetic based on smoothed l0 norm. Simulation experiments conformed that the arithmetic has faster reconstruct speed and well reconstruct quality compare other arithmetic. [C746]

#### "A clutter suppression method based on angle-doppler compensation for airborne radar with uniform circular arrays antennas"

The clutter distribution of airborne radar with uniform circular array antennas varies with ranges and received data in different range gates are not independent identically distributed vectors, so the statistical STAP methods degrade. In this paper, based on the detailed analysis of clutter distribution for airborne radar with uniform circular array antennas, the conclusion that the non-linear relation between space angle and number of arrays results in the nonhomogeneity at range for airborne radar with circular array antennas is gained. A clutter suppression method for airborne radar with uniform circular array antennas is proposed in this paper. This method involves in a preprocessing with MADC method to align the centers of clutter spectrum in different range gates and subsequently clutter suppression in other azimuths with DBU technology. Simulation results show the validity of this method. [C747]

#### "Regularized resolution enhancement of point-based features of synthetic aperture radar image using variable quasi-norm"

Nonquadratic regularization with  $l_p$ -quasi-norm has been widely used as an efficient and powerful tool for resolution enhancement of point-based features of synthetic aperture radar (SAR) images. However, adjustment of the  $l_p$ -quasi-norm usually requires a lot of time and labor. In this paper, we propose a modified model and method for choosing regularization term. Considering the sparseness of scatterers in the scene of a SAR image, we use the generalized Gaussian distributions (GGD) as prior distributions for sampled scattering field. Our regularization model is constructed based on variable  $l_p$ -quasi-norms, and the selection of  $l_p$ -quasi-norm is achieved through estimation of the shape parameter  $p$  of the GGD by adopting a moment method. The regularization model leads to an alternating iterative algorithm. Experimental results with simulated and real data show that the method can automatically select regularization term and produce SAR images with improved spatial resolution. [C748]

#### "Ionosphere interference suppression for HF/SWR using L-shape array"

In this paper, using L-shape array for ionosphere interference suppression for high frequency surface wave radar is proposed. The linear receive array, which is used by conventional HF/SWR systems, is replaced by an L-shape array, which is effectively a combination of two linear arrays arranged perpendicular to each other. This gives the radar additional resolving power in elevation angles, which is not available in conventional HF/SWR systems with one-dimensional linear arrays, so the ionosphere interferences with high elevation angles can be better suppressed. Measured data from real HF/SWR is used in experiments to compare the ionosphere interference suppression performance of conventional linear array and the L-shape array. The result shows great performance improvement by using the L-shape array. [C749]

#### "Cover page"

The following topics are dealt with: kinematics, compressive sensing radar imaging, discrete Hilbert transform, feature extraction, nondestructive testing, dynamic programming, STAP algorithm, spread spectrum communication systems, face detection, wireless sensor networks, signal denoising, anti-jamming, information fusion, game theory, shipborne radar echo, ad hoc networks, wavelet transform, Hough transform, wind farm power, acoustic echo cancellation, speed estimation, image enhancement, curve fitting, perceptron neural nets, statistic decoding algorithm, LDPC codes, diffraction tomography, video watermarking, pulse compression technique, image analysis, cognitive OFDM, analog signal, fault diagnosis, target recognition, adaptive beamforming, nonlinearity correction imaging, computer vision, image segmentation, mobile networks, synthetic aperture radar, Kalman filtering, hidden Markov model, support vector machine, network intrusion detection, network congestion control, mobile VoIP, inertial navigation, edge detection, image resolution, image reconstruction, power control, cognitive radio, speech processing, attribute reduction, routing protocol, and incremental learning. [C750]

#### "Stepped-Frequency waveform processing for moving target based on genetic-CLEAN algorithm"

Stepped-Frequency waveform (SFW) is a very important type of high range resolution radar signal. A novel processing method for SFW based on genetic algorithm and CLEAN technique is proposed in this paper. The parameters (i.e., position, amplitude and velocity) of a point scatterer can be found by global searching with genetic algorithm. And an iterative CLEAN processing is used to eliminate the extracted point from the received data of one SFW burst. Then the high range resolution profile (HRRP) of the target can be reconstructed with the estimated parameters. Finally the effectiveness of the algorithm is verified by the simulation results. [C751]

#### "Statistical relax method for super resolution ISAR imaging"

An effective statistical method of detecting the scatterers center for super-resolution ISAR imaging is presented. By exploiting the statistics of background noise and clutters, Gaussianity test (GT) is applied to extract the scatterers center in range cells under desired constant false alarm rate (CFAR). Combined with extended Relax algorithm, super resolution ISAR image of target is generated. Theoretical analysis and experimental results of real data show that proposed method exhibit better performance with expected to conventional high resolution method. [C752]

#### "Error estimate of quadrature sampling system via discrete Hilbert transform"

Pulse Doppler radar needs accurate measurement of the quadrature sampling system error for error correction to reduce false alarm rate and improve the clutter suppressing performance and the improvement factor. This paper firstly introduces the discrete Hilbert transform to estimate the relative amplitude error and phase error of quadrature sampling system using coherent testing signal. The error function with respect to each sample is derived theoretically. Computer simulation shows that the theoretical results are effective and accurate. The results can be used to evaluate and correct the errors in the quadrature sampling system to contribute to

suppress the background moving clutter and reduce false alarm rate for the pulse Doppler radar. [C753]

#### "Shipborne radar echo signal denoising based on improved threshold and shrinkage function"

In order to denoise shipborne radar (9 GHz pulse radar) echo signal in distortion-free, smooth, and less loss, A improved threshold and shrinkage function are proposed in this paper based on the Multi-analysis wavelet threshold denoising. The denoising effects of different shrinkage function for shipborne radar echo signal were compared. The results of experiment show that better SNR and similarity and smoothness and less loss can be reached by using the proposed function to shipborne radar echo signal. [C754]

#### "Multi-cycle signal processing based on Keystone transform in LFMCW radar"

In this paper a Keystone transform based MTD processing is proposed for multi-cycle signals to solve the MTRC (migration through range cell) problem in linear frequency-modulated continuous wave (LFMCW) radar. Analysis shows that MTRC is introduced by the linear coupling of fast time and slow time in multi-cycle beat signals. Resorting to the decoupling principle of Keystone transform and under consideration of the characteristics of beat signals, a transform expression is given, which is independent of target parameters. The relation between this transform and the direct motion compensation is further discussed, and a general applicable condition is derived. Simulation results testify the conclusion and the efficiency of the method. [C755]

#### "New spatial overlap method of transmitting beam for airborne phased array radar"

A novel scanning structure of cross-circumscribed beam overlap arrangement for airborne planar phased array radar is presented, which can reduce the beam shape loss under the triangular and rectangular beam overlap arrangements. The beam shape loss and energy distribution and the probability of central detection of these structures are analyzed and compared. Simulation results show that the cross-circumscribed lattice has the lowest beam shape loss, and it can elevate the probability of central detection, and in favor of the integrality of scanning. [C756]

#### "Research on nonlinearity correction imaging algorithm of FMCW SAR"

The frequency modulated continuous wave synthetic aperture radar (FMCW SAR) is a newly proposed radar imaging system, which combines FMCW technique with synthetic aperture imaging methods and has the advantages such as small cubage, light weight, cost-efficient, highresolution, etc. In practical SAR system, the frequency and time of the frequency modulated signal can't keep linearity absolutely. The effects of nonlinear frequency modulation on range resolution and FMCW SAR imaging are analyzed. A method of polynomial fit is proposed in order to estimate the nonlinearity of the frequency modulated signal, and the nonlinearity is corrected. Nonlinear FMCW SAR imaging algorithm is researched. Then the simulation results are presented. The results show that this method is valid. [C757]

#### "An intermediary method used in direction-finding location system"

In order to deal with the NP hard in the usual direction-finding location, an intermediary techniques of data association for multiple targets tracking by multiple passive sensors are discussed. The location will be fulfilled at the assistant of a range finder. Firstly, employ one of a passive sensors equipped with the range finder in the tracking net, get an integrated measurement of the target; Secondly, translate the integrated measurement into the reference frame of the other sensors one by one, then use the translated measurement as the medium, pick up the ones associated with the translated one as a gather, Finally, let the orientation line in the gather crossed, and find the precision location though the least mean square. The simulation results show the excellent performance of the new direction-finding location method. [C758]

#### "A segmentation-based CFAR algorithm for subsurface targets detection in FLGPSAR"

Forward-Looking Ground Penetrating Synthetic Aperture Radar (FLGPSAR) has the capability of forming two-dimensional high-resolution images of subsurface objects from a standoff distance. This paper addresses the detection of subsurface targets, i.e. landmines, in FLGPSAR images. The conventional Constant False-Alarm Rate (CFAR) algorithm has been widely used in SAR image target detection, but its performance will degrade in subsurface targets detection because of the presence of interfering targets and clutter power transition. In this paper, a segmentation-based CFAR (S-CFAR) algorithm is proposed. The S-CFAR algorithm can remove the interfering targets or clutter power transition before estimating the parameters of the clutter background to achieve a better performance than the conventional CFAR algorithm. The real data processing results are given to validate the efficiency of the proposed method. [C759]

### "Transmit-receive beamforming for MIMO radar"

MIMO radar with orthogonal signal transmission is equivalent to form virtual sensors at the receiver. The virtual sensors can be used to form narrower beams with lower sidelobes. The pattern of MIMO radar can be decomposed into transmit pattern and receive pattern by mathematical analysis. In this paper, we apply conventional beamforming and MVDR beamforming algorithms to MIMO radar. At last, the comparisons of two algorithms for phased-array radar and MIMO radar are given. [C760]

### "Estimation of aircraft altitude in 2D radar intelligence networking"

An observation model of altitude estimation in 2D radar network with 2 sensors which is based on the WGS-84 ellipsoid earth is designed, and a new algorithm for target altitude estimation is presented. Through a lot of simulations and academic analysis, the performance of the algorithm is detailed analyzed. The simulation and analysis result shows that the algorithm accords to the fact of observation, makes full use of the observations, and the estimation of target altitude is improved. [C761]

### "Inverse frequency scaling algorithm (IFSA) for SAR raw data simulation"

This paper presents a SAR raw data simulation approach using the inverse frequency scaling algorithm (IFSA) based on deramp processing. It is time-saving and can take motion error into account. The limitation of the inverse chirp scaling algorithm (ICSA) on transmitted waveforms is also overcome. Simulated results show the validity of the algorithm. [C762]

### "A Gaussian particle filter for track-before-detect"

A novel track-before-detect algorithm is proposed to perform detection and tracking a weak target in radar measurements. Firstly, a Gaussian particle filter based track before detect is presented for tracking target. Secondly because of the Gaussian particle filter is only tracking algorithm and can not perform detection target, the likelihood ratio based the Gaussian particle filter is derived. Finally based on this deduction, sequential fixed size (FSS) likelihood ratio test (LRT) is used to detect target. Simulation results show that this novel algorithm can realized detection and tracking a weak target simultaneously, and the performance of detection and tracking is improved than the particle filter. [C763]

### "3-D imaging algorithm for targets with micro-motion based on HRRP sequence"

Three-dimensional (3-D) radar imaging has been widely used in target scattering diagnosis, modeling and target identification. In this paper, 3-D imaging algorithm for targets with micro-motion based on high resolution range profile (HRRP) sequence is presented. Aiming at the difficulty of getting look angle parameters of the radar directly and considering the precession feature of targets with micro-motions, a way of turning precession parameters into angle parameters indirectly is proposed. Meanwhile, for the scattering centers association, two methods are discussed and compared. Finally, performance analysis under the influence of related factors is also covered and the parameter constraints are given, and thus provide a reference for the design of 3-D radar imaging system. Simulation results are presented in the end, which prove the efficiency of the proposed method. [C764]

### "A robust space-time multiple-beam STAP algorithm"

Considering the limited sample support and computational complexity, the traditional localized STAP algorithms restrict adaptive processing in localized processing region and for the most part they have fixed system degrees of freedom (DOF). A new idea about the localized STAP algorithm which adjusting system DOFs adaptively with variable interference environment are presented, and some practical issues, such as performance metric selection, initial system DOFs selection and the recursion fast algorithm of weight are discussed. The validity of the research is proved by measurement data processing results. This algorithm is more robust in complicated interference environment, and it reduces large computational complexity and improves the performance of jammer suppression. [C765]

### "New threshold and shrinkage function for shipborne radar echo signal denoising based on wavelet transforms"

In order to denoise shipborne radar (9 GHz pulse radar) echo signal in distortion-free, smooth, and less loss, a new threshold and shrinkage function are proposed in this paper based on the Multi-analysis wavelet threshold denosing. The denoising effects of different shrinkage function for shipborne radar echo signal were compared. The results of experiment show that better SNR and similarity and smoothness and less loss can be reached by

using the proposed function to shipborne radar echo signal. [C766]

#### "Anti-jamming filtering for DRFM repeat jammer based on stretch processing"

This paper addresses issues about the rejection of false jammer targets in the presence of digital radio frequency memory (DRFM) repeat jammer. An anti-jamming filtering technique is proposed that it can eliminate this type of jamming signal. By using a stretch processing with a particular selected reference signal, the presented method can fully separate the echoes being reflected from the true targets and the signals being re-transmitted by a jammer in frequency domain. Therefore, utilizing the nonoverlapping properties of the received signals, filters or suchlike techniques can be used to reject the undesired jamming signals. Particularly, this method does not require estimation of jamming signal parameters and does not involve a great computation burden. Simulations are given to show the validity of the introduced approach. [C767]

#### "A modified track-before-detect algorithm for radar weak target"

Track-Before-Detect (TBD) is an effective method for detection weak target. In TBD a doubted target is tracked through a time sequence of frames, and then the target's energy is integrated along the tracked trajectory to lead to detection. Therefore the key of TBD methodology is how to accurate tracking target. A novel TBD algorithm is proposed based on Modified Hough Transform (MHT) and Particle Filter (PF). Firstly trajectories that are possible true target path are initiated by the MHT to obtain the region of the target, after that, this region is provided to the PF as the prior knowledge. According to this prior knowledge the false trajectories are eliminated and target is detected by the PF. Simulation results show the proposed algorithm can detect and track the weak target as low as 3 dB SNR. [C768]

#### "Tracking ground targets with road constraint using multiple hypotheses tracking"

Data association in tracking multiple targets is of vital importance for airborne surveillance radar. Multiple hypotheses tracking (MHT) is generally accepted as the preferred method for solving the data association problem in modern multiple-target tracking (MTT) systems. However, there are usually too many hypotheses to process slowly. In this paper, map information has been used to prevent unnecessary MHT track branches and improve the state estimator. The simulation results show that this new algorithm improves tracking performance in realistic environment and effectively brings down the number of track branches, while reducing largely calculating time with better accuracy. [C769]

#### "A TBD algorithm based on improved Randomized Hough Transform for dim target detection"

For the detection of dim target, the track-before-detect(TBD) methodology has been employed to integrate the target's energy through a time sequence of frames. A TBD algorithm based on improved Randomized Hough Transform for dim target detection is proposed in this paper. This algorithm uses the sequence number of frames to make sure that the point pairs are selected randomly from different frames, avoiding the unreasonable situation that initiates target's track in the same frame data. Second, it also introduces a new vote method. Based on the minimum Euclidean distance criterion, this vote method finds the optimal parameter cell to vote, making the vote result better than traditional Randomized Hough Transform (RHT). In addition, we not only increase the poll of the optimal parameter cell but also update the corresponding parameter, avoiding the large deviation between the recovered track and the real track. By simulation, we conclude that this algorithm can detect dim target more speedily and accurately than traditional RHT, especially under the background of low Signal to Noise Ratio (SNR). [C770]

#### "The research of distributed power quality on-line monitoring system based on GRPS"

In order to satisfy the requirement of power quality on-line monitoring system which is always online, cheap price and a wide coverage, the thesis puts forward to methods that GPRS(General Packet Radio Service)communications technology is applied in power quality on-line monitoring system. The main content of the system is that:the combination of DSP and MCU is used in power quality on-line monitoring system to store, display, count and analyze the collected data of voltage and current from each terminal, and communicates with supervisory computer through GPRS communication module to realize power quality monitoring in the grid. According to the need of user, it can control field device to realize the research of distributed power quality on-line monitoring System. [C771]

#### "A GPR survey on a morainic lake northerly Turin (Italy)"

A waterborne GPR survey consisting of 50 profiles with a total length of about 37 km has been executed on the morainic lake of Candia northerly Turin (Italy). The survey tested the capability of GPR in shallow low-conductive

waters to estimate bathymetry, water volume, bottom sediment type, bedding and porosity. Spotty measurements of electrical conductivity and temperature allowed for a better processing of GPR raw data. The results seem to confirm the effectiveness of GPR to give useful information providing suitable geometrical (water depth) and physical (water conductivity) conditions. [C772]

### "Advantages and restrictions of holographic subsurface radars"

Holographic subsurface radars (HSR) are not in common usage now; possibly because of the historical view amongst radar practitioners that high attenuation of electromagnetic waves in most media of interest will not allow sufficient depth of penetration. It is true that the fundamental physics of HSR prevent the possibility to change receiver amplification with time (i.e. depth) to adapt to lossy media (as is possible with impulse subsurface radar or ISR). However, use of HSR for surveying of shallow subsurface objects, defects, or inhomogeneities is an increasingly proven area of application. In this case HSR can record images with higher resolution than is possible for ISR images. This paper presents experiments with HSR imaging in media with different degrees of attenuation, and illustrates the principle of HSR through an optical analogy. [C773]

### "Full-waveform inversion of multi-offset surface GPR data"

Common ray-based techniques for analysing common midpoint (CMP) ground penetrating radar (GPR) data use only part of the measured traces and return results with limited resolution and non-quantitative values for conductivity. Due to the fact that full-waveform inversion uses all information of the measured traces, a higher resolution image of the subsurface and quantitative conductivity values can be obtained. Using an experimental dispersive CMP dataset, the results of dispersion analysis, i.e. permittivity and thickness, define the start model parameters for full-waveform inversion. After estimating an effective source wavelet, the full-waveform inversion based on a simplex search algorithm returns reliable permittivity and conductivity values of the subsurface. [C774]

### "Estimation of soil electromagnetic parameters using frequency domain techniques"

In this paper two frequency domain methods for characterization of the dielectric properties of dry sand over a broad microwave frequency range will be presented. The investigated electromagnetic parameters of the soil relevant for most GPR applications are dielectric permittivity and loss tangent. Although the majority of GPR applications concentrate on frequencies below 1 GHz, this work will investigate the constitutive parameters of soil with very low water content in three microwave bands (X, Ku and part of K) ranging from 7 to 20 GHz. In particular, this study will focus on the evaluation of the complex permittivity by means of a numerically robust evaluation rather than the well-known Nicolson-Ross-Weir (NRW) method. The proposed procedure yields the apparent real part of the permittivity and the loss tangent without the inaccuracy in the vicinity of  $\lambda_m/2$  resonances known from the NRW method. The second approach utilizes a free space measurement, in which the soil is confined by a polystyrene probe holder in a mono-static GPR setup. The measurement result of the backscattered excitation will be compared with a commercial time-domain solver based on Finite-Integration-Technique (FIT). The material parameters of the electromagnetic model are adapted iteratively in the way that measurement and simulation results coincide. The measurement results of both frequency domain methods demonstrate the validity of the estimated dielectric parameters. [C775]

### "Full-waveform inversion of crosshole ground penetrating radar data to characterize a gravel aquifer close to the Thur River, Switzerland"

Imaging results of crosshole GPR can be significantly improved by using full-waveform inversion compared to conventional ray-based inversion schemes. A recently developed 2D finite difference time domain (FDTD) vectorial full-waveform crosshole radar inversion method was made more flexible to allow using an optimized acquisition setup that reduces the measurement speed and the computational cost. This improved algorithm was used to invert crosshole GPR data acquired within a gravel aquifer in northern Switzerland. Compared to the ray-based inversion, the results from the full-waveform inversion show significantly higher resolution images in the depth range of 6m-10m. Comparison of the inversion results with borehole logs shows that porosity estimates obtained from Neutron-Neutron data correspond well with the GPR porosities derived from the permittivity distribution in the depth range 6 m-10 m and that the trends are in good qualitative agreement. Furthermore, there is a good correspondence between the conductivity tomograms and natural Gamma logs at the boundary between the gravel layer and the underlying lacustrine clay sediments. [C776]

### "Exact solution of idealized subsurface sensing problem"

Identification of subsurface objects detected by GPR requires an accurate estimate of their size and shape. In this paper, as a generalization of the migration methods based on the "exploding reflector" approximation, we

consider a model of synchronously exploding volume sources. The excited impulse radiation is registered on the earth surface. We write down a closed-form solution of the inverse problem: reconstruction of the current spatial density from the transient electric field distribution along the surface. This model solution can be used to refine practical migration algorithms. It is also interesting as a model to estimate the basic factors limiting GPR spatial resolution. [C777]

### "3-D GPR imaging of central pillar of the Mireuk stone pagoda in Korea"

Mireuk Pagoda is a very important national treasure which is known to be constructed during late Baekje kingdom about 1,500 years ago. To investigate the inner structure of central pillar of this stone pagoda, 3-D GPR and tomography imaging was applied. During this geophysical survey, we could find and define a small room in the pillar. Since full coverage was available in the radar tomography, we could obtain very accurate image of this empty room. By the disassembly of the cover stone of central pillar after this investigation, we could find great historical remaining in this room. The findings include golden jars containing relics of Buddha and written documents explaining construction history of this pagoda. [C778]

### "Integrated GPR and archaeological investigations to study the site of Aquinum (Frosinone Italy)"

To enhance the knowledge finalised to the location and conservation of the unknown buried structures below the actual studied levels, in the territory of the Ancient Aquinum (Frosinone, Italy), an integrated archaeological and ground remote sensing study has been developed during 2008-2009 and it is still in progress. Analysis of the historical and oblique aerial photographs, combined with topographical and archaeological field-walking surveys, allowed the preliminary interpretation of the main town-planning of Aquinum. To verify this preliminary interpretation an extensive geophysical surveys, employing Ground Penetrating Radar (GPR) method, has been made during 2008-2009. The obtained results indicate the good matching between the interpretation of aerial photographs and GPR images at different depths. The location, depth and size of the individuated archaeological structures were effectively estimated. Archaeological excavations made during the summer 2009, in a southern portion of the investigated area, have confirmed the results obtained with GPR method. [C779]

### "Monitoring of sequential gasoline-ethanol releases using high frequency ground penetrating radar"

Our hydrogeophysical field experiment evaluated the ability of high frequency (450 & 900 MHz) ground penetrating radar (GPR) to monitor sequential releases of gasoline followed by ethanol. The initial GPR images of the gasoline release zone reveal the development of shallow (i.e., above 10 ns) high reflectivity events and a significant velocity pull-up of an underlying stratigraphic reflection. Temporal evolution of the impacted zone reflectivity and the velocity pull-up indicate a progressive redistribution of gasoline in the impacted zone. GPR profiles obtained during frozen soil conditions clearly show that the presence of gasoline affects the freezing process. Preliminary analysis of the sequential ethanol release GPR data indicates a significant expansion of the impacted zone following this release. [C780]

### "Application of Ground penetrating Radar (GPR) exploration in Karst mountain areas"

When highway is built in Karst mountain areas of China, it is important for us to detect Karst distribution which would trigger embankment sliding, subsidence and other geological disasters. So, karst caves under different conditions, such as stochastic ground surface, random covering layer thickness, different filling styles and depth were simulated by Finite Element Method(FEM), which got the reflecting features in GPR profiles. Then, exploration of GuiZhou highway and borehole verification were introduced. [C781]

### "Practical algorithms of geometrical migration"

Practical GPR survey schemes based on a geometrical migration algorithm are implemented and experimentally tested: (1) random GPR data collection from water surface along a tangled path and interpolation to a regular grid for bottom reconstruction; (2) double-pass B-scan with different antenna offset for estimation of the upper ground layer thickness and permittivity. An analytical relation between the shape of subsurface reflecting interface with measured signal travel times is used for the reconstruction of the layer parameters. [C782]

### "Miniature multimode deep ground penetrating radar"

Deep ground penetrating radar, as its name says, is able to image the deep buried objects with high resolution. It becomes an important tool for human to know the underground world. In this paper a stepped frequency deep penetrating radar system has been developed. This miniature system is designed for three operation modes: Mode 1 is fast measurement, real-time data storage, off-line data analysis and imaging. Mode 2 is wireless real-time detection and imaging. Mode 3 is on-line real-time detection and imaging. Three modes can be switched

flexibly for different working platform, such as low altitude aircraft, planetary rover or lander, UAV (unmanned aerial vehicle), remote control vehicle and robot, vehicles or just hand holding. The miniature radar host is designed based on the embedded frame to satisfy the multi-modes operation condition including light-weight, small volume and low power consumption. [C783]

#### **"Nine steps to concrete wisdom"**

This paper presents the results of a detailed 3D investigation of 9 structural tests pits (called cells) at our offices in Australia. The data were recorded using a GSSI SIR-3000 system coupled with a 2.6 GHz antenna, with 1024 samples per trace and 500 scans per metre. A range of 5-6 ns and 16 bit data were used throughout. [C784]

#### **"Underground asset mapping with dual-frequency dual-polarized GPR massive array"**

Nowadays, GPR is one of the most effective tool for enabling the safe use of the underground; in fact, amongst the various state-of-the-art methods available, it is a noninvasive technique capable of accurately locating both metallic and non-metallic buried objects. After a multi-year development, a new system has been recently introduced on the market; due to the combined use of low and high frequency antennas (dual-frequency antennas), the use of array of sensors in different polarization and dedicated data processing techniques, the equipment enables the recreation of a 3-D volume from spatially correlated data, with clear benefit in terms of achievable performance and productivity. [C785]

#### **"EISS: An HF mono and bistatic GPR for terrestrial and planetary deep soundings"**

EISS (Electromagnetic Investigation of the SubSurface) is an HF (~2MHz) impulse Ground Penetrating Radar dedicated to deep soundings (kilometric depths) of planetary sub-surfaces. This radar has the particularity to be operated from the surface in both monostatic (transmitter and receiver at the same location) and bistatic configurations (with a small receiver separated from the transmitter that can easily be displaced on the area to be investigated). A prototype has been developed in the frame of ExoMars mission B-phase. This article mainly focuses on the bi-static mode and details the selected design, its various subsystems and its operations. Preliminary tests involving antenna impedance measurements on Earth are shown. [C786]

#### **"Automatic classification of metallic targets using pattern recognition of GPR reflection: a study in the IAG-USP Test Site, Sao Paulo (Brazil)"**

In this work, a methodology to automatically classify of metal targets using pattern recognition techniques on GPR reflection data is presented. The methodology consists of designing a multilayer perceptron (MLP) classifier based on features extracted from the targets in the subsoil, and then using it to classify hyperbolas diffraction indicating their position and depth. The classification of reflections allows a high resolution reconstruction of the subsurface with reduced computing time. The system was developed in MATLAB and applied to GPR data obtained at IAG-USP test site, located in the city of Sao Paulo, Brazil, where metallic drums were studied under controlled field conditions. This site contains different targets of variable sizes buried under different depths and it served as a model for the computational experiment. The results indicate that the automatic classification of the metallic targets in the subsoil is efficient, contributing for the reduction of the ambiguities in the geophysical data interpretation, besides having application on the subsoil mapping of utilities. [C787]

#### **"Development of a bore-head GPR for Horizontal Directional Drilling (HDD) equipment"**

ORFEUS is a Specific Targeted Research Project (STREP), partly funded by the EC, that started in November 2006. One of the objectives of the project was to design and develop a radar mounted on the drill head of Horizontal Directional Drilling (HDD) machines to provide a real-time indication, to the operator, of obstacles in the drill path. The system consists of a GPR control unit (housed in a drilling rod) and two UWB antennas. These can detect buried infrastructure that the bore-head may strike and verify a clearance zone around the drill string to ensure that new pipes may be installed with a minimum separation from adjacent plant. During the 3 year project, several key technical problems, mainly concerning electromagnetic and mechanical compatibility issues, have been solved. The system was finally tested both in experimental and operational sites. These tests confirmed the capability of the equipment to provide useful information on the obstacles in the drilling path; detection range has been evaluated to be sufficient to generate a warning message to the operator to allow corrective action to be taken, thus enabling HDD equipment to be used in greater safety. [C788]

#### **"Crosshole GPR traveltime tomography in elliptically anisotropic media"**

Owing to relatively rapid water content variations with respect to electromagnetic wavelength at GPR frequencies,

the vadose zone usually exhibits significant velocity anisotropy. Neglecting anisotropy in traveltimes tomographic reconstruction leads to artifacts that can obscure important subsurface features, the vadose zone being subject to this problem. In this paper, an algorithm for crosshole GPR geostatistical traveltimes tomography in elliptically anisotropic media is presented. The advantages of the geostatistical tomography algorithm are that the solution is regularized by the covariance of the model parameters and that stochastic simulations can be performed to appraise the variability of the solution space. The implementation relies on a fast curved raytracing scheme specifically crafted for the problem at hand. The benefits of the algorithm to image the vadose zone are illustrated through a synthetic case that is representative of typical studies in quaternary geological settings. The results show that considering anisotropy yields better fit to the data at high ray angles and reduces reconstruction artifacts. [C789]

#### "A study of GPR vertical crack responses in pavement using field data and numerical modelling"

The application of ground penetrating radar (GPR) as a non-destructive technique for characterization of pavement structure on road networks has gained considerable attention during recent years. High resolution ground coupled GPR has the potential to provide important additional information on pavement deterioration, defects and cracks, the last being the focus of this study. Crack geometry and the electrical properties of the pavement surrounding the crack can be quite variable, resulting in often complex and hard to interpret data. Therefore, FDTD numerical modelling has been employed to help understand a range of GPR vertical crack responses observed in a variety of pavements. [C790]

#### "Recent advances in RF tomography for underground imaging"

Underground imaging for tunnel detection is proposed using the principles of radio frequency (RF) tomography. In RF tomography, a set of distributed transmitters and receivers are deployed arbitrarily above the ground, or slightly buried. These transmitters radiate suitable narrowband, low-frequency waveforms into the ground. The resulting wavefront impinges upon underground objects, scattering electromagnetic energy in all directions. Receivers sample the scattered signal, mitigate direct-path leakage, retrieve the phasor of the scattered signals, and relay this information to a base station. After adaptive processing of measured data, an image of the underground facilities is achieved. [C791]

#### "A simple inversion model for the estimation of subsurface features of Mars poles"

Radar observations from Marsis have demonstrated that Martian Polar Layered Deposits (PLD's) are very transparent to radar waves. Thus, the sounder is able to detect the presence of subsurface reflections in the polar regions below the ice-rich layered deposits. The analysis of radar data makes it possible to gain information about some physical features of Mars surface. In this work an electromagnetic inversion model is used to characterize the shallower structures. This approach assumes that structure consists of layers with parallel plane interfaces and that the electromagnetic properties of the first layer are known a priori. Under these assumptions it is possible to estimate the dielectric permittivity of the subsurface structure. The inversion method has been tested in an area of South Pole and reconstruction results are shown. [C792]

#### "Tackling the non-linearity problem in GPR waveform inversion"

Crosshole radar tomography is a non-invasive tool used in diverse geological, hydrogeological and engineering investigations. Conventional tomograms provided by standard ray-based techniques have limited resolution. Higher resolution radar tomograms can be derived by using full-waveform inversion schemes. However, despite the theoretical improvement in resolution, convergence problems can arise in the application of full-waveform schemes due to the ill-posed nature of the inverse problem and the high non-linearity of the relationship between the model parameters and the scattered fields (i.e. the forward problem). We present here a new inversion scheme that starts with a low-pass filtered version of the radargrams and progressively expands the frequency bandwidth as the iterations proceed, thus reducing the likelihood of the inversion getting trapped in a local minimum. The benefits over standard full-waveform time-domain inversion are demonstrated by means of three synthetic examples. [C793]

#### "Influence of interface roughness and heterogeneities on the waveguide inversion of dispersive GPR data"

To investigate the influence of interface roughness and heterogeneous media on the inversion of dispersive GPR data, we performed 3D FDTD modeling with GPRMAX. For both the broadside and endfire source-receiver configurations the responses were calculated for models with different interface roughness and for models that include media with heterogeneities in their dielectric properties. Due to the use of multiple source-receiver offsets to calculate the phase-velocity spectrum, the signal to noise ratio was relatively good and for low interface

roughness the medium properties could be reasonably well reconstructed. Only for the largest interface roughness the data contained significant diffractions and the medium properties could not be reliably reconstructed. For variations of the relative permittivity values equal to 10% and 20%, the model parameters could still be relatively well reconstructed. [C794]

### "Attenuation of large bandwidth microwave signals in water and wet sand"

Large bandwidth microwave signals propagate in dispersive media as pulses that attenuate according to a non-exponential law. Although this is a direct consequence of wellknown theory of propagation in dispersive media, this fact is rarely acknowledged. The aim of this paper is an experimental study of this effect in fresh water and wet sand, both media of interest in Ground Penetrating Radar, which performances dramatically rely on capability of microwaves to propagate through soil. [C795]

### "Electromagnetic monitoring of concrete structures"

Non-destructive evaluation of reinforced concrete structures is an increasingly important field in the construction and civil engineering community. A large number of pathologies that affect both the concrete and the reinforced bar inside concrete are related to the presence of water and its spatial development. In this context, the quantification of both water content and bar diameter is an important phase for the diagnosis of concrete. The propagation of electromagnetic waves is controlled by its electromagnetic properties, mainly influenced by the presence of water in the case of concrete. The dielectric properties of concrete were studied as function of volumetric water content. To measure the dielectric properties of concrete as function of volumetric water content at high frequency, a HP-impedance analyser was used. More than 800 samples of concrete were analyzed and a new relationship between relative dielectric constant and volumetric water content was obtained. Furthermore the study was focused on the simulations for one centre frequency GPR applied to a range of rebar sizes common used as concrete reinforcement. This is compared with real measurements of different known rebar sizes inside concrete structures using 1GHz centre frequency antenna. Furthermore empirical relationship between rebar sizes and electromagnetic parameters was established and analytical functions were proposed. [C796]

### "Tests of sommerfeld ground wave theory using ground-penetrating radar pulses"

We have used ground-penetrating radar pulse waveforms within moveout profiles that we recorded over dielectric ground, to test the geometric amplitude attenuation rates of interfacial surface air waves predicted by classic Sommerfeld theory. The pulses allow separation of interfacial wave modes. We used horizontally polarized pulses centered from 37-390 MHz, frozen ground, and an intermediate range of tens of wavelengths over which radial polarization is predicted to exhibit anomalously low rates. As predicted, azimuthal broadside polarization at 37-45 MHz attenuated in proportion to the square of range, but the radial endfire rate was closer to the 1.6 power of range. At 360-390 MHz, both rates exhibited predicted range-squared amplitude attenuation. Not readily extractable from the theory are the rates for subsurface direct waves, for which we found, from numerical experiments, that both polarizations attenuate in proportion to the square of range. This suggests that geometric rates for all types of subsurface interfacial waves attenuate in proportion to range squared and could be subtracted from actual rates to determine material loss rates. [C797]

### "Inversion of guided waves in georadar data"

We analyze the dispersive characteristics of the electromagnetic guided waves (at georadar frequency) to infer the electrical properties of materials that constitute a layered wave guide. WARR (Wide Angle Reflection and Refraction) georadar acquisitions could be carried out in both TE (Transverse Electric) and TM (Transverse Magnetic) configuration to collect the full wavefield at different offset from the source. The dispersive curves of TE and TM modes are obtained by transforming the space-time acquisition into phase velocity-frequency domain (f-v spectrum); the relative maxima in the fv spectrum represents the different propagation modes. We adopt both global and local inversion algorithms for minimizing the misfit function between measured and theoretical curves in order to obtain a 1D model of the layered subsoil (thicknesses and electrical permittivity). [C798]

### "Nondestructive detection of delaminations in concrete bridge decks"

To detect delaminations in concrete bridge decks, nondestructive techniques (NDT) permit a frequent and large inspection of the slabs without damaging structures. This research was devoted to detect simulated defects in twelve repaired concrete slabs. These were scanned with high frequency ground penetrating radar (GPR) with the common offset (CO) and common midpoint (CMP) methods. The electromagnetic waves speed was determined from CMPs. A 3D visualization program was also created to display the CO measurements. The visibility of the inserted defects revealed to be dependent on their lateral extension, their thickness and their

constitutive material. [C799]

### "GPR as an effective tool for safety and glacier characterization: experiences and future development"

In recent times, the GPR technique has assumed an important role in glacial environment exploration. Ice thickness, bedrock description, internal water floods or underground channel, glacial structures (as snow layering and crevasses detection) form part of our experience in Antarctica and in high alpine glacier ski areas. In this paper, we present some results of these investigations exploring the possibility of combining our technical expertise on Radio Echo Sounding (RES) instrumentation to develop a system for subglacial environment exploration. [C800]

### "Multi-channel Ground Penetrating Radar based on ultra-wideband short-pulse signal: Hardware and software"

In [1, 2] recent state of our multi-channel Ground Penetrating Radar (GPR) design is reflected. In this paper we compare that former design with the new one which is free of some drawbacks. Both GPRs are suitable for diagnostics of road coatings, detection and recovery of subsurface infrastructure (pipes, cabling). GPRs include TX/RX module, antenna switch, multi-element antenna, carrier vehicle and control/processing computer with dedicated software. This software allows GUI, controls TX/RX module, accepts the data from TX/RX module, builds 3D radio image of subsurface volume. As well, dedicated software enables to estimate the geometry and electrophysical parameters of subsurface volume and objects inside of it. For this, so-called Computational diagnostics method is implemented which is based on reverse problem solution. Experimental results are presented. [C801]

### "Application of ground penetrating radar in the urban environment"

Several nondestructive testing methods have been studied to detect subsurface voids. However, few focus on deploying nondestructive methods in the congested and complex subsurface environment found in typical urban locations. This research identifies the challenges with applying Ground Penetrating Radar (GPR) techniques to locating subsurface voids and buried infrastructure in a complex urban environment. The study cataloged GPR signals representing reinforcements, concrete pipes, trolley tracks, and a large range of subsurface voids from surveys collected in downtown Louisville, Kentucky. Building upon this research, the team recreated a typical subsurface urban environment on the University of Louisville campus to develop a library of GPR images taken from known targets with defined parameters for training purposes. [C802]

### "Tapered slot antennas for ground penetrating radar"

The paper presents current results of our ground penetrating radar system design proposed for military application. It is focused especially on antennas, but includes the properties of ultrawideband generator. Several tapered slot antenna structures are presented and some of them have been fabricated. Some modifications of double ridge horn antenna are presented and their parameters are compared and discussed. [C803]

### "Accurate tools for convergence prediction of series solutions of Contrast Source Integral Equations"

Source Type Integral Equations (STIEs) provide interesting alternative formulations for the scattering from dielectric objects. In particular, the underlying operators factor into the composition product of two other linear operators, whose norms can be separately evaluated with the aid of suitable universal diagrams. Then, a specific inequality suggests that the convergence of the formal Neumann series inverting the original integral equation can be established by means of the aforementioned tools. Anyway, such an inequality sometimes provides pessimistic (i.e. stronger than actually needed) conditions in many cases of practical interest. The previous observation motivated the authors to further investigations, so leading to sharper bounds on the relevant norm of the STIEs operators. Numerical examples are reported, confirming the usefulness of the new tools. [C804]

### "Imaging of 3D magnetic targets from multiview multistatic GPR data"

Ground Penetrating Radar surveys aimed at imaging magnetic anomalies are gaining an increasing attention in several applications. In this respect, we introduce in this communication an inverse scattering strategy based on a suitable reformulation of the Linear Sampling Method (LSM). The LSM is a reliable and computationally effective imaging approach, which is exactly cast as a linear inverse problem (i.e., no approximation is required). This is made possible by restricting the processing task to the reconstruction of the shape of the anomaly and

neglecting the retrieval of the electromagnetic features. Since the LSM has been never applied to the imaging of magnetic targets from electric field data, a preliminary assessment of its reconstruction capabilities towards purely magnetic anomalies is given by means of numerical examples. [C805]

### "Effects of surface topography and wind on reflection horizons in ice sheets"

Radar horizons within the great ice sheets of Antarctica are distorted by greater snow deposition on windward than on leeward slopes. In West Antarctica, this effect can change horizon depth by tens of meters but still leave the horizons surface-conformable and continuous for hundreds of kilometers. When viewed on a scale of tens of kilometers, the additional effect of ice speed makes horizons appear falsely recumbent and suggests false historical changes in ice speed. In large regions of the high East Antarctica plateau, deposition occurs only on windward slopes to form prograding bedding sequences up to tens of kilometers long and hundreds of meters thick. Beneath the leeward slopes, long-term metamorphism transforms the bedded strata into unconformable and unstratified pseudolayers that grow with burial, merge with others, form concatenated layers more than 70 km long and over 100 m thick, and generally account for all major englacial horizons. For the largest sequences, the bed topography controls the surface topography and in large part, the way accumulation is distributed on the high plateaus. [C806]

### "An intelligent non-contact wireless monitoring system for vital signs and motion detection"

An intelligent non-contact wireless patient monitoring system is presented in this paper. The monitoring system is capable of measuring the vital signs (respiration rate and heart beat) and detecting patients' motion without physically contacting them by using a miniature Doppler radar sensor system. The system can provide all-round near-real-time 24/7 monitoring, which can be used in hospitals and homes to protect patients as a first line of defense system for wireless acute-care and wireless assisted-living. [C807]

### "Context system using pervasive Controller Area Network bus system to improve driving safety"

With more than one million people dying worldwide on the roads every year and lots of money in property losses, traffic safety remains an unsolved matter. The potentials of in-vehicle safety systems are currently investigated to improve this situation. Hence, embedded system which can collect some important context information and warn the driver in order to improve the safety of driving is needed. A Controller Area Network (CAN) bus with nodes of sensors or the node which is connected directly to the vehicle's CAN bus is very practical and powerful to collect driver's context information. This context information should not be just kept in the vehicles; it should be shared with vehicles in the same neighborhood or be sent to the information processing center. In order to have a wireless communication, communication technologies like ZigBee, GPRS are needed to be used. In this paper, we propose a context aware system for improving road safety and efficiency as well as driving comfort. The studied system is composed of the CAN bus and wireless communication system, a prototype of this system on the vehicle was also designed and tested in Citroen C4 car. A CAN bus was designed and realized by authors. Then, some context information from the vehicle existent CAN is collected and an experimental test is made. [C808]

### "GPRS-based fault monitoring for distribution grid"

The GPRS is a useful mean to solve the communication problem in the automatic system of power distribution network system. This paper designs a GPRS-based real-time system to monitor the on-off states of the switching station in the power distribution system. The system is consisting of a low-power controller of MSP430F149, the module of GR64 from WAVECOM company and detection circuits of on-off states. The IEC60870-5-101 protocol is used in the system. Therefore, it can conveniently communicate with other SCADA systems. It is reliable and stable running on site. [C809]

### "The restoration of road coats and related objects parameters based on method of computation diagnostics-Ground Penetrating Radar antennas dipole approximation"

Several approaches are considered which allow to increase the reliability of diagnostics of plane layered medium in Ground Penetrating Radar (GPR) applications. This increase is reached due to accurate account of parameters of transmit-receive antenna (via electrodynamic modeling) and radio frequency channel of GPR. [C810]

### "3D high resolution GPR survey to help the reconstruction of the archaeological stratigraphy of Lecce (Italy)"

3D high resolution Ground Penetrating Radar (GPR) survey was performed in the Crypt of the Duomo of Lecce

(South Italy), built in 1114. The GPR data revealed us a stratified subsoil in which there is a distribution, with the depth, of several "remains" referable to different epochs. Here we present and discuss the experimental evidences, comparing them with the historical-archaeological documentation. We think that they constitute a valid contribution to the knowledge of the ancient stratigraphy, as well as of the Roman history of Lecce, especially because of many suppositions have not yet found a confirmation. [C811]

#### **"Dielectric and magnetic anomaly imaging from GPR data"**

This paper deals with the reconstruction of buried targets exhibiting both dielectric and magnetic characteristics, starting from GPR data collected at the interface air/soil. The problem is tackled under a two-dimensional geometry by means of linear scalar inverse scattering and the performances of the approach will be outlined against experimental data. [C812]

#### **"How many points per scan?"**

Increasingly manufacturers are promoting equipment which claims to increase the no of sample points per scan to over 1000 points. For inexperienced GPR users, this appears to be an advantage. In reality this is misleading and giving a false promise of "improved" data. This paper demonstrates, on the basis of the Nyquist theorem that 256 sample points per radar scan is more than enough. [C813]

#### **"Detection of accelerated reinforcement corrosion in concrete by ground penetrating radar"**

This paper presents a new approach to evaluate corrosion of reinforcement in concrete by ground penetrating radar (GPR). Pulse GPRs were used to monitor the continuous corrosion process in concrete, in which the changes of amplitudes, travel times and short time fourier transform (STFT) spectrograms associated with the bar reflections were continuously measured. The yearly long corrosion process of reinforcement bar was rapidly accelerated within 10 days by impressing 2A direct current across two embedded reinforcement bars serving as anode and cathode. When corrosion started, it was found that the travel times, amplitudes and the frequency spectra from the bar reflection reached a maximum or minimum, but the trends of these parameters were then reversed when the crack became wide open. The results presented in this paper will pave the way for future corrosion characterization using GPR, both in laboratory and in field. [C814]

#### **"Use of Ground Penetrating Radar to map subsurface features at Lapa do Santo archaeological site (Brazil)"**

In this article we present some results of Ground Penetrating Radar (GPR) studies carried out at Lapa do Santo archaeological site. This cave is within Lagoa Santa karstic region, Minas Gerais State, Brazil. In the first field work, 44 GPR profiles were acquired with 100 MHz, 200 MHz, and 400 MHz shielded antennas focusing on three mains objectives: (i) to characterize stratigraphic layer; (ii) to identify geological and archaeological anomalies, and (iii) to identify potential areas aiming at assisting archaeologists in an excavation program. GPR results indicated anomalous hyperbolic reflections, and areas with high sub-horizontal reflection amplitude suggesting archaeological and geological potential targets, respectively. These results were encouraging, and then they were used to guide excavations at this site. Excavation of test units (meter by meter) allowed identifying an anthropogenic feature, e.g., a fire hearth structure, and natural features, such as speleothems and top of bedrock. Results also indicated the importance of GPR survey as a tool for orienting archaeological researches, increasing the probability of finding archaeological interest targets in an excavation program an area of environmental protection. [C815]

#### **"GPR applied to map Jabuticabeira-II coastal sambaqui archaeological site (Brazil)"**

In this work, some GPR results obtained in Jabuticabeira-II coastal sambaqui archaeological site, located in Jaguaruna region, Santa Catarina state, southern Brazil, are presented. Sambaqui is a word in Guarani (Native South American language) that means: Tamba-shells, and Qui-conic mound, or shell mound. GPR profiles present interesting anomalous reflectors most likely related to archaeological interest targets. GPR depth slices exhibit anomalies with high amplitude probably related to point reflectors. In order to give greater reliability for real result interpretations, 2D FDTD numerical modelling was accomplished, and it shows good agreement with real data obtained in the field. Then, real and synthetic results results as reference guide to archaeological excavation activities. Archaeologist from Universidade de Sao Paulo excavated Jabuticabeira-II site after GPR results analysis. Horizontal reflectors were related to sambaqui structure, and its bottom, characterized by rich archaeological layers as well as water table level. Anomaly typified by hyperbolic reflection pattern was associated with a concentration of carbonatic shells, from 3160 to 2850 cal yBP. GPR results were very important for archaeological research in development allowing adjusting excavation, and guarantee this research success. [C816]

### "Experimental investigation of different soil types for buried object imaging using impulse GPR"

Performance of electromagnetic sensors which are used to detect buried objects, is varied according to properties of soil. Most common sensor pair is EMI (Electromagnetic Induction) and GPR (Ground Penetrating Radar) for buried object detection systems. Besides the surface roughness and overlying vegetation, electrical conductivity ( $\sigma$ , (S/m)), electric permittivity ( $\epsilon$ , (F/m)), and magnetic susceptibility affects the detection performance of sensors. The electromagnetic properties of soil cause wave attenuation and change reflection coefficient of electromagnetic wave reflected from soil surface. For this reason, different soil types create various effects on sensor data, therefore performance of GPR and EMI sensors may decrease. Moreover, burial depth estimation can be performed if the soil properties are known exactly. This paper contains the effects of different soil types on impulse ground penetrating radar data, experimentally. [C817]

### "Simulation and application of GPR in Artificial Freezing Engineering"

In Artificial Freezing Engineering (AFE), the distribution of freezing soil and its defects are important to engineering safety. Based on relative permittivity measured by vector network analyzer, electromagnetic models of artificial freezing walls were made. Then Ground Penetrating Radar (GPR) exploration of AFE was simulated by Time Domain Finite Element Method (TD-FEM) coupled with freezing temperature calculation. GPR were also used in AFE exploration. The research results show that GPR exploration and numerical simulation are in good accordance with each other. [C818]

### "Design and numerical analysis of a new reconfigurable antenna for georadar applications"

We propose a new completely variable reconfigurable antenna for Ground Penetrating Radar (GPR) applications. In particular, here we present the design and the numerical analysis of the structure in total geometry morphing approach, with the aim of simulating the specific behavior of a reference bow-tie dipole. The development environment of the new device was the numerical tool HFSS (High Frequency Structure Simulator) by Ansoft which exploits the Finite Element Method (FEM). Finally, we extend the analysis of a single antenna by investigating the effect of a receiving one on the radiation properties of the transmitting antenna in dependence on the distance between them. [C819]

### "Instability analysis of Villa Arianna site in Castellammare di Stabia (Naples)"

The paper is on the use of GPR to detect features of instability affecting the structures of Villa Arianna archaeological complex. GPR data were acquired with a 250 MHz antenna on a cave excavated from an in situ deposit and inside the Villa, which lies on the top of a tuffaceous terrace. The study shows a direct correlation between the time shifts and amplitude spectra variations of the ground direct wave with the detachment surface location. [C820]

### "Experimental approach for determining the received pattern of a Rascan holographic radar antenna"

Because of the nature of image formation for holographic radar, the role and relevance of antenna radiation pattern are different than for impulse radar, and thus have not been studied. We determine theoretical Rascan radiation patterns for different dielectric media, and compare simulations to experimental data from an antenna scanned across a spherical metal target at various ranges/depths. Positions at which the received signal (phase difference between object and reference beams) are the same within a single scan, and across scans at different depths provide a 3-D approximation of the effective radiation pattern that closely agrees with the simulations. [C821]

### "Using ground penetrating radar to estimate active layer moisture conditions in the Arctic"

Polar regions, especially the Arctic, are expected to experience the largest changes in climate parameters during the coming decades, as well as increased variability. Large amounts of carbon currently stored in the arctic permafrost are expected to be released when a larger portion of the upper permafrost thaws. This will result in a deepening of the active layer, the region above the permafrost that freezes and thaws annually. Changes in this layer is thus important not only as an indicator of climate change, but also because they will alter the conditions for the vegetation and hence the ecosystem. A climate effects monitoring programme in the Zackenberg valley in the continuous permafrost zone of Northeast Greenland, has since 1995 monitored the thawing of the active layer using manual probes. Ground Penetrating Radar (GPR), a noninvasive technique that provides continuous data on the subsurface, has been widely utilized in geosciences applications and implementation of this technique in Zackenberg can greatly enhance the spatial and temporal resolution of active layer monitoring.

Hence, supplying additional knowledge of the changes in the active layer and the processes involved. This paper reports a preliminary analysis of data from a pilot project that focused on the interactions between the snow, soil and vegetation. In 2009, a GPR signal at 500 MHz was used to identify the active layer depth and to assess moisture conditions ( $\theta$ ) along a gradient of five different soil and vegetation types. The results suggest that differences in returning radar velocity can be used to estimate variations in moisture content in the active layer. [C822]

#### "The shrine of edward the confessor: A study in multi-frequency gpr investigation"

Following an earlier investigation into the 13th Century Cosmati mosaic in Westminster Abbey, Ground Penetrating Radar (GPR) investigations were commissioned in order to locate the site of a large royal tomb. Antennas of 400MHz and 4GHz frequency were used in the area of the High Altar steps and on the floor of the current Shrine Chapel. The investigation uncovered evidence of the target tomb, a number of other graves, some previously unknown, and at least one buried object. The paper briefly discusses the frequencies selected and illustrates how these have resulted in better understanding of the archaeological and historical evidence. [C823]

#### "Object dimension Vs antenna frequency"

The study deals with the performance of antenna frequency in detecting objects as a function of their dimensions. The results refer to actual data acquired with an IDS instrument, equipped with antenna frequency of 200, 600 and 2000 MHz, on an ancient wall reinforced with micro-piles, and on a concrete beam reinforced with iron bars. The micro-piles and iron bars are 0.13 m and 0.02 m in diameter respectively. The study shows that the dimensions of the objects in relation to the wavelength and the heterogeneity of the host environment, play an important role in making the interpretation of the GPR data easy in a civil engineering context. The results were validated with theoretical data. [C824]

#### "An ultra-wideband high-dynamic range GPR for detecting buried people after collapse of buildings"

An ultra wide band high dynamic range GPR radar has been tested for buried victims detection. After a building collapse, for example due to an earthquake, the priority of search and rescue teams is to localize people trapped under debris. Several tools are available to help the detection of buried humans, such as micro-cameras, high sensitivity microphones, and so on. Many of these tools present some limitations such as low penetration depth and high susceptibility to external noises. In this paper the authors test the use of an Enhanced Ultra Wide Band (UWB), Continuous Wave Stepped Frequency (CW-SF) Ground penetrating radar as rescue equipment. The radar has been experimented both in controlled environment, and in a real test site, at the Fire-fighters Station of Pisa, Italy. [C825]

#### "Half-space estimation by time gating based strategy"

In this work we deal with an estimation procedure of the Fresnel reflection coefficients for an half-space starting from GPR measurements collected under a reflection mode single view/multistatic configuration. After, the estimation of the Fresnel coefficient, the related electromagnetic parameters of the soil can be evaluated via simple algebraic relations. The problem is faced by exploiting the plane waves spectrum representation. Unfortunately when an antenna is close to the air/soil interface, interactions arise so that the actual antenna plane-wave spectrum is dependent on the searched for soil properties and consequently not known. To overcome such drawbacks, a preliminary step is introduced in the overall estimation procedure, which allows us to erase the antenna/soil interface interactions thanks to a time gating method. Numerical simulations with synthetic data are presented with the aim of assessing the effectiveness of the procedure. [C826]

#### "ALIS: GPR for humanitarian demining and its evaluation in Cambodia"

The authors developed dual sensor ALIS, which is equipped with GPR and metal detector. The image reconstruction algorithm is useful for clutter reduction and buried landmine image can be obtained. The system has been evaluated by test in minefields in Cambodia and could detect more than 30 mines. We are planning to continue this evaluation tests, and plan real deployments. [C827]

#### "Design of a pseudorandom reference codes for reduced sidelobes and spectrally clean out-of-band emissions using an extended optimal filtering approach"

In this paper we propose an extended version of the classical optimal filtering techniques to be used with binary noise codes, called m-sequences, and complementary codes. We introduce here extended optimal filters to achieve lower ACF sidelobe levels and spectrally clean waveforms with out-of-band suppression (OBS) levels

directly proportional to the filter length. [C828]

### "Multi-path EM scattering calculation for ships over time-varying sea surface"

In this paper, in order to simulate the time-varying scattering characteristics of ships over sea surface, both the reflection coefficient model for time-evolving sea surfaces and the ship motion dynamics are established and introduced into the multi-path EM scattering calculation. By combining the high-frequency asymptotic techniques for radar targets with the variations in the ship aspects and reflection coefficients of time-evolving sea surfaces, a time-varying radar signature model for ships over sea surface is developed. [C829]

### "A comprehensive system-level simulation paradigm for UWB systems"

A comprehensive simulation paradigm for UWB systems has been outlined. Its use in accurately simulating the performance of actual experimental through wall imaging radar and indoor positioning systems has been presented. The accuracy of the simulation framework has been validated experimentally using our UWB imaging radar and indoor positioning prototypes. This general framework provides a robust solution for rapid prototyping and optimizing of mixed signal UWB systems and requires accurate channel modeling. [C830]

### "Characterization of ultra-wideband wave propagation inside human body"

Ultra-wideband (UWB) has potential applications in variety of medical areas such as implant wireless sensors, microwave hyperthermia, imaging and radar. The wave propagation inside human body must be known for an efficient system design for the different applications. In this paper, UWB signal propagation inside human body is characterized for line-of-sight (LOS) scenario inside chest of a human model for the frequency range of 100-1000 MHz. The radiograph of UWB power and the spectrum of the penetrated wave into body are analyzed. The power delay profile (PDP) and the root-mean-square (RMS) delay spread of the in-body channels are obtained for the potential applications on wireless medical implant communications. [C831]

### "A practical wireless charging system based on ultra-wideband retro-reflective beamforming"

Numerous portable electronic devices (such as laptops, cell phones, digital cameras, and electric shavers) rely on rechargeable batteries and must be routinely charged by the line power. A wireless charging technique capable of delivering electromagnetic energy to these portable devices would make them tether free and "truly portable." Wireless charging is especially valuable for devices with which wired connections are intractable, e.g., unattended radio frequency identification tags and implanted sensors. In recent years, enormous research efforts have been devoted to wireless charging. In 1990s, a case study is reported to construct a point-to-point wireless electricity transmission to a small isolated village called Grand-Bassin in France. In 2007, an inductive resonance coupling scheme, which makes use of near-field coupling between two magnetic resonators, was demonstrated able to power a 60-Watt light bulb over two meters by a team of Massachusetts Institute of Technology. In addition, several companies (PowerCast, WildCharge, WiPower, etc.) have developed products targeting specific applications. Nevertheless, several technical challenges remain to be resolved in order to accomplish practical wireless charging. Specifically, (i) to achieve efficient charging over long distance, severe power loss due to electromagnetic wave propagation must be remedied; (ii) humans' exposure to electromagnetic radiation should always be kept below safety level while sufficient power is delivered to devices; and (iii) some existing systems are unsuitable for ubiquitous deployment due to high cost, large size, and/or heavy weight. In this paper, an innovative wireless charging system based on ultrawideband retro-reflective beamforming is proposed to address the above challenges. The proposed charger consists of multiple antenna elements distributed in space. According to pilot signals (which are short impulses) they receive from the target device, the antenna elements jointly-- construct a focused electromagnetic beam onto the device (i.e., beamforming). Beamforming enables spatially focused/dedicated power delivery to devices while keeping power level in all the other locations minimal. As a result, the proposed system attains high charging efficiency and leads to little hazard/interference to other objects. Performance of the proposed wireless charging system is demonstrated by some simulation results obtained by a full-wave Maxwell's equations solver. [C832]

### "Design of a tapered slot array antenna for UWB through-wall RADAR"

Ultra-wideband (UWB) RADAR based technologies have been gaining popularity recently for through-wall detection and surveillance applications. In this paper, the design and implementation of antenna for such applications is presented. An exponentially tapered slot (Vivaldi) antenna[1] is adopted. The tapered slot element being a travelling wave structure has inherently wide bandwidth with added advantages of high gain and low weight. Arrays based on Vivaldi elements have been extensively studied[2,3]. The current design is based on a segmented approach[2] with design of antenna element or array configuration based on radiation pattern requirements, followed by design of balun feed for individual elements and finally the design of feed network for

broadside radiation. In each step, the objective of good impedance match and hence low insertion loss leads to the desired bandwidth performance in the final design. [C833]

#### "Evaluation and optimization of the specific absorption rate for multi-antenna systems"

A decomposition and superposition technique is developed for the SAR analysis of a multiple antenna system. Upper and lower bounds for the total SAR can be calculated if the vector electric field from each antenna is available, while a most conservative SAR upper bound can be calculated if only SAR data from each antenna is available. A method for increasing antenna reception while decreasing peak spatial SAR was also shown. This technique combined with a beam-forming technique can be used to maximize the overall system performance and minimize the peak spatial specific absorption rate for multi-antenna wireless systems. [C834]

#### "A low cost wafer based W-band phased array"

A method to dramatically reduce the cost of W band phased antenna array system is proposed by using wafer based package concept and sub-harmonic mixing. Such phased array systems are well suited as front-ends of W-band radar and wireless communication systems and shall find many applications in defense, security and commercial sectors. [C835]

#### "Simulation of the mutual couplings among multiple antennas on large platform using multi-region multi-solver domain decomposition"

Modern aircrafts are usually equipped with multiple antennas serving for different usages, including radar, communication, etc. Many of them have highly contrasting power levels and overlapping frequency bands. The mutual couplings among antennas may cause severe electromagnetic compatibility (EMC) problem, which prevents the multiple antennas from working simultaneously. This paper proposes a multi-region multi-solver domain decomposition method (MS-DDM) to simulate the EMC problem on electrically large platform. It has been successfully applied to analyze the mutual coupling between complex antennas mounted on a real F-16 aircraft at 2GHz frequency. [C836]

#### "Analysis of transmission characteristics of a circular pipe with two open ends"

In this paper, we extend the modal formulation to characterize the transmission characteristics of a circular pipe with two open ends. Our interest in this problem stems from the possibility of using an open pipe as a transmission medium to propagate waves through an opaque wall at radar frequencies. We begin this study by developing an approximate solution for the transmitted field through a circular pipe with two open ends due to an incident plane wave. Transmission data are then collected in the laboratory using a circular metal pipe and the results are compared to simulation. It is shown that our formulation agrees well with the measurement data and therefore can be used as a good approximation to the transmission through a circular pipe with two open ends. [C837]

#### "A resistive dipole antenna excited by an impulse generator for ultra-wideband radar applications"

For UWB radar applications, a small RD and an impulse generator have been designed and fabricated. The performance of the combined RD and the impulse generator has been proved through the radar scan experiment. The results show that the combined RD and the impulse generator functions well as a UWB radar components. [C838]

#### "Investigations on a triple mode waveguide horn capable of providing scanned radiation patterns"

Feedhorn reflector antenna assemblies have been widely used for both satellite communications and Radar applications [1]. A dual mode feedhorn is presented in [2-3] where  $TE_n$  and  $TM_{0i}$  modes are excited to generate multiple phase centers when employed as a feed source for a reflector antenna. These papers [2-3] presented a technique of beam scanning in the  $\varphi = 90^\circ$  cut plane only, thereby generation of multiple phase centers in the  $\varphi = 90^\circ$  cut plane by control of the amplitude and phase of the modes. In [4] authors presented a tri-mode feedhorn design that employed  $TE_n$ ,  $TM_n$ , and  $TE_{2i}$  modes, but the effort was to reduce the cross-polarization in the far-field pattern of a linearly polarized offset parabolic reflector antenna. In this paper, we present investigation results of a triple mode ( $TE_\pi$ ,  $TM_\pi$ , and  $TE_{21}$ ) circular waveguide horn antenna with corrugated chokes which is capable of providing radiation pattern beam scanning in the range of  $\theta = \pm 24^\circ$  in both  $\varphi = 0^\circ$  and  $90^\circ$  cut planes similar to the case of a conventional phased array antenna. This is achieved by exciting all the three modes simultaneously in proper amplitude and phase. Though not discussed here, it is capable of providing multiple phase centers in both the  $\varphi = 0^\circ$  and  $90^\circ$  cut planes. The simulation design of the horn was performed using finite element method (FEM) based full wave analysis software Ansoft HFSS. The geometry

and design of the horn is discussed in section II. Simulation results of the horn are discussed in section III. Finally, section IV presents conclusion and future study. [C839]

#### "Application of a fast equivalent currents based algorithm for scattering center visualization of vehicles"

For the development of new radar sensor concepts in the automotive market comprehensive and reliable system simulation capabilities are highly desired. Since the radar channel includes both, desired and undesired contributions from the sensors environment, deterministic channel and wave propagation models are a crucial part of the whole simulation chain. Unfortunately, for some applications even asymptotic ray-based models exceed the available computational resources and further simplifications are required. Instead of brute-force ray tracing with a detailed geometrical description of the scene, one approach is based on a precomputed scattering center representation of complex objects. In this case, inverse synthetic aperture radar (ISAR) is a promising technique to estimate the required number and positions of the scattering centers. The imaging process should be fast enough to enable an investigation of a large number of bistatic configurations. In the 2D case, for range and cross-range resolution, classical Fourier processing requires twodimensional scattering data in frequency and aspect domain, which can be quite costly. Therefore, an idea presented is adapted to the existing scattering simulation code and applied to the scattering center visualization of vehicles. [C840]

#### "Synthesis of arbitrary sidelobes sum and difference patterns with common excitation weights"

The synthesis of sum and difference patterns is a canonical problem widely dealt with by researchers working on antenna array synthesis. As a matter of fact, they are used as transmitting/receiving devices for search-and-track systems (e.g., monopulse radars). Recently, the synthesis of low-sidelobe sum and difference patterns with a common aperture has been carried out by perturbing the roots of the Bayliss distribution to match as much as possible a given Taylor distribution. The discrete linear arrays have been successively obtained by sampling the resulting continuous apertures. In this work, the same array synthesis problem dealt with is addressed, and an innovative approach based on a deterministic optimization strategy is presented wherein the problem is formulated as the minimization of a linear function over a convex set. Taking advantage from the approaches for the optimal synthesis of sum and difference patterns respectively, the proposed method allows one to synthesize patterns with arbitrary sidelobes. [C841]

#### "Microstrip patch antenna array for a scalable X-band radar system"

A 32-element X-band microstrip electronic scanning array (ESA) has been developed to serve as the radiating element in a preliminary system radar testbed. An array of microstrip aperture coupled patch antennas are fed equal power through a Wilkinson power divider network and the direction of radiation is controlled by surface mount phase shifters integrated into the RF control board. While bulky physical array steering mounts greatly impact the system weight and visual signature of traditional radar systems, the electronic beam steering mechanism employed in this system minimizes each of these attributes. The details of the antenna array element in this radar ESA design will be examined in the subsequent sections. [C842]

#### "Time domain radiating model for GPR antenna"

In this paper, we suggested a method to substitute any antenna by a model based on the use of dipolar sources in the FDTD method. This approach allows to model antennas with their supports or environnement context. Thus, it makes possible to model complicated structures and oriented in any direction of space. The effectiveness of this approach is validated with Feko simulation of the original antenna. [C843]

#### "Transmit beamforming for colocated MIMO radar"

MIMO radar has seen growing interest in recent years owing to the many advantages that it offers over conventional radar, including spatial diversity and enhanced target direction resolution. Unlike standard phased array (SIMO) radar that transmits scaled versions of a single waveform from its many transmit antennas, a MIMO radar can transmit distinct waveforms from each antenna. Such an increase in the number of degrees of freedom for waveform design can potentially be used to obtain beamforming performance similar to SIMO radars with a far fewer total number of transmit and receive antennas. In recent literature, the problem of finding a signal correlation matrix that achieves a desired transmit beam pattern has been addressed, but a closed form solution for this problem has been lacking. In this paper, we first formulate a new spatial ambiguity function that simultaneously specifies the transmit beam pattern as well as the cross-correlation beam pattern. We then provide a closed form solution for the signal correlation matrix whose spatial ambiguity function is closest to a desired function (in the mean square sense), when using colocated uniform linear arrays. Further, we show how a suitable tapering window could be applied on the signal correlation matrix to tradeoff sidelobe levels for

mainlobe width in the spatial ambiguity function. [C844]

#### "MOSAICS: Multiplexed optimal signal acquisition involving compressed sensing"

It is possible to sample signals at sub-Nyquist rate and still be able to reconstruct them with reasonable accuracy provided they exhibit local Fourier sparsity. Underdetermined systems of equations, which arise out of undersampling, have been solved to yield sparse solutions using compressed sensing algorithms. In this paper, we propose a framework for real time sampling of multiple analog channels with a single A/D converter achieving higher effective sampling rate. Signal reconstruction from noisy measurements on two different synthetic signals has been presented. A scheme of implementing the algorithm in hardware has also been suggested. [C845]

#### "Analysis of the detection modes of a human presence detection millimeter-wave radiometer"

Detection of non-moving humans is important for physical security, search-and-rescue, homeland protection, and military applications, although it has proven difficult to achieve because traditional techniques have significant drawbacks. For instance, IR sensors do not detect well in warm daytime environments and radars cannot easily discriminate stationary humans. The authors have recently presented a solution by applying millimeter-wave radiometry to the detection of stationary humans in cluttered outdoor environments. MMW radiometers operate in both day and night environments and are affected only by moderate to heavy rain. Fog, smoke, or dust, which render IR sensors inoperable, are also transparent to MMW sensors. The radiometric detection system was designed to operate from a moving platform, making image recognition prohibitive due to the high computational expense of image processing in real-time with a constantly changing background. The presence-detection radiometer operates on onedimensional sensor signals, resulting in lower computation time. The system uses four detection modes: two Ka-band total power radiometers (indicated by tp1 and tp2), one Ka-band correlation radiometer (cr), and one W-band total power radiometer (tpw). The authors' previous work has demonstrated the feasibility of the detection method and introduced detection algorithms, and a future publication will present the real-time performance characteristics of the method. In this paper an analysis of the detection capabilities of the sensor system is presented by selectively removing sensor modes from the detection algorithms. In this way the dependence of the individual modes on the overall system performance is determined. The performance is analyzed using the receiver operating characteristic. [C846]

#### "ADS interleaved arrays with reconfigurable polarization"

Polarization-reconfigurable arrays play a fundamental role in radar systems in order to enhance their detection probability and cancel clutters, chaffs, and jammers. In order to reach polarization flexibility, the integration of actively controlled elements in standard array configurations is often employed, but the overall system complexity and costs significantly increase. To overcome such limitations, the use of two shared aperture arrays with independent polarizations was proposed in by exploiting an interleaving scheme based on Difference-Sets (DSs). By combining the field generated by each sub-array, arbitrary polarizations, low sidelobes, large steering angles, and narrow beamwidths can be reached with a limited complexity of the underlying feeding network. Despite its theoretical and practical advantages, only few planar array geometries can be synthesized because of the limited number of available DS sequences. [C847]

#### "Feasibility study for IED detection using forward-looking ground penetrating radar integrated with target features classification"

In this paper, we examined the natural resonance frequency and polarization features of UXO-Like IED target in forward-looking GPR configuration. Based on the simulation results, we confirm that these feature not only exist but also measurable in the case of FLGPR. It is therefore, strongly suggested that these features be included in the target classification algorithms as they are expected to improve detection, increase stand off distance and minimize false alarm rate. [C848]

#### "Quantification of the impact of the antenna non-idealities in UWB transmission systems"

In this paper the quantification of the impact of the pulse distortion of antennas on the UWB transmission is presented. As a criterion for the evaluation the fidelity is derived. For verification the system performance of a line of sight transmission, i.e. the bit error rate, for a bow-tie antenna is evaluated, based on measurements. It is shown that the fidelity significantly influences the BER, excluding interference from noise or other sources. The result is that for UWB impulse operations in communications, but also in Radar applications, besides the signal to noise ratio also the fidelity of the antennas has to be taken into account. [C849]

#### "Impulse response of Vivaldi antenna using cubic-spline and exponential taper profiles for compact

### **ground penetrating radar applications"**

The measured impulse responses of Vivaldi tapered slot antennas employing conventional exponential and cubic-spline taper profiles are presented and compared. The method used to design the tapers is based on a Chebyshev impedance transformer given in which minimizes reflection. A brief presentation is given for this design method and the profile of the tapers. Then, the experimental results and analysis of impulse response of antennas are provided. Finally, peak values of the impulse responses of the antennas are compared to the theoretical maximum achievable values and are shown to be quite close to this fundamental limit. [C850]

### **"DOA estimation of correlated sources using SMT"**

This paper uses a recently developed technique that relies on the Sparse Matrix Transform (SMT) to estimate the covariance matrix of  $D$  signals received by  $M$ -elements linear antenna array, each signal is of length  $N$  (the number of snapshots is  $N$  where  $N < M$ ). SMT based covariance estimation is particularly suited for singular covariance matrices and those with small eigenvalues. Direction of arrival (DOA) estimation using the MUSIC algorithm relies on estimating the eigenvectors associated with the noise eigenvalues which are usually minimal. Also, when the sources impinging on an array are correlated, the covariance matrix is singular, and the performance of the MUSIC algorithm degrades significantly depending on the degree of correlation among sources. This makes SMT particularly suited for DOA estimation using MUSIC for partially or fully correlated sources, and especially scenarios where it is not practical to take a large number of snapshots (such as radar applications). This paper employs SMT in the MUSIC algorithm using real radar backscatter data as the sources. Limitations and benefits of SMT based DOA estimation are discussed. [C851]

### **"Design and analysis of a 5.88GHz microstrip phased array antenna for intelligent transport systems"**

Detection of blind spot area of an intelligent mobile vehicle is presented in this paper. In order to scan the concerning area, a phased array radar is designed. The approach is of two fold. Firstly, microstrip phased array antenna with progressive phased shifter is designed and subsequently, it is optimised for improvement of performance through parametric studies and array distribution using Tchebyscheff polynomial. [C852]

### **"An amplifying reconfigurable reflectarray element"**

Reflectarray antennas are strong candidates for addressing some of the challenges faced in space communication systems, RADAR and point-to-point terrestrial links. The long distances involved demand the use of high gain antennas and furthermore these applications can benefit from adaptable radiation patterns. The large size of reflectarray antennas ensures their capability to synthesize highly directive beams. To add beam reconfigurability to reflectarray antennas, the phase shifting techniques utilized in phased array antennas can be applied, since a reflectarray can be considered as an array of reflecting elements. Electronically-controlled reflectarray elements utilize different technologies such as varactor diodes, MEMS switches and liquid crystal materials to dynamically change the phase of the scattered wave from each element. [C853]

### **"On the influence of a glass slide on the SAR distribution in Petri dishes for in vitro exposure to 2.45 GHz EM fields"**

In this paper, a numerical dosimetric analysis has been carried out through CST Microwave Studio® 2009. The homogeneity of the SAR distribution and the coupling of EM fields within the liquid in the presence of a glass slide as support for living cells, has been investigated as a function of the incident field polarization. [C854]

### **"A novel broadband Fabry-Perot resonator antenna with gradient index metamaterial superstrate"**

In this paper, a novel broadband high gain Fabry-Perot resonator antenna is proposed. This antenna is composed of a gradient index metamaterial superstrate and a U shape slot radiator backed with PEC ground plate. A single-layer FSS with the taper-sized square rings pattern is distributed on one side of planar superstrate to realize the gradient index function, which is designed to transform the spherical wave-front excited by primary source into the planar wave-front. It is demonstrated that by adding such gradient index metamaterial superstrate, the fractional 3dB gain bandwidth of this antenna can be improved to 15.4%, as compared to that of single-layer FSS with the uniform-sized square rings pattern. These results show the potential feasibility of such kind of antenna in the broadband and high directivity applications, such as the radar and communication systems. [C855]

### **"Conformal array antenna with the aspirator for the microwave mammography"**

Recently, the microwave imaging techniques attract attentions as a screening method of early breast cancer detection that takes place of an X-ray mammography. There are two categories of UWB radar and microwave tomography. A lot of basic experiments using the phantom have been reported. For such experiments, antenna array and breast are soaked in the coupling liquid in order to maximize the amount of microwave energy coupled into the breast. In addition, we must know 3D surface of the breast to remove artifact reflected by skin using averaging technique in UWB radar or to solve illposed problem in microwave tomography. In this paper, we propose a conformal array antenna for microwave mammography. When we adopt this antenna, it is not necessary to soak the breast in coupling liquid and to know 3D surface of the breast. Several antenna elements are embedded in inside of hemisphere made by silicon resin. A valve is provided on the top of the hemisphere and is connected with the aspirator. Putting the hemisphere on the breast and pulling out air by the aspirator, we made skin surface contact with inside of the hemisphere. Antenna element is designed so as to match under the condition that breast contacts with the element. Since breast surface is formed with inside of hemisphere, it is not required to measure 3D surface of the breast. [C856]

#### "Ultra wideband hemispherical microwave imaging system"

This paper has reported an automated high resolution hemispherical imaging system using ultra wideband microwave signals. At present, the system operates in the monostatic radar mode. To achieve a hemispherical scan, the imaged object is placed on the turntable (rotational axis) for a 360° scan while the elements of the array antenna are fixed and suitably spaced in vertical and azimuth directions. The operation of this system has been illustrated in an example of a simple breast phantom. [C857]

#### "Advances in waveguide-fed slot arrays"

Waveguide-fed slot arrays are employed in numerous radar, remote sensing, and communication applications in ground and space systems. Professor Elliott's significant contributions paved the way for the eventual maturity of the slot array antenna technology to the point that it is possible to design such systems in one pass without the need for any experimental data. The author worked in a research group headed by Prof. Elliott and centered at Hughes Aircraft Company, Canoga Park, CA in the early eighties. Later the author collaborated with Elliott in the study of slot arrays for a decade with funding from the University of California and the Hughes Corporate office. Subsequent work was funded by many sponsors. This paper reviews the advances made in the field of slot arrays by the author in collaboration with colleagues and students. [C858]

#### "An implementation of the impedance-boundary CFIE using linear-linear basis functions and MLFMA"

The results show that first-order LL linear basis functions may be successfully used to discretize the impedance boundary CFIE using an approach derived from that developed by Collino et al. The LL expansion yields lower errors in the calculated bistatic radar cross-section than that given by zero-order RWG basis functions with the same surface discretization mesh in all cases examined. However, LL basis functions require double the number of unknowns with the same mesh, and therefore a higher computation time. [C859]

#### "A novel directivity/beam reconfigurable M-EBG antenna"

Directivity/Beam control antennas are an interesting solution for wireless communication and radar application. To achieve a reconfigurable radiation pattern, active printed arrays are well suited thanks to an easy interconnection between printed technology and active devices. But a low performance is often obtained because of microstripline losses and coupling between elements. Moreover, in such frequency range, phase shifters and amplifiers are scarce and expensive. As an alternative to these conventional beam switching technologies, reconfigurable Electromagnetic Band-Gap (EBG) antennas can be used. [C860]

#### "Parallel FETI-EM Domain Decomposition Methods optimized for antenna arrays and metamaterials periodic structures"

Domain Decomposition Methods have demonstrated efficiency and accuracy during the resolution of Maxwell equations in the frequency domain for both RCS applications and antenna structures interactions. In the domain of finite element methods, and for the resolution of acoustic Helmholtz equations, efficient sub-domain connecting techniques have been applied and called Dual-Primal Finite Element Tearing and Interconnecting. These techniques are known under the acronym FETI-DP and have been adapted to electromagnetic (FETI-DPEM) for the calculation of antenna arrays and metamaterial periodic structures. In this paper we describe the implementation of an algebraic parallel FETI solver developed at ONERA for both acoustic and electromagnetic applications. It has been called as a library in the FEM module of the FACTOPO tool developed for both antenna

and RCS applications. [C861]

### "Optimizing narrow-wall slotted waveguide arrays using HOBIES"

The narrow-wall slotted waveguide array is widely used in many radar applications and is complicated to analyze. Previous works have been reported on how to analyze the structure. However, it is the first time that the optimization results of this waveguide array antenna are presented in this paper. Two optimization examples are given and results show that the radiation patterns are improved after optimization. [C862]

### "FDTD electromagnetic-acoustic model: A 2-D numerical coding framework"

In this work, we present a model of the electromagnetic and acoustic wave propagation using the Finite-Difference Time-Domain (FDTD) (2,2) update scheme. The model can be used to validate various algorithms used in previous numerical studies of microwave radar imaging, microwave tomography, and microwave-induced thermoacoustic imaging. Our key contribution lies in the numerical coding framework, which incorporates the simulations of the two physical processes. The advanced efficiency and organization of the computational approach, in turn, will help the development of flexible solvers. [C863]

### "Design on elliptical lens monopulse antenna"

This paper demonstrated a novel kind of two-dimensional elliptical lens antenna for monopulse applications. Simulations show that the lens antenna exhibits a very clean and symmetrical pattern on both the sum and different ports. A very deep null is achieved in the difference pattern because of the circuit symmetry. [C864]

### "Beamforming through a circular pipe with two open ends"

In this paper, beamforming through a circular pipe with two open ends has been demonstrated using the least squares approach. Through simulation it was shown that using three sources it is possible to steer the main beam of the radiation at the other end of the pipe. The simulation results were then confirmed through measurement results. This one-way beamforming concept can be extended in a straightforward way to two-way detection of a target. Thus it should be feasible to detect the bearing to a target when using a pipe as a propagation medium for through-wall radar. [C865]

### "Classification of human activities on UWB radar using a support vector machine"

In this paper, we classify seven different human activities measured by a ultra wideband (UWB) radar using a Support Vector Machine (SVM). The classification is done using the time variation of a signature of a return from a human subject. This time varying signature is unique to a particular motion because human's returns vary based on the change in the orientation of their torso and limbs. We exploit this time variation of a human's radar signature in order to classify the human activity recorded by the radar. The signature is captured by the Principle Component Analysis (PCA). The Support Vector Machine (SVM) is proposed as a classifier. The training process and the resulting classification accuracy are reported. [C866]

### "Computation of physical optics integral by Levin's algorithm on NURBS"

Non-Uniform Rational B-Splines (NURBS) are very powerful modeling tools for geometric design due to several reasons including fast and numerically stable algorithms and unified mathematical basis for representing complex objects [1]. Although target modeling is easy with NURBS, applying some numerical tools directly on NURBS is not so straightforward. Since the surface point function and derivative computation is simpler for rational Bezier surfaces (RBS), NURBS surfaces are converted to RBS by Cox-de Boor Algorithm for numerical implementations [2]. Therefore, solving a problem for RBS corresponds to solving it for NURBS surfaces. Indeed, in this paper, RBS are used for surface modeling and radar cross section (RCS) computations. The RCS computations are performed by employing Physical Optics (PO) approximation which is accurate at high frequency regions [3]. Although PO is a more efficient technique for scattering problems at high frequencies, when compared to full-wave techniques, it may be intractable due to rapid oscillations of the PO integral. In the literature, there are several methods to handle the oscillatory integrals including the stationary phase method, which is already applied to PO computations on NURBS surfaces [2, 4]. Another method proposed for highly oscillatory integrals is the Levin's method which was previously applied to PO problems, particularly RCS computation of targets modeled by quadrilaterals [5]. In this paper, the same approach is utilized on RBS. [C867]

### "Edge wall slotted waveguide antenna with low cross polarization"

A travelling wave SWGA with low cross polarization level is designed using an easy to manufacture, non-inclined

slot geometry. The modeling of the slots is done with infinite array unit cell approach. Simulation results showed promising performance in terms of side lobe and cross polarization levels. This antenna will be produced and the measurements results compared with the simulations will be presented at the conference. [C868]

### "Comparison between genetic programming and Neural Network in classification of buried unexploded ordnance (UXO) targets"

In this paper, we present the results of our next step effort in comparison of classification performances between the NN and the GP techniques based on the simulated scattering patterns of UXO-like object and non-UXO objects. For this comparative study, 2 dimensional scattering images from one UXO target and four non-UXO objects were generated by numerical simulation tool (FEKO). For non-UXO objects, the most challenging targets to discriminate from UXO, since all these objects produce resonance signal as UXO-like targets do [6], were selected. Classification performances of both techniques (NN vs. GP) in different level of noise and in the case of presence of untrained data were examined and the results and observations are discussed. [C869]

### "Performance evaluation of subsurface target recognition based on ultrawideband short-pulse excitation"

Automated Target Recognition (ATR) based on Natural Resonance Frequencies (NRFs) embedded in Ultra Wideband (UWB) transient electromagnetic signatures have been extensively studied. To our knowledge, most studies concerning ATR using the E-Pulse technique are about radar targets in free space. Recent attempts have been made to apply the E-Pulse technique for subsurface target detection. In this paper, performance evaluation of a recently proposed subsurface target recognition technique based on the E-Pulse and Baum's transform under different signal-to-noise ratios (SNR) is considered. Examples of target recognition of three different perfect electric conductor (PEC) targets sited below a frequency-dependent lossy halfspace are presented. [C870]

### "Unidirectional low profile ultra-wideband antenna for radar and communication applications"

One of the important elements in all UWB radar and communication systems are the antenna elements, which are required to be compact, light weight and to have good radiation characteristics. The most commonly used directional UWB antennas are Vivaldi antennas and ridged horn antennas. Vivaldi antennas are typically required to be a few wavelengths long to have good matching a reasonable gain which limits their use in low frequency UWB radars such as GPRs and see-through-all radars where the low operating frequency is required to penetrate moist soil or lossy walls. Ridged horns offer significantly higher gain at a smaller size but they are relatively expensive and bulky. To overcome these limitations, we present a new compact lightweight UWB antenna that has comparable gain to ridged horns but is almost 1/5th the size. [C871]

### "Mechanical scanning with a dual-layer pillbox antenna for millimeter-wave applications"

A low-profile, high performance, multi-beam, low-cost multi-layer pillbox antenna has been recently proposed by the authors [1] [2], as a possible solution for high demanding millimeter-wave applications (surveillance systems, automotive radars, telecommunication applications, etc.). In these works a passive electronic system was used for steering the antenna main beam. However, thanks to the low profile, low weight and compactness of the structure, a mechanical scanning can be an attractive solution for those applications where a continuous steering of the main beam is required for tracking moving objects or connection maintenance (satellite based telecommunication applications). This solution would be a cheaper alternative compared to expensive phased approaches or hybrid combinations of mechanical and electronic scanning. The antennas structure is shown in Fig.1. It is based on a SIW (Substrate Integrated Waveguide, [3] [4]), double layer pill-box structure where the feeding and radiating parts are located in two different substrates connected by an integrated symmetric parabolic reflector and several coupling slots (quasi-optical system). In the following the three main parts of the system (quasi-optical system, input part and radiating part) are introduced together with some numerical results at  $f_0=24.15\text{GHz}$ . [C872]

### "Terahertz reflector antenna system for a scanned and multiplexed FMCW radar"

In this contribution, the paper presents the antenna design and implementation of a mechanically scanned and multiplexed terahertz imaging radar. By using of a quasi-optical waveguide, we can multiplex our signal into two different beams and double the time acquisition of the image without increasing the number of transceivers. Only few additional optical components are needed. [C873]

### "Active phase array SAR antennas"

The paper focuses on similarities and differences between RADARSAT-2 and RADARSAT Constellation SAR antennas radio frequency (RF) architectures, both in terms of the radiating panel designs and feed networks designs. An overview of the antenna RF architecture, functional requirements and design trade-offs that led to the concept is presented. Design of key antenna units is also described. [C874]

#### "Pressure measurement from the RADAR interrogation of passive sensors"

The pressure applied to passive sensors modifies their radar echo magnitude. From the FMCW radar interrogation of such passive sensors the pressure can then be remotely measured. The first experimental results presented here demonstrate the feasibility of the wireless measurement of physical quantities from radar echo measurement of passive sensors. [C875]

#### "Planar Yagi-Uda antenna array for W-band automotive radar applications"

Complementary to an already proposed antenna concept for millimeter-wave automotive radar sensors the design of a planar Yagi-Uda antenna array has been presented. The radar antenna concept consists of end-fire antennas (or arrays) and a cylindrical parabolic reflector that can directly be integrated into the sensor's metal housing. The proposed assembly reduces the antenna substrate area while maintaining a small installation depth. The achieved gain of 16 dBi can be increased up to 22 dBi for the 4-element array by an improved power-divider network and even higher if more antenna elements are used. [C876]

#### "Enhanced detection of planar retro-reflective arrays using polarization properties"

This paper presents a design concept to aid in the detection and tracking of objects in a cluttered environment at 26 GHz. Target tracking can generally be accomplished with the use of retro-reflectors which are able to return an incident signal back in the same direction with a radar cross section (RCS) that is independent of angle of arrival for a large range of incidence angles. [C877]

#### "High-performance compact HF antenna for radar and communication applications"

Over the years there have been many systems developed in the area of HF Surface Wave Radars (HFSWR) and Over the Horizon Radars (OTHR). The increased emphasis on applications such as maritime surveillance for national security and enforcement of Economic Exclusion Zones (EEZs) continues to drive the need for efficient yet mobile and low cost HFSWR and OTHR systems. For the HFSWR systems, propagation characteristics are based on vertically polarized, high frequency (3 to 30 MHz) electromagnetic waves and this provides distinct advantages when used in medium and long range coastal surveillance type operations. The high conductivity of seawater results in relatively low attenuation of vertically polarized radio waves thus allowing for effective long range HFSWR systems. OTHR systems, on the other hand, achieve long range propagation by utilizing the refractive properties of the ionosphere. Large changes in ionospheric layers between day and night cycles cause corresponding changes in the effective radar ranges. OTHR systems cover much longer ranges than HFSWR systems while HFSWR receivers have to handle the increased noise and signal clutter during periods of increased ionospheric activity. [C878]

#### "Full polarimetric calibration of a GB-SAR system with a thin wire"

In this paper, we present the full polarimetric calibration of GB-SAR system with a thin wire whose orientation angle is 0 degree, 45 degree and 90 degree. At first we measured 0 degree, 45 degree and 90 degree inclined thin wire in order to derive calibration parameters. We also measured 30 degree and 60 degree wire in order to confirm this calibration method works well or not by using the estimated parameters. Calibration results of 30 and 60 degree wire cases are also described in this paper. [C879]

#### "A partially transparent Jaumann absorber applied to an aircraft wing profile"

We designed a partially transparent Jaumann absorber. The metallic sheet of the Jaumann was replaced by a triangular lattice Gangbuster FSS together with a polarizer. This design was applied to a wing front end. We showed that the monostatic RCS performance of the wing improves. Furthermore, the resulting screen is partially transparent around 1GHz which is assumed to be an antenna operating frequency placed inside the wing. However the resistive layers of the Jaumann absorber cause a large loss at 1 GHz for the planar case. To reduce this loss, additional work is in progress where the Jaumann absorber is replaced with a capacitive circuit absorber. [C880]

#### "Accurate evaluation of the time-domain effective height for short-pulse antennas"

A singularity-expansion-method (SEM) based approach is presented for the analysis of radiation processes in short-pulse antennas. Any time-domain electromagnetic field solver can be used to derive a minimal pole/residue spherical harmonic expansion of the equivalent currents excited on a suitable Huygens surface enclosing the radiating structure. In this way, the time-domain effective height of the antenna is evaluated in closed form as the superposition of non-uniform spherical wave contributions attenuating along with the time according to the real part of complex poles accounting for the natural resonant processes occurring in the structure under analysis. [C881]

#### **"Noninvasive breast tumor localization based on ultrawideband microwave backscatter"**

The key to surgical planning for breast conservation is tumor localization. An accurate localization of the breast tumor is essential to guide the surgeon to the lesion, and ensure its correct and adequate removal with satisfactory excision margins. Current breast tumor localization techniques are invasive and often result in a cosmetic disfigurement. In this paper, we use the ultrawide band radar-based microwave breast imaging technique to non-invasively localize (impalpable) tumors in the breast. We consider four clinically important lesion features: location, size, depth and spatial orientation within the breast. A comparison of the energy of the received signal from healthy and cancerous breasts exhibits some significant differences in some frequency bands. We, therefore, use the energy spectrum of the receiving antenna signal decomposed by wavelet transform as the input to a genetic neural network (GNN) classifier. Furthermore, for improved efficiency, we optimize the structure of the GNN for optimum initial weights and number of hidden nodes. We use CST Microwave Studio to simulate benign and malignant breast conditions, and generate a data set of 1024 cancer cases with various tumor location, size, depth and spatial orientation within the breast. Our results show that the proposed algorithm gives accurate localization of the breast lesion, and possesses a high sensitivity to small tumor sizes. Additionally, it can accurately detect and classify multiple tumors. [C882]

#### **"The pulse sequence pattern and signal processing of complex radars"**

To the EW system, the conventional radar signal description is based on radar parameters and their features, which is hard to describe the modern complex radar. A new conception of Pulse Sequence Pattern (PSP), which uses a representative pulse sequence with multi-dimension parameters as the radar signal description, is proposed in this paper firstly. And the PSP of typical radar is described in detail. At last, the fast signal processing algorithm based on the PSP is given. The experiments and computer simulations show that the description of PSP is practicable and the recognition algorithm is more effective than the conventional method. [C883]

#### **"An improved chirp scaling algorithm with capability motion compensation for SAR"**

Since a motion error is the main phase error source in the aircraft synthetic aperture (SAR), the motion errors have to properly be compensated during the SAR image reconstruction. The chirp scaling (CS) algorithm is one of the best algorithms in the practice system. An improved CS algorithm which can compensate motion error is proposed. Specially, the proposed method is based on the constant acceleration movement and the sub-aperture technique. [C884]

#### **"The effects of input signal-to-noise ratio on compressive sensing SAR imaging"**

Synthetic Aperture Radar (SAR) is an active and coherent microwave high resolution imaging system, which has the capability to image in all weather and day-or-night conditions. The high resolution required by various modes of SAR results in a huge amount of sampling data, which brings a demand for bigger storage. Recently, a novel concept based on Compressive Sensing (CS) theory asserts that an unknown sparse signal can be recovered exactly with an overwhelming probability even with highly sub-Nyquist-rate samples. In this paper, a new scheme for the test bed of CS based SAR imaging is proposed. Experimental results on some real raw SAR data reveal that there are some practical limitations on the use of CS based SAR imaging, especially for complex imaging scenes and systems with low Signal-to-Noise Ratio (SNR). [C885]

#### **"Bistatic SAR imaging with parallel flight track based on monostatic SAR processor"**

Bistatic SAR uses separated transmitter and receiver flying on different platforms, and has the ability of the exploitation of additional information contained in the bistatic reflectivity of targets. This paper provides an efficient Nonlinear-Chirp Scaling (NCLS) algorithm for bistatic SAR with parallel track configure, which is based on the bistatic-to monostatic application (BTMA). The method described is a feasible solution for the image formation of bistatic SAR with such configure. The problem of Doppler ambiguity during the NCLS Processing and the choice of reference frequency are also discussed at last. This NCLS imaging algorithm is verified with a simulation experiment. [C886]

### "A fuzzy adaptive tracking algorithm based on current statistical probabilistic data association"

In this paper, a new fuzzy adaptive maneuvering target tracking algorithm based on current statistic model is proposed. How to track a maneuvering target is a key problem of target tracking in clutter. Current statistical model needs to pre-define the value of maximum accelerations of maneuvering targets. So it may be difficult to meet all maneuvering conditions. The Fuzzy inference combined with Current statistical model is proposed to cope with this problem. Given the error and change of error in the last prediction, fuzzy system on-line determines the magnitude of maximum acceleration to adapt to different target maneuvers. Furthermore, the difficulties of the maneuvering target tracking lies in the uncertainty of state model, and the clutter make it more complex. The algorithm combines current statistical algorithm with probabilistic data association algorithm. At last, the results show this algorithm can estimate a maneuvering target in clutter efficiently. [C887]

### "A new phase unwrapping method of interferogram"

In this paper, a new two-dimensional phase unwrapping method of interferogram will be present. The method is based on the Goldstein's Branch-cut method and Region-growing method. After the unwrapping of the interferogram by using Goldstein's Branch-cut method, the amplitude image and coherence image were used to extract the error regions. And the error regions were classified into two types, which were processed by Region-growing method and Inverse Distance to a Power interpolating method respectively. The proposed method was tested with the Etna SIR-C/X-SAR interferogram, and satisfied results were achieved. [C888]

### "Low velocity small radar target detection in maritime environment"

Researches on target detection are mainly focus on the amplitude characteristics nowadays. Sometimes the only use of amplitude characteristics is not enough to describe the signal, so that the target detection performance is usually poor. In this essay a method to make use of the information "hidden" in the signal phase is put forward, the theory is based on polynomial fitting of the signal phase train structure. At last, the method is validated using actual data. [C889]

### "A new time-delay echo jamming style to SAR"

This work is concerned with developing the time-delay-based jamming technology against SAR. Traditional time-delay echo jamming can only get a point or a line false imaging when through the SAR system, which can't protect distributed targets. This paper presents a modified time-delay echo jamming style, Time-delay Inter-pulse Jitter Echo jamming (TDIJEJ). The theoretic analysis and simulation show that this interference can obtain the fast time matched processing gain of SAR thus deduce the jamming power requirement, and generate a jamming swath output for the purpose of protecting distributed targets. [C890]

### "SAR interference signal feature vector extraction and simulation based on wavelet packet analysis"

This paper studies the use of wavelet analysis method to realize the non-coherent narrow-band SAR radar signal interference suppression. Based on the full study of Irregular wavelet tree in interference detection and filtering, an adaptive filter using wavelet packet decomposition to extract the interference signal feature vector has been proposed. Simulation experiments based on this method have been carried out, by using SNR improvement, interference rejection ratio, signal distortion and other evaluation criteria to evaluate the results of interference suppression, the results show that the effect of wavelet packet filtering interference suppression is good. [C891]

### "Phase noise in RF and microwave amplifiers"

The amplifier phase noise is a critical issue in numerous fields of engineering and physics, like oscillators, frequency synthesis, telecommunications, radars, spectroscopy, in the emerging domain of microwave photonics, and in more exotic domains like radio astronomy, particle accelerators, etc. We analyze the two main types of phase noise in amplifiers, white and flicker. Using the polynomial model, the phase-noise power spectral density is  $S_{\phi}(f) = b_0 + b_{-1}/f$ . Phase noise results from adding white noise to the RF spectrum around the carrier. For a given amount of RF noise added,  $b_0$  is proportional to the inverse of the carrier power  $P_0$ . By contrast,  $b_{-1}$  is a constant parameter of the amplifier, in a wide range of carrier power. Accordingly, the flicker phase noise  $b_{-1}/f$  is independent of  $P_0$ . This fact has amazing consequences on different amplifier topologies. Connecting  $m$  equal amplifiers in parallel,  $b_{-1}$  is  $1/m$  times that of one device. Cascading  $m$  equal amplifiers,  $b_{-1}$  is  $m$  times that of one amplifier. Recirculating the signal in an amplifier so that the gain increases by a power of  $m$  (a factor of  $m$  in dB) due to positive feedback (regeneration), which for integer  $m$  is similar to the case of  $m$  amplifiers, we find that  $b_{-1}$

1 is  $m$  times that of the amplifier alone. The simplest model for the  $1/f$  phase noise is that the near-dc  $1/f$  noise phase-modulates the carrier through some parametric effect in the semiconductor. This model predicts the behavior of the (simple) amplifier and of the different amplifier topologies. Numerous measurements on amplifiers from different technologies and frequencies (HF to microwaves), also including some obsolete amplifiers, validate the theory. This model also applies to other devices, including passive components. [C892]

#### "Resolution enhancement of SAR image using the modified IBP method"

Super resolution (SR) technique can produce a high-resolution (HR) image from a set of low-resolution (LR) images with complementary information. This paper proposes a modified iterative back projection (IBP) method for SAR image resolution enhancement. In this method, a SR image is assumed and modification which contains the different high frequency information of LR images is back projected to it to get an ideal HR image. Compared with the original IBP, the modified IBP method is simpler and the modification is more accurate to speed up the iteration. Both simulated and real SAR images are used to verify the validity of the method. The results show that details and definition of the LR image processed with the method are effectively improved. [C893]

#### "The improved phase-difference algorithm of 24GHz FMCW radar for fast level tracing of bulk solid material"

For the purpose of accurately and quickly level tracing of bulk solid material, a new 24GHz FMCW radar measurement system with fast frequency Improved Phase-Differential estimation algorithm on platform of TI DSP 28335 and the low cost multiplier frequency VCO and mixer is realized, Three kinds of the fast tracing algorithm, Improved CZT algorithm, Improved ZFFT algorithm and the new Improved phased-difference algorithm (IPDA) is compared for the real time and accuracy. The results show that the IPDA is more suitable for the measurement of bulk solid material, and can be higher accuracy and faster speed. [C894]

#### "Radar echo signal detection with sparse representations"

Sparse decomposition can explore the most important or interesting features of a signal, thus it is very favorable in data compression, noise reduction, signal analysis, correction and other applications. In this paper, we propose a method of radar echo signal detection with sparse representations. In the proposed method, we first design a waveform-matched dictionary according to the a priori knowledge of the transmitted signal to sparsely represent the radar echo signal. The components in the dictionary have exactly the same waveform as the transmitted signal. With this dictionary, the echo signals of a given radar system have very sparse representation. Using the sparse representation based on the waveform-matched dictionary, the radar echo detection can be achieved. Simulation results show that the proposed method is effective and has the high anti-noise ability. [C895]

#### "Analysis of micro-doppler effect in SIMO radar"

SIMO (Single Input Multiple Output) radar system capitalizes on the receiving diversity, so it can obtain more information about the target and highly improve the target recognition capability of radar. In this paper, the micro-Doppler effect induced by rotation and vibration parts of target in SIMO radar system which transmitting single frequency signal are deduced respectively. Both the micro-Doppler effect induced by rotation and vibration are sinusoidal curves, but their amplitude vary with the selection of different receiving radar. In addition, the translation of the target's body will lead some horizontal shifts to the micro-Doppler curves with different value according to the selected receiving radar. Simulations are presented to validate the theoretic conclusions. [C896]

#### "An approach for extracting the transmitted waveforms based on compound filter for MIMO radar"

Extracting the transmitted waveforms is crucial for MIMO radar. A new extracting approach is proposed in this paper based on the compound filter. The proposed method can compress the input pulse width to a narrower one and suppress range sidelobe level lower than a matched filter. The computer simulation proves the efficiency of the method. [C897]

#### "Fast computation of cross ambiguity function for DTTB based passive radar"

A new method is proposed to calculate the cross ambiguity function (CAF) for digital television terrestrial broadcasting (DTTB) based passive radar. The Doppler frequency of the targets is much lower than sampling frequency. The cascade integrator comb (CIC) filter is utilized to realize the large change of sampling frequency. The interpolated second-order polynomials (ISOP) filter is used to compensate the passband droop caused by CIC filtering. A half-band filter is employed to get narrow transition band. And then a short point FFT is performed instead of the long point FFT. The experiment results and computation complexity are given

compared with other methods. It shows that the proposed method doesn't affect detection and estimation performance, and the computation is reduced significantly. [C898]

#### "Improved method for deinterleaving radar pulse trains with stagger PRI from dense pulse series"

Stagger PRIs detection and deinterleaving of pulse trains with stagger PRI in dense pulse series are always difficult problems in radar signal processing. In this paper, an improved detecting threshold of stagger PRIs of pulse trains and deinterleaving approach for stagger radar pulses in dense pulse series are proposed. Computer simulation experiment results of deinterleaving pulse trains with stagger PRI are used to verify the validity of the proposed method by the present method in this paper. [C899]

#### "Two-dimensional diffraction tomography algorithm of underground objects located in planar multilayer medium1"

An efficient inverse scattering algorithm is developed to reconstruct the permittivity profile of two-dimensional(2-D) dielectric objects buried in planar multilayer environment. The forward model of this inversion scheme is based upon first order Born approximation and 2-D planar multilayer scalar Green function. A planar multilayer diffraction tomography algorithm is established subsequently. Numerical results are provided to illustrate the performance of the inversion scheme. [C900]

#### "Bearing-only target tracking with improved particle filter"

In this paper, we propose an improved particle filter, and apply this new algorithm to bearing-only tracking problems. The generic particle filter (also called bootstrap filter) suffers a main drawback of not incorporating the latest observations, which is the problem we mainly focus on. An improving scheme is presented to handle this problem, and the underlying idea of the new algorithm is that, at time  $k$ , each particle is updated using Kalman filtering equations. Through this update process, the algorithm incorporates the coming observations. In the experiment, we use a bearing-only tracking model to evaluate the performance of the proposed algorithm. The experimental results show its superiority to the generic particle filter. [C901]

#### "Pulse compression technique for multi carrier phase-coded radar"

The multi-frequency complementary phase-coded signal (MCPC) has caught much attention of researchers recently as a new system radar signal. This paper provides pulse compression technique for such radar signal. Direct match filtering and synthetic filtering are proposed to compress the echo signal. After comparing their performance via amount of calculations, a wideband-synthesizing method is brought forward. It takes full usage of the multi carrier structure of MCPC signal, while keeps low calculation complexity. The two-level compression scheme is proved to be flexible in different applications. [C902]

#### "Millimeterwave radar high-resolution imaging via OFDM waveforms"

A novel combination of millimeterwave linearly frequency modulated (LFM) technology and new radar imaging techniques can provide a good high-resolution imaging sensor that can be inboard in unmanned vehicles, in which stringent limitations of size, weight and power consumption are required. This paper presents an approach of multiple transmission and multiple reception in elevation for vehicle-borne millimeterwave radar high-resolution imaging. This radar employs orthogonal frequency diversity modulated (OFDM)-LFM waveforms, so as to obtain a high-resolution imagery over a wide swath coverage. The system concepts, geometry relations and signal models are provided. Computer simulation examples are also performed. Additionally, the generation of the OFDM waveforms with parallel direct digital synthesizer (DDS)-driven phase locked loop (PLL) synthesizer is discussed, and the block diagram of the synthesizer is provided. [C903]

#### "Directional pattern modeling and simulation of triangular grid circular planar array antennas"

Based on a long range early-warning phased array radar, the directional pattern of the triangular grid circular planar array antenna is studied. The mathematical model of triangular grid circular planar array antennas pattern is established, and its computer simulation method is described. In order to form a low side-lobe pattern, the method of Taylor circular array synthesis is used to optimize the amplitude distribution of the current excitations. The practice demonstrates that the simulation method presented is very efficient and practical. [C904]

#### "A novel design of SAR scattering signal simulator based on AWG"

Synthetic Aperture Radar (SAR) raw signal simulation is crucial for SAR system design and processing algorithms. This paper proposes the simulation method of SAR RF signal via utilizing Arbitrary Waveform

Generation (AWG). At first, the SAR imaging principle is analyzed. Then, the space-borne SAR scenario model is constructed. The echoes of point target are calculated, which is impulse response of the SAR signal acquisition. At the end, based on the scattering model expressions of a random roughness surface and the electromagnetic wave shadow theory, the Radar Cross Section (RCS) simulation parameters of terrain target is calculated. 2D-FFT method is utilized to improve simulation efficiency significantly. [C905]

#### "Improved image mosaic method of ScanSAR"

For ScanSAR the mosaic of subswaths' images is very important. An improved method for scanSAR to process the mosaicking by using Range-Doppler location model is proposed in this paper. It is based on the precision of the R-D location method. This method avoids the pixel defocused and the simulation results are satisfied in practice. [C906]

#### "Phase-coded pulse compression radar carrier frequency accurate estimation"

This A new frequency estimator for Phase-coded pulse compression radar carrier frequency is proposed. First, via square nonlinear transformation, the radar signal is become one tone signal, it is possible that transformed signal is sub-nyquist sampled, and estimation value of carrier frequency will be ambiguous, a method of solving frequency ambiguity is proposed, and using FFT(Fast Fourier Transform) +FT(Fourier Transform) to improve carrier estimation precision, a method of fast peaks search is proposed. Simulation results show that the results are efficient. [C907]

#### "A novel single-channel SAR-GMTI method based on defocusing shifted difference"

A novel single channel SAR-GMTI method is proposed in this paper. When the azimuth mismatch filter performs compression, it induces shifted difference between the stationary and moving targets because of having different Doppler center. The proposed method employs this character to separate moving targets from stationary targets. It can produce two images by pulse compression which make use of two symmetrical mismatch filters in azimuth direction, and then cancel stationary and retain moving targets by subtracting one image from another. Compared with traditional methods, it is applicable to both low and high squint case and the detection capability is significantly improved. The simulation results validate the effectiveness of the proposed method. [C908]

#### "Low speed target detection with short CIT in HF surface wave radar"

High frequency surface wave radar can detect targets beyond the horizon. It needs long coherent integration time (CIT) to detect low speed targets, such as ships, in the environment with sea clutter. In order to improve the efficiency of the radar system, and avoid the Doppler broadening caused by long CIT, it is necessary to shorten coherent integration time. Modern spectrum estimation technique is adopted to extract Doppler information from HF radar echo signals. It can provide high resolution to realize ship detection in short CIT. The real data processing and analysis show that the autoregressive spectrum estimation technology is effective to detect low speed target in short CIT in high frequency surface wave radar. [C909]

#### "Enabling technology for heart health wireless assistance"

Several advances have been done in wireless body area networks for bio-monitoring, as confirmed by the fine tuning of ad-hoc standards for networking, controlling and managing a distributed sensor platform around the human body. Efficient wireless networks are becoming commercially available for several applications. In spite of that, sets of "invisible" sensors for monitoring bio-signals are still expected as enabling technology for mass-market applications. This paper aims at reviewing the current state of the art, and identifying some existing open issues and added functionalities desirable for the future in heart health wireless assistance. Some results emerging from the on-going research are presented, focusing on the implementation of an innovative contact-less miniaturized radar sensor for cardiopulmonary monitoring within a wearable textile platform. The expected future developments toward a wireless body area network are reported and discussed. [C910]

#### "Evaluation of cloud liquid absorption models at 90 and 150 GHz"

The use of microwave observations in the frequency range of 90-150 GHz holds the promise to dramatically improve the retrieval of integrated liquid water in thin clouds due to the increased sensitivity of these frequencies to the presence of liquid water. One of the largest sources of retrieval uncertainty at these frequencies is the inaccuracy of liquid water absorption models at low temperatures. The purpose of this work is to assess the performance of four liquid water absorption models by comparing model simulations with measurements collected by a microwave high-frequency radiometer (MWRHF) located at the Atmospheric Radiation Measurement (ARM) Program Climate Research Facility (ACRF) in the Southern Great Plains, OK. Measurements at 90 and 150 GHz

were collected during cloudy and cold conditions. In an attempt to isolate different sources of possible errors we give an assessment of the instrument calibration and compare clear-sky measurements with model simulations using an updated formulation for the water vapor continuum. With the help of a ceilometer and cloud radar we identified several cases of cold, thin liquid clouds and for those cases we independently retrieved liquid water path using infrared frequencies. The independently retrieved liquid water path was then used to compute brightness temperatures at 90 and 150 GHz with the four liquid absorption formulations. Simulation results were then analyzed and compared with observations. [C911]

### **"Improved high wind speed retrievals using AMSR and the next generation NASA Dual Frequency Scatterometer"**

Microwave scatterometer measurements are the standard for satellite ocean vector winds (OVW) measurements. Unfortunately, in extreme weather events, where high wind speeds are frequently associated with strong rain bands, precipitation can significantly degrade the OVW retrieval accuracy. This study addresses the feasibility of exploiting passive measurements to improve high wind speed retrievals for such extreme weather events. The Jet Propulsion Laboratory (JPL) has developed a conceptual design for a Dual Frequency Scatterometer (DFS) proposed to fly onboard the future Japan Aerospace Exploration Agency (JAXA) GCOM-W2 mission with the Advanced Microwave Scanning Radiometer (AMSR). These two instruments will provide a complimentary dataset of simultaneous and coincident active/passive measurements, which can correct for rain effects and thereby improve the OVW retrievals. End-to-end computer simulations are performed using the Weather Research and Forecasting (WRF) numerical weather model tuned to Hurricane Katrina (2005) for the 3D nature run (surface truth). Results show that the new OVW retrievals compare well to the nature run surface wind vectors and that this active/passive technique offers a robust option to extend the useful wind speed measurements range beyond the current operating scatterometers for future satellite missions. [C912]

### **"AMSR-E observations of rain and flood events over vegetated areas of LA Plata basin"**

This work analyzes AMSR-E signatures collected in two sites of La Plata basin, in South America. Within the wide Chaco forest, an area close to Las Lomitas meteorological station was selected. Here the forest is uniform, but not very dense, with biomass values in the range 70-120 t/ha. After strong rain events, appreciable variations of polarization index at C and X band were observed. As expected, the better dynamic range is obtained at C band. Also AMSR-E signatures collected during a strong flooding event in the Delta of Parana River were analyzed. Variations of polarization index are strong, as expected. Information about the water level in the river was made available by hydrometric stations. We selected specific pixels characterized by different kinds of land cover: agricultural fields, marshes, and planted forests. A significant correlation between polarization index (at various frequencies) and water level is proved. A flood monitoring algorithm based on AMSR-E brightness temperature difference is tested. Optical and radar data are used as ancillary input for calibration and validation proposes. [C913]

### **"Radio frequency interferences investigation using the airborne L-band full polarimetric radiometer CAROLS"**

In the present paper, different methods are proposed for the detection and mitigation of the undesirable effects of radio frequency interference (RFI) in microwave radiometry. The first of these makes use of kurtosis to detect the presence of non-Gaussian signals, whereas the second imposes a threshold on the standard deviation of brightness temperatures, in order to distinguish natural emission variations from RFI. Finally, the third approach is based on the use of a threshold applied to the third and fourth Stokes parameters. All of these methods have been applied and tested, with a CAROLS radiometer operating in the L-band, on data acquired during airborne campaigns made in spring 2009 over the South West of France. The performance of each, or of two combined approaches is analyzed with our database. We thus show that the kurtosis method is well adapted to pulsed RFI, whereas the method based on the second moment is well adapted to continuous-wave RFI. [C914]

### **"An improved active/passive oceanic wind vector retrieval technique"**

This paper describes the advantages of combining passive and active microwave remote sensing observations for the purpose of ocean wind vectors retrievals. Previous studies have shown that a linear combination of horizontal and vertical polarized brightness temperatures contains a robust wind direction signal. In this paper, we present results from an end-to-end simulation of ocean measurements from a Ku-band (13.4 GHz) active/passive conical scanning satellite instrument. For this simulation, realistic wind fields from the NOAA National Center for Environmental Prediction (NCEP) numerical weather model were used to produce simultaneous brightness temperatures and radar backscatter measurements. These measurements were processed using a maximum likelihood estimation technique to yield ocean wind vector retrievals that were

compared to NCEP fields. Results demonstrate significant improvements over simulated measurements for an active (radar scatterometer) sensor. [C915]

#### **"Millimeter wave interferometric radiometry for passive imaging and the detection of low-power manmade signals"**

Millimeter wave detection and imaging is becoming increasingly important with the proliferation of hostile, mobile millimeter wave threats from both weapons systems and communication links. Improved force protection, surveillance, and targeting will rely increasingly on the interception, detection, geo-sorting, and the identification of sources, such as point-to point communication systems, missile seekers, precision guided munitions, and fire control radar systems. This paper describes the Naval Research Laboratory's (NRL) demonstration broadband passive millimeter wave (mmW) interferometric imaging system. In addition to limited active signal detection, the Ka-band system will provide the potential for detecting the passive signature of non-transmitting hostile systems along with a capability for meter-precision geolocation for imaged objects. The interferometer uses a distributed array of 12 antenna elements to synthesize a large aperture. Each antenna is packaged into an individual receiver, from which a baseband signal is recorded. The correlator is software-based, utilizing signal processing techniques for visibilities, and image formation via beamforming methods. [C916]

#### **"Utilization of airborne and in situ data obtained in SGP99, SMEX02, CLASIC and SMAPVEX08 Field Campaigns for SMAP Soil Moisture Algorithm Development and Validation"**

Field experiment data sets that include coincident remote sensing measurements and in situ sampling will be valuable in the development and validation of the soil moisture algorithms of the NASA's future SMAP (Soil Moisture Active and Passive) mission. This paper presents an overview of the field experiment data collected from SGP99, SMEX02, CLASIC and SMAPVEX08 campaigns. Common in these campaigns were observations of the airborne PALS (Passive and Active L- and S-band) instrument, which was developed to acquire radar and radiometer measurements at low frequencies. The combined set of the PALS measurements and ground truth obtained from all these campaigns was under study. The investigation shows that the data set contains a range of soil moisture values collected under a limited number of conditions. The quality of both PALS and ground truth data meets the needs of the SMAP algorithm development and validation. The data set has already made significant impact on the science behind SMAP mission. The areas where complementing of the data would be most beneficial are also discussed. [C917]

#### **"An Lidar data compression method based on improved LZW and Huffman algorithm"**

Lidar raw echo data has characteristics such as huge data quantity, strong discreteness and unpredictability. According to the construction of Lidar monitoring network of atmospheric environment, the existing network can not provide enough bandwidth to transmit Lidar data in real time. In this paper, we propose a novel hybrid lossless compression algorithm to reduce the transmission amount, namely the probability statistics lossless compression algorithm base on the improved LZW(Lempel-Ziv-Welch), which combines Huffman coding. With experiment on the raw two-value atmospheric data, we verify the effectiveness of our approach that the compression ratio is close to 9.5:1 and the coding efficiency is up to 98%. [C918]

#### **"A 1V 11fJ/conversion-step 10bit 10MS/s asynchronous SAR ADC in 0.18 $\mu$ m CMOS"**

This paper presents a 10-bit SAR ADC using a variable window function to reduce the unnecessary switching in DAC network. At 10-MS/s and 1-V supply, the ADC consumes only 98  $\mu$ W and achieves an SNDR of 60.97 dB, resulting in an FOM of 11 fJ/Conversion-step. The prototype is fabricated in a 0.18 $\mu$ m CMOS technology. [C919]

#### **"Low-cost gate-oxide early-life failure detection in robust systems"**

We present a new low-cost technique for detecting gate-oxide early-life failures (ELF) to overcome reliability challenges in robust systems without requiring expensive concurrent error detection. Our approach is enabled by an on-chip clock control technique, applied during periodic on-line self-test and diagnostics, to detect delay shifts over time before functional failures occur. Using 90 nm test chips, we demonstrate the following key results: 1. A gate-oxide ELF transistor inside a combinational logic circuit results in delay shifts over time before functional failures appear. 2. The delay shifts can be successfully detected during on-line self-test and diagnostics using our on-chip clock control technique. [C920]

#### **"CAROLS campaigns 2009: First Results"**

The CAROLS, L band radiometer, is built and designed as a copy of EMIRAD II radiometer of DTU team. It is a Correlation radiometer with direct sampling and fully polarimetric (i.e 4 Stockes). It will be used in conjunction

with other airborne instruments (in particular the C-Band scatterometer (STORM) and IEEE GPS system, Infrared CIMEL radiometer and one visible camera), in coordination with in situ field campaigns for SMOS CAL/VAL. The instruments are implemented on board the French research airplane ATR42. A scientific campaign with thirteen flights is realized over south-western France, Valencia site and Bay of Biscay (Atlantic Ocean) in spring 2009. In order to qualify the radiometer data, different types of aircraft movements were realized: circle flights, wing and nose wags. Simultaneously to flights, different ground measurements were made over continental surfaces and ocean. Results show a good quality of data. For continental surfaces, important Radio-Frequency Interferences (RFI) were observed over a large part of the studied region. [C921]

#### **"Track initiation in Monostatic-Bistatic Composite High Frequency Surface Wave Radar Network based on NFE model"**

Though a Monostatic-Bistatic Composite High Frequency Surface Wave Radar Network (MBC-HFSWR Network) is established to cover the shortage of the monostatic radar, how to judge the real target update from the plausible measurements to initiate tracks quickly and accurately still remains a challenging problem. A novel method utilizing unconventional characteristics for track initiation is proposed in this paper, which uses more accurate information and avoids the problem of low detection precision of high frequency radar. A highly intelligent information fusion model which is a combination of Neural network, Fuzzy reasoning and Expert system (NFE model) is presented to solve the problem above and the validity of the provided method is demonstrated by Monte Carlo simulations. [C922]

#### **"The exposed area analysis of Barrage-type Jamming to Bistatic SAR"**

In this paper, jamming equation is established which based on working mode of Barrage-type Jamming to Bi-SAR, and the coverage region is derived under a certain J/S (Jamming-to-signal ratio) from Bi-SAR. In such circumstances, the radar receiver can detect the target area through mathematical method analysis, namely exposed area. Finally, maximal exposure area, absolute exposure area, possible exposure area and definite protected area are divided. [C923]

#### **"A three-dimensional geographic and storm surge data integration system for evacuation planning"**

The rise of offshore water caused by the high winds of a low pressure weather system, or storm surge, is a hurricane's greatest threat to human life. As weather forecasters struggle to enable coastal residents to make timely evacuation decisions, the need arises for more visually compelling and interactive storm surge visualization tools. This paper presents an interactive and three-dimensional storm surge visualization system. It integrates road, topographic, and building data to construct accurate three-dimensional models of major cities in the State of Florida. Storm surge data are then used to construct a three-dimensional ocean positioned over the terrain models. Ambient details such as wind, vegetation, ocean waves, and traffic are animated based on up-to-date wind and storm surge data. Videos of the storm surge visualizations are recorded and made available to coastal residents through a web-interface. The three-dimensional visualization of geographic and storm surge data provides a more visually compelling representation of the potential effects of storm surge than traditional two-dimensional models and is more capable to enable coastal residents to make potentially life-saving evacuation decisions. [C924]

#### **"An adapted point based tracking for vehicle speed estimation in linear spacing"**

Vehicle velocity estimation is an important aspect of intelligent transportation systems. Normally velocity is estimated using dedicated laser speed traps and Doppler radars. Recently, the use of cameras is becoming more common for the purpose of traffic surveillance and smart surveillance system. It is thus the aim of this paper to propose a method for vehicle speed estimation using these existing video cameras. In this paper, we propose a vehicle speed estimation method from video analysis. The method proposed contains several steps; image preprocessing, centroid extraction and tracking. The proposed method transforms the 2D image points into a 3D virtual world to obtain actual vehicle position in 3D space. This is to account for perspective distortion commonly seen in images. Using these 3D points and measuring the time for displacement, the vehicle speed is obtained. Experimental results have shown that the proposed method gives accurate velocity estimation. [C925]

#### **"Performance improvement of pulsed OFDM UWB systems using ATF coding"**

In this paper, we examine an enhancement of pulsed Multiband Orthogonal Frequency Division Multiplexing (pulsed MB-OFDM) systems for Synthetic Aperture Radar (SAR) Ultra-Wide Band (UWB) applications. The pulsed MB-OFDM system offers an efficient option for fulfilling the UWB high bandwidth channel requirements. This system combines the two major implementations of UWB, namely the impulse radio and the MB-OFDM, in order to capture the advantages of low hardware complexity and low power consumption in both

implementations. A modified half-rate Algebraic Time Frequency (ATF) coding will be used to achieve the proposed enhancement of the pulsed system. This enhancement will result in energy efficiency, i.e. SNR vs. SER, improvement which is particularly useful for SAR systems operating under heavy clutter. Improvements in energy efficiency are tested under different UWB channel models. Simulation results are shown to establish these improvements. [C926]

### "Research on Visualization of Radar Beam Considering Virtual Environment Effect"

In a virtual battlefield environment, the 3D visualization of the abstract information of radar beam under the environmental influence of the terrain and weather is the current development trend of the visualization of electromagnetic information. In this article, we have designed two methods by the OpenGL function to complete the drawing of the spatial beam pattern that is inserted into the virtual battlefield environment. And then we combined the stereoscopic concept with the research, and studied the information visualization methods of the radar beam that were under the influence of different environmental factors with the premise of that the radar beam parameters and the terrain elevation data and other relevant parameters were acquired. At last, the users could be able to get electromagnetic battlefield information they need vividly and intuitively, which could make them determine more promptly. [C927]

### "An application of sensor networks with data mining to patient controlled analgesia"

We designed an information integration system, iPCA, which combined wireless sensor networks with a data mining system, to help anesthesiologists provide better post-operative pain control. To reduce labor work and to collect analgesic usage information and physiological data efficiently, we connected three kinds of medical instruments with Zigbee nodes through IEEE 802.11 and Zigbee networks. We developed a positioning system that allowed the medical staff to monitor the patient's locations, so they could give immediate care when necessary. The data mining system in iPCA analyzed the patient data, and made reasonable predictions about the total analgesic dosage and the need for PCA control readjustments. We completed a prototype of iPCA, which could help the medical staff monitor the patient's health conditions and locations, and provide the anesthesiologists with useful hypotheses for better PCA control to increase patient satisfactions. [C928]

### "Car monitoring, alerting and tracking model: Enhancement with mobility and database facilities"

Statistics show that the number of cars is increasing rapidly and so is the number of car theft attempts, locally and internationally. Although there are a lot of car security systems that had been produced lately, but the result is still disappointing as the number of car theft cases still increases. The thieves are inventing cleverer and stronger stealing techniques that need more powerful security systems. This project "Car Monitoring and Tracking System" is being proposed to solve the issue. It introduces the integration between monitoring and tracking system. Both elements are very crucial in order to have a powerful security system. The system can send SMS and MMS to the owner to have fast response especially if the car is nearby. This paper focuses on using MMS and database technology, the picture of the intruder will be sent via local GSM/GPRS service provider to user (and/or) police. The Database offers the required information about car and owner, which will help the police or security authorities in their job. Moreover, in the event of theft local police and user can easily track the car using GPS system that can be link to Google Earth and other mapping software. The implementation and testing results show the success of prototype in sending MMS to owner within 40 seconds and receiving acknowledgment to the database (police or security unit) within 4 minutes. The timing and results are suitable to owner and police to take suitable action against intruder. [C929]

### "Implementation and analysis of integration GSM/GPRS modem in a TMS320VC6713 digital signal processor for vehicle location"

The rapidly evolving wireless communications environment and 3G, where the standard are constantly created and modified, has given rise to the integration of GPS (Global Positioning System) and GSM (Global System for Mobile Communication). This integration has been widely applied in many disciplines including Intelligent Transportation System (ITS) and Logistic Management to aid the users to locate their vehicles remotely. Further on, the fast growth of city transportation also has stimulated the development of VMS where it is recognized as one of the major components of ITS. However, this system is rarely being implemented on embedded system using DSP processor. Thus, this paper discusses design and implementation of GSM/GPRS integration in a TMS320VC6713 for Vehicle Location that permits users to communicate with their vehicles via a Short Message Service (SMS). This system provides an alternative solution to solve vehicle theft and hijacking problems where the system is able track the real-time moving car location by using cellular phone. The system performance analysis has been carried out where the executions of three functions have been measured in clock cycles.

[C930]

### "A Digital Pulse Drive Circuit for Continuously Modulated Semiconductor Laser"

A digital designing way of laser drive circuit for continuously modulate the frequency, pulse width and amplitude of the output of semiconductor laser has been demonstrated. Complex programmable logic device (CPLD) was utilized to generate square waves with tunable frequency, the accurate delaying chip and logic circuit which are digital controlled were used to generate electrical pulses with adjustable pulse width. The pulses were amplified by the laser diode driver. The maximum output current of the driver can be up to 600 mA. When the signal was used to drive the semiconductor laser, the shape of the pulses generated by the laser is identical with the electrical pulses. The repetition rate and pulse width of the laser pulse can be continuously adjustable from 1 to 10 kHz and 3 to 20 ns, respectively. Furthermore, the time of rising and falling edges for the laser pulse were less than 2 ns. [C931]

### "The identification test of soil texture with ground penetrating radar"

The detection of soil texture needs nondestructive methods. Ground penetrating radar (GPR) develops fast in the fields of geological and agricultural survey in the recent years. To get a quantitative recognition of soil texture, experiments were designed with GPR of 500 MHz and 250 MHz frequency. Fine sand, sieved soil and natural soil were selected and tested indoors to acquire basic soil properties, amplitude attenuation characteristics and speed of electromagnetic wave. Compared to the experimental results outdoors, soil texture in the spots can be identified and classified. The strong signal changes only happened at the surface of the medium. The study results also showed GPR could recognize silt loam and sand loam, which help us analyze the effects of soil texture on soil dielectric characteristics in the further research. [C932]

### "Research on Early-Warning Detecting Tasks Re-scheduling and Sensor Resources Allocation Strategy of Midcourse Maneuverable Ballistic Targets"

Ballistic midcourse maneuverable targets bring huge challenge to early-warning detecting tasks. The incoming threats targets could be lost in detection range of sensors and early-warning detecting tasks may be failure, which retard the response of a ballistic missile defense system and the criticality of missiles would be increased. How can the Space-based early warning system detect and track the ballistic midcourse maneuverable targets in real-time is a new issue. In this paper, a early-warning detecting tasks re-scheduling and sensor resources allocation strategy based on multi-levels is designed, sensor resources allocation rapidly come true and satisfied the dynamics and real-time tracking requirements of detecting tasks, as well as the fewer adjusting amplitude to originally resources scheme. Finally, taking the space-based early-warning detecting task of maneuverable ballistic missile for example, by which the feasibility and efficiency of the strategy are explained and proved. [C933]

### "Remote monitoring of open numerical control system"

This paper investigates hardware and software architecture of numerical control (NC) system for remote monitor, and realizes in open numerical control system on field bus. Using principles of digital dictionary and data acquisition, the remote monitoring system of open NC system is designed. After in-depth analysis of needs, the design of hardware and software is completed, and applied research on NC EDM machines is conducted. Besides, the development of prototype is completed and the functions of online data acquisition, remote monitoring and remote machining services are realized. [C934]

### "Distributed GOSCA-CFAR Detection Based on Automatic Censoring Technique"

This paper present a new distributed constant false alarm rate (CFAR) detector based on automatic censoring technique. In the scheme, every local decision of individual detector, resulting from the comparison between its sample level and the estimation of the background based on GOSCA-CFAR (generalized order statistic, cell averaging-CFAR) algorithm, takes the value zero or one. Then, the fusion center makes the final decision utilizing the total local decisions, which are transmitted from each local detector. The overall decision, which is zero or one, is obtained at the data fusion center based on "AND", "OR", and "k/N" fusion rule. The results show that for the nonhomogeneous background caused by multiple interfering targets, particularly in multiple target situation, it exhibits good robustness in distributed sensor network. Under Swerling 2 assumption, the analytic expression of detection probability and false alarm probability are derived. [C935]

### "Research on Visualization of Electromagnetic Information in Virtual Environment"

In the article we research the visualization technology of electromagnetic information. It focuses on the drawing of the signals and multi-path signals transmission in the virtual battlefield environment. Firstly, we use the

OpenGL functions to complete the drawings of the time domain signals and spatial beam patterns. Secondly, we build the propagation model which is based on the theory of geometrical optics and realize the visualization of multipath phenomenon. Finally, those drawings are inserted into the virtual battlefield environment built by Vega. Accordingly, the commanders could be able to get electromagnetic battlefield information they need vividly and intuitively, which could make them determine more promptly. [C936]

#### "Horizontal Dilution of Precision Analysis for Loran C/ Beidou Integrated Navigation System"

The positioning precision of system plays a very important role in ship navigation. As a navigation system, Loran C cannot meet the orientation precision, even not be used in some areas. Based on the principle of hyperbola location, in this paper we propose Loran C/Beidou integrated navigation system. We analyze the effect on the positioning precision of two navigation systems and the simulation of orientation precision is implemented. Additionally, we give the definition of the horizontal dilution of precision (HDOP). Theoretical analysis and extensive experimental data show that by integrating Loran C and Beidou, the orientation precision and usable area of Loran C was improved and the shortage of Beidou position system was covered simultaneity. [C937]

#### "Power-aware distributed target detection in wireless sensor networks with UWB-radar nodes"

Distributed detection of targets is one of the major applications of wireless sensor networks. Many existing results on distributed detection are either derived from analytical models or are based on simulations. In this paper, the performance of a distributed target detection system is evaluated by real measurement data obtained by UWB-radar-based sensor nodes. After local processing of the radar signal, the sensor nodes transmit their local decisions about the absence or presence of the target to a fusion center. For this purpose, a power-aware algorithm for resource allocation, which is tailored for UWB communication links is discussed. The feasibility and the effectiveness of this algorithm is evaluated by a hybrid approach based on the measurement data and simulations. [C938]

#### "The HF surface wave radar WERA. Part I: Statistical analysis of recorded data"

Surface wave (SW) over-the-horizon (OTH) radars are not only widely used for ocean remote sensing, but they can also be exploited in integrated maritime surveillance systems. This paper represents the first part of the description of the statistical and spectral analysis performed on sea backscattered signals recorded by the oceanographic WEllen RAdar (WEERA) system. Data were collected on May 13th 2008 in the Bay of Brest, France. The data statistical analysis, after beamforming, shows that for near range cells the signal amplitude fits well the Rayleigh distribution, while for far cells the data show a more pronounced heavy-tailed behavior. The causes can be traced in man-made (i.e. radio communications) and/or natural (i.e. reflections of the transmitted signal through the ionosphere layers, meteor trails) interferences. [C939]

#### "LORAMbis A bistatic VHF/UHF SAR experiment for FOPEN"

LORAMbis is the experimental part of a joint research program between Sweden and France. The objective is to evaluate the performance of low frequency bistatic SAR for clutter suppression in various applications, e.g. under-foilage target detection or mapping of urban scenes. The airborne bistatic SAR data are acquired using the VHF/UHF component of the ONERA SAR system SETHI and the VHF/UHF LORA system operated by FOI. The first data collection campaign was conducted in December 2009. Focused bistatic SAR images have been formed and indicate that the implemented synchronization method is sufficient. It is based on a GPS disciplined 10 MHz reference signal that is generated in both systems. [C940]

#### "Passive bistatic ISAR based on geostationary satellites for coastal surveillance"

The paper proposes a new passive bistatic ISAR mode for coastal surveillance based on the exploitation of the signals transmitted by telecommunication geostationary satellites. Specifically it is demonstrated that ISAR images with acceptable quality of ship targets could be obtained by using telecommunication geostationary satellites as opportunity transmitters and stationary passive devices, located near the coast, as receivers. The geostationary satellites assure a continuous and complete coverage of wide areas: moreover satellites available in the near future should also provide a bandwidth suitable for the achievement of medium slant range resolutions. Since in ISAR the target motion is exploited to obtain cross-range resolution, a network of stationary low cost receiving only devices could be therefore properly located on the coast to obtain ISAR images of ship targets of interest for the surveillance and monitoring of the maritime traffic. [C941]

#### "Slow-time SAR signal processing for UWB OFDM radar system"

Orthogonal frequency division multiplexing (OFDM) signals, commonly used for a variety of purposes in modern

communication systems, are considered from the radar perspective. An experimental system configured as ultrawideband (UWB) software-defined radar (SDR) has been assembled and tested in the synthetic aperture radar (SAR) mode at Miami University. Phase history-necessary for slow-time processing of SAR signals-was previously extracted from a single sub-carrier of OFDM pulses; in this paper we examine a more robust solution of phase history estimation using all subcarriers. The results of the estimation are compared with the ideal single-frequency phase history reconstruction. Simulation examples of cross-range recoveries in noise using both methods are provided and discussed. It is shown that the proposed novel method of slow-time OFDM SAR signal processing is, indeed, a promising technique for multicarrier UWB systems. [C942]

#### "Bayesian parametric approach for multichannel adaptive signal detection"

This paper considers the problem of space-time adaptive processing (STAP) in non-homogeneous environments, where the disturbance covariance matrices of the training and test signals are assumed random and different with each other. A Bayesian detection statistic is proposed by incorporating the randomness of the disturbance covariance matrices, utilizing a priori knowledge, and exploring the inherent Block-Toeplitz structure of the spatial-temporal covariance matrix. Specifically, the Block-Toeplitz structure of the covariance matrix allows us to model the training signals as a multichannel auto-regressive (AR) process and hence, develop the Bayesian parametric adaptive matched filter (B-PAMF) to mitigate the training requirement and alleviate the computational complexity. Simulation using both simulated multichannel AR data and the challenging KASSPER data validates the effectiveness of the B-PAMF in non-homogeneous environments. [C943]

#### "Some aspects of designing real-time digital correlators for noise radars"

Real-time operation of a noise radar correlator requires massive processing power. At present, it can be provided at a reasonable cost only by FPGA devices. However, adopting this platform makes different aspects of the design important than in the case of microprocessor-based design. In particular, our efforts are directed towards minimizing device usage, rather than number of computations. Several options are reviewed in the paper with this purpose in mind. [C944]

#### "Detection performance comparison for wideband and narrowband radar in noise"

The detection performance of wideband radars in noise is better than that of the narrowband radars under some conditions, due to higher range resolution and less target return fluctuation. The detection probabilities of wideband and narrowband radars for the wideband non-fluctuation, Rayleigh and Ricean target models in white Gaussian noise are deduced. The detection curves show that the wideband radars outperform the narrowband radars in detection performance in the case of high detection probabilities. But the detection predominance of the wideband radars is meaningless when the bandwidth of the radar is increased to a certain extent, because the integration loss of the wideband radar energy integration detector is increased with the increasing range resolution. [C945]

#### "Deriving bistatic chirp scaling algorithm based on the signal model"

This paper provides a novel view on the chirp scaling algorithm. In this new way, the chirp scaling algorithm is analyzed through its range-Doppler (RD) expression first. The RD expression can be modeled with three basic functions. The different functions can be derived by the different methods. The proposed method can reduce the approximating error of the bistatic azimuth modulation and can produce the close-form bistatic range curvature factor. Though this paper's algorithm is derived under the azimuth-invariant bistatic framework, the proposed methodology can be extended into the general case. [C946]

#### "A target alignment algorithm for through-the-wall radar imagery classification"

Sensing through the wall using radar is a valuable capability. There is considerable work in generating radar images of the interior of a room by beamforming of the radar backscatter generated in a Synthetic Aperture Radar (SAR) configuration. However, high level interpretation of the scene is a more difficult task. In previous work a minimum distance classifier was successfully used to recognize various targets placed in the scene. The approach suffered from the dependency of target features on target location. This work presents a solution to this problem by bringing the target intensity profiles into alignment with the training data prior to classification. The alignment is performed by moving the intensity profiles between locations using an Autoregressive Moving Average (ARMA) model. The classification results before and after alignment show a marked improvement. [C947]

#### "SAR imaging of forest structure at longer wavelengths"

This paper is focused on the recovery of the vertical structure of forested areas from multi-baseline and multi-polarimetric SAR surveys at P-Band and L-Band. Baseline diversity provides sensitivity to the vertical structure of the vegetation layer, resulting in the possibility to yield Tomographic reconstructions of forested areas. Yet, far more information can be inferred basing on the joint exploitation of baseline and polarization diversity, which allows the decomposition of the SAR signal into ground-only and volume-only contributions. Ground-only contributions provide an easy and viable way to phase calibrate the data stack. Volume-only contributions, if correctly identified, allow a direct imaging of the vegetation layer. Results are shown basing on both P-Band and L-Band airborne data collected in the framework of the ESA campaign BioSAR 2008. The spaceborne case is also considered, basing on simulated BioMass data. [C948]

#### "Multipath Doppler signatures from targets moving behind walls"

Detection, localization, and tracking of moving targets are highly desirable in through-the-wall sensing applications. Since the indoor environment is rich in multipath reflective sources, such as walls, floor, and ceiling, the received signal is composed of the direct path and several multipath arrivals. However, on occasions, the direct path to the target may be blocked as the target traverses behind large metallic objects such as file cabinets, etc. In such cases, multipath is the only observable return and can be exploited to detect and maintain tracking of moving targets. In this paper, we provide range-Doppler analysis of multipath arrivals for a diffuse target moving in an enclosed urban structure, which provides insight for the development of through-the-wall detection and tracking techniques based on multipath exploitation. [C949]

#### "A precise signal model for ultra high resolution SAR"

A precise signal model for ultra high resolution SAR in the two dimensional (2-D) time and frequency domain is presented. The traditional signal model is challenged because the 'stop-go' assumption can't hold any more in ultra high resolution SAR. Considering the radar's motion between transmission and reception of a pulse, the precise echo expressions in 2-D time and frequency domain are deduced. The precise signal model allows more insight into the ultra high resolution SAR imaging. [C950]

#### "An interpretation of Woodward's ambiguity function and its generalization"

We suggest a new interpretation of Woodward's ambiguity function as the expected value of an operator. The operator represents the physics of the interaction of the waveform with the object. This approach provides a new approach to understanding the return signal at the receiver and can reveal more detailed understanding of the underlying interactions within the return signal that are not usually brought out by standard signal processing techniques. [C951]

#### "Radar target detect using particle filter"

A radar target track-before-detect (TBD) algorithm using particle filter (PF) is presented in this paper. System dynamic model and measurement model are established based on a sequence of radar range-Doppler measurements using the new algorithm. Furthermore, a linear extended target model is proposed, which is more capable of describing a maneuvering target than the conventional point target model. The likelihood ratio function of the new model is also derived in this paper. Due to the accumulation of the PF-TBD over time and the effectiveness of the proposed target model, an improved probability of detection for dim target is obtained. The experimental simulations demonstrate that the proposed method is capable of detecting and tracking a target with SNR of 1 dB robustly. [C952]

#### "Passive synthetic aperture radar imaging with single frequency sources of opportunity"

In this paper we consider passive airborne receivers that use backscattered signals from sources of opportunity transmitting fixed-frequency waveforms. Due to its combined passive synthetic aperture and the fixed-frequency nature of the transmitted waveforms, we refer to the system under consideration as Doppler Synthetic Aperture Hitchhiker (DSAH). We present a novel image formation method for DSAH. Our method first correlates the windowed signal obtained from one receiver with the windowed, filtered, scaled and translated version of the received signal from another receiver. This processing removes the transmitter related variables from the phase of the Fourier integral operator that maps the radiance of the scene to the correlated signal. We next use the microlocal analysis to reconstruct the scene radiance by the weighted-backprojection of the correlated signal. This imaging algorithm can put the visible edges of the scene radiance at the correct location, and under appropriate conditions, with correct strength. Additionally, it is an analytic reconstruction technique which can be made computationally efficient. We show that the resolution of the image is directly related to the length of the support of the windowing function and the frequency of the transmitted waveform. The image reconstruction method is applicable with both cooperative and non-cooperative sources of opportunity using one or more

airborne receivers. We present numerical simulations to demonstrate the performance of the image reconstruction method and to verify the theoretical results. [C953]

#### **"Mode-Selective OTHR: A new cost-effective sensor for maritime domain awareness"**

This paper presents a new sensor concept designed to provide maritime domain awareness over large ocean areas. The Mode-Selective OTHR introduced herein achieves significant detection and tracking capability against maritime vessels relative to traditional OTHR designs because it is designed specifically to reject disturbed ionospheric propagation modes and operate only using low distortion propagation modes. The architecture of the radar is such that this rejection occurs for both the transmitter-to-surveillance-footprint and the footprint return-to-receiver propagation paths. This is achieved using recently discovered techniques for non-causal adaptive and range dependent transmit beamforming and two-dimensional apertures for both transmission and reception. It also includes new methods for using planar transmit arrays operating with extreme steer angle. [C954]

#### **"High resolution radar tomographic imaging using single-tone CW signals"**

Radar tomographic imaging is a special radar imaging technique which can achieve very high spatial resolution (up to  $j$  wavelength) but with very narrow signal bandwidth. Although the theory of radar tomography had been developed for more than 20 years, very few experimental results can be found in public literatures. In this paper, the radar tomographic imaging is investigated and some measurement results of radar tomographic imaging using single-tone CW signals are presented. The theoretical spatial resolution is achieved and good agreement is obtained between the measured and simulated results. [C955]

#### **"Performance analysis of two-step algorithm in sliding spotlight space-borne SAR"**

The focusing performances of two-step algorithm are analyzed in the paper. The convolution processing in two-step algorithm is detailed analyzed. It can be found that the operation can reduce the Doppler bandwidth effectively and overcome the alias of azimuth echo by making the residual Doppler bandwidth smaller than PRF. The formula of residual Doppler bandwidth is derived here. According to the formula, range large bandwidth signal has influence on the residual Doppler bandwidth, which is not considered in the traditional imaging algorithm. In the high resolution sliding spotlight space-borne SAR system, the residual Doppler bandwidth is affected largely by the wide range bandwidth. PRF should be larger than the residual Doppler bandwidth in two-step algorithm; else it will result in defocus of the SAR image. The computer simulation is given to verify the presented analysis. [C956]

#### **"The HF surface wave radar WERA. Part II: Spectral analysis of recorded data"**

This paper covers the second part of the analysis of data recorded by the surface wave (SW) over-the-horizon (OTH) WEllen RADar (WEA). Data were collected by two WERA systems, on May 13th 2008, during the NURC experiment in the Bay of Brest, France. The principal aim of this work is to provide an accurate characterization of the spectral components of the received signal. Secondly, this information is exploited in order to provide a simple and reliable spectral modeling tool. For this reason, auto-regressive (AR) models, also known as linear prediction (LP) models have been investigated. Our results show that at long distances, when the clutter-to-noise power ratio (CNR) is small, the main components of the spectrum can be reasonably described by an AR(12) model, with a good compromise between accuracy and simplicity. As the CNR increases higher-orders are instead to be preferred. [C957]

#### **"Delay-Doppler radar tracking using moments"**

In this paper, we propose a new blind approach for joint time delay and Doppler estimation. The delay and Doppler have been imposed onto a signal modeled as a Gaussian mixture contaminated by a non-Gaussian and non-stationary noise. The estimation is done using the moments of received signal. This procedure provides lower complexity and more accuracy relative to other rival methods such as Wigner-Ville (WV) and wavelet transform. In this method, the noise power is assumed unknown and estimated as well. Then, the proposed delay and Doppler estimation is used for radar tracking. Based on the estimated delay and Doppler, we track the position and velocity of the target. We compare the new approach against extended Kalman filter and particle filter tracker. [C958]

#### **"A probabilistic model of the radar signal-to-clutter and noise ratio for Weibull-distributed clutter"**

We consider four effects relevant to the determination of the ratio of radar signal to clutter and noise. These effects are atmospheric turbulence, target fluctuations based on the Swerling models, zero-mean Gaussian background and receiver noise, and Weibull-distributed clutter. Radar return signal levels are affected by target

fluctuations and atmospheric turbulence, characterized by target fluctuations according to the Swerling models and a lognormal distribution, respectively. Since these distributions are not independent and identically distributed (IID), they cannot be simply added, and must be treated by combining them in a manner similar to convolution. Also, clutter and noise are not IID, and must be combined in a similar way. The ratio of these two combinations comprises a probabilistic model of the ratio of radar signal to clutter and noise. This ratio is the probability that a given signal level will be achieved in the presence of atmospheric and target scintillations divided by the probability that a given clutter and noise level will be observed. To determine the ratio of the actual signal to clutter and noise, we must multiply these probabilities by the mean powers resulting from these phenomena, as will be shown later. We treat several cases of interest by varying the average radar cross section, the log intensity standard deviation of turbulence, the radar threshold-to-noise and signal-to-noise ratios, and the distribution of Weibull clutter mentioned above. [C959]

#### **"Compressed Sampling for pulse Doppler radar"**

This paper presents a study of how the Analogue to Digital Converter (ADC) sampling rate in a digital radar can be reduced-without reduction in waveform bandwidth-through the use of Compressed Sampling (CS). Real radar data is used to show that through use of chirp or Gabor dictionaries and Basis Pursuit (BP) the ADC sampling frequency can be reduced by a factor of 128, to under 1 mega sample per second, while the waveform bandwidth remains 40 MHz. The error on the reconstructed fast-time samples is small enough that accurate range-profiles and range-frequency surfaces can be produced. [C960]

#### **"Evaluation of modulus-constrained matched illumination waveforms for target identification"**

In prior work, we have applied matched illumination strategies to target identification by a closed-loop radar system. In the closed-loop system, multiple waveforms are transmitted in succession, but each is customized based on the returns from prior transmissions. In this prior work, however, the matched waveforms were not constrained to be constant modulus. This current paper evaluates the performance of closed-loop radar with constant-modulus matched illumination. We also compare the performance of non-constant-modulus illumination under a peak power constraint. Finally, we use simple target models and assume unknown orientation, rather than the deterministic or Gaussian target models used in earlier work. [C961]

#### **"Super-resolution techniques in meteorological radars: The example of wind turbines"**

The use of wind turbines to generate electricity has become a major problem in meteorological radars. Due to the low frequency resolution that these radars show, the most representative wind turbine radar signature characteristics can't be observed in operational exploration modes by using the classical Fourier spectral estimation. In this paper, we propose super-resolution techniques to improve Fourier's Doppler resolution and provide experimental results. [C962]

#### **"Human gait classification using microDoppler time-frequency signal representations"**

A time-frequency classifier is applied for human gait classification. Time-frequency (t-f) quadratic distributions are used for time-frequency signal representations. Three specific motions are considered, corresponding to three different scenarios of arm motions which describe free and confined arm swings. The microDoppler signature in the time-frequency domain of each motion style is viewed as a feature and is incorporated in a distance-based classifications measured between the test data t-f distribution and the training average t-f distributions. It is shown that the time-frequency classifier performs properly, yielding low probability of classification errors, and its performance is rather insensitive to the type of time-frequency distribution employed. Among the possible distance measures used, which include the Correlation, Bhattacharyya and Kolmogorov, the Euclidean distance provided the best results. [C963]

#### **"Adaptive strategies for discrimination between mainlobe and sidelobe signals"**

We address adaptive discrimination between the signal of interest and a sidelobe interferer. To this end, we propose a detector derived resorting to a GLRT implementation of the generalized Neyman-Pearson rule and a two-stage detection scheme. The adaptive detectors rely on secondary data, free of signal components, but sharing the statistical characterization of the noise in the cell under test, in order to guarantee the CFAR property. [C964]

#### **"Performances and limitations of Persistent Scatterers-based SAR calibration"**

The PS calibration combines external devices, like corner reflectors, transponders and the stable targets in the scene to provide continuous monitoring of the radiometric quality of a SAR instrument. The goal is to provide, on

the bases of image blocks (say 10 Ч 10 km), the precise geolocation and the radiometric calibration information. The capability of selecting such targets, their intrinsic stability and the performances achievable by a PS-aided approach are investigated in this paper. [C965]

#### "UWB radar and leaky waveguide for fall on track object identification"

This paper presents a new system for detecting and identifying objects fallen onto railway tracks. The proposed solution is based on an ultra-wideband (UWB) radar technique combined with a slotted waveguide transmission line. A rectangular section, slotted waveguide is maintained all along the railway platform and used as a succession of monostatic radars. A design procedure is described. A procedure of extraction of target's electromagnetic signatures is discussed; simulation results are produced. [C966]

#### "Robust short-range clutter suppression algorithm for forward looking airborne radar"

The short-range clutter has serious range dependence for forward looking airborne radar (FLAR). As a result, when a radar detects moving targets on far range gates, the ambiguous short-range clutter degrades the performance of ground moving target indication (GMTI) obtained by space-time adaptive processing (STAP). The elevation three dimensional adaptive processing can well mitigate the problem, but, the computational load of the method is too heavy to be applied in real scenarios. A robust elevation pre-filtering algorithm is proposed. This method does not need adaptive processing on the elevation elements in a planar-array antenna. Therefore, the computational load can be reduced greatly. This method suppresses the ambiguous short-range clutter by multi-elevation angles restriction and the cancellation weight on the clutter has a deep and wide notch. Moreover, the method is robust to the elevation angle errors. Simulation results show the validity of the method. [C967]

#### "Blind multipath separation for waveform recovery"

The separation of multipath signal components by spatial filtering in a narrowband antenna array is addressed for cases where diffuse scattering and array calibration errors may cause the spatial signatures of the received propagation modes to deviate significantly from the plane-wave array manifold. The distorted wavefronts may have complex spatial signatures that are difficult to accurately characterize and mutually resolve on the basis of array manifold models described by few parameters. Furthermore, the temporal signature of the source waveform may also be quite arbitrary, with no known deterministic or statistical properties that can be utilized for multipath separation. This problem calls for blind waveform estimation methods that rely on relatively mild assumptions. An alternative blind spatial filtering technique referred to as the Generalized Estimation of Multipath Signals algorithm, or GEMS, is introduced for this purpose and tested on experimental data provided by the high frequency (HF) radar program of the Defence Science and Technology Organization (DSTO), Australia. [C968]

#### "Efficient construction of training database for identification of aircraft HRR profiles"

High resolution range (HRR) profiles show one-dimensional radar images including the electromagnetic scattering phenomena of a target. Thus, they are not only robust to noise, but also easily obtainable in real-time. However, in order to construct a training database for successful radar target identification, a huge number of HRR profiles are needed, because they are highly dependent on the relative angle between the radar and target. In order to alleviate this difficulty, a database construction method based on the scenarios of the target's movement is proposed. The proposed method is able to provide reliable target identification performance even with a small training database. [C969]

#### "The effect of clutter on the automatic target classification accuracy in FSR"

The clutter influence on the automatic target classification (ATC) accuracy in forward scattering radar (FSR) is presented. To study the ATC at various signal-to-clutter ratios (SCR), a simulated vegetation clutter is artificially added to the real clutter-free targets recorded signals. It is shown that using conventional clutter-uncompensated ATC system can achieve high target classification accuracy at high SCR only, but the accuracy drops significantly with SCR decreasing. The employment of clutter-compensated ATC system is shown to improve significantly the classification accuracy at low SCR. [C970]

#### "SAR raw signal simulation based on sub-aperture processing"

A novel algorithm for SAR(Synthetic Aperture Radar) raw signal simulation based on sub-aperture processing is proposed. The fundamental of the algorithm is analyzed, the signal model is deduced, as well as the simulation procedures are given. Simulation results of extended scene have shown that in the condition of meeting simulation precision, the simulation speed of the algorithm is higher than that of the echo simulation algorithm based on 1D FFT(Fast Fourier Transform). [C971]

### "Parallel implementation of the wideband DOA algorithm on the IBM Cell BE processor"

The Multiple Signal Classification (MUSIC) algorithm is a powerful technique for determining the Direction of Arrival (DOA) of signals impinging on an antenna array. The algorithm is serial based, mathematically intensive, and requires substantial computing power to realize in real-time. Recently, multi-core processors are becoming more prevalent and affordable. The challenge of adapting existing serial based algorithms to parallel based algorithms suitable for today's multi-core processors is daunting. One multi-core processor will be focused on, namely the IBM Cell Broadband Engine Processor (Cell BE). The process of adapting the serial based MUSIC algorithm to the Cell BE will be analyzed in terms of parallelism and performance for DOA determination. [C972]

### "Understanding the signal structure in DVB-T signals for passive radar detection"

This paper provides a detailed overview of Digital Video Broadcasting Terrestrial (DVB-T) signal structure and the implications for passive radar systems that use these as illuminators of opportunity. In particular, we analyze the ambiguity function and make explicit its features in delay and Doppler in terms of the underlying structure of the DVB-T signal. Ambiguities will be managed via the development of a set of mismatched filter weights that will be applied to the reference signal prior to range-Doppler map formation. The development of the mismatched filter is based on previous work with an extended improvement for ambiguity peak reduction a wider variety of DVB-T signals. [C973]

### "Experimental results for OFDM WiFi-based passive bistatic radar"

In this paper the practical feasibility of a WiFi transmissions based passive bistatic radar (PBR) is analyzed. The required data processing steps are described there including the adopted techniques for: (i) the control of the signal Ambiguity Function usually yielding a high sidelobe level and (ii) the removal of the undesired signal contributions which strongly limit the useful dynamic range. The performance of the conceived system is evaluated with reference to typical signals broadcasted by a IEEE 802.11 access point exploiting an OFDM modulation. The achievable results are presented against a real data set collected by an experimental setup. This allowed us to preliminarily demonstrate the potentialities of a WiFi-based PBR for local area surveillance applications. [C974]

### "Suppression of sidelobes and noise in airborne SAR imagery using the Recursive Sidelobe Minimization technique"

The Army Research Laboratory (ARL) has recently developed the Recursive Side-lobe Minimization (RSM) technique (patent pending). The technique is integrated with a standard back-projection algorithm to form synthetic aperture radar (SAR) images with significant reduction in side-lobes and noise. We have achieved significant improvements in noise reduction by applying the RSM technique to our Ultrawideband (UWB) Synchronous Impulse Reconstruction (SIRE) forward-looking radar. This paper presents the application of the RSM technique using data from a side-looking airborne SAR system from SRI International. We describe the RSM technique, the SAR data processing, compare the baseline and RSM SAR images, and quantify the image quality in term of signal-to-noise ratio (SNR) and the statistical distribution of the image pixels to show that significant improvement achieved using the RSM technique. [C975]

### "MIMO radar sparse angle-Doppler imaging for ground moving target indication"

We present in this paper a regularized sparse signal recovery algorithm, referred to as sparse learning via iterative minimization (SLIM), to provide ground moving target indication (GMTI) through multiple-input multiple-output (MIMO) radar angle-Doppler imaging. A slow-time modulation scheme with code division multiplexing is employed to achieve transmit diversity. In this way, we avoid the high correlation properties of orthogonal waveforms and the Doppler ambiguity that is encountered with Doppler division multiplexing schemes. After removing jammer and clutter effects using semi-unitary projections, we show that SLIM, using primary data only, is able to form sparse angle-Doppler images and to provide for accurate target localization. [C976]

### "Simulation of radar signal on wind turbine"

This paper describes the radar signal features of a typical wind turbine and the simulation of the wind turbine signal based on a high resolution Doppler radar. The simulated signal is under-sampled with lower PRF to match an air traffic control (ATC) radar. The simulated signal is compared to the ATC radar data collected at two different sites. Remarkable similarities of the signal features are identified. These features may help to improve the primary radar detection and tracking performance in the future. [C977]

### "Analysis of MIMO radar ambiguity functions and implications on clear region"

Multiple input multiple output (MIMO) radar offers the potential for improved performance over more traditional single input multiple output (SIMO) radar. MIMO radar operates by transmitting separable waveforms from multiple transmitters and the resulting radar echos are received by multiple receivers. While there is a great deal of literature discussing the benefits of MIMO techniques, a handful of publications discussing the limitations of MIMO radar techniques have appeared in the literature. Of particular interest is the work addressing the reduction of the clear area in range-Doppler space. Using a particular form of the MIMO ambiguity function, it was shown for a MIMO radar transmitting  $N$  waveforms there is a reduction of the clear area by a factor of  $1/N$ . In this paper, we repeat this analysis for the ambiguity function applicable to a coherent MIMO radar. We show the MIMO ambiguity function proposed in does not fully capture some important features of coherent MIMO radar and differs from versions of the ambiguity function proposed by other authors. In the second half of this paper, we derive the MIMO ambiguity function for coded pulse train waveforms. In addition to the traditional narrowband assumption, we develop the MIMO ambiguity function using the "start-and-hop" radar signal model. [C978]

### "Range and Doppler walk in DVB-T based Passive Bistatic Radar"

This paper analyzes the effects of range and Doppler walk for a Digital Video Broadcast-Terrestrial based Passive Bistatic Radar of both simulated and experimental data. Range and Doppler walk cause energy dispersal in the correlation, thus the coherent integration time is limited by the bistatic velocity and acceleration. A method using the readily available Doppler information to compensate for the range displacement during integration due to non-zero bistatic velocity of target is described. By compensating and non-coherently adding several coherently processed intervals, the target signal to noise ratio is increased. [C979]

### "An indoor S-band radar receive array testbed"

This paper describes a multi-channel S-band radar receive system designed as a laboratory testbed system for studying wideband radar array signal processing. The receive array was designed using a combination of low-cost commercial-of-the-shelf components and a custom-designed surface-mount printed circuit board assembly. It has been tested using LFM-CW waveforms with a center frequency of 2.4 GHz and a bandwidth of 600 MHz. By using components manufactured to operate in the "Wi-Fi" wireless communications band, the cost of the system has been minimized. This paper presents the design of the system, test results, and some sample ARD surfaces from the system. [C980]

### "SKP-shrinkage estimator for SAR multi-baselines applications"

The physical properties that can be inferred from Radar data are strictly related to the kind of diversity that characterizes the data itself. Spatial (i.e.: baseline) diversity provides information about target locations, temporal diversity provides information about target displacement, whereas polarimetric diversity provides information about the target electromagnetic behavior. In all cases, covariance matrix estimation is a key issue in the framework of coherent SAR analysis of scenarios characterized by the presence of distributed targets, such as bare or rock surfaces, forested areas, or ice shelves. In this paper we consider the case where two different kinds of diversities are present within the data, such as spatial and temporal or spatial and polarimetric, and investigate the effectiveness of the shrinkage estimator for the data covariance matrix. The shrinkage estimator is obtained as an optimum convex combination between the sample covariance matrix and the structured estimator. The structured estimator is based on the hypothesis of separability of the coherence losses due to the different kinds of diversities within the data, for each target that contributes to the received signal. This hypothesis leads to expressing the data covariance matrix as a Sum of Kronecker Products (SKP), for the estimation of which fast algebraic techniques exist. [C981]

### "A quantitative method for mono- and multistatic radar coverage area prediction"

The prediction of radar coverage as a function of the position of the radar has always been a key step in radar network planning. In the past, simple geometric models backed up by the deployment of siting radars were the only options for potential site evaluation, but the development of sophisticated propagation models (e.g. AREPS [1]) has moved the technology forward to another level of prediction accuracy. Modelling takes into account atmospheric refraction, as well as terrain effects and clutter. In previous papers [2], [3] we have shown that the modelling can also cater for multistatic radar systems. In this paper we have extended our modelling to give a statistical measure of the effectiveness of a site that measures the signal to noise ratio (SNR) or (for multistatic radar) the signal to interference ratio (SIR) over regions of interest. The area is pixellated into values of SNR and SIR, and pixels meeting the required SNR and / SIR are counted. We show some results for a multistatic radar.

We conclude by indicating how we plan to include ground clutter. We mention how this method of obtaining quantitative coverage performance can be used with all forms of radar, and will be able to improve future networks of cognitive radars. [C982]

### "Conjugate gradient parametric adaptive matched filter"

The parametric adaptive matched filter (PAMF) detector for space-time adaptive processing (STAP) detection is re-examined in this paper. Originally, the PAMF detector was introduced by using a multichannel autoregressive (AR) parametric model for the disturbance signal in STAP detection. While the parametric approach brings in benefits such as significantly reduced training and computational requirements as compared with fully adaptive STAP detectors, the PAMF detector as a reduced-dimensional solution remains unclear. This paper employs the conjugate-gradient (CG) algorithm to solve the linear prediction problem arising in the PAMF detector. It is shown that CG yields not only a new computationally efficient implementation of the PAMF detector, but it also offers new perspectives of PAMF as a reduced-rank subspace detector. The CG algorithm is first introduced to provide alternative implementations for the matched filter (MF) and parametric matched filter (PMF) when the covariance matrix of the disturbance signal is known. It is then extended to the adaptive case where the covariance matrix is estimated from training data. Important issues such as unknown model order and convergence rate are discussed. Performance of the proposed CG-PAMF detector is examined by using the KASSPER and other computer generated data. [C983]

### "Software-defined radar for MIMO and adaptive waveform applications"

The development of a software-defined radar testbed is described. The testbed is to be used to explore advanced techniques such as multiple-input multiple-output radar and adaptive waveforms. The system features a fully programmable, dual-channel, arbitrary pulsed waveform generator with a quadrature downconverting receiver. The system can generate waveforms of up to 500 MHz instantaneous bandwidth at a center frequency tunable from 2-18 GHz. The RF front end features two independent transmit and receive channels that can be multiplexed between four dual-polarized transmit and four dual-polarized receive antennas. [C984]

### "Design of unimodular sequences using generalized receivers"

This paper reviews recent advances in designing unimodular sequences with good auto/cross correlation properties along with a new approach that emphasizes on independent receiver design. The general problem is to design single or multiple sequences with constant modulus in the time-domain such that their respective matched filter outputs ideally resemble delta functions and the cross-matched filter outputs are zeros. In this context CAN (cyclic-algorithm new) and WeCAN (Weighted CAN) have been proposed for designing such sequences with good auto-cross correlation properties. In this paper, the equivalence of the CAN algorithms and the classic Gerchberg-Saxton (GS) algorithm involving the sequential magnitude substitution operations in the time and frequency domain is demonstrated. The design of unimodular sequences is further generalized here by considering the receiver design to be more general than the respective matched input sequences. The receiver design is carried out by taking care of the desired output requirements and the freedom present at the input can be used to further minimize the output side-lobe level. [C985]

### "Ambiguity Function analysis of WiMAX transmissions for passive radar"

In this paper the feasibility of a WiMAX transmissions based Passive Bistatic Radar (PBR) is analysed. The Ambiguity Function (AF) of the considered waveform of opportunity is characterized with reference to different transmission modes. The signal AF is shown to yield regularly spaced undesired peaks which might strongly limit the target detection capability of a WiMAX-based PBR. These sidelobe structures have a deterministic nature mainly related to the OFDM modulation exploited by WiMAX transmissions. A proper filter, based on the knowledge of the expected value of the signal Autocorrelation Function (ACF), is implemented to cope with this limitations and its performance is evaluated against simulated data generated according to the IEEE 802.16e Standard. The proposed approach is shown to yield an effective removal of the undesired peaks in the AF thus making the considered waveform more attractive for PBR medium range surveillance. [C986]

### "Radon transform and the modified envelope correlation method for ISAR imaging of multi-target"

In multi-target ISAR imaging, if the returned signals are range non-separable and the relative radial velocity is large. We can neither resolve them in range domain nor the Doppler frequency domain. In order to solve this problem, the use of the Radon transform and a modified envelope correlation method for multi-target ISAR imaging is presented. The radon transform is used to align the range profiles coarsely. For more accuracy alignment, a modified envelope correlation method is proposed. After range alignment, phase compensation is fulfilled by Discrete chirp-Fourier transform (DCFT). The simulation results show that the method proposed in

this paper is effective. [C987]

### "Tracking maneuvering target with particle filter techniques on passive radar using FM and DVBT broadcasting signals"

In this paper, we present a Track-before-Detect algorithm for maneuvering targets, with particle filter techniques on passive radar. The particle filter uses directly the correlation output from each transmitter to give Bayesian estimation for the position and the velocity of the target. We analyze the proposed technique with analog signals (FM broadcast signal) and digital signals (DVBT broadcast signals). [C988]

### "Distributed time reversal mirror array"

An array of independent, separate, distributed time-reversal mirrors (TRMs) that can function as a large array in a coherent (collective and co-operative) manner is described. Due to the unique feature of time-reversal to compensate for the propagation delay after round-trip, the DTRMA can perform coherent integration of signals across the array through distorting media without the need for complicated array calibration and precise geo-location procedures, even after the location of a TRM has been changed. Several proof-of-concept experimental results to show both temporal and spatial focusing properties of the DTRMA are demonstrated using commercially available off-the-shelf components and instruments. [C989]

### "3 GS/s S-Band 10 Bit ADC on SiGeC Technology"

In advanced applications such as digital radar, Ultra Wide Bandwidth communications and software defined radio, the need for instantaneous bandwidth often drives system design decisions. Access to high speed data converters enabling up and down conversion directly in the L Band and S Band removes the limit imposed by bandwidth scarcity and allows the design of flexible and simplified system architectures. Broadband ADC's (Analogue to Digital Converters) are key enabling components which open up new design opportunities for digital Receiver systems. In this regard, this paper describes a new 10bit 3GS/s ADC with 5 GHz Bandwidth, based on a 200 GHz SiGeC bipolar Technology, which enables the direct digitizing of 1GHz arbitrary broadband waveforms directly in the high IF region closer to the Antenna (L-Band or S-Band). [C990]

### "Ziv-Zakai lower bound on target localization estimation in MIMO radar systems"

This paper presents the derivation of the Ziv-Zakai bound (ZZB) for the localization problem in a MIMO radar system. The target is positioned in the near-field of a network of radars of arbitrary geometry. The radars have ideal mutual time and phase synchronization. The target location is estimated by coherent processing exploiting the amplitude and phase information between pairs of radars. An analytical expression is developed for the ZZB relating the estimation mean square error (MSE) to the carrier frequency, signal bandwidth, the number of sensors, and their location. From numerical calculations of the bound, three regions of signal-to-noise ratio (SNR) can be distinguished in the performance of the location estimator: a noise-dominated region, an ambiguity region, and an ambiguity free region. In the noise-dominated region, the signals received by the radars are too weak, and thus the localization error is limited only by the a priori information about the location of the target. In the ambiguity region, the performance of the location estimator is affected by sidelobes. In the ambiguity free region, estimation errors are very small and the ZZB approaches the Cramer-Rao lower bound (CRLB). [C991]

### "Analysis of multi-sensor radar detection based on the TBD-HT approach in ECM environment"

This paper describes in details the performance of an advanced detecting algorithm for multi-sensor target Track Before Detection (TBD) through the Hough Transform (HT). The detection algorithm employs the idea of using the Hough Transform for joint detection of linear trajectory targets. The polar modification of the TBD-HT approach is applied to a multi-sensor Polar Hough detector for multi-sensor target/trajectory detection in ECM environment with a Stand-off-Jammer (SOJ). A CFAR detector is proposed for signal detection in the (r-t) space instead of fixed thresholding in order to enhance the target detectability in ECM environment. In this paper a centralized structure of a multi-sensor Polar Hough detector is considered. The expressions calculating the probability characteristics, i.e. the probability of target/trajectory detection and the false alarm probability, are analytically derived. The multi-channel TBD-HT detector probability characteristics are compared with those for the conventional signal processing. [C992]

### "A spatiotemporal model for radar HRRP sequence recognition"

A temporal factor analysis (TFA) model which can describe both the spatial structure and temporal dependency of high range resolution profiles (HRRP) has been proposed for radar HRRP sequence recognition. Variational Bayes method and Bayesian classifier are adopted for model learning and classification task, respectively. The

favorable results based on measured data show the effectiveness of this model. [C993]

#### "A novel method to detect rotor blades echo"

In this paper, the effect of the main rotor of an armed helicopter on radar return signal and its modulation condition are considered. After analyzing references and experimental data, this paper proposes a new method based on inherent modulation in main rotor echo. This method is able to enhance the probability of detection. The simulation is performed for both simulated and practical echo signal. Simulation results confirm that our proposed scheme is effective. Moreover, a new domain for distinguishing and measuring the rotation feature of a rotary target is proposed. This paper is based on practical experiments (rotation domain). [C994]

#### "Autonomic subsystems for cognition in Passive Coherent Location"

In a previous paper we mentioned that Passive Coherent Location (PCL) can be thought of as Cognitive Radar. The deployment of PCL systems (also known as Passive Bistatic Radar-PBR) is fraught with difficulty, even in the situation of a spatially static network of transmitters and receivers. It is well known that PCL systems have to take into account the strong, direct signals of cooperative and opportunistic transmitters used, and try to use terrain or antenna nulls to mitigate the receiver dynamic range requirements. Receiver position in the terrain also influences the coverage. This results in a complex planning environment requiring propagation prediction tools to assist in selection of the best site. The situation becomes worse when the network of transmitter and receivers becomes dynamic. In this paper, we discuss the cognition and networking requirements for PCL systems consisting of moving transmitters and receivers, forming a cognitive, sensor network. We show that a sensible approach would use the structure of human intelligence, which consists of a higher level integrating function, together with autonomic, lower level, subsystems. [C995]

#### "Modeling and simulation study on radar Doppler signatures of pedestrian"

This paper focuses on radar Doppler signatures of pedestrian. Firstly, an improved human walking model which describes a pedestrian as a linear-rigid target is introduced. Then radar echoes of the pedestrian under the condition of continuous wave (CW) radar signal are acquired, formulas of instantaneous Doppler are derived and movement signatures of the target are analyzed. Simulation experiments are carried out to validate the model and theoretic analysis. [C996]

#### "Characterization of UWB Radar targets: Time domain vs. frequency domain description"

In this paper a characterization of UWB Radar targets is provided, both in the frequency domain and in the time domain. This is done by firstly giving a mathematical description of the Radar target in the UWB case, then providing measurement results. The proposed characterization allows for discerning and classifying UWB targets. Moreover, in this paper a full polarimetric analysis is taken into account. [C997]

#### "Cramér-Rao bounds and TX-RX selection in a multistatic radar scenario"

Multistatic radars utilize multiple transmitter and receiver sites to provide several different monostatic and bistatic channels of observation. Multistatic passive and active systems can offer many advantages in terms of coverage and accuracy in the estimation of target signal parameters but unfortunately their performances are heavily sensitive to the position of receivers (RX) and transmitters (TX) with respect to the target trajectory. As known, geometry factors play an important role in the shape of the ambiguity function (AF) which is often used to measure the possible global resolution and large error properties of the target parameters estimates. Exploiting the relation between the ambiguity function and the Cramer-Rao lower bound (CRLB), in this work we propose an algorithm for choosing in a multistatic scenario, along the trajectory of the tracked target, the pair TX-RX with the best asymptotic performance calculated in terms of CRLB on estimation accuracy. [C998]

#### "Preliminary results of ultra-wideband through-the-wall life-detecting radar"

It is often a difficult task of knowing the location or movement of people behind barriers. To address this problem, we develop a through-the-wall life-detecting radar (TWLDR) prototype. It is a kind of ultra-wideband (UWB) radar using impulse waveform, which can penetrate non-metallic walls to detect static and moving targets behind walls. We first introduce configurations of the radar system, then describe signal processing techniques, and present experimental results in different situations at last. Results indicate that the UWB TWLDR can penetrate non-metallic walls to detect people with different locomotion states such as standing, walking along cross-range direction, walking along range direction, and the signal processing algorithm could be applied to other complex environments. [C999]

### "A robust neural network based pulse radar detection for weak signals"

In this paper we develop a neural network capable of detecting targets with weak echoes in a pulse radar. This is possible as the network is designed as a pattern classifier (in contrast to earlier work) together with a suitable but simple pre-processing of the returns. We demonstrate through simulations that such a network exhibits better range resolution and noise tolerance when compared to previous work based on neural networks. In addition, we examine the Doppler tolerance and the overall robustness of the trained network. [C1000]

### "Digital beamforming with reduced number of phase shifting and time delay elements"

A bilinear representation of polynomials is shown to result in an efficient method for digital beamforming in phased arrays, with much reduced number of phase shifting elements. The proposed structure is also shown to extend to arrays with arbitrary complex weights. The number of phase shifting elements used is of the order of the square root of the number of phases used, with no limitations on the achievable patterns. Only phase shifters and combiners are used, with no splitters. The same concept applies to reduction of the number of delay elements in wideband beamforming, and also in reduction of the number of delay elements in continuous-time FIR filters. [C1001]

### "A robust Chinese remainder theorem with its applications in moving target Doppler estimation"

The Chinese remainder theorem (CRT) is an ancient result about simultaneous congruences in number theory, which reconstructs a large integer from its remainders modulo several moduli. It is well known that the CRT has tremendous applications in many fields, such as computing and cryptography, an important one of which could be radar signal processing and radar imaging. However, it is also well-known that CRT is not robust in the sense that a small error in any remainders may cause a larger error in the reconstruction result, which will lead to a non-robust estimation. In this paper, we introduce a robust reconstruction algorithm called robust CRT. We show that, using this robust CRT algorithm, the reconstruction error is upper bounded by the maximal remainder error range named remainder error bound, if the remainder error bound is less than one quarter of the greatest common divisor (gcd) of all the moduli. Although CRT has existed for about 2500 years, this robustness is the first time in the literature. Then, we show how this robust CRT can be used into the field of radar detection and Doppler ambiguity resolution, especially for fast moving targets, and later, simulations are given to illustrate the effectiveness and validness of this robust CRT algorithm. [C1002]

### "Modified Capon and APES for spectral estimation of range migrating targets in wideband radar"

In many radar and sonar applications, the narrowband signal assumption is not respected. To preserve good performance detection and/or parameter estimation for wideband signal, it is necessary to develop appropriate signal models and processing algorithms. More specifically, the range migration of the target during the processing interval induces a coupling between range and Doppler that is not taken into account by standard algorithms such as the Capon and APES methods. In this paper, we present a modified and enhanced version of the Capon and APES algorithms for a wideband signal model. These two algorithms are adaptive filters designed for spectral estimation. Performance of the wideband-Capon and the wideband-APES algorithms are studied via numerical simulations. [C1003]

### "On the design of mismatched filters with an adjustable matched filtering loss"

We present a method for the design of mismatched filters minimizing the interference from unwanted targets (point target or clutter) under the constraint of matched filtering loss. The method seeks to find the optimum filter minimizing the interference and having a desired cross-correlation with a given transmitter waveform. The method is applied to get the minimum integrated side-lobe level filters and to optimize the receivers of the pulse diversity systems. [C1004]

### "Impulsive noise excision and performance analysis"

Interference can be a major impediment to the operational performance of radar systems. A common source of interference is impulsive noise which may appear due to regional lightning discharges or local man-made noise sources. Impulsive noise is characterized as having a large amplitude and short duration and therefore only affects a small portion of the time series. Unpredictable frequency distortion may occur during the impulsive noise period, which is partially caused by the non-perfect response of the receiver front end. In this paper we present several linear prediction methods that are used to remove the impulsive noise without introducing frequency leakage over the signal band. Theoretical performances are analyzed and compared for these methods. The effectiveness of prediction methods relative to traditional excision techniques are also demonstrated using experimental data. [C1005]

### "Frequency domain motion compensation for stepped-frequency radar under multi-target scenario"

Target motion compensation method for stepped-frequency radar was studied. Under multi-target scenario, the conventional compensation method is invalid, and a method of compensation in frequency domain was presented. The method can be used for the compensation of multi-target with different velocities. Computer simulation results are given to verify the validity of the method. [C1006]

### "Three-dimensional reconstruction of a comet nucleus by optimal control of Maxwell's equations: A contribution to the experiment CONSERT onboard space craft Rosetta"

COMet Nucleus Sounding Experiment by Radio Wave Transmission (CONSERT) is one of 20 experiments onboard the ESA mission Rosetta and aimed at the reconstruction of the unknown internal material parameter distribution of a comet nucleus. The details on the experiment setup can be found in [1], [2]. CONSERT consists of a lander module which attaches to the surface of the comet and an orbiter module which circulates the comet in space. An electromagnetic sounding of the comet nucleus will be achieved by a signal link between the lander and orbiter antenna system. We propose an optimal control approach to solve for the unknown 3D material parameter distribution of the comet nucleus. We optimize the computed electromagnetic field distribution at the receiver locations for the measured (observed) electromagnetic field distribution by controlling the material parameters. The target functional, the difference between computed and observed field for all receiver locations and time steps is minimized by means of a gradient-based quasi-Newton optimization algorithm. The optimal control problem is solved if the target functional yields its global minimum. [C1007]

### "Joint Space-Based and Ground-Based Orbit Maneuver Identification Algorithms"

With the development of the outer space enterprise, it is very crucial to manage the spatial objects, especially in the way of the non-oneself object surveillance. However, orbit maneuver has brought the major difficulty to spatial object surveillance. To solve this problem, a new orbit maneuver identification algorithm, which is based on the joint of the space-based and the ground-based supervisory systems, is proposed in this paper. The simulation results show the reliability and feasibility of the proposed method. [C1008]

### "Research for D Stability of Uncertain Discrete Time-delay Systems"

D stability of uncertain discrete-time systems with time delay was studied. When the parameters were assumed to be time-varying within a certain interval matrices, the controller guaranteed that the closed-loop system was regular, causal and D stable. The explicit formula of desired controller WSS is provided by using the solution to the linear matrix inequalities (LMI). The numerical simulation result is provided to demonstrate the effectiveness of the presented method. [C1009]

### "Routing Path Selection and Power Allocation for Distributed Detection in Wireless Sensor Networks"

The design of wireless sensor networks for signal processing applications has to consider the limited battery power of the sensor nodes. In this paper, a combined routing path selection and power allocation strategy is presented that is especially designed for distributed detection in sensor networks with a serial topology. The objective is to minimize the global probability of detection error of the serial network under a total network power constraint. The cross-layer approach for the selection of a routing path through the network is based on the local observation SNR of the sensors as well as fading conditions and is efficiently implemented by a backward greedy algorithm. After the routing path is established, a subsequently performed power allocation algorithm aims to optimally distribute a total power budget with respect to the detection performance of the sensor network. [C1010]

### "Nondestructive Detection of Standing Trees and Radar Wave Detection"

To ensure the healthy growth of trees and avoid unnecessary loss, technologies and methods of nondestructive detection appears. In this article, a method, used in standing trees' nondestructive evaluation, is coming up after compared with several technologies' advantages and disadvantages which are now widely used in home and abroad. The method, radar wave detection of standing trees, is of practical significance because of its detection without any damage. The article presents its feasibility and how to implement it. [C1011]

### "Real Aircraft Navigation Data Statistic and Rule Analysis"

To understand the actual flying rules of aircrafts in air and discriminate real and simulated aviation, the actual

statistical navigation data is calculated in this paper. These data are collected from the real flight radar track and flight plan of ATC system. By means of statistical mathematics, the acceleration, deceleration, climb and descent rate, average speed, and probability densities of varieties of aircraft types are obtained. Varieties of aircraft types show different performance and flight rules by analysis of these graphs and charts. If the aircrafts are in a similar class such as A319, B737, and B757, their flying performance would have little difference in the analysis result above. Otherwise the difference is obvious, e.g. YN12 and A319 etc. The result indicates that it is very important to consider the influence of flight condition, performance, ATC rules, regulations of airline companies, and pilots' operation habits, which are important factors to improve the fidelity of flight simulation. [C1012]

### "Technology and innovation radar-Effective instruments for the development of a sustainable innovation strategy"

This paper summarizes several years of experience in process design and methodology implementation for sustainable innovation development as carried out by the authors within several innovation projects in different industries (e.g. fixed and mobile telecommunication, high tech, logistic). The formularization of our experience has led to a research innovation approach that enables an effective innovation intelligence and technology scouting through the use of a technology and innovation radar methodology. These instruments allow the identification and evaluation of emerging business and technology trends, provide an overview of the relative maturity and assess their relevance for the company. A rating mechanism helps companies to decide when to adopt an innovation and to develop new products and services. Furthermore, the technology and innovation radars are good strategic tools for early stage identification and prioritization in order to give an approximate value judgment without detailed return on investment justifications. In later stages of the planning process, the radar tools can be used as a high-level summary of an underlying prioritization process. [C1013]

### "A Bayesian perspective on sparse regularization for STAP post-processing"

Traditional Space Time Adaptive Processing (STAP) formulations cast the problem as a detection task which results in an optimal decision statistic for a single target in colored Gaussian noise. In the present work, inspired by recent theoretical and algorithmic advances in the field known as compressed sensing, we impose a Laplacian prior on the targets themselves which encourages sparsity in the resulting reconstruction of the angle/Doppler plane. By casting the problem in a Bayesian framework, it becomes readily apparent that sparse regularization can be applied as a post-processing step after the use of a traditional STAP algorithm for clutter estimation. Simulation results demonstrate that this approach allows closely spaced targets to be more easily distinguished. [C1014]

### "Autonomous Lockout Map Construction Technique for Secondary Surveillance Radar Mode S network"

Secondary Surveillance Radar (SSR) Mode S is an air traffic control radar system with improved surveillance and datalink capability. Recently, SSR mode S network attracts attentions as a way to solve problems such as the interrogator identifier code problem or radio frequency (RF) signal environment pollution. In SSR mode S network, each site has lockout map. Lockout is a command from GS to aircraft. Aircraft stops replying to all-call if it receives lockout. Lockout map determines area where GS lockout aircraft. There are several problems in current lockout map. First, it is difficult to create optimum lockout map. Second, it becomes complex to allocate and manage lockout maps if many sites join network. As the number of sites increase, Mode S operator has to prepare many maps. To solve these problems, we propose the Autonomous Lockout Map Construction Technique for SSR Mode S network. This technique enables Mode S GS to autonomously construct optimum lockout map by exchanging aircraft and site information through network. In this paper, we describe the background and details of the proposed technique. Then we show simulation results for validating the proposed technique. [C1015]

### "ISR sensor processing and data exploitation"

Intelligence, Surveillance, and Reconnaissance, commonly abbreviated as ISR, refers to the system of sensors (data collection assets) and data analysis and dissemination resources used to provide information about strategic and tactical threats. The advances in ISR sensor technologies and the large amount of data generated from ISR systems are putting a significant demand on signal processing and data exploitation. For example, an electro-optical system can easily generate several billion bits per second while searching an area the size of a small city. Therefore, onboard front-end signal processing is needed to reduce the amount of information to a manageable size and to make the outputs compatible with existing and future communication links. Similarly, there is increasing interest in allowing data exploitation on board the platforms. This talk will address examples of front-end signal processing, demands in data exploitation, and associated high-performance embedded

computing for ISR systems. The discussion will conclude with an emphasis on graph exploitation approaches to address the conversion of sensor information into knowledge that military forces and/or strategic analysts can act on in a timely manner. [C1016]

#### "Removing autocorrelation sidelobes of phase-coded waveforms"

This paper studies autocorrelation properties of a train of identical signals overlaid with a phase coding in the case when the uncoded signal forming the train consists of several groups of identical bits. It is shown that, if the coding patterns are the rows of a mutually orthogonal complementary set matrix, the waveform's autocorrelation sidelobes around the main lobe area can be completely removed. At the same time, repetition of some bits of the uncoded signal can be used to achieve a low sidelobe level in the close vicinity of the main lobe. [C1017]

#### "Radar sensitivity, receiver calibration, and sky noise"

Sky noise is highly anisotropic and well documented with maps available on-line. This sky noise can significantly affect radar sensitivity for radars with sensitive receivers. For ALTAIR at Kwajalein, the expected effect is as much as 8 dB. Documented changes of as much as 4 dB have been observed. The anisotropy of the sky noise can be used to calibrate receiver system noise. [C1018]

#### "The instagram: A novel sounding technique for enhanced HF propagation advice"

Modern OTHR systems make extensive use of propagation support information for parameter setup advice. A novel method for increasing dimensionality and temporal resolution of this advice is demonstrated here using an instantaneously wideband waveform on a one-way path. A composite of pseudo-randomly phased, discretized, massively multi-channel signals is synthesized through a simple summing scheme. Upon reception the composite is rapidly processed in the frequency domain to produce channel scattering information simultaneously across the band. The channels may be collapsed in the Doppler domain to reduce to conventional oblique ionograms. Total integration time required to produce the full Doppler ionograms, even with low transmit powers, is reduced over conventional methods by up to three orders of magnitude leading to the term 'Instagram'. The technique is implemented on an oblique sounding system that provides the necessary direct digital arbitrary waveform generation and reception capability. A result from the initial field trial is provided. [C1019]

#### "Modified Range-Doppler imaging method for the high squint SAR"

In this paper, a modified Range-Doppler (RD) algorithm with the Keystone Transform and the rank-deficient Capon is proposed for the shorter Synthetic Aperture Radar (SAR) imaging in the high squint mode. With the decrease of the aperture time under the squint mode, the linear range-walk becomes the dominant part of the range migration. The Keystone Transform is well suitable for removal of the range walk. In order to achieve higher resolution in the azimuth domain with the shorter SAR, the rank-deficient Capon which is an efficient non-diagonal loading spectral estimation based on rank-deficient sample covariance matrix is adopted. Simulation results can obtain the finer SAR images of the proposed approaches. [C1020]

#### "X-band FMCW radar system with variable chirp duration"

For application in a short range ground based surveillance radar a combination between frequency modulated continuous wave (FMCW) transmit signals and a receive antenna array system is considered in this paper. The target echo signal is directly down converted by the instantaneous transmit frequency. The target range  $R$  will be estimated based on the measured frequency shift  $f_B$  between transmit and receive signal. Due to an extremely short chirp duration  $T_{chirp}$ , the target radial velocity  $v_r$  has only a very small influence to the measured frequency shift  $f_B$ . Therefore the radial velocity  $v_r$  will not be measured inside a single FMCW chirp but in a sequence of chirp signals and inside each individual range gate. Finally, the target azimuth angle is calculated utilizing the receive antenna array and applying a digital beamforming scheme. Furthermore, in order to unambiguously measure even high radial velocities, a variable chirp duration is proposed on a dwell to dwell basis. [C1021]

#### "Differential approach for Through-the-wall life signs detection"

A very simple and effective method for detecting life signs for Through-the-wall Imaging applications is proposed and tested on experimental data. The proposed method properly exploits a Continuous Wave Microwave Transceiver working at 10 GHz and takes advantage from the displacement of the chest due to the respiratory movement for deriving a simple differential approach for detecting the respiratory and the heartbeat activities from the measured electromagnetic field. The proposed strategy allows to detect life signs of people in furnished room under concrete walls. The measurement set-up and the applied signal processing strategies are presented. [C1022]

### "Stochastic system identification approach to radar data processing"

Space-time adaptive processing (STAP) algorithms typically consist of a data transformation step to reduce the number of degrees of freedom and a sampling step wherein radar returns from adjacent range bins are used to estimate interference statistics. The reduction in degrees of freedom, inadequate sample support, presence of target in sampled data, and range dependence of interference are some of the main reasons for STAP performance loss. In this paper, we present another approach to target detection and localization that mitigates these performance losses. The approach is based on the well-known stochastic realization algorithm from system identification theory. In this approach, we use the radar return data for a given range bin to identify a minimal stochastic state space model for the return data. The angle and Doppler for all targets in the range bin are computed from the state space matrices. All the computations involved use standard linear algebra. As interference statistics are not directly computed and since there is no sampling from adjacent range bins, the proposed approach is more robust to sample support, target in training and range dependence of clutter. A numerical comparison of the proposed approach with beam-space post-Doppler STAP using simulated data is given. [C1023]

### "Cramér-Rao lower bounds for monopulse calibration using clutter returns"

Successful geolocation of ground moving targets utilizing monopulse techniques requires accurate characterization of the array manifold (i.e. monopulse response to off-boresight targets) and antenna pointing information. Utilizing techniques similar, in spirit, to those applied in synthetic aperture radar (SAR) to estimate the Doppler centroid of an image, we develop techniques to accurately estimate azimuth monopulse slope and boresight shift of an airborne ground moving target indicator (GMTI) antenna utilizing clutter returns from normally scheduled CPIs that are also used for target detection and geolocation. A statistical signal model is developed for the clutter returns as observed through the monopulse channels. Cramer-Rao lower bounds (CRLB) are developed for monopulse slope and boresight shift and compared to CRLB developed with SAR centroiding techniques as summarized in the literature. Analytical and numerical CRLB results show potential gains of one to two orders of magnitude at moderate to high clutter to noise ratios for a sum-difference system. [C1024]

### "Advanced signaling strategies for the Hybrid MIMO Phased-Array Radar"

The Hybrid MIMO Phased Array Radar, or HMPAR, is a notional concept for a multisensor radar architecture that combines elements of traditional phased-array radar with the emerging technology of Multiple-Input Multiple Output (MIMO) radar. A HMPAR comprises a large number,  $MP$ , of T/R elements, organized into  $M$  subarrays of  $P$  elements each. Within each subarray, passive element-level phase shifting is used to steer transmit and receive beams in some desired fashion. Each of the  $M$  subarrays are in turn driven by independently amplified phase-coded signals. This paper proposes new transmit signal selection strategies based on the observation that some MIMO signal sets, such as those proposed by us previously, cause a very rapid sequential or raster scan across some field of view. Exploiting this property allows one to create and process multiple beams simultaneously. Furthermore, there exists a range-angle coupling in the transmit and receive signals that may lead to high-resolution target localization. [C1025]

### "Processing-based tuner gain correction in a wideband multi-channel receiver"

Modern radar systems often capitalize on advanced radio frequency components in the receiver front end to include wideband tuners and amplifiers, highly stable local oscillators, and high-speed analog-to-digital converters. Yet, technology demonstrators often emphasize either the hardware or the processing algorithm rather than the end-to-end system. This paper presents the hardware characterization of tuner-gain mismatch in a wideband multi-channel array and the subsequent signal processing calibration model. The gain model is empirically found to follow a T-distribution and is used to balance the amplitude across the tuners as part of the processing for time-frequency-beamforming. Phase is also shown to be the critical factor to completely correcting phase mismatch. Here, we present details of the wideband receiver front-end and the signal processing backend. [C1026]

### "Distributed energy-efficient scheduling for radar signal detection in sensor networks"

In this paper, we consider the problem of Neyman-Pearson detection of fluctuating narrowband radar signals using wireless sensor networks (WSNs), and we are interested in finding some approach which can optimize the signal detection performance jointly with the energy expenditure. Towards this goal, we propose a distributed and energy-efficient scheduling scheme to coordinate the communications between each sensor node and the fusion center. This scheduling scheme allows each sensor to make its own decision about when to send data to the

fusion center, according to its own information and without consulting any other sensors. This distributed scheduling approach greatly reduces the dependence on the fusion center, and also attains an appealing balance between the detection performance and the energy efficiency. [C1027]

#### "Range profile specific optimal waveforms for minimum mean square error estimation"

Optimal waveforms for minimum mean square error range profile estimation are investigated. An idealized measurement and waveform adaptation process is developed that yields optimal scene and range specific waveforms. This process is idealized in that during each cycle of the process, a large number of dwells are required. As part of our method, a modified version of the Adaptive Pulse Compression (APC) estimation method is used to estimate the range profile after each dwell cycle. The proposed method is analogous to the APC method in that it yields a set of range specific optimal waveforms, while the APC method yields a set of range specific optimal pulse compression filters. In certain scenarios, the measurement and waveform adaptation process yields range profile estimates that are significantly better than those derived by the APC method alone. [C1028]

#### "Detection and estimation of multi-pulse LFM CW radar signals"

The Wigner-Ville Hough transform (WVHT) has been applied to detect and estimate the parameters of linear frequency-modulated continuous-wave (LFMCW) low probability of intercept (LPI) radar waveforms. The WVHT, which is optimal for a single linear frequency modulated (LFM) signal, becomes sub-optimal when applied to LFMCW signals since the observed waveform is composed of concatenated LFM pulses. We formulate the detection and estimation problem to take into account the multiple pulses that are available in an observation interval at the intercept receiver. The new algorithm, called the periodic WVHT (PWVHT), is shown to significantly outperform the WVHT for LFMCW signals. [C1029]

#### "Detection in heterogeneous clutter by filter output prediction"

This paper introduces an innovative method for ground moving target indication with a multichannel air or spaceborne radar. It is based on comparing the power of the filtered receive signal with a predicted power level. This prediction is found using data from the range line under test only. No potentially misleading prior magnitude information is employed. Thus, the false alarm probability is stabilized and the method is especially suited for rapidly varying heterogeneous terrain. [C1030]

#### "Resolution of two point targets using sub-arrayed MIMO radar"

Recent works on MIMO radar have shown benefits in optimising the signal covariance matrix for estimation of target parameters, over the performance of conventional radar and the orthogonal waveform approach used in much of the MIMO radar literature to date. The full diversity approach requires a large amount of flexibility at the transmitter and computation prior to transmission. In this work, we study the performance of a sub-arrayed transmit beamforming approach for MIMO Radar, which greatly reduces the requirements of the transmitter, for the important case of resolving two point targets. [C1031]

#### "Multi-modal sensor system integrating COTS technology for surveillance and tracking"

The feasibility of low-cost, Commercial Off-The-Shelf (COTS) sensor nodes is studied in a distributed network, aiming at dynamic surveillance and tracking of ground targets. Data acquisition by the low-cost (<\$50 US) miniature radar is described. We demonstrate the detection, ranging and velocity estimation capabilities of the mini-radar, and compare results to simulations. Furthermore, we integrate the radar output with supplementary sensor modalities, such as acoustic and vibration transducers, and infrared sensors. The method provides innovative solutions for detecting, identifying, and tracking vehicles and dismounts over a wide area in noisy conditions. This study presents a step towards distributed intelligent decision support and demonstrates effectiveness of small cheap sensors in identifying unique but similar events. Our work supports a pervasive sensor implementation relevant to the affordable open system architecture attribute of the U.S. Air Force Layered Sensing paradigm. [C1032]

#### "Validating multipath responses of moving targets through urban environments"

This work proceeds from the paper we published in RadarCon 2009 titled "Multistatic scattering from moving targets in multipath environments", where we explored the potential to track moving ground targets with radar as they enter urban areas and become obscured by buildings. An X-band radar data collection was performed which validates the predicted multipath response, and the received multipath power in relation to the line-of-sight (LOS) response. Results from a bistatic experiment are used to examine the spatial coherency of energy

reflecting from a large, rough surface, and the power distribution in angle that illuminates a target as it traverses in front of a building. This experiment may inspire knowledge-based methods to coherently process multipath returns, beyond that of standard GMTI processing, i.e., free-space matched-filtering (FFT) and CFAR detection. [C1033]

#### "Switched array concepts for 3-D radar imaging"

A number of antenna array concepts are investigated for three-dimensional radar imaging. The concepts are based on switched arrays and wide-band signals to generate a virtual array or co-array to span a sector volume in the wave vector space to get image resolution. The proposed arrays can be used for short range imaging in penetrating radar applications. This approach is quite general and it can also be used in other system concepts. Virtual arrays have mostly been used in radio astronomy and ultrasonic imaging. The related synthetic arrays with antenna motion have been more common in radar systems. [C1034]

#### "Null placement in a circular antenna array for Passive Coherent Location systems"

Passive Coherent Radar (PCL) is heavily constrained by the level of direct signal illumination. This paper investigates null steering techniques for a circular array antenna. An 8-element circular array has been designed and a method is proposed to steer multiple nulls in different directions. We present computed performance for two nulls achieved simultaneously. An 8 element dipole array has been constructed and the VSWR results are presented. This antenna will form the basis of practical null formation measurements. [C1035]

#### "Real-time tracking of bullet trajectory based on chirp transform in a multi-sensor multi-frequency radar"

Radar-based tracking technologies enable sub-time-of-flight bullet detection and trajectory tracking before the bullet reaches its target and thus lead to effective reduction of injuries and casualties. The capability of robust detection, tracking, and trajectory prediction in a weak signal environment directly translates to the awareness time for force protection. In this paper, we develop a multi-sensor multi-frequency radar platform and proposed the use of piecewise chirp transform for effective signal enhancement when the Doppler signatures are highly time-varying. Performed upon the time-frequency representations with improved phase information, multi-sensor multi-frequency radars uniquely localize and track bullets through unambiguous range and direction-of-arrival estimations. [C1036]

#### "Dynamic direction-of-arrival estimation via spatial compressive sensing"

This work addresses a problem of dynamic spatial spectrum estimation using linear sensor array via spatial compressive sensing (SCS). Static SCS approach is generalized for scenarios with dynamic far-field sources via Kalman filter, which provides the noncoherent minimum mean squared integration of instantaneous spatial spectrum estimations. The proposed dynamic SCS approach (DSCS) is shown to be efficient in low-SNR scenarios when the spatial spectrum is nonsparse, and therefore, the static SCS-based method cannot be used. Performance of the DSCS was evaluated in bearing-only target tracking scenarios where maneuvering target was considered. [C1037]

#### "A modified range migration algorithm for airborne squint-mode spotlight SAR imaging"

Due to the reference signal based on the fixed reference range is used in the range migration (RM) algorithm, the RM algorithm is not available to process an airborne squint-mode spotlight synthetic aperture radar (SAR) data. Thus, a modified RM algorithm is developed, which can be applied on processing large scene squinted-mode spotlight SAR data without division. Based on the squint-mode spotlight SAR imaging geometry, the modified reference signal is used to dechirp the received signal. Then, using the principle of stationary phase, the presented formulation of the modified RM algorithm is analyzed. Finally, the effectiveness of the proposed method is demonstrated by some numerical simulations via a squint-mode spotlight SAR simulator. [C1038]

#### "Terminal Doppler Weather Radar enhancements"

The design of an open radar data acquisition system for the Terminal Doppler Weather Radar is presented. Adaptive signal transmission and processing techniques that take advantage of the enhanced capabilities of this new system are also discussed. Results displaying data quality improvements with respect to problems such as range-velocity ambiguity and moving clutter are shown. [C1039]

#### "Firm track loss due to M of N track initiation of a radially inbound target"

This paper examines the firm track loss incurred by a fixed frame time radar performing track initiation using search detections. Firm track loss is the additional beam energy needed to achieve a desired firm track probability on a radially inbound target compared to a stationary target at that same firm track range. Firm tracks are established using an M or more detections out of N observations criteria. The firm track loss in dB is nearly linear with the product of velocity and frame time divided by firm track range. It is also insensitive to probability of false alarm and target radar cross section fluctuation models. It can be represented by a simple quadratic equation. The loss can be included in a radar range calculation worksheet such as a Blake chart to predict firm track range. A linear relationship is found between the firm track range of a moving target and a stationary target. [C1040]

#### "Moving targets tracking for homeland protection applications: A multi-sensor approach"

The paper deals with the problem of detecting, localizing and tracking individuals through the walls by means of radio-frequency based imaging techniques. The authors presents hereinafter a new imaging method for locating and tracking the position of hidden targets (e.g. human bodies in rescue missions) thanks to the use of a multi-sensor approach. A model-based signal processor has been also developed and tested. Numerical examples confirm the effectiveness of the proposed approach and procedures. [C1041]

#### "OFDM waveforms for multistatic radars"

In this paper, the benefits of OFDM waveforms are analyzed for multistatic radar systems, where several radar stations cooperate in the same frequency band. The signal is coded over a 2D pattern, in the time and the frequency domains, using orthogonal Golay complementary sets derived from Reed-Muller codes. Binary data are also encoded in the signal. The obtained ambiguity and cross-ambiguity functions show that the OFDM signal structure is well adapted for radar applications. Transmitted waveforms have relatively low interference and sidelobe levels in the range and Doppler axis. [C1042]

#### "Phase-coded-linear-frequency-modulated waveform for low cost marine radar system"

This paper proposes a continuous waveform to realize low transmitted power in a Radar system. The proposed waveform utilizes a pulsed compression scheme based on phase-coded modulation and linear FM which combines the desirable properties of both types of modulation. This paper also verifies waveform operation under channel effects such as multipath and noise. We determine power optimization due to waveform compression gain for given system specifications and use correlation values to detect both unambiguous range and Doppler shift. With a pre-determined noise and Doppler threshold, we can distinguish targets from sea clutter. Finally, we show the improvement in accuracy of elevation measurements by simulation when auto-correlation instead of signal strength ratios are used to determine target height. [C1043]

#### "Efficient pulse-Doppler processing and ambiguity functions of nonuniform coherent pulse trains"

We propose a DFT based pulse Doppler processing receiver for staggered pulse trains. The proposed receiver is a simple extension of traditional DFT based coherent pulse train processing. We show that P DFT processors are required to process the staggered train of pulses as a coherent signal, where P is the number of available pulse positions in each pulse repetition interval (PRI). Thus the complexity of the processing hardware only increases linearly with the number of available positions. We also look at the distribution of ambiguity volume around the delay-Doppler map by varying the pulse positions and the selection of pulse shapes. [C1044]

#### "Detection of complex point targets in a MIMO radar system with distributed assets and partially correlated signals"

A complex point target is a mathematical model for a radar target that is not resolved in space, but exhibits varying complex reflectivity across different bistatic view angles. The complex reflectivity can be modeled as a complex stochastic process whose index set is the set of all bistatic view angles, and the parameters of this stochastic process follow from an analysis of a target model comprising a number of ideal point scatterers randomly located within some radius of the targets center of mass. Six different models are summarized here, with different assumed distributions on the locations of the point scatterers within the target. We develop data models for the received signals from such targets in a MIMO radar systems with distributed assets and partially correlated signals, and consider the resulting detection problem. The problem reduces to the familiar Gauss-Gauss detection problem with hypoexponential test statistic. A related problem of adapting the transmitted signals to the target model is discussed. [C1045]

#### "Radacoustic detection of projectiles by a retrodirective radar"

An X-band retrodirective radar is shown experimentally to provide two signals from a firearm deployed at moderate range: (1) the normal reflection from the airborne projectile as it approaches the radar, and (2) a secondary reflection from the muzzle-blast acoustic wave. The combination of these two signals provides projectile bearing as well as an accurate estimation of range to the shooter by a differential time-of-flight calculation. [C1046]

#### "Low angle tracking using iterative multipath cancellation in sea surface environment"

In low angle tracking, signal reflection from sea surface leads to severe errors in the target angle of arrival (AOA) estimation owing to the presence of both a target and its image in the mainlobe. In this paper, we propose a new scheme that iteratively suppresses the specular reflected signal to alleviate estimation errors. The iterative processing, which includes estimating the target angle, calculating the reflected image angle and updating the null position in beamforming, is performed to eliminate the image signal; thus, the measured target AOA including error converges to the true value. Moreover, by exploiting phase comparison method using separate aperture, there is no need to consider the distortion of the monopulse slope caused by mainbeam nulling. Design examples are presented to explicitly ascertain the accuracy of the proposed technique in estimating the true target angle. [C1047]

#### "Scaling radar measurements for advanced algorithms"

This paper describes waveform diverse signal measurements using a two channel laboratory radar system. Using a combination of a Lab-Volt™ radar training system, Tektronix™ arbitrary waveform generator (AWG), Tektronix™ digital oscilloscope (DSO), and Tektronix™ real-time spectrum analyzer (RSA), a two channel, waveform diverse, multiple-input, multiple-output (MIMO) system is configured to collect both MIMO and bistatic radar measurements. In the experiments, the radar operates at X-band and samples the echoes at radio frequency (RF) before down-conversion into in-phase and quadrature (I/Q) channels. The laboratory environment does not need any special treatment as an anechoic chamber because the system uses very short duration and low power waveforms. Measured data for the MIMO radar is presented along with discussion of the bistatic configuration. [C1048]

#### "Feature extraction and optimization of representative-slice in ambiguity function for moving radar emitter recognition"

Radar emitter recognition is an important and challenging subject in radar signal analysis and processing. In this work, an ambiguity function (AF) representative-slice based feature extraction and optimization algorithm is presented for unintentional modulation recognition of moving radar emitters. It considers near-zero slices of AF as representative feature set of radar emitters, which not only coincides with the characteristics of real radar signals, but also mitigates the computation problem and avoids undesired cross terms in existing AF based method. Direct Discriminant Ratio (DDR) criterion is further utilized to preserve the most discriminant features and boost recognition accuracy, by ranking the kernel points along the representative-slice. Experimental results validate the practical usefulness and high stability of the proposed approach on real data of moving radar emitters, as well as synthetic radar data from U.S. Naval Research Laboratory. [C1049]

#### "Exponentially embedded families for multimodal sensor processing"

The exponential embedding of two or more probability density functions (PDFs) is proposed for multimodal sensor processing. It approximates the unknown PDF by exponentially embedding the known PDFs. Such embedding is of a exponential family indexed by some parameters, and hence inherits many nice properties of the exponential family. It is shown that the approximated PDF is asymptotically the one that is the closest to the unknown PDF in Kullback-Leibler (KL) divergence. Applied to hypothesis testing, this approach shows improved performance compared to existing methods for cases of practical importance where the sensor outputs are not independent. [C1050]

#### "Proportionate-type NLMS algorithms based on maximization of the joint conditional PDF for the weight deviation vector"

In this paper, we present a proportionate-type normalized least mean square algorithm which operates by choosing adaptive gains at each time step in a manner designed to maximize the joint conditional probability that the next-step coefficient estimates reach their optimal values. We compare and show that the performance of the joint maximum conditional probability density function (PDF) one-step algorithm is superior to the proportionate normalized least mean square algorithm when operating on a sparse impulse response. We also show that the new algorithm is superior to a previously introduced algorithm which assumed that the conditional PDF could be

represented by the product of the marginal conditional PDFs, i.e., that the weight deviations are mutually conditionally independent. [C1051]

#### "Multipath exploitation with adaptive waveform design for tracking in urban terrain"

We integrate multipath exploitation with adaptive waveform design in order to increase the tracking performance of a vehicle moving in urban terrain. Mitigation of both clutter and strong multipath returns can result in increased target detection. However, exploiting multiple bounces from obstacles such as buildings can be shown to increase radar coverage and scene visibility, especially in the absence of direct line-of-sight paths. For this purpose, we formulate the multipath propagation of an arbitrary number of specular bounces in urban terrain for three-dimensional motion. We then further exploit and optimize multipath returns by dynamically selecting the parameters of the transmitted waveform to minimize the predicted mean-squared tracking error. We demonstrate our proposed approach in a realistic urban environment by varying the type of measurement to include regions of obscuration and different number of multipath bounces. [C1052]

#### "A robust detector for uniformly distributed noise"

This paper proposes a robust detector for detection of known signals in impulsive noise environments. The distribution of the noise is assumed to be a mixture of Laplacian distribution giving a sharp peak around the true value of the signal of interest and uniform distribution modeling the contributions of completely unknown noise. This type of noise appears in problems related to estimated pitch periods. In the paper we derive a robust detector for this noise model and analyze its performance. [C1053]

#### "Performance analysis of the GLRT-based array receivers for the detection of a known signal corrupted by noncircular interference"

This paper presents a performance analysis of likelihood ratio test (LRT)-based and generalized likelihood ratio test (GLRT)-based array receivers for the detection of a known signal corrupted by a potentially noncircular interference. Studying the distribution of the statistics associated with the LRT and GLRT, expressions of the probability of detection (PD) and false alarm (PFA) are given. In particular, an exact closed-form expression of PD and PFA are given for two LRT-based receivers and asymptotic (with respect to the data length) closed-form expression are given for PD and PFA for four GLRT-based receivers. Finally illustrative examples are presented in order to strengthen the obtained results. [C1054]

#### "Statistical Resolution Limit for multiple parameters of interest and for multiple signals"

The concept of Statistical Resolution Limit (SRL), which is defined as the minimal separation to resolve two closely spaced signals, is an important tool to quantify performance in parametric estimation problems. This paper generalizes the SRL based on the Cramer-Rao bound to multiple parameters of interest per signal and for multiple signals. We first provide a fresh look at the SRL in the sense of Smith's criterion by using a proper change of variable formula. Second, based on the Minkowski distances, we extend this criterion to the important case of multiple parameters of interest per signal and to multiple signals. The results presented herein can be applied to any estimation problem and are not limited to source localization problems. [C1055]

#### "A closed-form pseudolinear estimator for geolocation of scanning emitters"

A closed-form solution for scanning emitter localization has been available for the case of three sensors. For more than three sensors the traditional approach is to employ the maximum likelihood estimator, which is a nonlinear estimator with no closed-form solution. This paper develops a new closed-form pseudolinear estimator for passive localization of scanning emitters for four or more sensors. The proposed estimator achieves localization performance on par with the maximum likelihood estimator at a much reduced complexity and free from stability problems that plague iterative numerical methods for finding the maximum likelihood estimate. The new estimator is based on a modification of the pseudolinear estimator for bearings-only localization. The superior performance of the developed estimator is illustrated with numerical examples. [C1056]

#### "Distributed TDoA estimation for wireless sensor networks"

A novel distributed TDoA (Time-Difference-of-Arrival) estimation method for wireless sensor networks (WSN) is proposed in this letter. Linear frequency modulation (LFM) waves are emitted from two anchors simultaneously to create an interference field. Through the frequency measurement of local RSSI (Received Signal Strength Indication) signal, the TDoA is estimated independently at each sensor to detect range difference from the sensor to the two anchors. Furthermore, an extended method applied to mobile sensors is also presented. The proposed method only relies on radio transceivers and requires no time synchronization for sensors. Simulations

results demonstrate the effectiveness of our method. [C1057]

#### **"A sparsity-driven joint image registration and change detection technique for SAR imagery"**

This paper presents a novel Sparsity-driven joint Image REgistration and Change Detection (SIRE-CD) technique for SAR imagery. The proposed algorithm simultaneously performs two main tasks: (i) locally register the test and reference images; and (ii) perform the change detection between the two. The key innovative concept here is the sparsity-driven transformation of the signatures from the reference image to match to those of the test image at the local image patch level. In other words, we are constructing a large dictionary from the reference data and use that to find the sparsest representation that best approximates the new incoming test data. The accuracy level of the approximation determines the detected changes between the reference and the test image. We demonstrate the performance of this technique using both simulated data and real SAR imagery from the Army Research Laboratory ultra-wideband (UWB) SAR forward-looking radar. [C1058]

#### **"Single antenna time reversal detection of moving target"**

This paper is concerned with a moving target detection using time reversal in dense multipath environments. We show that the Doppler shift in the time reversal re-transmission simplifies the detector design, yet still achieves the focusing effect. Thus, the Doppler diversity is utilized to achieve high target detectability by time reversal. [C1059]

#### **"Feature extraction in Through-the-Wall radar imaging"**

This paper deals with the problem of automatic target classification or Through-the-Wall radar imaging. The proposed scheme considers stationary objects in enclosed structures and works on the SAR image rather than the raw data. It comprises segmentation, feature extraction based on superquadrics, and classification. We present a recursive splitting tree to obtain optimum parameters for feature extraction. Support vector machines and nearest neighbor classifiers are then applied to successfully classify among different indoor targets. The classification methods are tested and evaluated using real data generated from synthetic aperture Through-the-Wall radar imaging experiments. [C1060]

#### **"Distributed target detection in Through-the-Wall Radar Imaging using the bootstrap"**

The problem of distributed detection and decision fusion in Through-the-Wall Radar Imaging (TWRI) is considered. We deal with the multi-viewing case in which images corresponding to different radar locations can be collected. We present a method to adapt conventional distributed detection schemes to the scenario when no a priori knowledge about image statistics from any view is available. Further, a new scheme for estimating quality information of local detectors in a distributed detection scenario is proposed. We apply bootstrap techniques to draw inference from the radar measurements of the behind the wall scene. Simulation results as well as experimental data are used to demonstrate the performance of the proposed approach. [C1061]

#### **"Multi-target tracking using multi-modal sensing with waveform configuration"**

We investigated the joint multi-modal operation of the asymmetric character of the fields of view of radar and electro optical (EO) sensors for multi-target tracking applications. We proposed a joint multi-modal sensing mode based on using dynamic agility selection to optimize the tracking performance of multiple maneuvering targets. The proposed method jointly designs waveforms for radar sensing and resolution switching modes for EO sensing, when both sensor measurements experience high false alarm rates. Rao-Blackwellized particle filtering is used to track an unknown number of targets within an adaptive framework that yields the optimized joint sensor configuration. We demonstrated the performance of the proposed adaptive tracking system using numerical simulations. [C1062]

#### **"Multichannel SAR Autofocus using multiple low-return constraints"**

MultiChannel Autofocus (MCA) and Reversed-step MCA (RMCA) for Synthetic Aperture Radar (SAR) assume a region of low return in the focused data, and work best when the region is known accurately. In practice, the returns from within the side-lobes of the antenna footprint are highly attenuated; thus a region of highly-probable low returns is provided. However, scene-dependent features like strong reflectors in the presumed low-return region may violate the assumptions underlying MCA and RMCA, with resulting performance degradation. We consider such a scenario and propose scene-independent, random selection methods of the low-return constraints. Our simulation results show that a well-focused image can be obtained within a few trials, even when the number of anomalies is moderately large. [C1063]

### "Bandwidth-intensive FPGA architecture for multi-dimensional DFT"

Multi-dimensional (MD) Discrete Fourier Transform (DFT) is a key kernel algorithm in many signal processing algorithms, including radar data processing and medical imaging. Although there are many efficient software solutions, they are not suitable for applications that require fast response time. In this paper we focus on FPGA-based implementation of MDDFT. The proposed architecture is based on a decomposition algorithm that takes into account FPGA resources and the characteristics of off-chip memory access, namely, the burst access pattern of the Synchronous Dynamic RAM (SDRAM). The architecture can support 2D, 3D, and even higher dimensional DFT with high performance. It has been implemented on a Xilinx Virtex-5 FPGA platform and its performance for 2D and 3D DFT measured and analyzed. [C1064]

### "Step-frequency radar with compressive sampling (SFR-CS)"

This paper proposes a novel radar system, namely step-frequency with compressive sampling (SFR-CS), that achieves high target range and speed resolution using significantly smaller bandwidth than traditional step-frequency radar. This bandwidth reduction is accomplished by employing compressive sampling ideas and exploiting the sparseness of targets in the range-speed space. [C1065]

### "Radar HRRP statistical recognition with Local Factor Analysis by automatic Bayesian Ying Yang harmony learning"

Radar high-resolution range profiles (HRRPs) are typical high-dimensional non-Gaussian and inter-dimensional dependently distributed data, the statistical modelling of which is a challenging task for HRRP based target recognition. Considering the inter-dimensional dependence, a recent work applied Factor Analysis (FA) to model radar HRRP data and showed promising recognition results, which however still restricts to Gaussian distribution. This paper aims to simultaneously consider the inter-dimensional dependence and the non-Gaussian distribution, by using Local Factor Analysis (LFA) model. For not only learning parameters but also appropriately selecting the component number and local hidden dimensionalities, we adopt the automatic Bayesian Ying-Yang (BYY) harmony learning, in order to relieve the extensive computation and inaccurate evaluation encountered in the conventional two-phase implementation. Moreover, a heuristic aspect-frame partition is implemented based on the BYY harmony criterion rather than AIC or BIC in the previous work, to tackle the radar HRRP's target-aspect sensitivity. Experiments show improved recognition performances over on the same measured HRRP dataset, i.e., for both equal interval and heuristic aspect-frame partitions, LFA automatically learned by BYY always outperforms FA selected by a two-phase procedure with either AIC or BIC. [C1066]

### "Joint sparsity-driven inversion and model error correction for radar imaging"

Solution of inverse problems in imaging requires the use of a mathematical model of the observation process. However such models often involve errors and uncertainties themselves. The application of interest in this paper is synthetic aperture radar (SAR) imaging, which particularly suffers from motion-induced model errors. These types of errors result in phase errors in SAR data which cause defocusing of the reconstructed image. Mostly, phase errors vary only in cross-range direction. However, in many situations, it is possible to encounter 2D phase errors, which are both range and cross-range dependent. We propose a sparsity-driven method for joint SAR imaging and correction of 1D as well as 2D phase errors. This method performs phase error correction during the image formation process and provides focused, high-resolution images. Experimental results show the effectiveness of the approach. [C1067]

### "Synthetic Aperture Radar autofocus via Semidefinite Relaxation"

Synthetic Aperture Radar (SAR) imaging can suffer from image focus degradation due to unknown platform or target motion. Autofocus algorithms use signal processing techniques to remove the undesired phase errors. The recently proposed multichannel autofocus models formulate the problem as the solution to  $Ae^{j\phi} \approx 0$ , where  $A$  is a given matrix and  $\phi$  are the unknown phases. Previous methods approximated  $e^{j\phi}$  using the null vector of  $A$ . We propose to approximate  $e^{j\phi}$  using conic optimization and call this new autofocus algorithm Semidefinite Relaxation Autofocus (SDRA). Experimental results using a simulated SAR image shows that SDRA has promising performance advantages over existing autofocus methods. [C1068]

### "Synthesizing speech from Doppler signals"

It has long been considered a desirable goal to be able to construct an intelligible speech signal merely by observing the talker in the act of speaking. Past methods at performing this have been based on camera-based observations of the talker's face, combined with statistical methods that infer the speech signal from the facial motion captured by the camera. Other methods have included synthesis of speech from measurements taken by

electro-myelo graphs and other devices that are tethered to the talker-an undesirable setup. In this paper we present a new device for synthesizing speech from characterizations of facial motion associated with speech-a Doppler sonar. Facial movement is characterized through Doppler frequency shifts in a tone that is incident on the talker's face. These frequency shifts are used to infer the underlying speech signal. The setup is farfield and untethered, with the sonar acting from the distance of a regular desktop microphone. Preliminary experimental evaluations show that the mechanism is very promising-we are able to synthesize reasonable speech signals, comparable to those obtained from tethered devices such as EMGs. [C1069]

#### "Cramér-Rao lower bound for time reversal range estimators in N-multipath scattering environments"

As an improvement to the conventional radar range estimation based on a single forward propagation of the probing signal, the paper presents a time reversal (TR) based range estimation technique for radar tracking applications and develops the Cramer-Rao lower bounds (CRLB) for the conventional and TR range estimators in an N-multipath scattering environment, where N may assume any value. The CRLBs quantify possible improvement offered by the TR range estimator over the conventional approach. Stronger secondary multipath improves the performance of the TR range estimator as its CRLB decreases with a higher number of multipaths. [C1070]

#### "Sensitivity to basis mismatch in compressed sensing"

Compressed sensing theory suggests that successful inversion of an image of the physical world from its modal parameters can be achieved at measurement dimensions far lower than the image dimension, provided that the image is sparse in an a priori known basis. The assumed basis for sparsity typically corresponds to a gridding of the parameter space, e.g., an DFT grid in spectrum analysis. However, in reality no physical field is sparse in the DFT basis or in an a priori known basis. No matter how finely we grid the parameter space the sources may not lie in the center of the grid cells and there is always mismatch between the assumed and the actual bases for sparsity. In this paper, we study the sensitivity of compressed sensing (basis pursuit to be exact) to mismatch between the assumed and the actual sparsity bases. Our mathematical analysis and numerical examples show that the performance of basis pursuit degrades considerably in the presence of basis mismatch. [C1071]

#### "Physical Layer Techniques for Enhanced Situational Awareness"

Wireless devices are being developed that can scan spectrum to take advantage of spectrum opportunities for enhanced communication. For these devices to communicate better, it is desirable that they have an awareness of their setting. In this paper, we present a collection of techniques, which we call PLATEAU: Physical Layer Techniques for Enhanced Situational Awareness, which leverages physical layer properties from existing signals to gain an accurate picture of a device's environment as well as understanding of that device's mobility. We show through experiments using measurements from a software defined radio that, by utilizing radar and machine learning signal processing, a device can make more informed operational decisions. [C1072]

#### "Blind source extraction of cyclostationary sources with common cyclic frequencies"

A new method for blind source extraction of cyclostationary sources is presented. It is assumed that the cycle frequencies of the sources are known a priori and some of the sources have common cycle frequencies. Necessary and sufficient conditions are introduced and Jacobi method for diagonalization of complex matrices is used to find the estimations. The proposed algorithm is applied to simulated data, and effectiveness and performance of the algorithm are verified. [C1073]

#### "Constant envelope waveform design for MIMO radar"

A method for generating constant envelope (CE) waveforms to realise a given covariance matrix for a closely spaced MIMO radar system is proposed. In contrast to available algorithms, the technique provides closed form solutions for finding the required waveforms and suggests that waveforms can be chosen from finite alphabets such as binary-phase shift keying (BPSK) and quadrature-phase shift keying (QPSK). Gaussian random-variables (RV's) are mapped onto CE non-Gaussian RV's using memoryless non-linear functions. The relationship between the correlation of Gaussian RV's at the input to the nonlinear functions and non-Gaussian RV's at their output is established. Simulation results are presented to demonstrate the effectiveness of the methodology. [C1074]

#### "A ternary pulse compression code: Design and application to radar system"

In this paper, we present new developed ternary code-punctured binary sequence-pair, give its definitions and

the autocorrelation properties. We also investigate Doppler shift performance of the proposed code. The significant advantages of this ternary codes over conventional pulse compression codes, such as the widely used Barker codes, are zero autocorrelation sidelobes and the longer length of the code which can be as long as 31 so far. We apply our new ternary codes to radar system for target detection and observe that our codes outperform some other conventional pulse compression codes. [C1075]

#### "Through-the-Wall Radar Imaging using compressive sensing along temporal frequency domain"

There are increasing demands on Through-the-Wall Radar Imaging (TWRI) systems to deliver high resolution images in both range and cross range. This requires using wideband signals and large array apertures, respectively. Wideband signals are typically implemented by transmitting a series of the narrowband signals. As such, the TWRI system operation involves transmitting and receiving multiple step-frequencies at each antenna location in either a physical or a synthetic aperture radar. Compressive sensing (CS) is an effective approach for decreasing the number of samples and, subsequently, reducing the data acquisition and post-processing time. In this paper, we propose a TWRI scheme based on CS in which a sizable reduction in the number of samples along the frequency axis is achieved without significant degradation in the image. The proposed approach applies the well-known Fourier-like measurement matrix and generates radar images of almost the same desirable quality as the image employing all data samples. [C1076]

#### "MIMO radar detection under phase synchronization errors"

We consider the problem of target detection for coherent multi-input multi-output (MIMO) radar with widely separated antennas in the presence of phase synchronization mismatch between the transmitter and receiver pairs. First, we introduce a data model using von-Mises distribution to represent the phase error terms. Then we employ expectation-maximization algorithm to estimate the error distribution parameter and target returns as well as the noise variance. We develop a generalized likelihood ratio test (GLRT) target detector using these estimates and demonstrate the effect of phase uncertainties on the detection performance using Monte Carlo simulations. [C1077]

#### "Slow-time multi-frequency radar for target detection in multipath scenarios"

We propose a method to detect a target in the presence of multipath reflections, employing sequential transmission of multiple frequencies in a slow-time (pulse-to-pulse) approach. First, we develop a parametric measurement model that accounts for the multipath components at multiple frequencies as well as Doppler shifts. Then, we develop a statistical detection test and analytically evaluate its performance characteristics. Based on the performance analysis, we propose an adaptive algorithm to select the best combination from a subset of frequencies that maximizes the detection performance. Our numerical examples show that the sequential approach requires more coherent pulses to match the performance of the simultaneous usage of multiple carriers in OFDM format. We also study the extent of performance degradation due to employing a subset of available frequencies. [C1078]

#### "Design and implementation of a passive UHF RFID-based Real Time Location System"

A passive Ultra-High Frequency (UHF) Radio Frequency Identification (RFID) based Real Time Locating System (RTLS) is presented in the paper. For the validation, a reader has been developed and complemented with a tag modulator to form a complete UHF RFID-based real time locating system focused on backscattering communication. PN sequences have been used to measure the TOA and estimate the distance between reader and tag. A TX-to-RX leakage canceller has been applied in the reader RF front-end to increase the isolation and enhance the sensitivity. Measurement results indicate that the estimation accuracy in real time is about 1.6 meters and the mean estimation error of 1000 times' measurement in 1 second is less than 0.5 meter. [C1079]

#### "Cramér-Rao bound for time reversal active array direction of arrival estimators in multipath environments"

In this paper, we study the Cramer-Rao bound (CRB) for time reversal (TR) based direction of arrival (DOA) estimators operating in a rich multipath environment. Our setup is based on an array of active antennas capable of estimating the range and DOA of a passive target. We derive an analytical expression for the CRB of the TR/DOA estimator and compare it with that of the conventional DOA estimator by expressing the two CRBs in terms of the multipath parameters (multipath's attenuations and delays). Our analytical results are verified by running Ground Penetrating Radar (GPR) simulations using the electromagnetic Finite Difference Time Domain (FDTD) models. Our simulations illustrate the potential of superior performance with gains of up to 15 dB possible with the TR/DOA estimator over the conventional approach. [C1080]

### "Analytical performance assessment for multi-dimensional Tensor-ESPRIT-type parameter estimation algorithms"

Subspace-based high-resolution parameter algorithms such as ESPRIT, MUSIC, or RARE are known as efficient and versatile tools in various signal processing applications including radar, sonar, medical imaging, or the analysis of MIMO channel sounder measurements. Since these techniques are based on the singular value decomposition (SVD), their performance can be analyzed with the help of SVD-based perturbation theory. Recently we have demonstrated that in the  $R$ -dimensional case ( $R \geq 2$ ), the estimation accuracy of these schemes can be improved by replacing the measurement matrix by a measurement tensor and the SVD by the Higher-Order SVD (HOSVD). In case of ESPRIT, this gives rise to the family of Tensor-ESPRIT algorithms, e.g., standard Tensor-ESPRIT and Unitary Tensor-ESPRIT. In this paper we derive the analytical performance for Tensor-ESPRIT-type algorithms via a recently introduced perturbation theory for the HOSVD-based signal subspace estimate. All expressions are asymptotic in the SNR, but not in the sample size. We first present the explicit equations as a function of the current noise realization, where no assumption on the statistics of symbols or noise are required. Next, we show the result of performing statistical expectation over white Gaussian noise. To demonstrate the usefulness of the results we also present a compact expression for the asymptotic efficiency in the case of a single source, which is only a function of the array size. [C1081]

### "Knowledge-aided Bayesian covariance matrix estimation in compound-Gaussian clutter"

We address the problem of estimating a covariance matrix  $R$  using  $K$  samples  $z_k$  whose covariance matrices are  $\tau_k R$ , where  $\tau_k$  are random variables. This problem naturally arises in radar applications in the case of compound-Gaussian clutter. In contrast to the conventional approach which consists in considering  $R$  as a deterministic quantity, a knowledge-aided (KA) approach is advocated here, where  $R$  is assumed to be a random matrix with some prior distribution. The posterior distribution of  $R$  is derived. Since it does not lead to a closed-form expression for the minimum mean-square error (MMSE) estimate of  $R$ , both  $R$  and  $\tau_k$  are estimated using a Gibbs-sampling strategy. The maximum a posteriori (MAP) estimator of  $R$  is also derived. It is shown that it obeys an implicit equation which can be solved through an iterative procedure, similarly to the case of deterministic  $\tau_k$ s, except that KA is now introduced in the iterative scheme. The new estimators are shown to improve over conventional estimators, especially in small sample support. [C1082]

### "Energy-efficient, decision feedback equalization Using SAR-like capacitive charge summation"

A capacitive charge-sharing, decision feedback equalization (DFE) circuit is presented for use in high-speed serial link receivers. Similar to the capacitive DAC (digital-analog converters) used in successive approximation-based ADCs (analog-digital converters), the proposed one-tap DFE with half-rate quantizer demultiplexing operates at 4Gbps, consuming 0.32 mW from a 1-V supply, excluding clock power. The proposed architecture, scalable to a large number of filter taps, shows considerable advantage in regards to energy efficiency over conventional, current-switched structures. [C1083]

### "Design of intelligent node based on distributed hybrid net control system"

TMS320F2182 DSP chip is applied in the design of intelligent node hardware, and the embed system design method, Microsoft Message Bus and modularization technique are adopted in the realization of intelligent node. The paper gives the software design method of intelligent node based on CAN Bus. The data collected by intelligent node can be transmitted to computer in real time, and the distributed control system based on CAN Bus and GPRS presents the characters such as safety, real-time and economic, which is worth applying in process control field. [C1084]

### "Pulse radar altimeter terrain return model and its simulation"

A simulation model for pulse radar altimeter video echo is proposed, the calculation of all parameters in this simulation model and the correlative arithmetic of echo simulation based on this model are discussed in detail. The simulation is completed with the using of real digital elevation graphs as data source. The results shows the validity of the proposed model and simulation method. [C1085]

### "ARM9-based real-time acquisition of orchard soil information and GPRS wireless transmission control system"

This paper presents a new ARM+GPRS structure which can apply in the orchard soil information collection and transmission. It is a design of data acquisition and wireless transmission control system based on ARM9 with a microprocessor chip S3C2410, it is used for orchard soil realtime acquisition, data transmission and control

between upper and lower computers through GPRS module. It describes that how the hardware platform works and how to accomplish the design by software. The hardware platform consists of core processor, orchard soil data acquisition module and GPRS communication module. It has been proved by experiments that the system has features of small size, high performance, real-time and low-cost. [C1086]

#### **"A fast phase unwrapping algorithm based on minimum discontinuity by blocking"**

Two-dimensional phase unwrapping is one of the key problems in many signal processing applications. Flynn's minimum discontinuity phase unwrapping is one of the algorithm which can solve many different kinds of phase unwrapping problems successfully, but its computation efficiency is too low. To overcome this drawback, a blocked minimum discontinuity phase unwrapping algorithm is proposed. In the proposed algorithm, the wrapped phase image is tessellated into small blocks. Each block is unwrapped separately by minimum discontinuity phase unwrapping algorithm, and then the unwrapped blocks are merged together using minimum discontinuity approach again. The merging process has been divided into two steps. The discontinuities between the blocks are minimized firstly, and then the unwrapped image is taken as a whole to minimize the total discontinuities. This proposed algorithm is described in detail and tested on an IFSAR experimental wrapped phase image and the Etna wrapped image. Results show that the proposed algorithm works well and is more efficient than the Flynn's minimum discontinuity algorithm. [C1087]

#### **"An embedded wireless transmission system based on the extended user datagram protocol (EUDP)"**

As the application of embedded wireless communication system spreads fast in many fields, it is becoming a significant problem to obtain both high speed and reliability during the transmission of large amounts of data. This paper extends the traditional UDP protocol by adding the mechanism of package sequencing and accumulative retransmission, so as to combine the speed of UDP protocol and the reliability of the extended upper protocol and build an embedded system for transmitting large amounts of data quickly and reliably. The system is designed based on STM32 microcontroller and wireless module. Through the General Packet Radio Service (GPRS), the system can communicate both data and instructions with the remote control center via Internet. Experimental results reveal that the extended UDP protocol (EUDP) reduces the transmission delay significantly compared with the usual TCP protocol, while ensuring a considerable degree of reliability. Thus the system is ideal for transmitting large amounts of data in real time. [C1088]

#### **"The denoising method of SAR image based on Retinex"**

The traditional SAR image denoising methods are not considered a shadow of image, but the shape of shadow is used for recognition. In order to take full use of SAR image dark areas information, the method of SAR image noising based on Retinex is proposed. Firstly, SAR image is decomposed into irradiated SAR image and reflected SAR image based on Retinex model; secondly, the decomposed irradiated SAR image carries through NSCT and threshold select according to context, then NSCT inverse transform; thirdly, reflected SAR image carries through NSCT, and the dark areas information and non-dark areas information are obtained by image binarization processing to irradiated SAR image according to certain threshold value. Bilateral filtering to dark areas information and context threshold select to non-dark areas information, then NSCT inverse transform; at last, image synthesizes according to Retinex model. The method takes full use of SAR image dark areas information, and the simulation results show that the denoising effects of the method is better than other methods. [C1089]

#### **"MAP-PF wideband multitarget and colored noise tracking"**

The maximum a posteriori penalty function (MAP-PF) approach is applied to tracking the bearing and bearing rate of multiple wideband sources in unknown colored noise. The track estimation problem is formulated directly from the array data using the maximum a posteriori (MAP) estimation criterion. The penalty function (PF) method of nonlinear programming is used to obtain a tractable solution. A sequential update procedure is developed in which penalized maximum likelihood estimates of target bearings, spectra, and noise parameters are computed and then used as synthetic measurements in a set of Kalman filter trackers. The two steps are coupled via the penalty function. During parameter estimation, the penalty function prevents erroneous outlier estimates which can cause the tracker to lose track. During the tracking step, it determines the influence of the parameter estimates on the final track estimates by adaptively adjusting the measurement error variance. Performance is demonstrated on a typical sonar scenario. [C1090]

#### **"A new Fractional Fourier Transform based monopulse tracking radar processor"**

Conventional monopulse radar processors are used to track a target that appears in the look direction beam

width. The distortion produced when additional targets appear in the look direction beam width can cause severe erroneous outcomes from the monopulse processor. This leads to errors in the target tracking angles that may cause the target tracker to fail. A new signal processing algorithm is presented in this paper that is based on the use of optimal Fractional Fourier Transform (FrFT) filtering to solve this problem. The relative performance of the new filtering method over traditional based methods is assessed using standard deviation angle estimation error (STDAE) for a range of simulated environments. The proposed system configurations with the optimum FrFT filters succeeds in effectively cancelling additional target signals appearing in the look direction beam width.

[C1091]

#### "Radar-based human detection via orthogonal matching pursuit"

Many current radar-based human detection systems employ some type of Doppler or Fourier-based processing, followed by spectrogram and gait analysis to classify detected targets. However, Fourier-based techniques inherently assume a linear variation in target phase over the aperture, whereas human targets have a highly nonlinear phase history. This mismatch leads to significant loss in SNR and integration gain. In this paper, an Enhanced Optimized Non-Linear Phase (EnONLP) detector is proposed that employs a dictionary to store possible target returns generated from the human model for each combination of parameter values. An orthogonal matching pursuit algorithm is used to compute a sparse approximation to the radar return that is optimal in the least squares sense. Performance of the EnONLP algorithm is compared to that of a parameter-estimation based algorithm and conventional, fully-adaptive STAP. [C1092]

#### "Bayesian Rao and Wald test for radar adaptive detection"

This paper deals with the adaptive detection of a signal of interest in the presence of Gaussian noise with unknown covariance matrix (CM). To this end, we resort to a Bayesian approach based on a suitable model for the probability density function (PDF) of unknown CM. Under this assumption, the maximum a-posteriori (MAP) estimation of CM is derived. The MAP estimate is in turn used to yield Bayesian version of Rao and Wald test. And the importance of the a priori knowledge can be tuned through scalar variable. Remarkably the devised detectors outperform Kelly's GLRT and non Bayesian Rao and Wald test in the presence of strongly heterogeneous scenarios (where a very small number of training data is available). Meanwhile, the coincidence of Bayesian GLRT and Wald test is proved. [C1093]

#### "Multiple-frequency interferometric velocity SAR location and imaging of elevated moving target"

Locations of moving targets in synthetic aperture radar (SAR) images are determined not only by their geometric locations but also by their velocities that cause their SAR images defocused, smeared, and mis-located. With a linear antenna array, velocity synthetic aperture radar (VSAR) can detect, focus, and locate slowly moving targets well. However, it may mis-locate fast moving targets in the azimuth (cross-range) direction, and sometimes even in the ground range direction if the targets are elevated above the ground. In this paper, we propose an antenna array approach with cross-track interferometry, in which multiple wavelength signals are transmitted. It is shown that our proposed multiple-frequency interferometric velocity SAR (MFin-VSAR) can locate both slowly and fast moving elevated targets correctly. [C1094]

#### "Target detection in MIMO radar in the presence of Doppler using complementary sequences"

In this paper, we present a method for detecting a point target using multiple antennas when the relative motion between the receivers and the target induces a non-negligible Doppler shift. As a key illustrative example, we consider a 4x4 system employing a unitary matrix waveform set, e.g., formed from Golay complementary sequences. When a non-negligible Doppler shift is induced by the target motion, the wave-form matrix formed from the complementary sequences is no longer unitary, resulting in significantly degraded target range estimates. To solve this problem, we adopt a subspace based approach exploiting the observation that the receive matrix formed from matched filtering of the reflected waveforms has a (non-trivial) null-space. Through processing of the waveforms with the appropriate vector from the null-space, we can significantly improve the detection performance. We provide simulation results to confirm the theoretical analysis. [C1095]

#### "Iterative design of MIMO radar transmit waveforms and receive filter bank"

In this paper, we propose an iterative design approach to jointly optimize probing signal waveforms and a receive filter bank for a multiple-input multiple-output (MIMO) radar under a constant modulus constraint. The design goals are to approximate a desired beampattern and to minimize the auto-/cross- correlation levels of the probing signal waveforms for different time lags and between different spatial angles. Since the overall design problem is nonconvex, we propose to optimize the transmit probing signals and receive filter bank separately and alternately. The optimization of receive filter bank is a standard least squares problem, while the optimization of

the constant modulus transmit signal waveforms is a norm-constrained least squares problem which can be approximately solved using a low-rank semidefinite relaxation procedure. We demonstrate the effectiveness of our proposed approach through a simulation example. [C1096]

#### "Robust MIMO radar detection for correlated subarrays"

Previously, the well-known Optimum Gaussian Detector (OGD) has been extended to the Multiple-Input Multiple-Output (MIMO) case where all transmit-receive subarrays are considered jointly as a system such that only one detection threshold is used. In this extension, all subarrays have been assumed to be widely separated and the transmitted waveforms are assumed to be orthogonal. However, the necessary separation needed for each subarray to be uncorrelated depends on several factors and it might not be possible to ensure that this condition is always respected, especially in the case of moving platforms. Moreover, perfectly orthogonal waveforms do not exist. Hence, we consider in this paper, a new robust MIMO detector that is able to maintain the same Probability of False Alarm (Pfa) regardless of the correlation between the subarrays. [C1097]

#### "Fixed-point based autoregressive parameter estimation for space time adaptive processing"

Space time adaptive processing (STAP) is useful in radar processing to detect a target by filtering the clutter and the additive thermal noise. A derived version based on a multichannel autoregressive (M-AR) model of the clutter has the advantage of reducing the computational cost. Nevertheless, the estimation of the AR matrix parameters is a key issue because the clutter is not Gaussian in real cases. When dealing with an off-line solution, the multichannel least squares method (MLS) can be considered, but the estimation of the disturbance covariance matrix is required. In this paper, we suggest using the so-called fixed point method since it has "matrix- and texture-constant false alarm rate" property (matrix-CFAR and texture-CFAR) and it provides an unbiased and consistent estimate in a non-Gaussian case. A comparative study is then carried out between off-line M-AR based STAP methods and it points out the relevance of the solution we propose. [C1098]

#### "The role of the ambiguity function in compressed sensing radar"

As is clear from the ambiguity function (AF) uncertainty principle and the underlying matched filtering operation, pulse compression (PC) radars cannot accurately and simultaneously measure both the time delay and Doppler shift of moving targets. On the other hand, compressed sensing (CS) radar would seem to be emerging as a means to do just that, jointly to estimate the delay and Doppler shift, through convex optimization instead of matched filtering, such that PC resolution limits no longer apply. However, it turns out that the AF is closely related to the CS "dictionary coherence coefficient," which affects the optimization recoverability. In this paper we formalize this relationship. [C1099]

#### "Knowledge-aided reduced-rank STAP for MIMO radar based on joint iterative constrained optimization of adaptive filters with multiple constraints"

In this paper, a reduced-rank knowledge-aided technique for MIMO radar space-time adaptive processing (STAP) design is proposed. We focus on the advantage of MIMO radars in achieving better spatial resolution by employing the colocated antennas. The scheme is based on knowledge-aided constrained joint iterative optimization of adaptive filters (KAC-JIOAF) and takes advantage of the a priori covariance matrix by employing additional linear constraints in the design. A recursive least squares (RLS) implementation is derived to reduce the computational complexity. We evaluate the algorithm in terms of signal-to-interference-plus-noise ratio (SINR) and probability of detection PD performance and compare it with the state-of-the-art reduced-rank algorithms. Simulations show that the proposed algorithm outperforms existing reduced-rank algorithms. [C1100]

#### "Knowledge-aided STAP algorithm using convex combination of inverse covariance matrices for heterogeneous clutter"

Knowledge-aided space-time adaptive processing (KA-STAP) algorithms, which incorporate a priori knowledge into radar signal processing methods, have the potential to substantially enhance detection performance while combating heterogeneous clutter effects. In this paper, we develop a KA-STAP algorithm to estimate the inverse interference covariance matrix rather than the covariance matrix itself, by combining the inverse of the covariance known a priori,  $R_0^{-1}$ , and the inverse sample covariance matrix estimate  $R^{-1}$ . The computational load is greatly reduced due to the avoidance of the matrix inversion operation. We also develop a cost-effective algorithm based on the minimum variance (MV) criterion for computing the mixing parameter that performs a convex combination of  $R_0^{-1}$  and  $R^{-1}$ . Simulations show the potential of our proposed algorithm, which obtain substantial performance improvements over prior art. [C1101]

### "Performance analysis of a Robust Low-Rank STAP filter in low-rank Gaussian clutter"

In this paper, we consider that the disturbance of a STAP system is composed of a low-rank Gaussian clutter and a white Gaussian noise. From this model, the theoretical SNR Loss of a Robust Low-Rank STAP filter based on the Normalized Sample Covariance Matrix is derived by means of a perturbation analysis. Theoretical results are shown to be in good agreement with simulations for a realistic STAP configuration. Our analysis extends previous result on the SNR loss of Low-Rank STAP filtering based on the Sample Covariance Matrix. [C1102]

### "Angle-Doppler processing using sparse regularization"

The detection of moving objects on the ground by airborne radar is one application of space-time adaptive processing (STAP). The goal is to estimate the position and velocity of objects. This paper considers the problem as a linear inverse problem and uses  $\ell_1$ -norm regularization to promote sparsity in the solution. It is proposed that the angle-Doppler plane be explicitly segmented into the clutter ridge component and a non-clutter-ridge component. We propose that the second component be modeled as sparse-as the moving objects are assumed to be well isolated in the angle-Doppler plane. [C1103]

### "On sand ripple detection in synthetic aperture sonar imagery"

A model for the detection of sand ripples in synthetic aperture sonar (SAS) imagery is proposed. The approach is based on searching for patterns characterized by three highlight-shadow pairs-corresponding to ripple-wave crests and troughs-at different orientations and at different length-scales. The model also provides an estimate of the orientation of any ripples detected. No training data is required as the underlying physical phenomenon of ripples is modeled directly. The promise of the proposed method is demonstrated on five real, measured SAS images, for which a high probability of (ripple) detection is achieved while maintaining a very low false alarm rate. [C1104]

### "Compressive sensing-based SAR tomography"

The problem of imaging multiple scattering components in SAR tomography is addressed in this work. It is proposed to exploit the sparsity of scattering components in the elevation domain by invoking the recently-proposed compressive sensing (CS) theory to achieve the separation of multiple scattering centers with fine elevation resolution. The major advantages of the proposed CS-based method over other conventional methods are evident in single snapshot scenarios with correlated scattering components. The proposed CS-based imaging method for SAR tomography is compared to the conventional MUSIC-based imaging method and the advantages of the proposed method in a variety of imaging scenarios is shown via simulations. [C1105]

### "On the concept of MIMO radar"

Two classes of MIMO radars are briefly considered. MIMO radars with colocated antennas and coded signals represent a new and prospective concept. MIMO Radars with widely separated antennas ("Statistical MIMO radars") are a particular case of well-known Multisite (Multistatic) radar systems. Most results presented by the authors of "Statistical MIMO radars" were obtained under much more general conditions and published many years ago. Besides, ignoring some specific features of radar has led to serious errors. [C1106]

### "Clutter properties for STAP with smooth and faceted cylindrical conformal antennas"

Conformal antennas, which assume the shape of the platform, have several advantages; like reduced weight and space, aerodynamic design and increased field of view. We are interested in detection of moving ground targets with air-borne radar with faceted or smooth vertical half-cylinder or planar antennas with different subarray sizes. We simulate radar systems and study clutter properties which are important for suppressing the clutter with STAP (Space-Time Adaptive Processing), properties by which we can compare the antennas. We use old analysis tools and propose some new which are easy to interpret and draw conclusions from. We find that the faceted and smooth half-cylinder antennas have no significant differences in clutter suppression performance. The plane antenna has poorer performance. The subarray division is more important than the antenna geometry. The number of antenna channels is related to the clutter rank and the clutter fraction of the signal space. [C1107]

### "On the use of HRR data to improve target kinematics estimation: CRLB computation and comparison with simulated results"

An innovative approach to jointly estimate and compensate the radial velocity and acceleration of non-

cooperative targets in HRR (High Range Resolution) processing for a frequency stepped radar has been proposed in. The estimation is performed using different approaches mainly based on the maximization or the minimization of a proper functional (contrast, correlation-like or entropy) of the reconstructed profile. The partial improvement found for the target velocity and acceleration estimation indicates that the three analyzed "cost functions" don't reach ideal performance. Scope of this paper is to quantify the best theoretical achievable performance by means of the Cramer-Rao Lower Bounds (CRLB) and compare the obtained results in with the CRLB. [C1108]

#### **"Adaptive polarization processing for improved detection/classification of stationary targets"**

A new technique for detection of stationary or slow-moving over-resolved targets on the ground, based upon a Hotelling T-squared test/generalized inner product (GIP) approach to signal analysis is presented. This robust detector separates radar returns from interference via a coherent process. This GIP-based processing can be applied to single-receiver channel systems, multiple spatial channel systems, multiple polarization channel systems or systems with multiple spatial and polarization channels. [C1109]

#### **"Optimal block quantization for SAR data"**

A variable bit rate coding scheme designed for new generation SAR satellites is presented. This coding is based on previous schemes of Block Adaptive Quantizer (BAQ) and is intended as a possible improvement over Sentinel-1 FDBAQ. In this project, the number of quantizers is considered a design choice and the optimization is carried out looking for a set of reflectivity classes in which partition all the imaged areas on the Earth. Superior performances to those envisaged for Sentinel-1 FDBAQ are obtained in terms of SNR vs. average rate. Results come from simulations based on a 16-bit mosaic of C band reflectivity obtained by ESRIN from ENVISAT GM data and Wien University database of ENVISAT WSM radar reflectivity. [C1110]

#### **"Space-Range Adaptive Processing for waveform-diverse radar imaging"**

Waveform-diverse radar arrays have been proposed as a method to facilitate single pulse imaging as well as to potentially enable simultaneous multi-mode operation. Transmitting different waveforms on the elements of a uniform linear array consequently raises the spatial and temporal sidelobes of the receiver matched filter. In this paper a recursive minimum mean square error based receiver design denoted as Space-Range Adaptive Processing is presented. The new method is capable of mitigating space range sidelobes thereby providing enhanced sensitivity for this transmission scheme. [C1111]

#### **"The SlimSAR: A small, multi-frequency, Synthetic Aperture Radar for UAS operation"**

The SlimSAR is a small, low-cost, Synthetic Aperture Radar (SAR) and represents a new advancement in highperformance SAR. ARTEMIS employed a unique design methodology that exploits previous developments in designing the Slim-SAR to be smaller, lighter, and more flexible while consuming less power than typical SAR systems. With an L-band core, and frequency block converters, the system is very suitable for use on a number of small UAS's. Both linear-frequency-modulated continuous-wave (LFM-CW), which achieves high signal-to-noise ratio while transmitting with less power, and pulsed mode have been tested. The flexible control software allows us to change the radar parameters in flight. The system has a built-in high quality GPS/IMU motion measurement solution and can also be packaged with a small data link and a gimbal for high frequency antennas. Multi-frequency SAR provides day and night imaging through smoke, dust, rain, and clouds with the advantages of additional capabilities at different frequencies (i.e. dry ground and foliage penetration at low frequencies, and change detection at high frequencies.) [C1112]

#### **"Multistatic measurements in a controlled laboratory environment"**

In recent years, a novel mathematical framework for analyzing and designing multistatic radar systems has been proposed. It was argued through numerous simulation examples that multistatic radar system performances can be significantly improved by shaping the multistatic ambiguity function. Based on this framework, rules for waveform selection, sensor positioning and adequate weighting of different receivers have been developed. In this work, we present multistatic measurements obtained in a controlled laboratory environment to support some of these recent findings and conclusions. The experimental setup consists of a Lab-Volt™ radar system operating at X-band, Tektronix arbitrary waveform generator and Tektronix digital oscilloscope. Multistatic point target radar measurements for different system configurations are analyzed. [C1113]

#### **"Use of reference architectures to achieve low-risk, affordable radar designs"**

The availability of radar reference architectures for software and hardware can enable the development of

affordable radar systems through maximal reuse and low-risk designs. Affordability through reduced design cycle times and efficient integration and test of new radars is crucial to remain competitive and to maintain leadership in developing world-class phased-array radars. Necessary complements to these developments are reusable radar processing algorithms and functions necessary to rapidly synthesize these new radar designs. A compilation of algorithms used by common ground-based and sea-based radar reference architectures is described. Notional radar software and hardware building blocks or "widgets" are also identified. These architectural building blocks can be used to synthesize scalable radar architectures by employing software and hardware reference architectures. This synthesis approach is illustrated by providing examples using two different radar applications. This approach is applicable to all radar systems, in addition to systems-of-systems, where the building architectural blocks are the component system reference architectures. [C1114]

#### "High density FPGA based waveform generation for radars"

Various modulation techniques are usually utilized to enhance the radar performance, or to add more capabilities to the radar that otherwise would not have been possible. Digital generation methods of frequency modulated continuous wave signals include direct waveform synthesis and frequency synthesis. The implementation of waveform generation and upconversion method are described in this paper with a simplified digital implementation technique using FPGAs (Field Programmable Gate Array). The design follows a systematic approach following steps of timing generation from external encoder, baseband modulated waveform generation, upconversion of the waveform to intermediate frequency, filtering and finally frequency synthesis using external DDS (Direct Digital Synthesizer). The design is also capable of generating BITE waveform for test checking in the system. Our design is capable of generation of waveform for stationary as well as non-stationary radars. For non-stationary radars, the waveform is so generated that the doppler effect due to the movement of the radar is compensated. The paper explains more on this. This work mainly focuses on the fact that the total design has been implemented on a single FPGA and the implementation solution utilizes the efficient FPGA resources so as to meet the timings in crucial applications. Moreover, the paper enhances the features of the design with simulation and real time results used to validate the design. [C1115]

#### "A robust estimation method to coregistration error for InSAR interferometric phase"

In this paper, we propose a robust estimation method to coregistration error for synthetic aperture radar interferometry (InSAR) interferometric phase. In the method, the optimal joint data vector is determined, the true steering vector is computed according to the data vector, and then the beamforming technique with the steering vector is used to estimate the InSAR interferometric phase. The method can carry out image coregistration and interferometric phase estimation simultaneously. Theoretical analysis and computer simulation results show that the method can provide accurate estimate of the terrain interferometric phase (interferogram) even when the coregistration error reaches one pixel. [C1116]

#### "ACF-based classification of phase modulated waveforms"

Classification of radar waveform phase modulation based on a sequence of observations is a simple problem complicated by a number of nuisance parameters. Without prior knowledge of waveform carrier frequency, time offset, amplitude, initial phase, and bandwidth, application of a matched filter classifier is not achievable. One must instead rely on waveform features that are invariant to these parameters. This paper presents an invariant feature set for waveform classification. Testing of these features on simulated radar waveforms has illustrated the desired invariance properties and robustness to low signal-to-noise ratio. [C1117]

#### "Ambiguity function of SAR based on OFDM waveform"

Recently many researchers have turned their interests to Orthogonal Frequency Division Multiplexing (OFDM) signal since its promising features in radar. This paper concerns a novel Synthetic Aperture Radar (SAR) system which employs this OFDM signal. Though the OFDM will bring lots of advantages, the performance may be changed since the signal of SAR is different from conventional ones. To evaluate the change, this paper will give a theoretical analysis and the corresponding simulation results from the viewpoint of ambiguity function. This ambiguity function is equivalent to the role of Point Spread Function (PSF) which is often used in SAR for evaluating resolutions. Comparing to the conventional SAR with LFM signal, it is proved that the resolution of SAR based on OFDM is equivalent to the conventional one or even better. This ambiguity function also provides a principle for selecting various OFDM signals as the transmit signal of SAR. [C1118]

#### "Space-time array processing based on ultrawideband throb signal"

Advanced radar and radio communication systems employ space-time array processing to improve performance in terms of detection, resolution, and interference rejection. In this paper, we present the principle of space-time

array processing based on ultrawideband (UWB)-throb signal. Analogous to the well known (delay-Doppler) ambiguity function, a space-time resolution (STR) function is derived and analyzed, by computer simulations, for different signal and array parameters, i. e., pulse width, throb rate, array interelement spacing, and number of array sensors. The structure of the STR function is composed of a narrow mainlobe and low-level sidelobes located on the temporal-angular plane. Antenna energy patterns generated from the STR function clearly demonstrate the dependence of angular resolution on the various signal and array-design parameters. The trade-offs between the various design parameters for achieving high-angular resolution as well as high-temporal resolution are attractive in practice. [C1119]

#### **"Stable filters: A robust signal processing framework for heavy-tailed noise"**

The radar systems of the twenty-first century are being pushed to improve signal detection beyond current capabilities. Current systems perform poorly when the clutter departs from the Gaussian model and becomes heavy-tailed. We introduce stable filters as a general framework for signal processing in heavy-tailed scenarios. The performance gains attainable from these filters can provide significant improvements to digital systems in impulsive noise. Stable filters make use of advanced numerical optimizations to overcome the computational complexity that is common in non-linear approaches. Current performance results show superior performance of stable filters when compared with conventional linear approaches. [C1120]

#### **"Spatially-varying calibration of along-track monopulse synthetic aperture radar imagery for ground moving target indication and tracking"**

In this research, we have developed an algorithm to reduce the residual artifacts of the background clutter (that is, stationary targets) that appear in the MTI imagery that are generated by Global Signal Subspace Difference (GSSD) of the monostatic and bistatic images of an along-track monopulse synthetic aperture radar (SAR) data. We have also established the theoretical foundation for estimating the motion track and parameters of the detected moving targets. We will show the results of these algorithms on measured SAR data. [C1121]

#### **"Characterization of Doppler effects in the context of over-the-horizon radar"**

This paper addresses the problem of the characterization of Doppler effect of maneuvering targets in the context of over-the-horizon radar. The received signal has a complex Doppler structure which is composed of several arrivals, each corresponding to a particular path. In essence, it consists of several close time-frequency components with non-linear signatures in the time-frequency domain. The nonlinearities are the projections of the target's motion vectors on the propagation paths. Estimating the time-frequency contents of all paths reveals the Doppler effects characterizing the target's trajectory. Analysis of such signals in the presence of strong clutter requires effective non-stationary signal processing techniques. In this paper, we propose a new technique based on local analysis of the phase information using warped high-order ambiguity function. The results depict resolvable multipath estimates which are very close to the ground truth. [C1122]

#### **"Analysis of sea clutter distribution variation with Doppler using the compound k-distribution"**

Sea clutter is the backscattered returns received by a radar system from the sea surface. Maritime radar signal processing has the ability to partially compensate for clutter to achieve effective detection of targets on or near the sea surface. This paper investigates the fit of the compound k-distribution model to sea clutter amplitude statistics, within individual Doppler bins across the Doppler spectra. The data used was recorded with a monostatic coherent X-band radar on an airborne platform; both horizontally and vertically polarized data has been analysed. The statistics of the sea clutter distributions have been evaluated using the probabilities of false alarm (PFA), which are calculated from the sea clutter cumulative amplitude distributions. These curves are plotted as a function of detection threshold. K-distributions have been fitted to the PFA of the sea clutter across the Doppler spectrum. The variation of the fitted shape parameter with Doppler bin has been used to identify the relationship between backscattered sea clutter and Doppler. The results show a clear variation with Doppler of the shape parameter obtained from the fitted distribution. The variation is also found to change with polarisation. [C1123]

#### **"Experiments showing an improvement of angular resolution by LMMSE-based processing"**

Azimuth target resolution is of crucial importance in many applications of radar. The primary radar parameter affecting the azimuth resolution is the antenna beamwidth. However, in practice, standard signal processing techniques require the distance between targets to be more than one resolution cell. This can prove inadequate for several relevant applications. This paper describes the results obtained from experiments aimed at testing the capabilities of angular resolution between targets separated by less than the beamwidth in azimuth by means of linear minimum mean square error, LMMSE, -based processing. Results show the capabilities of this technique

of separating targets in such a scenario. The processing scheme shows a strong improvement in the resolution capability with respect to standard techniques. [C1124]

#### "Fast computations of constant envelope waveforms for MIMO radar transmit beampattern"

Designing transmit beampattern with MIMO radars generally requires the waveforms to be able to have arbitrary cross-correlation values. In contrast to the available algorithms, the proposed technique provides a closed-form solution for the synthesis of covariance matrix,  $R$ , of the waveforms to obtain desired beampattern match. To synthesis  $R$  the constraints and redundant information in  $R$  are leveraged, which convert the constrained problem into un-constrained problem. Next a novel method for generating the constant-envelope (CE) waveforms to realise the synthesised covariance matrix,  $R$ , is proposed. This method also yields a closed-form solution and choose the symbols from the binary-phase shift-keying (BPSK). Here, Gaussian random-variables (RV's) are mapped onto the CE RV's by a memoryless non-linear transformation, which converts the problem of finding the non-Gaussian RV's to realise a given covariance matrix  $R$  into finding the Gaussian RV's to realise covariance matrix  $R_g$ . Simulation results are presented to demonstrate the effectiveness of both methodologies. [C1125]

#### "Detection of runway boundary in ATC ground radar"

The radar environment is usually nonstationary and an efficient adaptation requires real-time exploitation of a priori knowledge concerning the environment surrounding the radar. In an airport contest, the radar scenario is heavily influenced by the inevitable presence of interferences, the background clutter, but other interferences (presence of vehicles and unwanted signs on the runway) contribute to make difficult the target detection. In particular, the paper addresses the detection of the runway boundary in ATC (Air Traffic Control) ground radar signal which can be not well defined due to the grass growth in different period in the islands near the runways. The grass growth can cause critical situation because the signal level of the grass zones is equal to that of the asphalt and it needs a visual analysis by a human operator to determine the presence of objects and targets in this clutter area. An active contour search algorithm (Snake algorithm) is used for detecting the runway boundary in SMR radar images. In our application a standard Snake algorithm is adapted and it is possible to obtain a reasonable approximation of the actual contour, which greatly reduces drawbacks related to the presence of the local minima. The performance of the active contour algorithm is tested on a set of radar images extracted from SMR radar images acquired in Italian airports. [C1126]

#### "A fast FRFT based detection algorithm of multiple moving targets in sea clutter"

On the basis of the detection and estimation model of multiple moving targets, a new algorithm based on wavelet packet transform (WPT) and fractional Fourier transform (FRFT) is proposed for weak moving targets detection in sea clutter. The multi-resolution property of WPT and the characteristic of good energy concentration on LFM signals in FRFT domain are combined together. At first, optimal wavelet tree is calculated using "minimum Shannon entropy" and threshold censored method is used to suppress sea clutter of different frequency bands. Then, take the absolute amplitude of signals after FRFT as test statistic and search for peaks in two dimensions with the threshold. Grading iterative method is used for parameter estimation with fast calculation speed and the shading problem between multiple targets is solved through "CLEAN" method. In the end, simulations with IPIX data indicate that the proposed algorithm has good performance of detecting low-observable moving targets in sea clutter. [C1127]

#### "STAP analysis using multi-channel airborne radar data from flight trials"

Flight trials have been performed within the NORA program in order to acquire multi-channel clutter data for different types of terrain, terrain scattered interference, and SAR data. The acquisition of clutter and terrain scattered interference has been made in order to prepare a database for future development of operational space-time adaptive processing (STAP) algorithms applicable to active electrically scanned antenna (AESA) systems employing multiple sub-aperture configurations. In this paper we show some preliminary results that illuminate the benefit of using all four dimensions of multi-channel radar data in a clutter rejection perspective. To illustrate the behavior of multi-channel clutter we employ spatial spectrum estimation methods such as Fourier and MUSIC. We also demonstrate post-Doppler STAP results for the air-to-air case. The results are very promising and indicate that multi-channel processing will indeed enhance the ability to detect targets obscured by clutter. [C1128]

#### "Signal modelling for ground moving target in complex image domain of multi-channel SAR"

For along-track multi-channel synthetic aperture radar (SAR), this paper proposes a novel ground moving target signal model in the high-resolution complex image domain. It is shown that moving targets can be divided into

three types according to the 2D motion distribution and the SPP approximation conditions. Moreover, a single target can be split into two targets in the image. All types of targets will have the same Doppler interferometric effect along multichannel images, which is decided by the target's ambiguous Doppler frequency. Furthermore, with our derived signal model, the complex image properties, i.e., amplitude reduction, azimuth shift, azimuth defocus, range blur, 2D slant, second-order phase modulation, split, interferometry and the effects of 2D accelerations are analyzed for airborne and spaceborne SAR, respectively. Finally, some experimental results are also provided to demonstrate the effectiveness of the proposed signal model and analysis. [C1129]

#### "Scan rate selection for coherent high-resolution maritime surveillance radar: An experimental study"

Scan rate selection has a crucial impact on the performance of maritime surveillance systems. In this work, a sea clutter database has been used to obtain experimental insight on the trade-off between within-scan and scan-to-scan integration. This paper extends the previous empirical studies to the case of sub-meter range resolution Ka-band coherent sea-clutter data. Results show a clear performance improvement for faster scan rates provided that the number of coherently integrated samples is high enough. [C1130]

#### "RELAX based estimation of signal and clutter echoes modeled as discrete point scatterers"

We consider the radar signal return to be originating from discrete point scatterers, and utilize this to estimate clutter echoes and calibrate a multi-channel array. The point scatterers are parameterized with a specific Doppler and spatial frequency ( $u$  and  $v$  direction). Previous work considering this formulation of clutter is the SCHISM approach. Their estimation is based on the radar version of CLEAN. For many cases where the scatterers are well separated, the CLEAN algorithm is fast and accurate. However, for closely spaced scatterers (in either Doppler or space), the CLEAN method suffers. Thus, to enhance the ability to resolve such scatterers we instead employ a new estimator (RESCUE) that uses the approach introduced in RELAX. As for SCHISM, range gates are processed individually and independently from each other and sample covariance matrices are avoided. Real world multi-channel data are used to demonstrate the proposed method. The results are very promising and indicate that this approach can indeed be used as an alternative to traditional STAP. [C1131]

#### "Maximum likelihood speed and distance estimation for OFDM radar"

A distance and speed estimation algorithm for OFDM based radar is analysed statistically. The maximum likelihood estimator is derived and compared to previous results. A connection to spectral analysis is drawn, simplifying the analysis of the estimator in question. Finally, a method to evaluate the performance of the algorithm is presented and conclusions for the structure of the OFDM signals are drawn. It is shown that the estimation algorithm works well above an SNR threshold, but rapidly degrades below. [C1132]

#### "Simplified model of dismount microDoppler and RCS"

Our goal is to be able to detect and classify dismounts, but we were lacking a quick way to estimate dismount parameters, especially with respect to angle of motion and depression angle of the radar. Micro-Doppler models have been developed which attempt to predict the human micro-Doppler response, and here we present a simplified model to quickly estimate dismount RCS and some micro-Doppler characteristics across a range of angles of motion. This model was extracted from measured radar data. We focus on modeling and measuring the characteristics of human walking parameters to determine response of dismounts to radar signals. We determine a simple closed form for RCS as a function of angle for walking dismounts as well as several rules of thumb, and we also determine a closed form for front-view micro-Doppler. [C1133]

#### "Analysis of measured radar data for Specific Emitter Identification"

Measured radar data assisted in the successful development and implementation of Specific Emitter Identification (SEI) signal processing algorithms. The aim of the algorithm is the identification of a specific emitter within a single class of emitters. The processes developed are pulse extraction, feature calculation, dimensionality reduction and classification. A pulse is detected whenever the phase changes from being random to being linear. Time domain features are then calculated from these extracted pulses to populate a feature vector. Some redundancy exists in the feature vector and a process of dimensionality reduction is followed to obtain the optimum set of features. A Fuzzy ARTMAP classifier completes the process of specific emitter identification to demonstrate the improvement in Correct Classification Decisions (CCD) using the reduced feature vector. [C1134]

#### "Waveform decorrelation for multitarget localization in bistatic MIMO radar systems"

The autocorrelation and crosscorrelation properties of transmit waveform set have great effect on the performance of MIMO radar systems. However, it is difficult to design waveform set which have ideal autocorrelation property as well as crosscorrelation one. In this paper, a decorrelation method has been proposed to cancel the effects of the autocorrelation and crosscorrelation of the transmit waveform by exploiting the given statistical properties of waveform. The correlation property of noise after decorrelation is also analyzed. Then a close form solution for localization of the multiple targets is presented via ESPRIT. Simulation results demonstrate the effectiveness of the proposed methods. [C1135]

#### **"Performance verification of symbol-based OFDM radar processing"**

In this paper a recently proposed novel processing approach for OFDM radar is verified with measurements. This processing algorithm directly calculates a radar image from the transmitted and received modulation symbols that compose the OFDM signal without the need for performing correlation operations. The implementation of a suitable system setup is described. The measurement results confirm that with this approach a very high dynamic range can be obtained. Moreover, the SNR in the measured radar images is investigated. The results prove that the proposed algorithm provides high processing gain. [C1136]

#### **"Performance prediction of Firefinder radar using high fidelity simulation"**

Thales Raytheon Systems' PC Simulation (PCS) tool allows a rapid simulated evaluation of Firefinder radar performance from a personal desktop computer. Firefinder radars are designed to track hostile rocket, artillery and mortar (RAM) projectiles in order to accurately estimate weapon ground location. The Firefinder tactical code is used within PCS. This design provides a low risk path to rapid prototyping and evaluation of candidate software changes. PCS is used to evaluate candidate software changes to the Firefinder. Candidate design changes which perform well in PCS testing require minimum system level checkout before being checked into the tactical software baseline. The PCS tool contains a simulation engine which reads program control information from input data files. The PCS tool also generates and maintains simulated targets and clutter, simulates the radar signal processing function, performs Monte-Carlo "batch" processing, produces complex target trajectories internally or from an input text file and creates simulation data recording files identical in format to those created by the actual radar. This paper summarizes the capabilities of the latest PCS. [C1137]

#### **"Automatic through the wall detection of moving targets using low-frequency ultra-wideband radar"**

This paper presents a time-domain, Moving Target Indication (MTI) processing formulation for detecting slow-moving personnel behind walls. The proposed time-domain MTI processing formulation consists of change detection and automatic target recognition algorithms. We demonstrate the effectiveness of the MTI processing formulation using data collected by an impulse-based, low-frequency, ultra-wideband radar. In this paper, we describe our radar system and algorithms used for the automatic detection of moving personnel. We also analyze the false alarm and detection rate of four operational scenarios of personnel walking inside wood and cinderblock buildings. [C1138]

#### **"A track-before-detect algorithm for statistical MIMO radar multitarget detection"**

This paper investigates the early detection problem of multiple moving targets in statistical MIMO radar systems using the track-before-detect (TBD) techniques. At first, assuming prior knowledge of the number of targets, a binary generalized likelihood ratio test (GLRT) is derived, which shows that the optimal implementation of the GLRT requires multidimensional joint search. To reduce the implementation complexity, a suboptimum multitarget TBD algorithm using successive-target-cancellation and polar Hough transform (STC-PHT) is proposed. In addition to low complexity, the new proposed algorithm doesn't need the prior information of the number of targets, and can avoid the implementation of multi-hypothesis test when the number of targets is unknown. The simulation results show that this algorithm can effectively improve the detection performance of statistical MIMO radar at low signal-to-noise ratio (SNR). [C1139]

#### **"Time-varying wideband underwater acoustic channel estimation for OFDM communications"**

We investigate two methods for estimating the matched signal transformations caused by time-varying underwater acoustic channels in orthogonal frequency division multiplexing (OFDM) communication systems. The underwater acoustic channel for this 12-20 kHz medium frequency range OFDM system is best modeled using multipath and wideband Doppler scale changes on the transmitted signal. As a result, our first channel estimation method is based on discretizing the wideband spreading function time-scale representation of the channel output using the Mellin transform. The second method is based on extracting the time-scale features of distinct ray paths in the received signal using a modified matching pursuit decomposition algorithm. We validate and discuss both methods using data from the recent Kauai Acomms MURI 2008 (KAM08) underwater acoustic

communication experiment. [C1140]

### "A study of several model selection criteria for determining the number of signals"

Addressing the problem of detecting the number of source signals as selecting the hidden dimensionality of Factor Analysis (FA) model, we investigate several model selection criteria via a new empirical analyzing tool that examines the joint effect of signal-noise ratio (SNR) and sample size  $N$  on the model selection performance. The contours of the model selection accuracies visualize a three-region partition on the space of SNR and  $N$ , and a diminishing marginal effect which trades off SNR and  $N$  on the performance. Moreover, the newly derived Variational Bayes algorithm and three variants of Bayesian Ying-Yang (BYY) algorithms are more robust against reducing SNR and  $N$ , where the BYY with priors' hyperparameters updated is the best in general. [C1141]

### "Resolution selective change detection in satellite images"

In this paper, we propose a novel method for unsupervised change detection in satellite images. A feature vector for each pixel is extracted using the multiresolution representation of the difference image which is computed from the multitemporal satellite images of the same scene acquired at different time instances. A metric for automatically estimating the number of resolution levels used in multiresolution analysis is proposed. The dimensionality of each feature vector is reduced using principal component analysis (PCA). The feature vectors are then classified into "changed" and "unchanged" classes using k-means clustering with  $k = 2$  to achieve a change detection map. Results are shown on real data and comparisons with the state-of-the-art techniques on advanced synthetic aperture radar (ASAR) images are provided. [C1142]

### "A new far field measurement method for antenna polarization characteristics based on calibrator target"

A new far-field measurement method of antenna is studied in this paper. The received signal model of antenna's beam scanning the calibrator target has been built and the measurement method is considered. The full analysis formula and practical procedure was given. The validity of research work was demonstrated by processing the observational data and simulation. This can greatly reduce the development complexity and production cost of far field test, increased the fidelity at the meanwhile. [C1143]

### "Markov model for convergence analysis of the adaptive Kronecker MIMO OTH radar beamformer"

We introduce an iterative procedure for design of adaptive KL-variate linear beamformers that are structured as the Kronecker product of  $K$ -variate (transmit) and  $L$ -variate (receive) beamformers. Focusing on MIMO radar applications for scenarios where only joint transmit and receive adaptive beamforming can efficiently mitigate multi-mode propagated backscatter interference, we introduce a Markov model for the adaptive iterative routine, specify its convergence condition, and derive final (stable) signal-to-interference-plus-noise ratio (SINR) performance characteristics. Simulation results demonstrate high accuracy of the analytical derivations. [C1144]

### "Gala Dinner/Banquet Speaker"

{no data available} [C1145]

### "Computationally efficient resampling of nonuniform oversampled SAR data"

A computationally efficient technique is developed to resample SAR data oversampled in the slow-time domain for a platform accelerating along the track. The algorithm segments the data between uniformly spaced points on the synthetic aperture, then performs a weighted average on the demodulated SAR data in each segment to adjust the effective sample position on the aperture. The weighting is derived using a first-order Taylor series approximation and used parameters from the velocity and acceleration of the platform and the radar waveform. [C1146]

### "USRP technology for multiband passive radar"

The purpose of the paper is to show how the Universal Software Radio Peripheral (USRP) technology, typically used for implementing telecommunication systems, can be used for realizing passive radars. Specifically in this paper a multiband passive radar is considered. A preliminary study on the signals of opportunity is presented where real and simulated radar ambiguity functions have been evaluated. An experimental system has been set up and live data acquired both for UMTS and DVB-T signals in order to verify the capability of the proposed passive radar demonstrator. [C1147]

### "An iterative algorithm for the construction of notched chirp signals"

This paper describes an iterative algorithm for the design of a constant-modulus finite-duration chirp-like signal having a notch in its frequency spectrum. Frequency-notched signals with good pulse compression properties are needed in wide-band radar systems that must avoid radiating into frequency bands assigned to other systems (e.g. communication and navigation systems). The algorithm is computationally efficient and provides explicit control of the notch frequency and notch order. [C1148]

### "The periodic ambiguity function-Its validity and value"

The periodic ambiguity function (PAF) relates to Woodward's ambiguity function (AF) like periodic autocorrelation relates to autocorrelation. AF is defined for a finite signal, processed by its matched filter. PAF can handle periodic signals with infinite (or large) number of periods, and a processor that is matched to fewer periods. PAF suits practical scenarios found in radar employing coherent pulse train or CW waveforms. This paper revisits the PAF and its properties, demonstrating its value and viability. [C1149]

### "Cross ambiguity function analysis of the '8k-mode' DVB-T for passive radar application"

One of non-cooperative illuminators recently considered for passive radar applications is the DVB-T (Digital Video Broadcasting- Terrestrial) station. The thumbtack ambiguity function of the DVB-T signal in addition to being stationary makes such signal a good candidate for such applications. However, certain ambiguities in its ambiguity function necessitates certain issues to be carefully considered when DVB-T signals are to be utilized in these scenarios. In this paper, after studying the origins of these ambiguities, we propose special processing schemes to resolve them. [C1150]

### "Enhanced monopulse radar tracking using filtering in fractional Fourier domain"

Monopulse radars are used to track a target that appears in the look direction beam width. The distortion produced when additional targets appear in the look direction beam width can cause severe erroneous outcomes from the monopulse tracking processor. This leads to errors in the target tracking angles that may cause target mistracking. A new monopulse radar structure is presented in this paper which offers a solution to this problem. This structure is based on the use of optimal Fractional Fourier Transform (FrFT) filtering. The improved performance of the new monopulse radar structure over the traditional monopulse processor is assessed using standard deviation angle estimation error (STDAE) for a range of simulated environments. The proposed system configurations with the optimum FrFT filters is shown to effectively cancel the additional targets' signals and to minimize the STDAE for monopulse processors even if these targets have the same Doppler frequency. [C1151]

### "The phase retrieval problem for the Radar Ambiguity Function and vice versa"

The first part of this note is based on a joint paper with A. Bonami and G. Garrigos [3] in which the phase retrieval problem for the Radar Ambiguity Function (i.e. the Radar Ambiguity Problem) has been tackled. In particular it was shown that for wide classes of signals, the radar ambiguity problem has a unique solution, up to trivial transformations. In the second part of this note, we report on ongoing work by the author where the radar ambiguity function is used as a tool to solve other phase retrieval problems. [C1152]

### "Passive bistatic WiMAX radar for marine surveillance"

In this study we investigate the feasibility of using passive bistatic radar to exploit WiMAX communication signals as transmitters of opportunity for marine surveillance. The range and Doppler characteristics of such a system are first assessed through ambiguity function analysis on a typical set of WiMAX data transmission waveforms. Theoretical simulations are then used to investigate the ability of passive WiMAX radar for detecting marine vessels within three busy shipping areas in the UK, and in the presence of noise and interference signals. The initial analysis shows a range resolution of 5.6 m is achievable. Additionally, the simulations demonstrate specific scenarios where WiMAX radar may be used as a low cost surveillance device for detecting both small and large marine vessels in port areas and open waters. [C1153]

### "Application of the CLEAN Detector to low signal to noise ratio targets"

This paper expands on the author's previous work by adapting the CLEAN algorithm to address low signal to noise (SNR) targets. The Reformulated CLEAN Detector is presented which is shown to allow the detection of low SNR targets in the presence of large targets. Performance results are presented that show how good performance can be attained by combining the correlator, CLEAN Deconvolver and Reformulated CLEAN Detector. [C1154]

### "Phased array weather / multipurpose radar"

The first phased array radar dedicated to weather observation and analysis is now instrumented with eight, simultaneous digital receivers. The addition of these additional channels will enable the use of advanced signal processing to improve signal/clutter in an adaptive mode. Elimination of strong point and ground clutter returns from the low-level, volumetrically distributed weather cell returns is a new application of adaptive processing. The NSF funded 8-channel receiver has been added to the National Weather Radar Testbed (NWRT) system in Norman, OK to enable operation as a multifunction and/or adaptive processing system. This paper will describe the system concept, system installation and early results from fielded weather data returns. [C1155]

### "Modeling terahertz heterodyne detection based on photomixing"

We present a simple model for continuous wave (CW) terahertz heterodyne detection based on photomixing. This model takes into account the antenna parameters as well as the properties of the substrate. Results from our analytical analysis can be used to obtain the appropriate values for the substrate parameters to maximize received THz signal. Focusing on the dipole antenna, we derive a simple expression for the current created by the THz field in terms of antenna length and parameters of the photomixer. [C1156]

### "False alarm control of CFAR algorithms with experimental bistatic radar data"

False alarm control performance of different constant false alarm rate (CFAR) algorithms is experimentally investigated using bistatic radar data. The CFARs under investigation include cell-averaging (CA-CFAR), smaller-of (SO-CFAR), greater-of (GO-CFAR), ordered-statistic (OS-CFAR), censored cell-averaging (CCA-CFAR), and the homogeneity detector mean-to-mean ratio (MMR) test. The experimental data was collected using an Illuminator of Opportunity (IOO) bistatic radar that is under ongoing development at DSTO. For this set of experimental data, it is observed that CFAR algorithms that have a higher CFAR loss in a homogeneous environment will have a larger theory-experiment false alarm mismatch, especially at smaller false alarm rates and larger CFAR window sizes. [C1157]

### "Establishing a common phase reference for comparing synthetic data to RF range measurements"

Discrepancies can result when creating common data sets consisting of comparable synthetic and measured range complex scattered field samples when the phase references of each do not coincide. This can be especially true when using signal processing techniques to produce one dimensional (range profiles) or two dimensional (Synthetic Aperture Radar or SAR images) representations of the target scattered field where range bins and cross-range bins are formed. Range profiles and SAR images can be misaligned or have different bin amplitudes due to target scatterers in synthetic and measured scenarios shifted with respect to one another. Obtaining equivalent data samples requires attention to the measured data calibration process and phase reference location. This paper will address the common phase reference problem by an analysis of experimental data for specific targets and rotation system. Suggestions are provided for possible solutions to current challenges. The data analysis will include synthetic and measured range data comparisons, range calibration, and target position and range alignment processes using Theodolite laser measurements. [C1158]

### "The radar information channel and system uncertainty"

The radar information channel is developed as a theoretical model for the study of uncertainty within the design, development, and research of radar signature exploitation systems. Information measures are developed which characterize sources of uncertainty and propagate the associated impacts to system performance. Sources of uncertainty are studied to form an information loss budget for trading component design options against overall system performance. [C1159]

### "A novel signal processing method for MIMO radar based on channel estimation"

Multiple Input Multiple Output (MIMO) radar is a new radar technique. It has many advantages over conventional phased radar in many ways such as anti-intercept of radar signal, low velocity target detection, and resolution. The signal transmit matrix of MIMO radar has much information such as target angle. In this paper, we analyze the signal model for MIMO radar. And then we present a new method to estimate the target angle from the matrix. At last, we show the efficiency by some simulations. [C1160]

### "Coupling optimal method of segmentation with restoration for target detection in SAR images"

High-quality segmentation is there in a need in SAR images for appropriate target detection. In this paper, the features of Wiener filter are utilized with region of interest and Boundary based segmentation technique in SAR

images. The discrete Wiener filter exhibits both linear and nonlinear characteristics. This filter compensates for the blurring due to the linear term and conserves the edges which are mainly used to distinguish the various objects with the gross representation of object of interest. The filter is defined both for edge preserving along with speckle noise cancellation in SAR images. A combination of features from two different types of multi-resolution and multi-channel filters, in general provides superior classification of SAR images. The experimental results show that the proposed boundary based and ROI technique segments the SAR image while the opted filter preserves significant features and noise removal. The fusion performance is evaluated on the basis of Mean square error, time, and signal-to-noise ratio. [C1161]

#### **"A complex SAR image compression algorithm combining set-partitioning and context prediction"**

This paper presents a new wavelet transform coding algorithm for complex Synthetic Aperture Radar (SAR) image compression. It uses a improved recursive set-partitioning procedure to compress the large blocks which are abundant in zero bits, and uses entropy coding based on adaptive context prediction model to compress the small blocks which contains non-zero bits. The experiment results showed that the new algorithm gained better compression efficiency than SPECK. We also compared with common complex SAR image compression algorithm in references using professional parameters in SAR, such as Means Phase Errors (MPE), complex spatial correlation efficient, the new algorithm gets better performances too. [C1162]

#### **"Field test implementation to evaluate a flash LIDAR as a primary sensor for safe lunar landing"**

From May 2 through May 7 of 2008, the Autonomous Landing and Hazard Avoidance Technology (ALHAT) Exploration Technology Development Program carried out a helicopter field test to assess the use of a flash LIDAR as a primary sensor during lunar landing. The field test data has been used to evaluate the performance of the LIDAR system and of algorithms for LIDAR Hazard Detection and Avoidance, Hazard Relative Navigation, and Passive Optical Terrain Relative Navigation. Reported here is a comprehensive description of the field test hardware, ground infrastructure and trajectory reconstruction methodologies. [C1163]

#### **"Analysis of flash lidar field test data for safe lunar landing"**

In May 2008, the Autonomous Landing and Hazard Avoidance Technology (ALHAT) Project conducted a helicopter field test of a commercial flash lidar to assess its applicability to safe lunar landing. The helicopter flew several flights, which covered a variety of slant ranges and viewing angles, over man-made and natural lunar-like terrains. The collected data were analyzed to assess the performance of the sensor and the performance of two algorithms: Hazard Detection (HD) and Hazard Relative Navigation (HRN). The collected flash lidar data were also used to validate a high fidelity flash lidar software model used in ALHAT Monte Carlo simulations. The field test results, combined with prior simulation results, advanced the technology readiness level of the HD algorithm to TRL 5 and the HRN algorithm to TRL 4. [C1164]

#### **"Design and Realization of an Online Power Quality Monitoring System Based on GPRS"**

In order to evaluate power quality more accurately, this paper presents a three-layer distributed online power quality monitoring system (PQMS), which uses the General Packet Radio Service (GPRS) wireless network as its communication channel. This PQMS consists of three parts: the power quality monitor (PQM), the monitoring software (MS) in upper computer and the web platform (WP). The PQM which is designed on the structure of DSP (Digital Signal Processor) + CPLD (Complex Programmable Logic Device) ensures the realtime and precise monitoring. Then the MS collects and analyzes the monitoring data. At the same time, GPRS network provides the communication channel for PQM and MS. The WP provides the monitoring data and the analysis results through internet, and supervisors can monitor and manage the power quality from a long distance. The detail design and its realization of each part are explained. Precision test of the PQM and field monitoring results with the PQMS are also discussed. [C1165]

#### **"Wavelet analysis of impulse ultra-wideband radar"**

In this paper, we have enhanced ultra-wideband (UWB) radar signal-to-noise ratio (SNR) by applying a wavelet transform (WT) based matched filter. The wavelet transform algorithm (WTA) provided enhanced reliability relative to conventional background template subtraction (BTS) approach, increasing reliability detecting targets in the nonlinear close in (<50 cm) and at the maximum distance tested (29 m.) We extrapolated the WTA can support a maximum radar range of 60 m, about twice that available with the conventional constant false alarm rate (CFAR) methods. [C1166]

#### **"Radar signal processing based on DCT compression"**

This paper has analyzed and researched the correlative characteristic of data on Synthetic Aperture Radar, adopted DCT algorithm to compress the radar video data, and verified the compression effect through simulation. The compression ratio is 1:3, so that the disadvantage should be resolved that the bandwidth of video data transmission during wireless channel is not enough. [C1167]

#### "TWR signals de-noising by using WNN"

The de-noising issue of through-the-wall radar (TWR) signal is an essential TWR's performance on detecting lives. This paper introduces TWR signal de-noising algorithm based on a wavelet neural networks (WNN). WNN owns the property of time-frequency localization of wavelet transform, as well as the excellent characteristics of artificial neural networks, self-learning and fault-tolerance, which make it a powerful tool for removing noises from noisy through-the-wall radar signals. Experimental results show that the proposed WNN based de-noising algorithm can achieve good de-noising performance and hold the useful detail of TWR signals. [C1168]

#### "Cognitive Radio under Conservative Regulatory Environments: Lessons Learned and near Term Options"

In recent regulatory decisions, spectrum regulators have been very conservative in permitting use of cognitive radio systems requiring large "safety margins". This paper describes the nature of these safety margins and the factors that lead to them. New research that might counter such concerns is suggested. Cooperative approaches involving primary user systems that actively cooperate with cognitive users are also suggested. [C1169]

#### "On the MIMO interference channel"

We propose an iterative algorithm to design optimal linear transmitters and receivers in a K-user frequency-flat MIMO Interference Channel (MIMO IFC) with full channel state information (CSI). The transmitters and receivers are optimized to maximize the Weighted Sum Rate (WSR) of the MIMO IFC. Maximization of WSR is desirable since it allows the system to cover all the rate tuples on the Pareto-optimal rate region boundary for a given MIMO IFC. The proposed algorithm is rooted in a recent result [S.S. Christensen et al., 2008] showing a correspondence between local optima of the Minimum Weighted Sum Mean Squared Error (MWSMSE) and Maximum Weighted Sum Rate (MWSR) objective functions for the MIMO Broadcast Channel (BC). This connection between the MWSR and MWSMSE is shown to hold true also in the MIMO IFC and is exploited to design an alternating minimization algorithm for MIMO IFC that maximizes the WSR. The MWSMSE-MWSR connection also allows to solve the transmit filter design subproblem in the alternating algorithm by invoking a heuristic solution first proposed in [M. Joham et al., 2002]. Another contribution of this paper is to propose an extension of [M. Stojnic et al., 2006] to MIMO problems, following the philosophy of [S.S. Christensen et al., 2008] in part. This path is shown to lead in fact to the same iterative algorithm, showing the optimality of the heuristic of [M. Joham et al., 2002] when applied in the context of the alternating transmitter-receiver optimization approach of [S.S. Christensen et al., 2008]. [C1170]

#### "3D passive source localization by a multi-array network: Noncoherent vs. coherent processing"

This paper investigates the three-dimensional passive source localization problem by a system of multiple antenna arrays. It is well-known that centralized and coherent processing of all sensor antenna outputs offers a performance benefit in comparison to decentralized processing, where the latter is easier to implement. We compare the Cramér-Rao bound on the source locations for both cases, review the decentralized direct position determination approach and outline the near-field source localization approach generalized to the three-dimensional problem. Finally, we discuss the trade-off between performance benefit and implementation complexity. [C1171]

#### "Array geometry optimization for direction-of-arrival estimation including subarrays and tapering"

This paper focuses on the estimation of the direction-of-arrival (DOA) of signals impinging on a linear sensor array. In contrast to conventional arrays, where the number of channels equals the number of sensors, we use tapered subarray structures. For this type of array, each channel consists of several sensor elements with different amplitude tapering. By this means, a pre-focussing can be achieved for angular regions, where targets are likely to appear. As a consequence, the DOA mean squared error in the corresponding regions is reduced. As the subarrays affect the statistical properties of the baseband signal model, we extend the well known definitions of the Maximum Likelihood DOA estimator and the Cramér-Rao bound (CRB). Furthermore, we present an expression for the ambiguity function for a single signal based on the Maximum Likelihood estimator. This function and the CRB are used to optimize the sensor geometry, subarray tapering and subarray configuration. As external conditions such as the range of possible DOA's, the DOA region of interest and the signal power range are also included in the optimization, the array can be adjusted to external requirements

defined by a specific application and function. By this means, optimum (single source) DOA estimation performance for a specific area of application can be achieved. An evolution strategy is used for the optimization. To show the DOA estimation performance of the optimized arrays and to confirm the validity of the extended CRB, simulation results are presented. Compared to conventional arrays, the optimized tapered subarray structures provide a significantly better DOA accuracy. [C1172]

#### "Investigation of the Tiler processor for real time hazard detection and avoidance on the Altair Lunar Lander"

The High Performance Processor (HPP) Task of the Advanced Avionics and Processor Systems (AAPS) Project, part of the Exploration Technology Development Program (ETDP), was to evaluate several high performance multicore processor architectures with respect to their ability to provide real time hazard detection and avoidance for the Constellation Program's Altair Lunar Lander. In this paper we review the Tiler Tile64 processor, the hazard detection and avoidance algorithm, strategies for parallelizing these algorithms, and preliminary performance study results. We were presented with the requirements of 30 Hz LIDAR frame processing rate and 10 second processing time for ALHAT HDA processing and were able to meet that requirement with the Tile64. We then project the performance of these algorithms on the OPERA MAESTRO Processor, a radiation tolerant version of the Tile 64 being developed by the Boeing Company. [C1173]

#### "STS-128 on-orbit demonstration of the TriDAR targetless rendezvous and docking sensor"

Neptec has developed a vision system for autonomous rendezvous and docking in space that does not require the use of cooperative markers, such as retroreflectors, on the target spacecraft. The system uses an active TriDAR 3D sensor along with embedded model based tracking algorithms to provide, out of the box, 6 degree of freedom (6DOF) relative pose information in real-time. The TriDAR (triangulation + LIDAR) sensing technology combines active triangulation and Time-of-Flight (TOF) ranging techniques within a single optical path. This design takes advantage of the complementary nature of these two technologies to provide optimal 3 dimensional data from several kilometers all the way to docking. A thermal imager is also included to provide bearing information at long range. In partnership with the Canadian Space Agency (CSA) and NASA, Neptec has space qualified the TriDAR vision system and integrated it onboard the Space Shuttle Discovery to fly as a Detailed Test Objective (DTO) on the STS-128 mission. The objective of the TriDAR DTO mission was to demonstrate the system's ability to perform acquisition and tracking of a known target in space autonomously and provide real-time relative navigation cues. Autonomous operations involve automatic acquisition of the ISS, real-time tracking as well as detection and recovery from system malfunctions and/or loss of tracking. This paper presents an overview of the TriDAR system as well as results from on-orbit testing of the TriDAR during the STS-128 Space Shuttle mission. [C1174]

#### "SMAP Observatory configuration, from concept to preliminary design"

SMAP (Soil Moisture Active and Passive) is a scientific mission to provide global mapping of Earth soil moisture and freeze/thaw state. In order to accomplish this mission the Observatory accommodates two primary Instruments L-band (1.26 GHz) Radar and L-band (1.4 GHz) Radiometer. Both Instruments use a shared 14.6 RPM spinning Antenna System with 6 m diameter deployable Reflector. The key challenges for the Observatory configuration are accommodation of the primary Instruments (Radar and Radiometer), and the supporting subsystems, all the while meeting all operations, pointing, environment requirements, and launch vehicle accommodation. This paper will describe the evolution of the SMAP Observatory configuration and major trade-offs from conceptual to preliminary design. [C1175]

#### "Statistical analysis of CloudSat data for climate model parameterization"

The development of realistic cloud parameterizations in climate models requires accurate characterizations of sub-grid distributions of thermodynamic variables. To this end, cloud liquid water content (CLWC) distributions are characterized with respect to cloud phase, cloud type, precipitation occurrence, and geo-location using CloudSat radar measurements. The probability density function (PDF) of CLWC is estimated using Maximum Likelihood Estimation. The best-estimated PDF of CLWC is found to closely follow either a gamma or a lognormal distribution depending on temperature (cloud phase), cloud type, precipitation, and geo-location. In the regions from the lower to mid-troposphere (altitudes of 1-6 km) and between the tropical and the subtropical latitudes where non-precipitating and pure-water phase clouds are dominant, the PDFs of CLWC are best described by lognormal distributions. In contrast, at altitudes above 6 km and in regions poleward of the midlatitudes, the CLWC exhibits a gamma distribution due to a high frequency of occurrence of supercooled liquid clouds, which results in the increased occurrence of low CLWC values. The data sub-sampling with respect to cloud phase and precipitation significantly affects the distribution characteristics of CLWC in some

regions. After removing the contributions of supercooled water and precipitation the CLWC PDFs transition from gamma to lognormal distributions in two types of regions: (1) the high altitude and middle-to-polar latitude regions where the contribution of mixed-phase cloud is significant; (2) the region near the surface where the contribution of precipitating cloud is considerable. [C1176]

### "Space-based passive radar enabled by the new generation of geostationary broadcast satellites"

In this paper we investigate the possibility to develop a passive radar system for mid-range air target surveillance using, as illuminator of opportunity, a high EIRP level geostationary broadcast transmitter. These satellites are being introduced recently for Satellite Mobile Digital TV broadcast purpose. Since they are designed to allow mobile users to receive satellite TV without large antennas, a sufficiently high signal power is being transmitted, making them suitable as illuminators of opportunity in a passive radar system. The possibility to resort to a quasi-stationary transmitter is shown to highly simplify the signal processing required by the passive radar system. A preliminary evaluation of the achievable SNR is conducted, showing that mid-range target detection can be achieved with reliable performance. In addition, a detailed analysis of the Doppler frequency contributions is conducted. Specifically, the Doppler frequency contribution due to the motion between target and transmitter is shown to be locally independent over the target position. The overall bistatic Doppler frequency behavior is evaluated for several possible target trajectories and some critical trajectories are identified. Finally, some remarks referred to the 2D Cross Correlation Function (2D-CCF) evaluation are reported. [C1177]

### "New detection manifolds for radar signal processing"

This paper examines direct data domain (DDD) moving target detection for multi-channel space-based radar (SBR). DDD techniques differ from data-adaptive processing methods in that they do not rely on statistically stationary and homogeneous training data in order to estimate and null out clutter or interference and thereby reveal potential targets; instead, they operate on each range-Doppler cell independently, after any necessary preprocessing to compensate for platform motion and/or array calibration. Prior work examined a maximum-likelihood angle-of-arrival (AOA) technique and the associated target power estimator to detect slow moving targets. In this paper, we extend that methodology and propose novel detection manifolds for optimally partitioning the two-dimensional statistical space. The two dimensions are formed by the passive AOA likelihood function and the estimated target power. A computer simulation of a space radar system and associated geometry is used to assess the characteristics and performance of the new concept. We show that the two-dimensional probability densities corresponding to the target absent and target present hypotheses ( $H_0$  and  $H_1$ , respectively) occupy regions in this space that are not optimally separated by independent thresholds. This immediately leads to the novel detection manifolds (or curved boundaries between detections and non-detections) that improve the detection probability while also reducing the false alarm rate. [C1178]

### "Autonomous deployment of the UAVSAR radar instrument"

The UAVSAR program was formed to provide repeat pass radar interferometry on an uninhabited aircraft platform. The UAVSAR imaging radar system is housed in an external unpressurized pod that may be attached to an Uninhabited Aerial Vehicle (UAV), although initial flight tests were performed aboard a Gulfstream-III aircraft with flight test personnel on-board. Since the radar science missions are to be eventually flown without an on-board operator, all data collection must be performed autonomously from take-off to landing. The Automatic Radar Controller (ARC) is the main instrument flight computer responsible for a myriad of tasks, including commanding the radar configuration and monitoring the aircraft flight path to search for data collection waypoints provided by an on-board flight plan. The pod environment and various hardware units are monitored during the mission to assure the radar instrument remains within an operable range. The ARC communicates with a Radar Operator Workstation (ROW) to receive updated real-time operational commands and to download up-to-date hardware status and telemetry. The ROW provides operator displays for monitoring the health of the radar system and also displays sampled radar waveforms in time and frequency domains. The aircraft location is provided by the on-board GPS/INU and downloaded by the ARC for plotting the current location onto Google maps using software developed at JPL. The UAVSAR platform has been flown throughout most of California and has recently completed successful deployments to Greenland and the Aleutian Islands. A nearly identical UAVSAR pod will be attached to a Global Hawk UAV platform in early 2010 for uninhabited operational flight tests. An additional pod containing another L-band antenna and GPS/INU unit will also be attached to the Global Hawk platform providing dual Lband data collection capability. The command and communication implementation for Global Hawk has been modified from the original GUI test U--.S. Government work not protected by U.S. copyright ? IEEEAC paper#1558, Version 1, Updated 2009:10:27 platform. During flight tests on the GUI the Radar Operator Workstation (ROW) was on-board with the test team. For the Global Hawk flight tests, the Radar Operator Workstation will be in the Global Hawk Operations Center located at the Dryden Flight Research facility. Communications to the ARC will utilize a relatively low speed Iridium satellite communications link. This

paper will describe the functionality of the UAVSAR Global Hawk radar instrument flight and ground systems. We will also discuss fault detection and recovery options provided by these systems. We will describe the capabilities of monitoring and controlling the radar instrument during flight from the Global Hawk operations facility and describe the operational timeline for a typical science mission. [C1179]

### "Improving situational awareness training for Patriot radar operators"

Situational awareness (SA) is the understanding of an environment and how one's actions affect it. We present the Cognitive Air Defense Training System (CADTS) Engagement Control System Simulator (ECS2), currently installed at Fort Bliss, Texas; which aims to increase the cognitive awareness and SA of radar operators of the MIM-104 Patriot surface-to-air missile system. The ECS2 presents multiple visualizations of environmental data on four levels: "Tactical"-the ECS operator's perspective; "Operational"-highly detailed realistic 3D representations; "Strategic"- a representational view containing the entire Earth; and "Time"- real-time game play, with pause and replay abilities. The levels vary in presentation, scope, and accuracy, so the instructor can alternate between 'available' and 'actual' information, to emphasize real world uncertainties as they may appear. Network shared objects are used to allow the differing views of the environmental data to be interchangeable during instruction and in After Action Review. The training system has an Observer Emphasis, where the observers in a classroom have access to all scenario views and a larger context, and the ECS operators in the ECS Digital Interactive Virtual Environments (DIVEs), only have access to the Tactical View as they will during actual deployment. Multiple perspectives can be presented by the instructor during instruction and in After Action Review. We will look at the Player and Observer roles, the four presentations of the environmental data within ECS2, and the technological issues involved in their creation. [C1180]

### "On the use of UWB Radio Interface for EHF satellite communications"

In this work authors investigate the use of IR (Impulse Radio) UWB (Ultra-Wide Band) technique for satellite communications at frequency bands beyond Q/V bands. In particular, the paper shows how an IR UWB communication system is sensitive to typical hardware non-idealities at those frequency bands and compares its performance with the ones of a more classical continuous wave communications system with FSK (Frequency Shift Keying) modulation. Simulation results show that BER (Bit Error Rate) performance for IR-UWB Payload (P/L) architecture operating in W band (with same data rate and bandwidth occupation) are better than a 2-FSK scheme operating at same frequencies range and considering Dirty RF (Radio Frequency) effects. [C1181]

### "LMRST-Sat: A small, high value-to-cost mission"

The Communications, Tracking, and Radar Division at NASA's Jet Propulsion Laboratory (JPL) and the Space and Systems Development Lab (SSDL) at Stanford University are collaborating to fly a nanosat-class mission for costs usually associated with small technology development tasks, a few \$100K. The mission hosts a JPLdeveloped Low Mass Radio Science Transponder (LMRST) on a university-class CubeSat bus as a satellite that occupies a total volume of two liters plus deployable antennas. In low earth orbit, the LMRST payload will provide a far-field source for calibration of Deep Space Network X-Band equipment in the form of an integer turnaround X-Band transponder with support for ranging modulation. The CubeSat bus provided by SSDL supplies power, structural support, and command and telemetry while on orbit. CubeSat development and operations are conducted as a student project. In addition to the payload functions, mission goals include space qualification of the LMRST, demonstration of nanosat capabilities and costs within NASA, and expansion of student-class projects toward eventual deep space missions. This paper describes the work completed thus far, "Phase One": development of the LMRST, satellite bus, and integrated testing; and outlines the work planned for "Phase Two": acceptance testing, launch, and operations. [C1182]

### "Performance evaluation of hazard detection and avoidance algorithms for safe Lunar landings"

Unmanned planetary landers to date have landed "blind", that is, without the benefit of onboard landing hazard detection and avoidance systems. This constrains landing site selection to very benign terrain, which in turn constrains the scientific agenda of missions. Systems for automatic surface reconstruction and for hazard detection, mapping, and assessment are becoming mature. Before they can be put to practical use, it is essential to be able to characterize their performance for the purposes of scientific evaluation and their utility to engineers planning and designing landed missions. It is also important to be able to predict performance for a variety of scenarios. The evaluation metrics need to be simple enough to be readily comprehensible but still to capture the important relevant performance parameters. In this paper we describe the process, metrics, results, and algorithm improvement recommendations from the evaluation of the performance of the hazard detection and avoidance (HDA) algorithms developed in the Autonomous Landing and Hazard Avoidance Technology (ALHAT) Project by means of Monte Carlo simulation of thousands of Lunar landings. [C1183]

### "Distributed prognostic health management with gaussian process regression"

Distributed prognostics architecture design is an enabling step for efficient implementation of health management systems. 12A major challenge encountered in such design is formulation of optimal distributed prognostics algorithms. In this paper, we present a distributed GPR based prognostics algorithm whose target platform is a wireless sensor network. In addition to challenges encountered in a distributed implementation, a wireless network poses constraints on communication patterns, thereby making the problem more challenging. The prognostics application that was used to demonstrate our new algorithms is battery prognostics. In order to present trade-offs within different prognostic approaches, we present comparison with the distributed implementation of a particle filter based prognostics for the same battery data. [C1184]

### "Differential Geometric Estimation for spacecraft formations orbits via a cooperative wireless positioning"

The estimation of relative and absolute positions of spacecraft in a formation, using a novel wireless local positioning system (WLPS), is addressed. The WLPS enables one spacecraft to measure another spacecraft's relative position vector. The Differential Geometric Filter is implemented to estimate the absolute and relative positions of the spacecraft in the formation. Two different scenarios are studied: (1) the observations include WLPS measurements only, and (2) the observations include WLPS measurements in addition to measurements for the absolute position of one spacecraft. Results show that the Differential Geometric Filter provides a fast convergence rate and stable estimation. [C1185]

### "Ground-based orbit determination for spacecraft formations"

Spacecraft formations offer interesting challenges to orbit determination, especially for ground-based tracking. In fact, the limited distances between spacecraft and the possible ambiguity of the observables gathered from the ground have an impact on the solution process. The paper aims to apply the filtering techniques on a refined dynamical model, which can include the main perturbation effects-due to the oblateness of the Earth and, at the lower altitudes, the air drag-on spacecraft trajectories, representing them in series with a remarkably limited number of terms even in eccentric case. The idea is to focus on theoretically expected behavior rather than dealing with an enriched but heavier state including parameters directly related to the perturbing effects. In such a way, it could be possible to obtain a good estimate even with limited spacecraft tracking information. This is an important asset in navigating a formation from the Earth, due to the needed partition of ground station resources among different platforms belonging to the formation, and to the possible ambiguity among the measurements, which further reduce the available data. The specific nature of the dynamic model calls for an estimator with a flexible and ?open? architecture, easily allowing for changes and additions in the model itself. Therefore, the estimator selected for testing the approach has been the Unscented Kalman Filter, versatile enough to allow for increasing model accuracy without the need for tedious computation of the Jacobian. This approach is also intended to offer a different way to investigate special perturbed configurations, via the semi-analytical and almost exact representation of the trajectories. In such a perspective, one of the first application, which is shortly outlined in the paper, will be the analysis of spacecraft formations under the J2 effect. In fact, recent studies identified a set of almost periodic relative configurations among the spacecraft. This s--et (sometimes referred as the special or magical inclination's one) has been recently identified by means of numeric search, and has also received some (partial) explanation. Due to the interest in control effort reduction, it is deemed that a better understanding of this special dynamics, possibly provided by means of a selected modeling approach, can be of some interest. [C1186]

### "Automatic Measurement of Radar Receiver Sensitivity"

This paper puts forward a method to measure the receiver sensitivity automatically. Taking an airborne radar as example, the method utilizes signal integration to improve the accuracy of the measurement. The implementation circuitry and experimental waveforms are given to demonstrate the utility of the method. [C1187]

### "The Research of Families of Odd-periodic Perfect Complementary Sequence Pairs"

The theory of families of odd-periodic perfect complementary sequence pairs(OPCSPF) is given. OPCSPF can be derived from the odd-perfect almost binary sequence and sequence pairs. Some characteristics of OPCSPF are discussed, and the necessary conditions for existence of OPCSPF is given. The methods are studied and proved which construct OPCSPF. [C1188]

### "Design of Wireless Dam Security Information System"

This paper proposed design proposal of wireless dam security information system through the GPRS technical

superiority, introduced hardware system set up based on the GPRS dam security information system in detail, proposed the functional requirements of software modules, has the actual application value. Using the GPRS technology to carry on the network data transfer, easy to use, no region limit, in the field of remote monitoring and control, especially in hydraulic engineering security information system, it has a very good application prospect. [C1189]

### "The Angle-Measuring Algorithm for the Stepped-frequency Radar Based on Dual-line Digital Phase Interferometer"

The phase interferometer is very important in the direction-finding and position of target. In this paper, the phase interferometer is employed to angle measurement of the stepped frequency radar target. By the way of dual-line digital phase interferometer, the contradiction between direction range and direction accuracy is solved. The effect of SNR and AOA on the accuracy of angle measurement is also analyzed. In order to remove the errors of amplitude and phase which is introduced by the antenna element, cable and receiver, an error correction method is presented. The algorithm of angle measurement and the method of removing errors of amplitude and phase are verified by the experiment. [C1190]

### "PMHT with Application of Road Information Based on GMTI"

Probabilistic Multi-Hypothesis Tracking (PMHT) is an algorithm for multiple target tracking when association of measurement and track is unknown. PMHT is an efficient algorithm for GMTI in cluttered environments of which the computational complexity is linear in the number of targets and measurements. An algorithm is presented in this paper to apply road information to PMHT. Road information is used to adjust estimated target state during the process of Kalman filter. Tracking performance of PMHT is increased apparently with the application of road constraint. [C1191]

### "A Wideband Beamformer Extended to MIMO Radar"

MIMO radar algorithms are the latest generation of techniques which can be applied to phased array radars. They offer the potential to improve the resolution, number of targets that can be identified, and flexibility in beam pattern design. To date, most of the work on MIMO radar has been performed assuming the signals are narrowband. However, wideband signals can also improve radar resolution, among other benefits, and are sometimes unavoidable when stringent range resolution specifications must be met. This paper presents a method for extending the MIMO narrowband model to a wideband model. This is necessary to obtain improved results from parameter estimation when the transmitted signals are wideband. The results show that the method greatly improves the results compared to those obtained when no techniques are implemented to compensate for a wideband signal. However, best performance is still obtained with a narrowband signal, and therefore the technique presented might only be of interest when a wideband signal is required. [C1192]

### "An Intelligent System on Water Quality Remote Monitor and Water Bloom Prediction"

An intelligent system on water quality GPRS remote monitor and water bloom prediction based on neural network are proposed in this paper, which can realize the automatic real-time monitor for the change of water quality and via the prediction by neural network for water bloom, thereby solve the lagging state of water quality monitor and the problem of water bloom prediction at present. [C1193]

### "Fault Diagnosis Platform For Radar Circuit Based on Virtual Instrument"

In order to improve the efficiency of the Radar circuit maintenance, in this paper, based on PXI & GPIB Hybrid Bus and virtual instrument technology, a fault diagnosis platform for Radar circuit is developed, and also a fuzzy fault tree reasoning algorithm is presented. This platform is composed of two parts: hardware and software. The hardware consists of a built-in controller and 3 kind of virtual instruments which are digital storage oscilloscope, digital multimeter and spectrum analyzer. The software is constructed by a fuzzy fault tree reasoning algorithm and an expert knowledge database which includes 198 fault tree flow charts of 20-style Radars. By experiment of this platform, the result shows that, with virtual instruments, fuzzy fault tree reasoning algorithm and expert knowledge database, the platform can locate the Radar circuit fault effectively. [C1194]

### "Time resources allocation in cognitive radar system"

This paper considers the problem of simultaneously detecting and tracking multiple targets. The main problem discussed here is the time allocation of cognitive radars in a multitarget environment. Radars are used to detect, to locate and to identify target. The radar performs three main functions: search, tracing and weapon engagement. Each of functions occupies amount of time. It is a key point that to allocate radar time resource

effectively. For cognitive radar, it should have the basic function which is learning. The radar needs to manage its resources dynamically and interactively between the setting of radar parameters to optimize the tasks the setting of radar parameters to optimize the tasks to be carried out and perceive environment highlights the role in which knowledge and intelligence will be central in cognitive radar performance. In this paper, we develop the optimization criterion based on the detection probabilities. [C1195]

#### **"Noise analysis for noncontact vital sign detectors"**

A method for analyzing the overall noise performance of vital sign detectors is introduced. For demonstration purpose, the noise analysis on a quadrature direct-conversion vital sign detector is performed. The detector is divided into three sub-systems including RF Front-end amplifiers, mixer with LO, and baseband amplifiers. The noise characteristics of the sub-systems are studied individually and combined to form the overall noise evaluation of the detector. The study on mixer sub-system results in a key design consideration of mixer. The signal-to-noise ratio at the sampler input is defined as the output SNR and is used to measure the overall noise performance of the vital sign detectors. The effect of output SNR on vital sign detection is presented. Tradeoff between output SNR and detection distance is verified by the experimental results. [C1196]

#### **"Research on Physiological Parameters Monitor Based on Multi-Functional Device"**

In accordance with the special requirements of medical devices, this paper describes the software design process of a physiological parameters monitor based on multi-functional device. The physiological parameters monitoring software achieved serial communication with physiological parameter acquisition module by adding MSComm widget. The monitoring software is designed into multi-view structure for the 5-lead ECG and 7-lead ECG drawing and it displays various parameters of patient and monitor on its dialog bar and status bar. When the monitor gets dangerous physiological signal from patient, the software drives speaker to sound in corresponding way, at the same time, it drives GSM/GPRS module to call for help by sending corresponding message to preset phone number. Test results showed that the monitoring and operational performance of the monitor reached expected requirements and both the two alarm modes could work correctly. [C1197]

#### **"A New Three-satellite High-precision RDSS/RNSS Combination Positioning Method"**

Under the guidance of the comprehensive RDSS, a new three-satellite high-precision RDSS/RNSS combination positioning method is proposed in this paper, which uses a special designed RDSS/RNSS satellite and the others RNSS satellites to determine user position. The key research focuses on its principle and intending performance and lifesaving application. [C1198]

#### **"Stochastic dynamic programming model of adaptive waveform selection"**

In cognitive radar, it is very important to select proper waveform to transmit according to different environment. The adaptivity of waveform corresponding to environment can be realized in many ways. In this paper, stochastic dynamic programming model of adaptive waveform selection is proposed. With this model, dynamic programming algorithms can be used to solve the problems of adaptive waveform selection. The necessity of adaptive waveform selection has been shown with simulations. Finally, the whole paper is summarized. [C1199]

#### **"FM jammer excision by using time-varying AR filter in spread spectrum communication systems"**

The time varying jammer signal degrades the performance of spreading spectrum communication systems. In this paper, time-varying autoregressive (TV-AR) modelling is used to represent nonstationary jammer signals. The modelling approach leads to an effective technique for jammer excision. In this work, jammer components parameterized by their instantaneous frequencies (IF) are effectively removed using the TV-AR filtering. The approach results in a minimum distortion to the desired DS/SS signals in communications. In order to reduce the computation complexity, orthogonal polynomials are used for the basis function of TV-AR model. [C1200]

#### **"Image Fusion Based on Multi-scale Kalman Filtering"**

An image fusion algorithm, based on the Multiscale Kalman Filter (MKF), has been applied to combine remotely sensed data, acquired by radars having different resolutions and can improved information carried by each input image. The considered images have been acquired during the AIRSAR Mission and SIR-C/X-SAR Mission. The data have been co-registered to refer each pixel of each image to a common regular grid. The image fusion algorithm has been tested, and the merged images have been presented at different resolutions. A lineament detection algorithm based on the Hough transform, has been applied to the full resolution input data and to the full resolution merged data. The Golden Gate bridge has been detected in both images, but the computed probability of false alarm is lower in the case of the finest scale merged image than in the finest scale input

image. This fact demonstrates that the knowledge provided by the coarser resolution data has been transferred to the merged image, improving the performance of the lineament detection algorithm. [C1201]

### "The Applications and Methods of Pedestrian Automated Detection"

Pedestrian safety is a primary traffic issue in urban environment. The use of modern sensing technologies to improve pedestrian safety has remained an active research topic for years. The applications and difficulties of pedestrian automated detection were investigated, and the existing sensing technologies such as piezoelectric sensor, infrared sensor, ultrasonic sensor, microwave radar, laser scanner and computer vision were assessed for their suitability to pedestrian automated detection, their advantages and limitations were analyzed. As any one particular type of technology may have difficulties meeting all necessary requirements in various conditions, it is pointed out that a complete and reliable sensing system for pedestrian detection can benefit from the combined use of multiple sensors. [C1202]

### "Calibration Technology of Palmer Scanning Airborne Lidar with Vector Measurements"

It is prerequisite to calibrate misalignment matrix between laser scanner and Position and Orientation System (POS) before airborne Light detection and ranging (Lidar) system being putted into survey application. A palmer scanning Lidar can present forward and backward scan intensity images of ground control areas. The pairs of biases between ground control points and central points of forward/backward scan areas are used to adjust the vector measurements of laser footprints. With a pair of non-collinear laser beam vectors and the corresponding footprint measurements of one single control area, the optimal q-method is adopted to solve the orthogonal rotation misaligning matrix. Hardware-in-loop simulation results show that algorithm satisfies the precision requirement of airborne Lidar calibration and performs robustly under various scenarios. [C1203]

### "Synthetic Aperture Radar Image Segmentation Based on Markov Random Field with Niche Genetic Algorithm"

Markov Random Field (MRF) has been found to be effective in the domains of image segmentations, since the problems can be simplified to search the optimal label fields. The challenges in MRF image segmentations arise due to the complexity of optimization. Although Genetic Algorithm (GA) has been applied into the image segmentation with MRF, yet most of algorithms defined an individual as a pixel with gray-scales coding, which is powerless to restrain the noise. On the other hand, GA emphasizes the evolution of whole label field, which could cause the over-propagation in some local areas and the convergence to partial optima. To avoid trapping into the local optima, Niche Genetic Algorithm (NGA) is introduced into the MRF image segmentation in this paper. NGA uses the sharing function to restrain the mutation between two individuals with high similarity, which could preserve the diversity of populations. Furthermore, a mechanism of fitness interaction in neighborhoods is proposed to contribute to eliminate the isolated sparkle noise in Synthetic Aperture Radar (SAR) image. The followed segmentation experiment for SAR image proved that MRF segmentation with NGA could reach a satisfied result among the noise restraint, edges preservation and computation complexity. [C1204]

### "A Modified SPECAN Algorithm for Synthetic Aperture Radar Imaging"

We present a modified SPECAN algorithm for missile-borne SAR in flat flight mode. Using the proposed technique, long azimuth sequence can be processed at memory constraint which is helpful for real time imaging. In addition, spectrum overlap can be avoided by changing kernel of chirp-z transform and data selection. Experiments on simulated data are carried out to validate the theory. [C1205]

### "Application of Butterworth Filter in Display of Radar Target Track"

The noise in the radar data results in the flutter of the flight target in display screen, which may disturb observer. A rounding method for radar target track using Butterworth filter is proposed in this paper. With the spectrum characteristics of radar target track being analyzed, the filter's parameters can be designed and figured out. Therefore, after the noise in radar signal is magnified by a transformation algorithm, it can be smoothed online. The results of MATLAB illustration show that the method has a reliable denoising performance. [C1206]

### "The Application of Long-Distance Inspecting Electric Power Parameter Based on GPRS Communications"

The system of inspecting electric power parameter based on GPRS communications was designed and the inspecting data worked by CPU was transmitted to the control center by GPRS and INTERNET net. Inspecting industrial signal in real time and long distance was realized. [C1207]

### "3D Reconstruction for Robot Navigation Based on Projection of Virtual Height Line and its Performance Evaluation"

3D reconstruction is a challenging work for the autonomous navigation of robots. This paper proposes a novel 3D reconstruction method based on projection of virtual height line (PVHL). At first partition the scene scope uniformly into grids with a certain size. Then introduce virtual height lines (VHLs) which do not exist in the scene. Each VHL is projected on left image and right image, and two projection lines are generated. Each projection line has a point of intersection with the scene, which is the only existent and visible point on the projection line. So this point has the maximum similarity metric, and the height of the point is that of the corresponding scene. Finding the height of the scene is converted to prove whether the point of intersection has the maximum similarity metric or not. The experiments to reconstruct 3D scene are performed and the results show the proposed method is feasible and effective. [C1208]

### "New Technology and Applications on Millimeter-Wave Sensors"

Some new technology and applications on millimeter-wave sensors are reviewed. A novel method of human presence detection using passive millimeter-wave (MMW) sensors is presented. The method focuses on detecting a standing human from a moving platform in a cluttered outdoor environment using MMW radiometry. Millimeter-wave stepped-frequency sensor and millimeter-wave interferometric sensor are completely realized using microwave integrated circuits (MICs) and microwave monolithic integrated circuits (MMICs). The millimeter-wave stepped-frequency sensor operates from 29.72 to 37.7GHz and has demonstrated abilities in surface and near-surface sensing, including profile mapping, liquid-level monitoring, and anti-personnel mine locating. The millimeter-wave interferometric sensor operates at 35.6GHz and has demonstrated its multi-functional capability for measurement of displacement and low velocity. A new radar sensor architecture comprising an array of transceiver modules. Target applications of the sensor are automotive driver assistance systems. Experimental results with an eight channel radar sensor in the 76-77GHz frequency band are presented, which demonstrate the feasibility of the proposed architecture and show the performance of the modulation sequence and signal processing. Finally the technical challenges of millimeter-wave sensor systems are discussed. [C1209]

### "Ground Clutter Removing for Wind Profiler Radar Signal Using Adaptive Wavelet Threshold"

Wind profiler radar signal is subject to contamination from various non-atmospheric signal. A new wind profiler radar signal processing method based on wavelet is presented for the suppression of ground clutter using adaptive threshold. By using the discrete multi-resolution analysis, we developed the adaptive wavelet domain thresholding method, which allow us to identify the coefficients relevant for clutter and to suppress them in order to obtain the reconstructed clear-air signal. The adaptive algorithm for choosing threshold that allow the processing to adjust automatically to environmental conditions. Experiments for the real radar signal show that the method presented can suppress the ground clutter from the radar signal effectively. [C1210]

### "Automated Detection in SAR Images by Using Wavelet Filtering and Hough Transform"

A novel method of automatic detection of straight lines in Synthetic Aperture Radar (SAR) images is presented in this paper. The proposed technique has been tested on a simulated SAR image, and on a real SAR image. It is based on the joint exploitation of a Wavelet Filtering Algorithm (WFA) and Hough Transform (HT) to extract geometric regular features and to detect lineaments in the considered image. The detail images produced by the proposed Wavelet Filtering Algorithm have the same resolution as the original image. The algorithm has been integrated with a moving mask method on the detected lines in order to find the beginning and the end of the segments. The experiment shows that it has a more efficient tool with respect to the traditional approach. [C1211]

### "Scattering Centers Extraction of Radar Target Using Biquaternions"

Scattering centers estimation results are significant for radar target recognition in high frequency section. This paper introduces biquaternion theory into full-polarization scattering centers extraction of radar target. Firstly, we define full-polarization scattering centers as a biquaternion model. It makes a close connection between polarization parameters. Then, we propose Bihan's BQ-MUSIC thought to extract scattering centers' position parameters. Simulations illustrate that our theory gets better estimation results compared to polarization MUSIC algorithm of complex model. [C1212]

### "Design of Solar Photovoltaic Remote Data Transmission System Based on GPRS"

Taking the Solar Sail System combined by building construction and photovoltaic generation for example, this paper designs Solar Photovoltaic Remote Data Transmission System based on GPRS which completes data

receiving, processing and evaluation indicators' calculation. The framework, composition and communication protocol of the active energy transmission were discussed in detail. The design of Data Centre including data receiving and processing based on .NET platform as well as the mathematical models of the system evaluation indicators is the focus of this paper. According to field test, the test results show that the system perfectly realized remote transmission of solar photovoltaic power and it can not only lay data foundation for calculation of system evaluation indicators, but also provide an effective and reliable basis to the model of renewable energy demonstration. [C1213]

### "Nanosecond Pulser Based on Serial Connection of Avalanche Transistors"

Generation and measure of nanosecond pulse with large amplitude are difficult problems in the field of exploration. The principle of avalanche transistor is analysed and four-stage serial connection of avalanche transistors is designed. Experimental results show that across the 50Г,В load the amplitude of the output pulse can reach 666V and half-width is 3.4 nanosecond. Repeat frequency of the pulse can reach 10KHz. Time-domain waveforms of the pulse and the measure data are shown in the paper. The pulser and the RL-loaded bowtie antenna get matched. The pulser can be fabricated easily and works well. It can be used in UWB Ground Penetrating Radar to improve its validity. [C1214]

### "Improving geometric accuracy of optical VHR satellite data using Terrasar-X data"

The very high geometric accuracy of geocoded data of the TerraSAR-X satellite has been shown in several investigations. This precision has been reached fully automatically without any human interaction and is due to good sensor calibration, high accuracy of satellite position and the low dependency on the satellites attitude solution. High resolution optical images from space don't show this high geometric precision and need further ground control information, which is mainly due to insufficient attitude knowledge. Therefore TerraSAR-X data can be used as Г,В ground control Г,В to improve the exterior orientation and thereby the geometric accuracy of orthorectified optical satellite data. The technique used is the measurement of identical points in the images, either by manual measurements or through local image matching using adapted mutual information (MI) and to estimate improvements for the exterior orientation or Rational Polynomial Coefficients (RPCs). To be able to use this intensity based method, the radar data have to be filtered before starting the matching procedure. Through adjustment calculations falsely matched points are eliminated and an optimal improvement for the attitude angles is found. The optical data are orthorectified using these improvements and the available DEM. The results are very promising and compared using conventional ground control information from maps or GPS measurements. [C1215]

### "Wearable Doppler radar with integrated antenna for patient vital sign monitoring"

A 2.45 GHz wearable Doppler radar unit with radio data link is presented for use in portable patient monitoring and emergency response. Unlike portable Electrocardiograms (ECG) or Photoplethysmography (PPG), the near-field Doppler unit enables monitoring of the person's heart rate without the need for electrical contact or optical access to the patient's skin. The Doppler unit is designed to be embedded in a clothing garment such as a shirt or vest, or used by medical emergency personal in an instrumented blanket or medical stretcher. Since the Doppler unit is placed directly on or behind the patient's torso, the extraneous signals due to relative motion artifacts is greatly reduced. Low-cost design is achieved by employing PWB microstrip elements for the integrated patch antenna, microwave oscillator, and tuning elements. Also, since the distance between the Doppler unit and the patient is fixed, it was possible to tune the detection phase to enable the use of a single mixer diode and eliminate the need for quadrature detection. Measured heart data from this technique shows clear waveform substructure similar to PQRST complex features found in captured ECG data. [C1216]

### "Hybrid array for the detection and imaging of termites"

This paper describes a 24 GHz radar receiver array, designed to detect and image termite activity, behind a wall, floor or ceiling. This hybrid array is composed of two sub-arrays. A Direction of Arrival (DOA) sub-array for wide area detection of termites, and a 3D high resolution imaging sub-array for imaging individual termites. Here, we introduce an enhanced DOA algorithm, to resolve arbitrary numbers of targets, and compare simulation results with video of actual termites. [C1217]

### "Routing and Tracking System for Mobile Vehicles in Large Area"

The paper describes a practical model for routing and tracking with mobile vehicle in a large area outdoor environment based on the Global Positioning System (GPS) and Global System for Mobile Communication (GSM). The supporting devices, GPS module-eMD3620 of AT&S company and GSM modem-GM862 of Telit company, are controlled by a 32bits microcontroller LM3S2965 implemented a new version ARM Cortex M3 core.

The system is equipped the Compass sensor-YAS529 of Yamaha company and Accelerator sensor-KXSC72050 of Koinix company to determine moving direction of a vehicle. The device will collect positions of the vehicle via GPS receiver and then sends the data of positions to supervised center by the SMS (Short Message Services) or GPRS (General Package Radio Service) service. The supervised center is composed of a development kit that supports GSM techniques-WMP100 of the Wavecom company. After processing data, the position of the mobile vehicle will be displayed on Google Map. [C1218]

#### "UHF measurement of breathing and heartbeat at a distance"

The detection of breathing and heartbeat from a distance is important for medical triage and mass casualty events as well as routine monitoring of higher-risk patients. Typical approaches include wiring up patients to devices and wearable devices, but remote detection and monitoring is both easier on the patient and easier to administer. Monitoring at low frequencies means that there is less patient risk as well as extended range and reduced power. In this paper we look at the measurement of breathing and heartbeat of human subjects at UHF frequencies. We characterize the system design and capabilities as well as the algorithmic approach to extracting the signal. We measure biometric ground truth using heartbeat sensors, respiration monitors, and accelerometers. We do accurately measure breathing, and can measure heartbeat when the subject is holding his breath, but have not yet separated the heartbeat from breathing when both are being done simultaneously. [C1219]

#### "Effects of I/Q mismatch on measurement of periodic movement using a Doppler radar sensor"

In this paper, the effect of I/Q mismatch in a 5.8 GHz direct-conversion quadrature Doppler radar sensor detecting periodic movement is studied. The measured movement amplitude under specific I/Q amplitude or phase mismatch is affected by the residual phase, which is determined by the nominal distance from the target to the antenna. It was found that there exist optimal residual phases minimizing the degradation of detection accuracy caused by amplitude and phase mismatches. Experiments were conducted to verify the theory. [C1220]

#### "A coherent low IF receiver architecture for Doppler radar motion detector used in life signs monitoring"

Continuous Wave Doppler radar has been used in human life signs monitoring from a distance. Such systems are basically motion detectors that rely on phase modulation of the radar's reflected signal due to physiological motion which is of a low frequency nature and has significant signal content close to DC. Homodyne receiver architecture is simple, but has its own limitations including DC offset and contribution of low frequency noise from mixers and baseband amplifiers. A coherent low IF architecture has been proposed for this case to improve the performance. It will be shown that SNR is improved using a simple coherent low IF configuration. This is the first reported coherent low IF transceiver architecture for Doppler radar motion sensing. [C1221]

#### "Maximizing Sum of Image Intensity Square Autofocus Algorithm"

This High quality Synthetic Aperture Radar (SAR) imaging requires that azimuth frequency modulation rate is accurately estimated. A new algorithm is proposed for autofocus in synthetic aperture radar imaging. Based on image contrast, the paper analyses the relationship between maximizing sum of image intensity square and image contrast function, and maximizing sum of image intensity square autofocus algorithm is presented. Then the bisection which substitutes for advance and retreat method reduces computation. The processing results of the measured data shows better convergence speed of bisection and the validity of the proposed algorithm. [C1222]

#### "A comparative study of nonlinear filters for target tracking in mixed coordinates"

The measurement model nonlinearity is a major challenge in target tracking. This paper presents a comparative performance study of seven nonlinear filters in handling the measurement model nonlinearity. They are: the extended Kalman filter, the unscented filter, the second order divided-differences filter, the Gauss-Hermite quadrature filter, the two-step Kalman filter, the Gaussian particle filter, and the linear minimum mean-square error tracking filter with polar measurements. Comprehensive performance evaluation and comparison of all of the above mainstream nonlinear filters over the same tracking scenarios are conducted via Monte Carlo simulation. The results can facilitate the choice and design of nonlinear tracking filters in mixed coordinates. [C1223]

#### "Turn rate estimation based on curve fitting in maneuvering target tracking"

Tracking of highly maneuvering targets with unknown behavior is a difficult problem in state estimation. This

paper presents an interacting multiple model algorithm (IMM) utilizing adaptive turn rate models to track a maneuvering target. The turn rate is calculated at each step from the estimator of velocity and the radius of curvature of the trajectory of the target by using Least Square (LS) and curve fitting theory. Simulation in different scenario proves that the turn-rate estimation techniques in this adaptive framework can significantly solve the problem of tracking maneuvering targets. [C1224]

#### "Analysis of induced surface currents on high velocity target using a relativistic approach"

Radar is an electromagnetic system used for the detection and location of objects based on reflection. It operates by radiating energy into space and detecting the echo signal reflected from an object or target. This work analyzes how currents are induced on targets by the electromagnetic waveforms radiated by an antenna when the object is moving at high velocity. It is assumed that the target is a perfect electric conductor moving at high velocity. This work analyzes how the amplitude, the frequency and the duration of these currents are affected by the target velocity. The transmitted electromagnetic waveforms can then be calculated using vector potentials and by using the Lorentz transformation, the electromagnetic waveform is transformed from the stationary reference frame to a moving reference frame. Currents induced on the object can be modeled by using the transformed waveform and the equivalence principle. The object radiates an electromagnetic waveform as a consequence of the induced currents. The radiated waveform is calculated using the vector potentials and once more the reflected waveform is transformed from the moving reference frame to the stationary reference frame using the Lorentz transformation. Finally the equivalence principle was used to calculate currents induced in the antenna by the reflected electromagnetic waveforms. The relationship of the induced current on the antenna as a function of the target velocity is analyzed. [C1225]

#### "Application of Fuzzy Logic control in automated transport systems"

This paper describes a vehicle position control strategy in relation to other vehicles and nearby obstacles with the aim of collision avoidance and improving safe driving in personal transport systems. A simplified probabilistic model together with fuzzy logic control strategy has been proposed, which considers the probability of detection of sensors to be processed by probability coverage matrix. Simulation results in Matlab (Fuzzy logic toolbox) show that the proposed method for the system can yield to more sophisticated and elaborate control strategies. Detailed probabilistic models along with a global optimisation of parameters has been found to enhance the applicability of the Fuzzy Logic scheme. The sensors are based on the radar systems. The sensor fusion to enhance the driver, vehicle, and environment are also discussed. [C1226]

#### "The comparison between the TE<sub>21</sub> mode and the four-horn monopulse technique for LEO satellite tracking"

One of the most well-known techniques, which are used in the ground stations in order to track the LEO satellites, is monopulse. Two most popular of them are four-horn and TE<sub>21</sub>mode monopulse techniques. In this paper the monopulse tracking technique using TE<sub>21</sub>mode is analyzed and compared with the four-horn monopulse tracking technique. The key parameters of TE<sub>21</sub>mode monopulse technique including the linearity and slope of the error signal are calculated. It is demonstrated that the linearity of the error signal is improved in comparison with the four-horn monopulse technique. Although the slope of the error signal decreases in the TE<sub>21</sub>mode tracking technique, the estimation of the satellite angle is more accurate in most of the cases compared to the four-horn tracking technique. [C1227]

#### "Scattering of electromagnetic radiation for a perfect electric conducting cylinder by using multiple angles of polarization"

Radar is a device which detects distant or non visible objects by means of reflected radio waves. The quality of the reflected signal depends on the shape and orientation of the target with respect to the type of polarization used. Most of the antennas currently used on radar systems employ one type of polarization at a time for target detection. This paper describes the importance of employing polarizations of multiple angles on targets, approximately at the same instant of time. To implement this idea a generalized set of equations have been derived which represent the backscatter generated by a cylindrical object. Using different angles in these equations would give the backscatters of different polarizations employed on the same target, at small time intervals. The logic behind this is that there would be at least one angle that would have the maximum signal strength in the backscatter. The backscatter for this angle would satisfy the best quality criterion as compared with the rest of the polarization angles. [C1228]

#### "Kahn-technique transmitter for L-band communication/radar"

This Kahn-technique (Envelope Elimination and Restoration) transmitter operates at 1.2 GHz and produces a PEP output of 50 W. It employs a GaN-HEMT class-F RF-power amplifier, class-S modulators, and a digital signal processor. An overall (driver + final) efficiency of 50 percent or more is maintained over the top 6 dB of the output range. The driver and final are operated to maximize overall efficiency and the predistortion corrects for amplitude and phase errors. While originally intended for pulsed radar applications, the transmitter is capable of producing a wide variety of signals with good linearity and average efficiency. [C1229]

#### **"Imaging method: A strong tool for moving target tracking by a multistatic UWB radar system"**

In this paper, imaging method for moving target tracking by a multistatic ultra-wideband radar system is described. The task of moving target tracking consists in estimation of a target trajectory based on processing of raw radar data obtained from all receiving channels of a radar system. Then, the imaging method applied for target tracking consists of such signal processing phases as raw radar data pre-processing, background subtraction, fusion of the data obtained by receiving antennas of a radar, detection, localization and tracking itself. The performance of the imaging method described in this paper is demonstrated by signal processing obtained by M-sequence UWB radar for a scenario represented by through wall tracking of a single moving target. The obtained results confirm the excellent performance of the discussed method. [C1230]

#### **"Nonparametric techniques for graphical model-based target tracking in collaborative sensor groups"**

Target tracking using collaborative sensor groups is an effective mechanism for reducing the scalability issues in distributed sensor networks. Using graphical models for such a sensor group together with appropriate class of nonparametric message passing algorithms, we explore efficient approaches to handle the related data fusion problems characterized by spatially distributed observations. Messages consisting of multiple Gaussian components have been efficiently handled with the help of nonparametric belief propagation techniques. The advantage of such an approach in a myopic radar network has been verified here using Monte Carlo simulations by comparing the tracking performance obtained with centralized and distributed fusion schemes. [C1231]

#### **"A GLRT detector in partially correlated texture based compound-Gaussian clutter"**

This paper addresses the problem of target detection in the presence of a non-Gaussian clutter modeled in compound-Gaussian form which realizes the clutter process as a product of two independent random processes 'texture' and 'speckle'. The likelihood ratio test (LRT) detector applied to this detection problem reduces the detector to a matched filter (MF) when the texture is considered as completely correlated during a coherent processing interval (CPI). However, in practical applications, the textural component exhibits a correlation which is less than unity. The conventional form of MF based detectors existing in the literature yield a significant fall in the detection performance in such clutter scenarios. In this paper, we propose a generalized likelihood ratio test (GLRT) detector which can effectively detect a fluctuating target in the presence of a compound-Gaussian clutter with partially correlated texture. The results are presented to show the performance superiority of the proposed detector over the existing MF detector in such varying texture scenarios. [C1232]

#### **"A New Detection Method for MIMO Radar Using Hidden Markov Model"**

MIMO radar is a new radar technique developed recently. It can achieve better detection performance than conventional phased radar. Based on the scattering statistic of clutter and man-made target, we propose that hidden Markov models (HMM) can be used to model the clutter and target signals, and that the HMMs can be used to detect target. Simulation results verify its efficiency. [C1233]

#### **"An Algorithm of Weak Signal's Detection on the Condition of Strong Interference"**

An algorithm which can detect weak signals on the condition of strong correlated interference is designed in the paper. The algorithm based on conventional beam forming (CBF) can put nulls on given directions. And the weights only relating to interference's direction is given in the paper. Comparing to adaptive methods, the algorithm is robust and the calculation account is smaller. Simulation results show the algorithm can put null on the strong interference's direction, getting a clear bearing track recorder while the CBF even can't get the target's track. [C1234]

#### **"RF Effect Algorithms of Terrain Environment in Signal-Level Radar System Simulation"**

In radar system simulation, the reliability of simulation results depends not only on radar and target models, but also on RF (radio frequency) environment models, including clutter, multipath and diffraction. In radar function simulation, all of these factors are treated as a single pattern-propagation factor and can only give limited

information for radar models. In signal-level simulation, radar models require that simulated echoes should include information such as delay, phase shift, doppler frequency, polarization, etc. By discussing and analyzing the principles and algorithms of RF environment effects of ground, a ground RF environment model is proposed, which can provide a reliable RF environment for signal-level simulation of radar systems. A simulation example involving clutter model is carried out and analyzed. [C1235]

#### "A Method of Weak Signal Detection Based on Duffing Oscillator"

A new signal detection and estimation method based on the intermittency transition between order and chaos is proposed. Using Melnikov function to determine the threshold of the detection system is introduced. The characteristic of Duffing oscillators with the changing of dynamics of the system is analysed. The method of detection of weak signals in strong noise based on Duffing oscillators is studied by exploiting characteristic of phase changing from chaos state to great periodic state of system nearby critical coefficient. Through analysing the intermittent chaos mechanism of Duffing oscillator, it was found that the system output is a intermittent chaotic signal when input frequency deviates the compulsory drive frequency slightly, and the deviation can be estimated by the statistic characteristic of output chaotic signal. The experiments results indicate that the signal detection method based on Duffing oscillator can detect weak sinusoidal signals with extremely low signal to noise ratio and accurately calculate to-be-detected signal frequency. [C1236]

#### "A 4.5mW digital baseband receiver for level-A evolved EDGE"

A digital baseband receiver ASIC that supports GSM/GPRS/EDGE and Evolved EDGE is implemented in 0.13  $\mu\text{m}$  CMOS technology. The design centers around two main blocks: an adaptive channel equalizer processes GMSK/8PSK/16QAM and 32 QAM modulated signals and a flexible channel decoder supports convolutional and turbo codes, as required for Evolved EDGE. The receiver occupies 2.0 mm<sup>2</sup> and the average power consumption during burst reception and processing is less than 5 mW in each of the modes. [C1237]

#### "A novel 77-GHz radar frontend with 19-GHz signal distribution on RF-PCB substrate"

A novel radar frontend for 77 GHz mid-range-radar (MRR) and short-range-radar (SRR) applications is presented. The radar sensor makes use of a Colpitts oscillator, frequency multipliers, and a transceiver (TRX) mixer. A single sensor contains up to four channels using antenna arrays for angular detection relative to the sensor. The characterization of the integrated circuit's parameters has been carried out using a two-channel sensor with waveguide (WG) transitions. A radar measurement scenario has been realized using a four-channel sensor with a differential antenna array. All sensors have been implemented on off-the-shelf printed circuit board (PCB) substrate. [C1238]

#### "MIMO radar based on reduced complexity compressive sampling"

In their previous work, the authors considered a multiple-input multiple-output (MIMO) radar implemented by a set of randomly dispersed nodes within a small scale network. Exploiting the sparseness of targets in the angle-Doppler space, compressive sampling was exploited for obtaining joint angle-Doppler information on potential targets based on a small number of observations. That approach achieves the superior resolution of MIMO radar with far fewer samples than required by conventional approaches. However, it involves a discretization of the angle-Doppler space, and as the discretization step decreases in order to achieve high resolution, complexity increases. In this paper, a scheme to reduce the complexity of the aforementioned approach for the case of slowly moving targets is considered. The complexity reduction is achieved by decoupling angle and Doppler estimation. An approach is also proposed for identifying angle estimates that correspond to jammers. [C1239]

#### "Data Transmission over GSM Adaptive Multi Rate Voice Channel Using Speech-Like Symbols"

This paper introduces a new method to transmit digital data through Global System for Mobile communications (GSM) voice channel. A novel algorithm is proposed to design a set of Speech-Like (SL) symbols which leads to design a GSM voice channel data modem to modulate and demodulate data on GSM Adaptive Multi Rate (AMR) voice codec which consist of different bit-rates. Designing a set of time-symbols is an off line procedure with the aim of minimizing symbol detection error. This modem is useful in real-time data communication with high priority. The introduced modem encodes data into SL symbols to be transmitted over GSM voice channel and the received SL symbols are decoded back to data. [C1240]

#### "Content Dependent Data Hiding on GSM Full Rate Encoded Speech"

This paper introduces a steganographic approach to embed data on compressed speech bit stream in order to hide secret data. This method may be used by any kind of encoded bit stream, but this research concentrates on

full rate (GSM 6.10) encoded bit stream. This method allows user to adjust embedded data bit-rate or speech quality. Speech quality is determined by Perceptual Evaluation of Speech Quality (PESQ) which is an objective testing. The effect of embedding data to each specific bit of GSM Full Rate coefficients, on speech quality has been investigated and the less important bits are selected to embed secret data. Meanwhile for approaching a higher speech quality, the data embedding positions are based on different speech frame types. In other words the proposed technique is modified to achieve a content dependent algorithm. [C1241]

### "The Chaotic Behavior of the Chaos-Based Phase-Coded Pulse Train Signal"

The article gives two forms of chaos sequence phase-coded radar signal, and uses ergodic criterion of chaos sequence-Lyapunov exponent as a criterion, under which the chaos-based PM radar signal having the desired autocorrelation curve, if the constraint is violated, its autocorrelation curve would be degraded. The conclusion is ensured by several simulation results. [C1242]

### "Performance analysis of range sensors for a real-time power plant coal level sensing system"

A coal-fired power plant typically has silos, bunkers or stock piles in which the fuel is placed for storage purposes. Real-time feedback sensors are utilized to sense the coal height so data can be sent to downstream systems for further processing. These systems are required to accurately sense the height of coal within the bunker or stock pile. The range information is then fed in a real-time fashion to a control system. Inaccurate measurements can result in severe environmental and safety consequences. There are many types of ranging sensors available in the marketplace. The coal-fired power plant application is especially daunting due to the particularly harsh operating conditions and reliability requirements. This research project analyzes the performance of three types of range sensors: ultrasonic, radar and laser systems. These systems are currently operational at a plant located in the North East Texas area. The ultrasonic and radar sensors were part of legacy systems and the new laser sensor was integrated as a part of this study. The feedback signals from each sensor were recorded over time and compared to measured data. The laser sensor proved to be slightly more accurate than the others, but it has some drawbacks that were listed. [C1243]

### "Determination of parameters for digital meter of doppler radars systems for the artillery systems"

Analytical choice of the digital meter parameters based on digital systems of phase synchronization (DSPS) is considered, also the simulation model design in order to perform the optimization of its parameters and to determine the temporary characteristics and the accuracy of the motion parameters of objects estimating, for the systems with autonomous navigation and ballistic training artillery systems. [C1244]

### "Optimized FPGA implementation of Multi-Rate FIR filters through Thread Decomposition"

Multirate (decimation/interpolation) filters are among the essential signal processing components in space-borne instruments where Finite Impulse Response (FIR) filters are often used to minimize nonlinear group delay and finite-precision effects. Cascaded (multi-stage) designs of Multi-Rate FIR (MRFIR) filters are further used for large rate change ratio, in order to lower the required throughput while simultaneously achieving comparable or better performance than single-stage designs. Traditional representation and implementation of MRFIR employ polyphase decomposition of the original filter structure, whose main purpose is to compute only the needed output at the lowest possible sampling rate. In this paper, an alternative representation and implementation technique, called TD-MRFIR (Thread Decomposition MRFIR), is presented. The basic idea is to decompose MRFIR into output computational threads, in contrast to a structural decomposition of the original filter as done in the polyphase decomposition. Each thread represents an instance of the finite convolution required to produce a single output of the MRFIR. The filter is thus viewed as a finite collection of concurrent threads. The technical details of TD-MRFIR will be explained, first showing its applicability to the implementation of downsampling, upsampling, and resampling FIR filters, and then describing a general strategy to optimally allocate the number of filter taps. A particular FPGA design of multi-stage TD-MRFIR for the L-band radar of NASA's SMAP (Soil Moisture Active Passive) instrument is demonstrated; and its implementation results in several targeted FPGA devices are summarized in terms of the functional (bit width, fixed-point error) and performance (time closure, resource usage, and power estimation) parameters. [C1245]

### "COTS implementation of a Sensor Planning Service GetFeasibility operation-Interim status"

This paper reports on the progress of the design and implementation of a Web-based Sensor Planning Service (SPS) that discovers sensors, formulates sensor collection tasks, and determines feasibility of collection tasks for optical and radar Earth imaging spacecraft. The design is founded on Commercial off the Shelf (COTS) mission modeling capabilities from Analytical Graphics, Inc. (AGI). An SPS providing a COTS GetFeasibility operation will make it easier for users to discover sensors that fulfill their needs. A COTS common interface will provide the

user with one well-known set of operations for the initial discovery of candidate sensors. A final selection of sensors can be carried out using the SPS operations of the individual Data Providers. The first step is a Proof of Concept Sensor-Planning Service (PoC-SPS). It includes the design and implementation of a Standard Object Catalog (SOC) and the design and prototyping of the work flow. The work flow prototyping also supports the design of an interface between system modeling language (SysML) system modeling and AGI mission modeling capabilities. The SOC is a community driven library of spacecraft, facilities and other assets with accurate and thorough descriptions of mission capabilities. The SOC is initially populated with optical and radar Earth imaging spacecraft and sensors. [C1246]

#### "Analysis of the information contained in amplitudes of the reflected signals received by space diversity radars"

In this paper cross-correlation treatment of the narrow-band signals of two different frequencies of one band of lengths of events reflected from the radar target is examined. Thus the mathematical model of reflecting characteristics of radar target is used. [C1247]

#### "Economic aspects of realization of the government programs of development of the technical systems"

In this paper the situation of information possibilities in Azov and Black Seas region is given. The search of optimal creation of complex distance monitoring system is proposed. [C1248]

#### "Input microwave devices for space surveillance radar system with identical phase-frequency characteristics"

The results of design and production of input microwave devices for space surveillance radar system with identical phase-frequency characteristics are presented in this paper. Functional design schema is suggested. [C1249]

#### "Initialization of ballistic targets tracking filters with detection probability lower than unity"

Radar tracking of a projectile flying in the Earth's atmosphere is a very complex issue to cope with, due to the need of (suboptimal) nonlinear filtering techniques. Almost all cases found in literature assume that the target trajectory is observable from the firing point to the impact point on the ground, namely the trajectory observation gets under way from the first available measurement. The radar track initiation time is actually a stochastic quantity that has to be treated by means of a statistical procedure. In this paper a preliminary analysis of the effect of a more realistic filter initialization is proposed. [C1250]

#### "Multitarget track before detect with MIMO radars"

Recent advances in Multiple-Input-Multiple-Output (MIMO) radar systems show that they have the potential to improve detection and localization performance of targets over bistatic and multistatic radars. Unlike beam forming, which presumes a high correlation between signals either transmitted or received by an array, the MIMO system exploits the independence between signals at the array elements due to transmit diversity. Previous works focus on waveform design, signal processing and target localization with MIMO radars while no attention has been given to tracking algorithms. In this work, the problem of tracking multiple targets using MIMO radars is considered. The scenario includes multiple targets in a widely-separated MIMO architecture in which Radar-Cross-Section (RCS) diversity can be utilized. Multi target version of Track-Before-Detect (TBD) algorithm is implemented for the collected  $M \times B - N$  orthogonal signals at the receiver, where  $M$  is the number of transmitters and  $N$  is the number of receivers. Besides having the advantage of integrating information over time on unthresholded measurements to yield detection and tracking simultaneously, the TBD technique enables tracking and detecting targets in low Signal-to-Noise-Ratio (SNR) environments. Also, a modified multiple sensor TBD, which weights the target observability to the sensor as a result of target RCS diversity in the likelihood calculation to best fit the centralized MIMO tracking is proposed. Finally, Monte Carlo simulations are performed to evaluate the performance of the proposed tracking algorithm. [C1251]

#### "Design of Schmidt-Kalman filter for target tracking with navigation errors"

In most target tracking formulations, the tracking sensor location is typically assumed perfectly known. Without accounting for navigation errors of the sensor platform, regular Kalman filters tend to be optimistic (i.e., the covariance matrix far below the actual mean squared errors). In this paper, the Schmidt-Kalman filter (SKF) is formulated for target tracking with navigation errors. The SKF does not estimate the navigation errors explicitly but rather takes into account (i.e., considers) the navigation error covariance provided by an on-board navigation

unit in the tracking filter formulation. Including the navigation errors leads to the so-called  $\Gamma, \tilde{B}$  consider covariance.  $\Gamma, \tilde{B}$  By exploring the structural navigation errors, the SKF is not only more consistent but also produces smaller mean squared errors than regular Kalman filters. Monte Carlo simulation results are presented in the paper to demonstrate the operation and performance of the SKF for target tracking in the presence of navigation errors. [C1252]

### "Bearings-only tracking using derived heading"

In conventional bearings-only tracking, the target states are estimated from just the bearing measurements. The accuracy of these estimates can be improved by using the heading, which can be derived from a set of measured bearings, as an additional measurement. In this paper, the target heading has been computed from a set of bearing measurements. This, along with bearings, has been used to obtain state estimates. The Cramer-Rao lower bounds for these estimates is derived and compared with that of the conventional bearings-only tracking. The use of derived headings improves the position estimates during target maneuver. This technique has been applied to multi-target tracking and is found effective particularly during target crossing. The tracking results are obtained using particle filters and compared to that of an extended Kalman filter implementation. The simulation results demonstrate the improved estimates obtained for certain target states. [C1253]

### "Kinematic separation point estimation using PMHT"

When two objects separate there is typically a period of time after the separation when the two objects are unresolved by a radar. This is due to the radar range bin resolution, which will keep two returns as one measurement until there is a clear separation. At that point, a new track will start, but where exactly did the objects separate? The actual separation point may be of interest and finding that separation point is the topic of this paper. Using the PMHT algorithm allows measurements to be  $\Gamma, \tilde{B}$  shared  $\Gamma, \tilde{B}$  between tracks, and therefore, makes an excellent algorithm for when there are closely-spaced unresolved measurements. After a separation event, while the measurements are still unresolved, there will be only one measurement for the two objects. PMHT is quite comfortable with this situation when there are fewer measurements than there are objects because the PMHT has to know a priori how many objects there are. When a new track starts, the PMHT separation point estimation algorithm will be called. Then the PMHT algorithm can add in the unresolved measurements backwards in time to determine the likely separation point. [C1254]

### "Tracking multiple unresolved targets using MIMO radars"

Multiple Input Multiple Output (MIMO) radars are a new generation of radar systems that may bring about many benefits compared to traditional phased-array and multistatic radars. Although different aspects of MIMO radars have been discussed in the literature, the application of MIMO radars in target tracking problems has not been explored in depth. Target localization using MIMO radars with co-located antennas has been discussed in the literature. The main limitation of those approaches is that the number of targets that can be uniquely localized in one cell is restricted. This paper presents a new application of MIMO radars in Multi-Target Tracking (MTT) problems. The main contribution is to show that the use of prior information about the motion of targets relaxes the limitation on the number of targets that can be uniquely detected. A general MTT problem with several targets in the same resolution cell is considered. The goal is to propose a technique to estimate targets' states and the number of targets in one cell. Because multiple targets may fall in the same cell, the measurement in a cell is associated with more than one target. Measurements are outputs of matched filters and range bins that are nonlinear functions of targets' states. Multiple hypotheses are generated based on the uncertainty in target-to-cell association. Then, the best model which gives the number of new targets whose estimates are obtained by the localization algorithm, is selected according to its likelihood. Finally, due to the nonlinearity in measurement model, a UKF based method is used to update estimates of new targets and initialize new born targets. Simulation results show the superiority of the proposed method for joint localization and tracking compared to the previous localization approach suggested in the literature for unresolved targets. [C1255]

### "A track purity approach for tracking metrics"

Proper analysis of a simulated sensor tracking problem requires the ability to correctly determine the true trajectory that underlies each track. Traditionally, kinematic assignment of tracks to truth has been used. More recently, a "track-purity" approach has been proposed to both assess the performance of kinematic truth-to-track assignment algorithms and to overcome some of the anomalies that occur when kinematic assignment is used; particularly for unresolved closely-spaced targets. The track-purity approach relies on a simulation's unique ability to identify which truth objects contribute to each measurement. Less clear are the following issues: 1) When a measurement is formed, what is the percentage contribution from each truth object in each measurement primitive, 2) How should truth contributions be combined and modified as measurement data are

passed through the various data and signal processing algorithms found in a typical monopulse phased-array radar (e.g., closely-spaced unresolved objects, direction-of-arrival estimation, measurement clustering, data assignment, filtering, and multi-sensor fusion), 3) How should truth content values be used to produce a content-based association between tracks and truth? The complete process for establishing the truth content of a track from the initial truth content of each detection to the final truth content at the output of track filtering is discussed. This discussion includes the effects of measurement clustering and centroiding, ambiguity in the measurement-to-track assignment, filter gains used to update the track's state estimate, and a truth-contribution-based method for establishing track-to-truth assignment. [C1256]

#### "Experimental radar with 64-channel digital antenna array"

In this article are analyzed a results of experimental radar with digital antenna array full-scale test against above-water targets. [C1257]

#### "Impulse radio signal processing considering the internal phase-frequency instability"

The impulse radio signal processing method is considered with taking into account their internal phase-frequency instability. [C1258]

#### "Sidelobe cancellation method at the exit of correlation processing scheme"

The criterion of sidelobe cancellation in the receiving tract of radar receiver in the case of usage binary phase-shift keying is considered. [C1259]

#### "Non-stationary EMF measurements"

Problems of accuracy improvement of non-stationary electromagnetic field (EMF) measurement is discussed. New method of calibration is proposed that allows reduction the meter's calibration error to  $\Gamma, B \pm 1$  dB. [C1260]

#### "Essence of radio signals processing in close range reconnaissance"

In this paper the approach to make a high resolution in radar is given. The structure of radar system with projector matrix filters is depicted. [C1261]

#### "Adaptive lattice filters for band-inverse covariance matrix approximations"

Theory of adaptive lattice filters, developed originally for stationary processes with Toeplitz covariance matrices, was well-established by the pioneering contributions of Burg, Kailath, Friendlander. The lattice filters are intimately related to the well-known Levinson algorithm, that requires  $O(N^2)$  operations for  $N \times N$  Toeplitz covariance matrix inversion, and exploit Burg technique for adaptive estimation of reflection coefficients that naturally preserves positive definiteness of the estimated Toeplitz covariance matrix. [C1262]

#### "Application of clustering methods for recognition of technical objects"

In this paper the clustering methods with different similarity measures were used to classifying the intercepted signals generated by electromagnetic sources to one of the previously identified  $L$  classes in  $N$ -dimensional feature space. The quality of these methods performing technical objects recognition was examined by using the computer simulated date. [C1263]

#### "Passive hindrances suppression using complex polyphase signals"

Using complex signals we get possibility of indemnification of passive hindrances in the single channel system of radio monitoring due to the use of correlation and spectral characteristics of certain class of complex signals. [C1264]

#### "Some results of radar signal detections by the use of compressive receiver"

The paper presents some results of weak, pulsed and continuous radar signals detection by the use of compressive receiver. [C1265]

#### "An analytical, imitation and experimental design of device of surveillance is after bearing frequency"

Speech goes in this lecture, about research of device of surveillance after bearing frequency, at the dynamic

change of frequency on an entrance. [C1266]

#### "Application of AR model for radar recognition of meteorological objects"

The algorithm and measuring radar for recognition of meteorological objects are described. [C1267]

#### "Measurement of parameters of solid aerosols in polydisperse medium using double frequency radar"

In this paper the double frequency method for remote sensing of solid aerosols are considered in the case of polydisperse medium, when aerosols particles are distributed by lognormal law. The results of numerical simulation for two extreme cases- $\Gamma, B_{\text{inarrow}}$  and  $\Gamma, B_{\text{wide}}$  distribution law are presented and the limits of the method applicability are estimated. [C1268]

#### "Object recognition with surveillance radar systems"

In this thesis have written description and principle of radar systems and them classification. As well as radar systems are used where and for what. The most optimal signal transmission and principles of systems in general. [C1269]

#### "Information approach to estimation of the multispectrum monitoring device efficiency"

The technique of self-descriptiveness estimation by hyperspectrum "information cube" of video spectrometers is adapted for multispectrum monitoring devices (MMD). [C1270]

#### "Multiprotocol transceiving, Formatting and Temperature monitoring FPGA based unit"

The FCT (Formatting, Communications and Temperatures) electronic unit developed at INTA's radar laboratory as part of the X-Band synthetic aperture radar project (RBX SAR, see ref) is capable of receiving up to four channels of radar pulses and echoes at 1.5 Gbps line rates, with the use of aurora protocol on top of the Virtex 5 gigabit transceivers, format these data and send them to the system's storage unit (UAD) with a parallel protocol. In addition, the FCT communicates with other units through a VME bus. It also handles the memory map of the X-band transmitting unit, as well as translates the VME parallel bus communications to this unit to a 1.5 Gbps serial aurora protocol through optical fiber. Besides, the FCT monitors and stores temperature data gathered from different units of the radar system through a serial SMBus protocol, and manages access to these data through VME bus. Finally, with a second Virtex 5, it formats, decimates and filters the received radar echoes and sends them to the real time processing unit through a serial sFPDP protocol (1.0625 Gbaud). [C1271]

#### "A stochastic-gradient method to design optimal space-time codes for MIMO radar detection"

We consider a MIMO radar system with widely-spaced transmit/receive antennas and study the problem of designing the signal waveforms transmitted by each source node so as to maximize the detection probability for a fixed false alarm rate under correlated Gaussian clutter. The proposed design procedure relies on a stochastic-gradient search and is general enough to be applied to any statistical target model. Examples are provided to compare the performance of the proposed codes with other known coding schemes. [C1272]

#### "A Hotelling T-squared GIP test for detection of over resolved targets"

A new technique for detection and discrimination of stationary or slow-moving over-resolved targets on the ground, based upon a Hotelling T-squared test/generalized inner product (GIP) approach to signal analysis is presented. This robust detector separates radar returns from interference via a coherent process. This GIP-based processing can be applied to single-receiver channel systems, multiple spatial channel systems, multiple polarization channel systems or systems with multiple spatial and polarization channels. [C1273]

#### "Microwave Doppler radar sensor with enhanced immunity against interferences"

Modern anti-armor missiles represent enormous threat for any military vehicle. Simple hand-held missiles are able to penetrate 300 mm, more sophisticated missiles up to 1000 mm of the best steel armors. Active defense methods seem to be promising ways how to face this problem. These systems are based on sensors able to detect and measure approaching threat missile and generate signals that activate a suitable counter-measure. The paper describes Doppler radar sensors designed for active defense configurations. The designed version solves one of potential problems connected with employment of these radars at military vehicles. This concerns

sufficiently high immunity against both unintentional and intentional interfering signals. [C1274]

### "System performance prediction of Firefinder radar"

Thales Raytheon Systems' PC Simulation (PCS) tool allows a rapid simulated evaluation of Firefinder radar performance from a personal desktop computer. Firefinder radars are designed to track hostile rocket, artillery and mortar (RAM) projectiles in order to accurately estimate weapon ground location. The Firefinder tactical code is used within PCS. This design provides a low risk path to rapid prototyping and evaluation of candidate software changes. PCS is used to evaluate candidate software changes to the Firefinder. Candidate design changes which perform well in PCS testing require minimum system level checkout before being checked into the tactical software baseline. The PCS tool contains a simulation engine which reads program control information from input data files. The PCS tool also generates and maintains simulated targets and clutter, simulates the radar signal processing function, performs Monte-Carlo "batch" processing, produces complex target trajectories internally or from an input text file and creates simulation data recording files identical in format to those created by the actual radar. This paper summarizes the capabilities of the latest PCS. [C1275]

### "Using an FPGA digital clock manager to generate sub-nanosecond phase shifts for lidar applications"

When using a Light Detection and Ranging (LIDAR) gun for civil engineering applications, anomalous data were observed. A laboratory system was developed to simulate ranging to moving targets in a controlled environment in order to study the anomalous data and the performance of the LIDAR gun. The laboratory system was found to require the ability to generate sub-nanosecond phase shifts which can be updated in real time. This capability is available in high-quality laboratory, but the required equipment was not available to the authors. This research examines the design and implementation of a low cost system. The final design uses an embedded processor for computation of the necessary phase shifts and possible anomalies and an FPGA system to generate the dynamic precision phase shifts. [C1276]

### "Security threats in Cognitive Radio applications"

In this paper we shall consider security aspects of Cognitive Radio (CR) and its applications. We shall cover design of a security simulation model for cognitive radio and discuss results of conducted experiments using Omnet++ simulation tool in the . Net environment. The aim of this paper is to provide an overview of various applications of CR as well as the security threats faced when applying this technology. The functions, benefits and applications of CR are analyzed, along with the challenges faced by the technology. We shall discuss in detail a several security threats faced by CR and carry out selected research on techniques used to mitigate such malicious attacks and provide examples of simulation experiments in Omnet++. [C1277]

### "A mainlobe interference suppression system based on mismatched filtering"

External interference is the major performance limiting factors of High frequency surface wave radar (HFSWR) for array signal processing. Especially when the interference falls into the main lobe, the beam pattern is distorted with conventional adaptive digital beam former for the sake of suppressing the main lobe interference. In this paper, a system for suppressing external interference is proposed. This system includes three processing modules. The first module receives the main array radar data and produces matched radar data while the second one receives the virtual auxiliary array radar data and produces mismatched radar data based on mismatch filtering. And the last one is an adaptive beam former based on the Coherent Side-lobe Cancellation (CSLC) algorithm which is connected with the former two modules. Effectiveness and practicality of this interference suppression system are confirmed by simulation data and real data processing results. [C1278]

### "SAR images segmentation using edge information"

In this paper a new segmentation method for SAR images is presented which requires applying edge detector such as Sobel, Robert, Prewitt, or canny. Then, use edge information in order to estimate the threshold values required for image segmentation. Segmenting SAR images with low contrast using the proposed method was very satisfactory and the obtained results are very promising. [C1279]

### "An improved adaptive maneuvering target tracking algorithm"

During the process of maneuvering target tracking, the difference between observation value and extrapolated value is processed as noise or maneuvering acceleration according to the range of the difference. However the maneuvering target could not be tracked while the difference is large. In this paper, a new adaptive  $\alpha$ - $\beta$  algorithm is brought out. It is that two extrapolated values are considered, while the target is being tracked. They

are normal extrapolated value and maneuvering extrapolated value. In the end of the paper, the concerning experiments are introduced. The result is that the maneuvering target can be continuous tracked. The performance of the new algorithm is also compared with that of Kalman filter. [C1280]

#### "Tomographic approaches towards focused SAR image development"

Although the similarities of synthetic aperture radar (SAR) and computer aided tomography (CAT) imaging systems have been discussed in several previously published papers, a rigorous implementation of algorithms from one modality have not fully ventured into the other modality(ies). This paper proposes image formation of synthetic aperture radar (SAR) data using techniques developed from CAT systems. The paper provides an overview of the typical signal processing involved with SAR, B-mode ultrasound, and CAT imaging systems. Simulations of SAR received echo data processed using techniques from ultrasound and CAT imaging systems are provided to showcase the possibilities. Further discussions of our proposed future work by incorporating CAT techniques to inverse SAR and real time parallel implementation using general purpose graphical processing units are presented. [C1281]

#### "Automated detection of near surface Martian ice layers in orbital radar data"

An algorithm is presented to automatically detect near surface ice layers in images from the Shallow Subsurface Radar (SHARAD) on NASA's Mars Reconnaissance Orbiter. Mars' ice-rich Northern Polar Layered Deposits (NPLD) represents an extensive geologic record of climate history. Identifying ice layers in cross-sectional images leads to understanding the three-dimensional structure of ice layers. Scientists have manually identified layers in large data volumes, but the automated algorithm will allow studying more images from over a thousand orbital crossings. A unique coordinate transformation, based upon the surface reflection, makes subsequent filtering and detection more effective on near surface layers. Results show promising capabilities for automatically detecting ice layers on Mars. [C1282]

#### "Using full motion 3D Flash LIDAR video for target detection, segmentation, and tracking"

It is now the case that well-performing flash LIDAR focal plane array devices are commercially available. Such devices give us the ability to measure and record registered 3D point cloud sequences at video frame rates. For target detection and tracking applications this allows the processes of structure from motion or multi-view stereo reconstruction to be circumvented. This allows us to construct simple and robust real-time 3D detection and tracking systems. The goal of this work is to demonstrate for the first time a proof-of-concept system using a commercial 3D Flash LIDAR camera. The system will accomplish the detection, segmentation, and tracking of human sized objects using a combination of fundamental point cloud processing algorithms. With marginal refinement efforts the result of this work is directly applicable to perimeter surveillance and site security. [C1283]

#### "Effects of signal distortion in a FMCW radar on range resolution"

Frequency Modulated Continuous Wave (FMCW) radars are used in many range measurement applications. The effects of phase errors in radar antenna, circuit dispersion and of frequency modulation nonlinearity on FMCW radar resolution have been analyzed using computer simulation and experiments with a radar prototype in the 10 GHz band. [C1284]

#### "Rough Terrain Reconstruction for Rover Motion Planning"

A two-step approach is presented to generate a 3D navigable terrain model for robots operating in natural and uneven environment. First an unstructured surface is built from a 360 degrees field of view LIDAR scan. Second the reconstructed surface is analyzed and the navigable space is extracted to keep only the safe area as a compressed irregular triangular mesh. The resulting mesh is a compact terrain representation and allows point-robot assumption for further motion planning tasks. The proposed algorithm has been validated using a large database containing 688 LIDAR scans collected on an outdoor rough terrain. The mesh simplification error was evaluated using the approximation of Hausdorff distance. In average, for a compression level of 93.5%, the error was of the order of 0.5 cm. This terrain modeler was deployed on a rover controlled from the International Space Station (ISS) during the Avatar Explore Space Mission carried out by the Canadian Space Agency in 2009. [C1285]

#### "Automated Classification of Operational SAR Sea Ice Images"

The automated classification of operational sea ice satellite imagery is important for ship navigation and environmental monitoring. Annually, thousands of large synthetic aperture radar (SAR) scenes are manually processed by the Canadian Ice Service (CIS) and pixel-level interpretation is not feasible. Trained ice analysts

divide SAR images into "polygon" areas and then identify the number and type of ice classes per polygon. Full scene unsupervised classification can be performed by first segmenting each polygon into distinct regions algorithmically. Since there is insufficient information to assign a sea ice label for each region within an individual polygon, a Markov random field formulation using joint information to label each region in a full SAR scene has been developed. This approach has been successfully applied to operational CIS data to produce pixel-level classified images and is the first known successful end-to-end process for automatically classifying operational SAR sea ice images. [C1286]

#### "Evaluation of the electric and magnetic field levels of around the medium voltage power lines in related to public health"

In this study, the electric and magnetic fields which are occurred around the medium voltage power distribution lines in the residential areas close to housing are calculated analytically. Study, different MV-LV power transmission lines (PTL) which are settlements in Antalya city center have been selected. The electric and magnetic field values which are occurred around the lines have been examined and the results were evaluated in terms of safety standards and public health. [C1287]

#### "Target localization by a multistatic UWB radar"

Moving target localization and tracking are of great interest for rescue, surveillance and security operations. The radar signal processing procedure providing the target position estimation consists of such phases of signal processing as raw radar data pre-processing, background subtraction, detection, time of arrival estimation, localization and tracking. In this paper, we will focus on the localization phase where we assume that for the target localization UWB radar equipped by one transmitting and N receiving antennas is used. Following this intention, the accuracy of the target localization provided by the least-squares method, the spherical-interpolation method and the Taylor series method applied within localization phase will be compared based on processing of radar signals obtained from real target tracking by UWB radar. The acquired results confirm that the Taylor series method can provide the best accuracy of the target positioning. [C1288]

#### "CFAR detectors for through wall tracking of moving targets by M-sequence UWB radar"

In this paper different CFAR detectors for detection of multiple targets for UWB radar system will be described. In this paper, the cell averaging CFAR (CA-CFAR) cell averaging with greatest of (CAGO-CFAR) and ordered statistics CFAR (OS-CFAR) will be represented. The detectors outputs will be illustrated and compared. The properties of all detectors will be illustrated by real radar signal processing obtained by the measurement with the M-sequence UWB radar. [C1289]

#### "Weak signal enhancement in radar signal processing"

In through wall tracking of multiple targets it is able to detect many times only a target moving closest to the radar antenna system. It results from the fact that the reflections from targets located further from the radar antennas are very weak in comparison to that target. The methods for weak signal enhancement can solve the outlined problem. In the paper, three such potential methods are described and tested on real radar signals. The achieved results confirm their ability to enhance the weak signal components with low computational complexity. [C1290]

#### "Classification of fibromyalgia syndrome by using fuzzy logic method"

Fibromyalgia syndrome (FMS), which appears frequently in females, exhibits itself the form of common pain and decreases life quality of a person significantly, is a musculoskeletal disease. Nowadays FMS diagnosis can be made according to the strict rules set by American College of Rheumatology (ACR). However, using strict rules in making diagnosis of FMS disease is not suitable, because FMS is affected from a good many systems and caused to complicated complaints. On the other hand the fuzzy logic method provides a flexible classification, because it has a rule base set by experts' personal experience alongside the ACR criteria. In this study a classification that is based on fuzzy logic is done for FMS. The measurements are taken from 30 healthy and 60 patient subjects who are also under cure at Suleyman Demirel University, Faculty of Medicine, Physiotherapy and Rehabilitation Center. Consistent results are obtained from comparing the fuzzy logic and experts' comments and experiences for the classification both classification disease and disease's degree. [C1291]

#### "Microwave FMCW Doppler radar implementation for in-house pervasive health care system"

In recent years, the research in the area of ubiquitous healthcare has intensified. There are many technological advances regarding the development of unobtrusive sensors for cardiac and respiratory activity, but the current

scenario is still far away from an everyday life fulfilled with ubiquitous healthcare systems. In this paper, it is described the usage of 24GHz microwave FMCW (frequency modulated continuous wave) Doppler radar (MDR) as one of the main components of a pervasive biomedical system that is part of an assistive environment for the people with less mobility or people with long term health condition. As parts of the present work, in this paper are mentioned the design and implementation of an assistive environment based on a MDR sensor, an experimental study concerning the microwave Doppler radar characteristics and remote sensing of heart rate and breath rate, based on acquisition and processing of the signals delivered by the used radar. [C1292]

#### **"Direction Finding via Beam Scanning and Sparse Reconstruction"**

An improved direction finding method is proposed based on unimodal characteristic of antenna pattern and sparse property of received data. Unlike the conventional methods based peak-searching and symmetric constraint, the sparse reconstruction algorithm requires less pulse and takes advantage of compressive sampling. Simulation results validate performance of the proposed method. [C1293]

#### **"Improving Performance in Neural Network Based Pulse Compression for Binary and Polyphase Codes"**

Pulse compression is important for improving range resolution, and the application of neural networks for pulse compression has been well-explored in the past. However, the practical importance of extracting rather weak echoes of targets that are either distant, or have small radar cross-section, appears to have been overlooked. Addressing this issue, neural networks with improved performance are developed in this paper for both Barker and Polyphase codes. We demonstrate that our networks perform better in such practical situations together with better noise tolerance and range resolution. [C1294]

#### **"The effects of seasonal weather differences on the bio-heat loss transferred from the human body in Antalya city"**

In this study, the effects of seasonal weather differences in Antalya city on the bio-heat losses from the human body have been investigated. For application, the monthly atmospheric temperature, relative humidity, wind speed and atmospheric pressure data, which are observed in 2006, have been used. The sensible and latent heat losses from the human body in terms of skin surface and respiration have been calculated and compared to each other. According to the obtained results, the latent and sensible heat losses from the human body have been varied considerably from season to season. Approximately ninety percent of bio-heat transferred from the human body to the surrounding is caused by the skin and the rest of 10% by respiration. [C1295]

#### **"Magnetic resonance imaging shows that muscle myofascial force transmission causes substantial sarcomere length heterogeneity in human muscles, in vivo"**

In this study, it is aimed to show, using magnetic resonance imaging (MRI), effects of epimuscular myofascial force transmission (EMFT) on sarcomere length distribution in human muscles in lower leg in vivo. The ankle angle of the subjects was fixed and 3D MR image sets were acquired for two different knee angles. Intensity based non-rigid demon algorithm was used to calculate displacement fields and Green-Lagrange strain for each voxel. To calculate the strain in local fiber direction diffusion tensor images (DTI) were acquired. It was showed that m. gastrocnemius crossing the knee has major strain distribution ( $0.125 \pm 0.010$  in proximal and  $0.073 \pm 0.014$  distal) in local fiber direction. Despite remaining isometric during the experiment, synergistic m. soleus (e.g.  $0.088 \pm 0.017$  in proximal,  $0.078 \pm 0.019$  in distal) and even antagonistic muscles ( $0.157 \pm 0.070$ ,  $0.108 \pm 0.037$ ) also show major strain distribution in the local fiber direction. [C1296]

#### **"Charged particle/cell manipulation in spiral microchannels with concentric electrodes"**

In this study, a solution has been proposed by investigating the manipulation and separation of charged particles in spiral microchannels and concentric electrodes. Proposed structure has been fabricated by using MEMS technology and characteristics of electrophoretic force has been demonstrated successfully. Negative charged particles could be manipulated at different speeds and in opposite directions depending on the amplitude and the polarity of the applied electric field. It has been planned that results of this study will be used in the differentiation of charged cells. [C1297]

#### **"The analysis of ground penetrating radar signal of small objects based on generalized S transform"**

In order to do some preliminary analyses on characteristics of ground penetrating radar (GPR) signal of objects

in time and time-frequency domain, and discuss how to roughly estimate the size of an object as well as distance between two objects, firstly the characteristics of GPR signal in time domain was studied in this paper as the size and the distance were changing respectively, secondly the characteristics in time-frequency domain was studied through generalized S transform (GST), the extraction rule of twin-peak attribute was analyzed, the determination of transformation parameter and frequency point was solved. It is pointed out that the size of an object can be estimated in combination of time domain waveform and twin-peak attribute, the definition of a small object can be given according to the size and objective, the resolution of two objects can be improved by twin-peak attribute and the distance can be roughly estimated combined with the attribute and time domain waveform. [C1298]

### "Modeling and Simulation of Adaptive Thresholding in Marine RADARs"

In order to detect targets upon sea surface or near it, marine radars should be capable of distinguishing target reflections from the sea clutter. Our proposed method in this paper relates to detection of dissimilar marine targets in an inhomogeneous environment with clutter and non-stationary noises, and is based on adaptive thresholding determination methods. Variation and mean values of the noise have been estimated in this paper, based on non-stationary, statistical methods and thresholding has been carried out using the suggested two-pole recursive filter. Fixating the rate of false alarm, the concerned threshold resolves the assumption problem of existence or absence of the signal. Performance of the mentioned algorithm has been compared with method known as CA-CFAR in terms of decreasing the losses and increasing calculation speed. The algorithm provided for detection of signal has been implemented at the end of signal-processing algorithms of sea marine radars. The results obtained from the algorithm performance in a real environment indicate appropriate workability of this method in heterogeneous environment and non-stationary interference. [C1299]

### "Intrinsic Membrane Noise in Living Cells and Its Coupling to External Fields"

The phospholipid bilayer membranes surrounding the living cells, play a crucial part in cell signaling and fundamental physiological processes responsible for sustaining life. The study reports physical rationale and some interesting experimental findings on the existence of intrinsic membrane noise (distinct from well-known  $1/f$  and Johnson noise) and coupling of living cell membranes with ambient electromagnetic fields in the Extremely Low Frequency (ELF) regime. The manifestation of these interactions is reported to be seen in the form of amplification of ambient electromagnetic fields by cell membranes and resulting currents, as detected with the help of sensitive pico-ampere and femto-ampere amplifier instrumentation. An experimental technique is introduced to measure such minuscule biological signals existent in living cells. [C1300]

### "Sensing, Triggers and Mobile (Meta)Data"

Processing spatio-temporal queries pertaining to the whereabouts of a large number of mobile entities has traditionally been the topic of the Moving Objects Databases (MOD) research. More recently, due to the advances in sensing and communication technologies, part of the Wireless Sensor Networks (WSN) applications have focused on tracking of mobile objects. These two observations are enough of to warrant a "call" for a confluence of two relatively new but established disciplines. However we observe that a research field of its own right and, historically older than both MOD and WSN-traffic/transportation management-can also capitalize on merging the existing experiences for its own information fusion desiderata. In this talk, we will overview applications from seemingly disparate domains and identify their commonalities in terms of the spatio-temporal contexts, and we will discuss how a reactive behavior with pro-active consequences can be efficiently used for large-scale management of mobile data and meta-data. [C1301]

### "Adaptive thresholding for high dual-tone signal instantaneous dynamic range in digital wideband receiver"

A primary concern in current radar receiver design involves the critical issue of setting a threshold level that is optimal for all operating conditions. A novel adaptive thresholding technique is presented to maximize both receiver sensitivity as well as dual-tone signal instantaneous dynamic range (IDR) for digital wideband receivers. The additional constraint placed for signal detection improves the false alarm rate with minimal hardware increase due to the simplicity of the proposed algorithm. Using our adaptive thresholding technique, the dual-tone IDR is very much independent from the primary signal's strength. The receiver's maximum IDR remains in a constant range, between 30 dB to 34 dB, which is below the primary signal for primary signal strengths between -4 dBm and -24 dBm. [C1302]

### "Analysis of a built-in test architecture for direct-conversion SiGe millimeter-wave receiver frontends"

This paper presents an architecture and corresponding analysis of a direct built-in test of integrated millimeter-wave radar receiver frontends. The proposed test is able to evaluate the gain of the device as well as its noise figure. Focus of this work is the prediction of the accuracy of the tested performance parameters during the design of embedded test solutions. The introduced architecture provides an advantage for cost-efficient development of next generation multigigahertz receiver frontends. The proposed test system is theoretically analyzed as well as evaluated in a simulation environment. [C1303]

#### "A New Model for Rain Clutter Cancellation in Marine Radars"

In this paper we propose a probability density function for signal contaminated by sea and rain non-stationary clutter and noise. Afterward, using the proposed pdf we estimated unknown parameters and using Hilbert transform and obtain an analytical signal to pass its imaginary part through a designed Hilbert filter. In the cell under test, we compare adaptive threshold output from the calculated real and imaginary parts of signal and make an automatic decision to whether anti rain clutter filter must be used or not. This algorithm will decrease adaptively destructive effects of rain clutter just in such cells that are contaminated with rain reflections. Our proposed algorithm is tested on real RADAR signature and implemented in a sea marine RADAR. Results show that the method has good performance in inhomogeneous clutter and different sea states. [C1304]

#### "Privacy-Aware Location-Aided Routing in Mobile Ad Hoc Networks"

Mobile Ad-hoc Networks (MANETs) enable users in physical proximity to each other to exchange data without the need for expensive communication infrastructures. Each user represents a node in the network, and executes a neighbor discovery. Typically, nodes broadcast beacon messages that are received by other participants within the sender's communication range. Routing strategies are computed on-line based on the locations of nearby nodes, and geocasting is employed to deliver data packets to their destinations. However, mobile users may be reluctant to share their exact locations with other participants, since location can disclose private details about a person's lifestyle, religious or political affiliations, etc. A common approach to protect location privacy is to replace exact coordinates with coarser-grained regions, based on the privacy profile of each user. In this paper, we investigate protocols that support MANET routing without disclosing exact positions of nodes. Each node defines its own privacy profile, and reports a cloaked location information to its neighbors. We adopt a novel strategy to advertise beacons, to prevent inference of node locations. We also propose packet forwarding heuristics that rely on cloaking regions, rather than point locations. Our extensive experimental evaluation shows that the proposed routing scheme achieves low delays and high packet delivery ratios, without incurring significant overhead compared to conventional MANET routing protocols. [C1305]

#### "Design and Development of Embedded Intelligent Public Transport Vehicular Terminal"

Intelligent public transport vehicular terminal is an important part of intelligent public transportation system. In view of the fact that the municipal transportation structure in our country and status of the public transportation-vehicular equipment, the paper presents a new type of system-design of the intelligent transportation vehicular equipment. System that is based the embedded intelligent transportation vehicular terminal and take the S3C2410A processor as the core is designed. The paper mainly makes the detailed introduction to this terminal's hardware platform design and software design based on the WINCE embedded operating system. [C1306]

#### "Portable Calibration System for Air Traffic Control Surveillance Radar"

In this article, we design a portable calibration system for air traffic control surveillance radar. This system realizes the automatic flight calibration for Secondary Surveillance Radar (SSR), and also can provide a simple flight calibration capability for any aircraft without standard equipments onboard. On the basis of high-precision GPS technology, this system is composed of a portable dual-frequency & dual-antenna GPS receiver, a portable PC and a software system by our own R&D. By analyzing the position accuracy of GPS and dual-antenna, the portable calibration system has the ability of providing automatically conversion arithmetic of coordinate system between WGS-84 and radar station center. A ground dynamic test for this system has been finished, and an actual flight data processing mission for an airport has been accomplished. [C1307]

#### "Design of Command and Dispatch System of Airport Support Vehicle"

Based on the technology of GPS/GIS/GPRS, the airport support vehicle command and dispatch system is designed in this paper. The information transmission between the vehicle mobile termination and the monitoring control center is established. The function of graphic display and phonetic warning of the airport support vehicle's working process is realized. [C1308]

### "Twin target correction for ultra-wideband radar imaging of breast tumours"

Ultra-wideband radar imaging is a promising modality of imaging for breast cancer detection, based on the dielectric contrast between healthy and pathological tissues. Its aim is to create a map of microwave scattering, and has already proven encouraging results. Unfortunately, the tumor extraction procedure used for reconstruction of the scattering volume leads to the appearance of an artifact called twin target, where a single tumor is expected. In this paper, a signal processing technique is presented to remove this twin target and enhance the contrast of the final image. The radar system and image formation algorithm are first described to explain the origin of the twin target. Experimental data are then acquired and processed by our correction algorithm, demonstrating its ability to fix the twin target issue. [C1309]

### "The vertical handoff between GSM and Zigbee networks for vehicular communication"

Wireless communication becomes important part of everyday life, and in the future, there will be new wireless technologies. Vertical handoff between networks with different wireless network interface becomes so important especially in mobile devices that move at high speed such as vehicles. The vertical handoff is required for a vehicle to connect to different wireless networks for different purpose. For example, vehicles may connect to cellular network to send short messages such as news or email, and may connect to short range networks to acquire some localized information. In this paper, we investigate the possibility and the performance of using GSM/GPRS module as an interface to cellular networks and Zigbee module as an interface to short range networks. In our experiments, we set up both soft and hard handoff scenario to measure the packet round trip time and delay. From the results, it shows that the packet round trip time (RTT) in GPRS networks on the average is around 1-2.5 seconds and in Zigbee network is less than 100 msec. In case of a hard handoff, mobile device needs to prepare for a connection to attach to networks before transferring data. From the results, the network attach time in GPRS network on the average is around 4.5-5 seconds while in Zigbee network is less than 10 msec. [C1310]

### "A neural network based optimization for wireless sensor node position estimation in industrial environments"

The sensor node position estimation is essential in wireless sensor networks. Among many localization schemes, the position estimations based on Received Signal Strength Indicator (RSSI) are mostly used in various systems and applications. However, RSSI data are highly affected from multipath propagation caused by the reflections from walls or objects. These reasons conduct the improper phenomena to radio signals. The significant variation of RSSI influences to the position estimation error especially in industrial environments. In this paper, we present a sensor node position estimation method in industrial environments and its optimization to reduce the error from multipath propagation by using neural networks. An experiment was performed in an electrical machine laboratory to evaluate the designed system in the real environment. The experimental results show that the average position error was reduced to 0.5 m. [C1311]

### "A real-time FPGA-based implementation of target detection technique in non homogenous environment"

This paper presents a high speed real-time target detection system for non homogenous environment based on FPGA Technology. The system implements a Backward Automatic Censored Ordered Statistics Detector (B-ACOSD) to maintain a Constant False Alarm Rate (CFAR) for Radar system with a time constraints in term of signal computing and target identification. The design flow and the hardware implementation of each module are introduced in detail. The proposed system can operate up to 115 MHz by using full pipeline organization and parallel computing which increase the speed up of the target detection system to satisfy the real-time constraints. The proposed architecture is designed, implemented, and tested using Stratix II EP2S60F672C3N FPGA Board. The system has the advantages of being simple, fast, and flexible with low development cost for a reference window of length 16 cells. [C1312]

### "Capability evaluation framework of multichannel ship-to-air missile weapon system against anti-ship missile saturation attack"

Anti-ship missile saturation attack is one important campaign mode in the high-tech sea battle. Aimed at the absence of capability evaluation framework of multichannel ship-to-air missile weapon system against anti-ship missile saturation attack currently, from operation control point of view, it put forward the capability evaluation simulation framework and model respectively so that it can evaluate the campaign capability under the anti-ship missile saturation attack tactics scheme, which assisted the commander decision-making effectively. [C1313]

### "Window memory accesses method in alternate row/column matrix access systems"

Many systems, such as Synthetic Aperture Radar (SAR) processing, two-dimensional image processing, 2d-FFT calculation, need access the row and column data of their matrix alternately. The DRAM memory should be used due to huge data in these systems. To improve the usage of memory bandwidth in such systems, this paper theoretically analyses the optimal window size to minimize the total number of opening/closing pages when performing in such instances by balancing the number of handling physical pages between row and column accesses. This paper presents a window-based optimal memory access method, and we implemented an FPGA-based SDRAM controller with eight simple ports, which is based on window accessing mechanism and supports commercialized SDARM. The experimental results show that the effective I/O bandwidth of external SDRAM using our window layout approach increases from 114.2MB/s of naive implementation to 730.2MB/s with over 6X speedup. In addition, we implemented two SAR processing systems with four FFT processing elements using our window-based SDRAM controller and Corner Turn method separately in FPGA chip. Results show window-based method can achieve a speedup of 2.6 compared to Corner Turn method. [C1314]

### "Remote video monitoring system based on embedded linux and GPS"

This paper presents a design and realization method for remote video monitoring system based on embedded Linux and GPRS (General Packet Radio Service) network. Monitor terminal hardware takes ARM9 S3C2410 processor for centralization, in virtue of SDRAM, USB, GPRS module, etc. Software system adopts embedded linux, the main function realized by C programming to achieve real-time camera data acquisition, image compression and network transmission through GPRS module. Monitoring center receives image data and displays after connects with the terminal. It is easier to be used in windows system. Image data can be transmitted to the monitoring center in 3-6 seconds after JPEG compression. The results showed that the monitoring system has the advantage of high reliability, high efficiency and low cost with ARM9 and GPRS network, and it provides a feasible method for remote video monitoring. [C1315]

### "Remote monitoring system for oil wells based on GPRS technology"

In order to overcome the shortcoming of traditional methods of monitoring oil wells, a design of remote monitoring system based on ARM and GPRS was presented. And then the hardware and software design methods of RTU, system networking method and the design method of background monitoring center were detailed. Using GPRS module and relying on GPRS wireless network and Internet, RTU distributed in different geographic locations can communicate with the background monitoring center. This system broke through the geographical restrictions of oil wells, provided some functions such as oil wells' data collection, remote data transmission, real-time monitor and oil wells' information release, and improved the level of automation in oil production management. The experiment showed that the system could achieve the goal of real-time monitoring of oil wells by the existing mobile communication network. [C1316]

### "Research on optimal wireless city network using mobile network"

By analyzing the various technologies, considering the network development and full use of network resources, the conclusion is gotten that the access side should combine network with 2/3G and Wi-Fi technology. Among them, 2/3G mobile network is mainly used to achieve wide-area coverage, and Wi-Fi network is used to the hot areas with high bandwidth demand for complementary coverage. Also, the core network is researched by several methods using SIM, Web and WAPI. [C1317]

### "Research on long-range and metering reading for water meter based on GPRS"

A kind of long-range and centralized automatic metering reading for water meter system is designed. The function of the GPRS network meter reading and the USB centralized meter reading are accomplished by the M23 GPRS module and the C8051F340 single chip micro-controller. The system is composed of water meter, data collector, concentrator and administer computer. The data of water consumption which will be converted into pulse signals are collected by the water meter, and these pulse signals are disposed by the data collector which can use RS-485 communication with concentrator, water user's machine can be controlled when the upper instructions are received by the way of controlling the electromotion valves. The Concentrator plays an important role in data transit and bus segregation. A USB interface is set up in the concentrator in order to avoid the failure of GPRS network, and the staff can copy the datas by computer or hand-written. The administer computer can manage the user's purchase of water and control the user's machine by sending specific instructions. [C1318]

### "Detecting and assessing the land subsidence in coal mining area using PALSAR data based on D-

### **InSAR technique"**

Land subsidence induced by mining coal is one major issue in terms of damage to infrastructures. In this paper, the potential of L-band repeat-pass differential SAR interferometry for land subsidence in coal mining area is evaluated using ALOS PALSAR data. The focus is to detect and assess the land subsidence using PALSAR data based on D-InSAR technique. Firstly it introduced the basic principle and some applications of D-InSAR. Then it introduced the information of PALSAR and test data of coal mining area. It described the procedure of data processing of two-pass D-InSAR. And it got the deformation of coal mining area. It carried out interpretation and analysis on the D-InSAR results in details. The maximum settlement of land subsidence in this coal mining area was up to 42.4cm in vertical direction in 46 days. At last, it got some valuable conclusions in monitoring the land subsidence in coal mining area using two-pass D-InSAR technique. The test proves that PALSAR data is suitable for monitoring the land subsidence in areas with vegetated land cover, such as coal mining area.

[C1319]

### **"Error analysis in phased array antenna pattern simulation"**

This paper is mainly focused on the errors leaded by improper use of approximate antenna pattern formula and common errors in phased array radar antenna pattern simulation. First, the formula of linear and planar phased array antenna pattern is derived. Then, the precise definition of argument is presented and some precise and approximate expressions of antenna pattern are listed. Finally, simulation result is shown about errors between precise and approximate antenna pattern expression. The discrepancy caused by approximate expression and common errors is also summarized and analyzed in this paper. [C1320]

### **"A novel algorithm of coherent integration for moving target detection"**

The problem of detecting moving targets which migrate between rang cells is considered. The traditional MTD method can not effectively integrate the energy of targets, because it integrates multi-pulse in the same range cell in a CPI. This paper introduces a novel algorithm of coherent integration for moving target detection (MTCI), which is calculated along the track of the moving target. A mathematical formula of MTCI algorithm is derived based on the signal model of a moving target in Chirp Radar. The integrating results of MTCI and MTD methods in the Gaussian white noise background are also compared. A Monte Carlo simulation has been performed to evaluate the detecting performance of MTCI algorithm, and the detection curves are also given. [C1321]

### **"Probability hypothesis densities for multi-sensor, multi-target tracking with application to acoustic sensors array"**

Random sets theory offers a uniform framework for the multi-source data fusion, and all problems of the data fusion could be describe, analyzed and solved in this framework. The multi-sensor multi-target tracking problem could be natural represented in the framework. It is of engineering importance to tracking low altitude moving targets with acoustic methods due to the blindness of the traditional radar detecting. In this paper, an algorithm for tracking the low altitude or ground moving targets is put forward based on the Probability Hypothesis Density (PHD) Filter. The PHD Filter based on Finite Set Statistics doesn't need consider data association for multi-target tracking, which propagates the PHD or first moment instead of the full multi-target posterior, and it could estimating the unknown and time-varying number of targets and their states under clutter environment. In the practical, we use the Sequential Monte Carlo (SMC) method to approximate the PHD. The paper presents a novel and fundamentally well-grounded framework for tracking multiple acoustic targets using PHD Filter and passive acoustic localization technique. Simulations are also presented to demonstrate the performance in tracking a randomly varying number of targets in a clutter environment. [C1322]

### **"Study on air formation to ground attack-defends decision making in duple-fuzzy condition"**

With the development of modern military technology, uncertain decision-making problems become more and more exigent to be solved in military command and control. Based on game theory, and taking air formation to ground attack-defends campaign as the background, this paper establishes an opposed dynamic decision-making model. As to the problems in military decision-making in duple-fuzzy condition in uncertainty, this paper puts forward a duple-fuzzy-influence-factor, which reflects the duple-fuzzy influence on battle units, and establishes a duple-fuzzy opposed decision-making model in anticipant value and in correlative chance way farther to get strategy equilibrium. It can be seen from the simulating results that the model disposes the duple-fuzzy status in battlefield reasonably, analyzes the fighting results objectively, and offers a powerful decision-making support for military operation. The method proposed in this paper is practically and effectively, and has a good future in its application. [C1323]

### "A novel range alignment algorithm for ISAR"

A novel technique is proposed for range alignment in inverse synthetic aperture radar (ISAR) imaging. The correlation of complex High Range Resolution Profiles of two echoes is calculated as the quality measure of range alignment, and its applicability is analyzed. The shifts introduced by the echoes are obtained in the frequency domain without interpolation, so the computation burden is greatly reduced. In addition, the shift is implemented by introducing a phase ramp in the frequency domain, which removes the integer steps in the time domain. [C1324]

### "A novel approach to synthesize the range profile via predesigned stepped-frequency waveforms"

In stepped-frequency radar systems, the phase error due to target motion in each burst makes range profiles blur. Conventional technology, such as motion compensation, requires velocity estimation to eliminate the distortion of the synthetic range profile. However, it suffers a major drawback, namely that it is difficult to achieve real-time accurate estimation of the velocity of the target. A novel technology is presented to achieve a focused target range profile via predesigned stepped-frequency waveforms. By applying a new stepped frequency waveform, HRRP of the target can be obtained by the Fourier transform without any other process. The simulation results demonstrate the effectiveness of the proposed technology. [C1325]

### "Signal and data processing for radar sensor head network"

This paper deals with basic blocks for processing and pre-processing of data acquired from radar sensor heads in developing system for the trajectory tracking. Signal processing is concentrated in acquisition unit and thus an acquisition unit and their cooperation in network are described in detail. The acquisition unit provides the capturing data from a Doppler radar head and processing a beat frequency spectrum. Collected data are transferred through a system network and controller to computer where the investigated trajectory is calculated. [C1326]

### "An Efficient Method of Pulse Repetition Interval Modulation Recognition"

A novel recognizer that automatically reports the PRI (Pulse Repetition Interval) modulation type of a radar pulse signal is developed. The proposed method utilizes the features based on the properties of PRI sequence for each PRI modulation type both in time and frequency domain. These features are defined as zeros-crossing density, harmonic amplitude ratio and sign properties of difference of the PRI sequence, which can be easily extracted from PRI sequences with small samples size. In addition, the proposed method also can be used to estimate the PRI modulation period for the periodic PRI modulation type signals. Simulation results show that the proposed approach is robust in the presence of measurement noises, missing and spurious pulses. [C1327]

### "Signal Filtering Based on Wavelet Transform and its Application in Ground Penetrating Radar"

Towards wavelet transforms part characters in time domain and frequency domain, a practical GPR signal processing method is proposed. Based on continuous wavelet transform, the main component of echo signal is extracted by energy analysis. Through scaled decomposition and frequency filtering, the disturbed component is eliminated. The SNR of reconstructed echo signal is improved. The experiments of real data indicate it improves the processing performance of underground target detecting than continuous wavelet transform. [C1328]

### "A Bayesian approach for SAR images segmentation and changes detection"

In the context of image processing and classification, an important problem is the development of accurate models for Synthetic Aperture Radar (SAR) image segmentation. In this paper we propose a highly efficient unsupervised algorithm for image segmentation and changes detection, based on the Generalized Gaussian mixture model. Our work is motivated by the fact that SAR images are highly corrupted by speckle noise, and contain non-gaussian characteristics impossible to model using rigid distributions. Generalized Gaussian mixture models are robust in the presence of noise and outliers, more flexible to adapt the shape of data, and less sensible for over-fitting the number of classes compared to Gaussian mixture. [C1329]

### "Latency-information theory"

In this paper the mathematical-physical theory of communication-observation that is part of latency-information theory (LIT) is reviewed. LIT surfaced from the confluence of classical information theory, relativity theory, quantum mechanics, statistical physics and a 1978 conjecture by the author of a structural-physical certainty-uncertainty duality for quantized control. Control, radar, physics and biochemistry applications illustrate the theory. As part of the review, LIT is revealed to communicate through latency-certainty channels and/or information-uncertainty channels for observation across latency-certainty sensors and/or information-uncertainty

sensors, a mathematical-physical efficiency perspective of the Universe in a four quadrants revolution. While the first and third quadrants are concerned with the life time of physical signal movers and the life space of physical signal retainers, respectively, the second and fourth quadrants are about the intelligence space of mathematical signal sources and the processing time of mathematical signal processors, respectively. The four quadrants of LIT are conjectured to be physically independent with their system design methodologies guided by dualities and performance bounds. Moreover, the tools of statistical physics bridge them, and inherently lead to the discovery of a novel certainty dual for thermodynamics named lingerdynamics. [C1330]

#### **"Reconfiguration-aware spectrum sharing for FPGA based software defined radio"**

This paper focuses on reconfigurable systems for software defined radio applications in which the underlying hardware is dynamically reconfigured for packet processing of multiple protocols. However, due to non-negligible reconfiguration delay overhead, the physical layer may not be able to respond to all the packets scheduled by MAC layer. In this paper, we present a reconfiguration-aware spectrum sharing and spectrum access scheduling at MAC layer. We considered four protocols similar to WiFi, WiMax, GPRS, and WCDMA on a FPGA-based system. Our results show that the optimal solution outperforms the adopted existing heuristic for time slot scheduling by 13.29%. [C1331]

#### **"Robust Novel EM-Based Direction-of-Arrival Estimation Technique for Wideband Source Signals"**

Direction-of-arrival (DOA) estimation for wideband source signals using near-field acoustic sensor networks has been drawing a lot of research interest recently. A wide variety of DOA estimation approaches are based on the predominant maximum-likelihood objective. In this paper, we would like to tackle with the DOA estimation problem based on the realistic assumption where the sources are corrupted by spatially non-white noises. We explore the respective limitations of two popular DOA methods for solving this problem, namely the SC-ML and AC-ML algorithms, and design a new expectation maximization (EM) algorithm. Through Monte Carlo simulations, it is demonstrated that our proposed EM algorithm outperforms the SC-ML and AC-ML methods in terms of the DOA accuracy. [C1332]

#### **"The Integrative Application of Anti-Jamming Technology for Radar"**

This paper analyzed some primary techniques of anti-jamming technology for radar. Simulation results show the merit of each method. And it proposed a new idea that combines some typical anti-jamming techniques together. It was a more effective way of the integrative anti-jamming technology. [C1333]

#### **"On the modelling of transient scattering under ultra wideband short-pulse electromagnetic excitation"**

Accurate modelling of electromagnetic radiation, scattering and propagation using ultra wideband (UWB) sources has been of significant interest with ongoing application in areas such as short-range communications, through-the-wall imaging, ground-penetrating radar and medical imaging etc. Numerical modelling of these applications is vital to the evaluation and enhancement of their performance. In this paper, a review of different methods for numerical modelling of the transient electromagnetic response under UWB short-pulse excitation is undertaken. The advantages, limitations and challenges of both direct and indirect time domain methods are described in detail and numerical examples of transient scattering demonstrate the use of an indirect time domain method. [C1334]

#### **"A new judging method for radar electromagnetic compatibility analysis"**

This paper proposes a new judging method of EMC based on signal detection theory. First of all, the traditional judging method of interference measure is introduced, and its disadvantage is pointed out. Then, the signal processing of radar system is analyzed, and the relationship of detection probability ( $p_d$ ) and interference to noise ratio (INR) is established. Based on the definition extension of detection probability,  $p_d$  is used to judge radar electromagnetic compatibility. Finally, simulation results indicate that the detection probability fall to 50% as the interference power exceeds the threshold 1.7 dB. This method can illuminate the interference condition between radars quantitatively and objectively. [C1335]

#### **"Computational electromagnetic modeling & simulation of ultra wideband sub-surface sensors for the detection and imaging of buried objects using spatial and spectral diversity"**

An enhanced remote sensing technique for the detection and identification of deeply buried objects is presented in this paper. A new RF Tomographic Technique is proposed for developing RF CAT Scans of buried objects using spectral and spatial diversity. This imaging technique uses an embedded ring of subsurface radiators as

the source of strong underground radiated transmissions. Distributed surface-contact sensors are used to collect the tomographic data for relay to a remote control site. Three-dimensional numerical imaging algorithms have been developed to detect, image, and characterize deeply buried objects. Distributed transmitters and receivers significantly increase unwanted mutual coupling and EM emissions that interfere with signal reception; however, by embedding the transmitters underground, reduced mutual coupling and EM emissions, and improved signal-to-noise ratios, can be achieved. Simple 2D surface SAR experiments over deep mine shafts were performed to validate and verify (V&V) the 3D processing algorithms using 2D surface SAR sensor data. The WIPL-D CEM Code was used to model and simulate (M&S) the embedded and distributed sensors and to verify the significant enhancement in the received signal-to-noise ratio obtained by burying the radiating antennas. [C1336]

#### "Some Analysis of Fuzzy CAGO/SO CFAR Detector in Non-Gaussian Background"

In order to improve radar's detection performance under non-Gaussian background clutter. We design a new distributed fuzzy CAGO/SO-CFAR detection system including two sensors. Both sensors compute the value of the membership function mapping to the false alarm space according to the samples of the reference cells, in the fusion centre two values are combined according to four kinds of fusion rule to estimate the background clutter power. The simulation results prove the detection improvement of CASO based on algebraic-sum rule under multi-target environment, and present better false-alarm-control capacity of CAGO based on MIN rule under clutter-edge environment. [C1337]

#### "Performance Analysis of OSAP-CFAR Detector in K Distribution Background"

The OSAP-CFAR employs soft rule based on fuzzy logic to give better detection probability than that of OSGO and OSSO-CFAR detectors for Weibull clutter. However, studies show that the K distribution provides a better fit for many clutter situations. The performance of the OSAP -CFAR is studied and compared with OSGO and OSSO-CFAR for the Swerling II target model in K distributed clutter. The results represent that the detection performance of OSAP-CFAR detector is superior to that of OSGO and OSSO-CFAR detectors both in the homogenous background and in multiple interfering targets situations. [C1338]

#### "Fast electric field change pulses location technique"

Using both fast and slow electric field change sensors and field mill, multi-station observations on lightning flashes in Chinese Inland Plateau was conducted during the summer of 2004. All of the stations were synchronized by GPS with a time-resolution of  $\pm 50$  ns. Using the different time of arrival (DTOA), a lightning radiation location technique, based on the fast electric field change sensor, was developed. Radiation pulses in the five intra-cloud (IC) lightning discharges which occurred on 20th August and cloud-to-ground (CG) lightning discharges which occurred on 16th July were analyzed. The results indicated that the technique developed could effectively locate the lightning radiation sources. Furthermore, the lightning discharges were compared with the Doppler radar data. Results showed that the radiation sources were well associated with the storm development. [C1339]

#### "All-optical parallelization for high sampling rate photonic ADC in fully digital radar systems"

Optical samples of RF signals are all-optically parallelized for further processing in low-speed electrical digitizers. This technique enables high-rate sampling with no additional jitter and limited SNR degradation, making this solution suitable for radar systems. [C1340]

#### "Transmit policies for MIMO radar detection and time-delay estimation"

This paper is aimed at investigating the role of Space-Time Coding (STC) for target detection and time-delay estimation through MIMO radars with widely spaced antennas. To this end we formulate the waveform optimization problem as a constrained maximization of some detection-oriented figures of merit under an accuracy constraint. Interestingly, such an additional constraint deeply modifies the optimal transmit policy. We also offer closed-form formulas of the Fisher Information in target delay estimation as a function of the singular values of the code matrix. Numerical results validating the theoretical findings are also given. [C1341]

#### "Localization performance of coherent MIMO radar systems subject to phase synchronization errors"

Localization advantages of coherent Multiple-Input Multiple-Output (MIMO) radar systems are reliant on full phase synchronization among all participating radars. Phase synchronization errors are practically inevitable, reflecting on the system localization performance. In this paper quantitative tools to assess this effect are provided. The lower bound on the mean-square error (MSE) is set by the hybrid Cramer-Rao bound (HCRB) for

the joint estimation of the target location and the phase synchronization offsets at the radars. The latter are modeled as random unknown. The HCRB of the unknown target location is shown to be equal to the CRB derived by discarding the random phase synchronization errors through marginalization, i.e., treating them as nuisance parameters. Therefore, the HCRB closed-form expression provides an asymptotically tight bound on target location estimation MSE at high signal-to-noise ratio (SNR). The bound is shown to follow the CRB in the absence of phase errors up to a threshold point, determined by the synchronization error variance, the SNR, and the number of mismatched transmitting and receiving sensors. Beyond this point, the HCRB asymptotically reaches a lower limit, proportional to the synchronization errors variance and independent of the SNR. The value of the threshold point and lower limit are determined for symmetrical radar deployments. [C1342]

#### "Diversity gain for MIMO radar employing nonorthogonal waveforms"

Initially we formulate a very general hypothesis testing problem where we attempt to distinguish between zero-mean Gaussian clutter-plus-noise only and returns which are a linear transformed version of a zero-mean Gaussian random vector plus this clutter-plus-noise. We show that the diversity gain of the optimum processing for this hypothesis testing problem must be less than or equal to the rank of the linear transform. Next we apply this result to study diversity gain for optimum MIMO radar processors for cases with  $M$  transmit antennas,  $N$  receive antennas, and a target composed of  $Q$  scatterers. If the transmitted waveforms span a lower dimension  $M'$  than  $M$ , then the largest possible diversity gain is no greater than  $\min(NM', Q)$ . We also show a diversity gain of  $\min(NM', Q)$  can be achieved under certain conditions. For a general correlated Gaussian clutter-plus-noise model and a general correlated Gaussian reflection coefficient vector, the diversity gain for noncoherent and coherent processing is discussed. Extensions of all results to cases with nonGaussian reflections and clutter-plus-noise are discussed. [C1343]

#### "Neural network-assisted reconstruction of full polarimetric SAR information"

This paper describes a novel approach to the reconstruction of synthetic aperture radar (SAR) fully polarimetric data from compact polarimetry (CP)  $\Gamma, B/\pi/4$  mode. A method is developed which utilises a multi-layer perceptron (MLP) based neural network, to perform reconstruction of scenes with various ground-cover types. In particular, the approach shows potential for the reconstruction of full polarimetry for built-up areas as a complement to existing techniques which are more suitable for natural land cover areas. Performance assessment is presented, using both L-band and C-band data, involving comparison with existing techniques using mean-squared and mean-squared-log measures. [C1344]

#### "Sparse representations for automatic target classification in SAR images"

We propose a sparse representation approach for classifying different targets in Synthetic Aperture Radar (SAR) images. Unlike the other feature based approaches, the proposed method does not require explicit pose estimation or any preprocessing. The dictionary used in this setup is the collection of the normalized training vectors itself. Computing a sparse representation for the test data using this dictionary corresponds to finding a locally linear approximation with respect to the underlying class manifold. SAR images obtained from the Moving and Stationary Target Acquisition and Recognition (MSTAR) public database were used in the classification setup. Results show that the performance of the algorithm is superior to using a support vector machines based approach with similar assumptions. Significant complexity reduction is obtained by reducing the dimensions of the data using random projections for only a small loss in performance. [C1345]

#### "Range estimation for MIMO step-frequency radar with compressive sensing"

The authors recently proposed a parameter estimation technique for multiple-input/multiple-output (MIMO) radar systems that employ compressive sensing (CS), and which applies to the case of slowly moving targets. This technique is based on the use of a step-frequency technique, and it allows angle, Doppler and range information to be estimated in a decoupled fashion. This decoupling significantly reduces the complexity of parameter estimation without a concurrent performance loss. The current paper considers the range-estimation performance of this method for the particular cases of linear and random step-frequency techniques. It is shown that the linear step-frequency technique requires less bandwidth than the random step-frequency technique in order to achieve the same performance. [C1346]

#### "MIMO radar target detection with parametric scattering correlation model"

Multiple-input multiple-output (MIMO) radars utilize various sources of diversity to improve the performance of the radar. A MIMO radar in which angular diversity is achieved by using widely distributed antennas has been proposed to reduce the impact of the fluctuations of the target radar cross-section. This type of system is also known as the statistical MIMO radar. Typically, it has been assumed that the signals received by different

antennas are either fully correlated or independent depending on the configuration. In this paper, we assume more realistically that the scattering from the target is correlated. We show that taking the correlation of the scattered signals into account can improve the probability of detecting the target. This is achieved by using a parametric model for the scattering which allows one to efficiently estimate the scattering covariance matrix. The numerical examples demonstrate that the probability of detection remains good even when parameters of the model are inaccurate. [C1347]

### "Cramer-Rao bound for joint location and velocity estimation in multi-target non-coherent MIMO radars"

In this paper, we focus on a performance bound for joint location and velocity estimation in non-coherent MIMO radars with multiple targets, which has not been studied before. Closed-form expressions for the Cramer-Rao bound are provided for a two-target case. We use numerical simulations to validate the Cramer-Rao bounds and use these bounds to study the performance of a non-coherent MIMO radar system. We analyze the influence of the distance between two targets on the estimation performance. Simulation results reveal that the spatial advantage, which was uncovered previously for a single-target case, also applies for two targets. [C1348]

### "Feasibility of range estimation using sonar LPI"

Using a detailed waveform-based simulation framework, a study on the feasibility of LPI sonar is performed for covert range estimation. A frequency selective channel filter is applied for realistic ocean simulation. The platform uses matched filtering and the target uses energy detection for processing the received signal. The objective of the platform is to estimate the range to the target while ensuring that the target still fails to detect the platform's pinging LPI waveform. A platform-target encounter scenario was designed for Monte Carlo simulation. Evaluation of system parameters was performed to assess for the feasible conditions for covert range estimation. [C1349]

### "Ordering for estimation"

A discretized version of a continuous optimization problem is considered for the case where data is obtained from a set of dispersed sensor nodes and the overall metric is a sum of individual metrics computed at each sensor. An example of such a problem is maximum likelihood estimation based on statistically independent sensor observations. By ordering transmissions from the sensor nodes, a method for achieving a saving in the average number of sensor transmissions is described. While the average number of sensor transmissions is reduced, the approach always yields the same solution as the optimum approach where all sensors transmit. The approach is described first for a general optimization problem. A maximum likelihood target location and velocity estimation example for a multiple node non-coherent MIMO radar system is later described. In particular, for cases with near ideal signals, sufficiently small surveillance region and sufficiently large signal-to-interference-plus-noise ratio, the average percentage of transmissions saved approaches 100 percent as the number of discrete grid points in the optimization problem  $Q$  becomes significantly large. In these same cases, the average percentage of transmissions saved approaches  $(Q-1)/Q \approx 100$  percent as the number of sensors  $N$  in the network becomes significantly large. Similar savings are illustrated for general optimization (or estimation) problems with well designed systems. [C1350]

### "A combined Teager-Huang and Hough Transforms for LFM signals detection"

A new method for linear FM (LFM) signals detection in the time-frequency plane using Teager-Huang Transform (THT) is proposed. Time-Frequency Representation (TFR) is viewed as an image where image processing techniques are applied to detect frequency patterns of interest. THT is used in conjunction with Hough Transform (HtT) called (THHT), where the output is a TFR free of cross-terms. THHT is applied to signals composed of LFM and the results are compared to Wigner-Ville Distribution-HtT and smoothed Wigner-Ville Distribution-HtT. Results show the good performance of the THHT in terms of detection and estimation compared to WVD based methods. [C1351]

### "Non-coherent MIMO radar in a non-Gaussian noise-plus-clutter environment"

The initial papers on MIMO radar have triggered a tremendous amount of research work recently. How the MIMO radar detector, previously designed for Gaussian noise, performs when the noise-plus-clutter is non-Gaussian is still unknown. In this paper, we evaluate the detection performance of the Gaussian detector under the non-Gaussian noise-plus-clutter in a non-coherent MIMO radar system. Using the theory of Spherically Invariant Random Vectors (SIRVs), we study three non-Gaussian noise-plus-clutter models employing the K, Laplace, and Student-T distributions, respectively. Simulations are carried out for different numbers of antennas, SNRs and false alarm probabilities. The results show that non-Gaussian noise-plus-clutter has no impact on the diversity gain of a MIMO radar system although it degrades the detection performance in some other ways. We

also verify some known results on the optimality of the Gaussian detector for SIRV noise-plus-clutter models, while showing this is not true for non-SIRV models. [C1352]

### "An Investigation on the performance of receiving Optical Beam-Forming Networks"

Next generation wideband and ultra-wideband radar antenna arrays need efficient true-time delay networks for array control. Following the great interest for optical control of antenna array beam steering, performance analysis of optical beam-formers is a must. In this paper signal to noise ratio and dynamic range of simple optical beam-forming structures with components off the shelf are investigated theoretically. Especially the effects of certain power combining components such as arrayed wave guide gratings, broadband passive optical combiners and microwave combiners inspected. It turns up that an efficient microwave combiner would surpass the optical combiners in both SNR and dynamic range. [C1353]

### "Receiver antenna array"

Our aim is to develop a microwave receiver antenna system, which can form its radiation pattern (main lobe direction, null-point direction, structure of the side lobes), measure the direction of the RF source in milliseconds. In this paper we will show the theoretical background of the antenna system, the build-up of the realized system and some measurement results. [C1354]

### "Implementation of a radar tester for air traffic control applications"

In this paper we present a method, and a fully implemented and tested hardware, for testing the operation of primary radars, may it be used in air traffic control or in military service. The realization of the radar tester was based on the theory of controlled radar cross section (CRCS), this way creating spurious targets or clutters, with known parameters, on the screen of the radar. According to the difference between the created and the measured parameters (e.g. velocity, fluctuation and distance), any minor or major degradation or failure can be detected. The tester is capable of scanning the radar system from the antenna, via microwave hardware elements, all through to the digital signal processor (DSP) unit, achieving great diagnostic properties. Emphasis was put on the realisation of the hardware. The produced equipment was tested in real life using a primary ATC radar in Hungary, with satisfying results. [C1355]

### "Modulation constellation analysis of GNSS signal using SDR receiver"

Modulation analysis is a dispensable item for the quality evaluating of GNSS signal. Tradition method based on instruments is limited to process signal with low dynamic although its accuracy is very high. This paper proposes a new method for modulation constellation analysis using GNSS software defined radio(SDR) receiver, which makes good use of the tracking module of SDR receiver to accommodate signal with great dynamic. The experiment results demonstrate the similarity between the accuracy of this method and that of instruments, as well as adaptability for signal with different dynamic. [C1356]

### "Design and implementation of real-time SAR echo simulator for natural scene"

This paper presents a real-time echo simulator for natural scene. The simulator generates SAR echo according to the radar flight trace in real time. The key technique of the echo simulator is presented first and the experiment result is shown. This simulator has been used as a general purpose verification platform for SAR real-time imaging system. [C1357]

### "Method of phase unwrapping-free DEM reconstruction of InSAS"

In this paper a kind of phase unwrapping-free digital elevation model(DEM) reconstruction method of interferometric synthetic aperture sonar(InSAS) is described. Firstly, a new method of coarse DEM generation is proposed. In the method, a pair of images are divided into small blocks and resampled to a set of reference planes. The height of each block pair is estimated by measuring the maximum coherence of the corresponding pair resampled to different reference planes. The entire heights of the blocks are interpolated to obtain the coarse DEM. After that, the resulting coarse DEM is used to flatten interferogram. The residual interferogram generally is unwrapped. Therefore phase unwrapping can be avoided. Simulation result is presented. The resulting DEM indicates that the proposed method has good potential for topographic mapping of the seafloor surface. [C1358]

### "The imaging analysis of asynchronous bistatic SAR with parallel tracks"

The imaging of bistatic SAR with asynchronous transceiver positions is studied in this paper. First of all, the geometry of the asynchronous transceiver model is constructed, and the approximation model of the echo from

the bistatic SAR is obtained based on the analysis of the instantaneous transceiver distance. Asynchronous transceiver positions will lead to non-uniform SAR data. This paper first analyzes the method for transforming the asynchronous bistatic model into a monostatic variable motion model. Then with the non-uniform FFT, it resolves the non-uniform sampling problems induced by nonconstant velocities. The simulation experiments show that the bistatic SAR images have good quality, which verifies the validity of the method presented in this paper. [C1359]

#### "Parameters extraction of crop based on PolSAR Data"

It is beneficial to extract the parameters of the objects by rich information of PolSAR (Polarimetric Synthetic Aperture Radar) data. With polSAR data of Radarsat-2, the polarimetric character of winter wheat in booting and milk stage is studied based on polarization theory. The results show that: there is a great difference between the polarimetric characters of two stages due to the change of wheat structure. Winter wheat growth can be retrieved by entropy, which changes in different way in the two stages. In booting stage, with LAI increasing, the scattering mechanism tends to be more complex. While in milk stage, with plant density increasing, the scattering mechanism tends to be simpler. The eigenvalue of  $\lambda_2$  is a valuable parameter to retrieve soil moisture with crop cover. Results show the potential advantage of polarimetric radar. [C1360]

#### "Design and implementation of embedded monitoring system for grain storage"

Meeting the requirement and development of large granaries, an embedded environmental monitoring system for grain storage based on ARM technology is designed in this paper. The overall structure of the proposed monitoring device consists of two components, one is the host computer located in control room for information processing and prediction of grain situation, the other is the lower computer terminal in the granary with grain data acquisition, signal processing and communication functions. They transmit data to each other over industrial Ethernet or GPRS networks. On this basis, the implementation methods of data monitoring terminal for grain situation based on S3C2410 microprocessor are studied in detail. The human machine interface of the terminal is developed by Qt/Embedded. Finally, the feasibility and reliability of the system has been proved by the laboratory test. [C1361]

#### "Turbines can suppress Loop Current to reduce Gulf of Mexico hurricane threat"

When the Loop Current (LC) intrudes into the Gulf of Mexico (GoM) it collects a deep pool of warm water that can energize a hurricane which passes through it. Data is presented to support the hypothesis that the LC is driven by gravity, and that its intrusion is a way of dissipating extra hydraulic drive power caused by the higher mean sea level at Grand Cayman Island compared to Grand Bahama Island. If some of this extra drive power is converted by submerged turbines into electric power for the shore grid, and the rest is dissipated by eddies shed by mooring cables and turbine structures, there will be no warm pools to energize hurricanes. Some turbine design estimates are made and a possible configuration is shown. [C1362]

#### "Mapping Geo-Pathogenic Zones and required instrumentation"

Geo-Pathogenic Zones, the areas on Earth's surface where drastic disturbances of natural electromagnetic field are detected, and their dire effects are no longer a mystery. Present human health issues cannot be resolved without considering the influence of the natural environment on human organisms. In light of recent advances in physics this important problem can no longer be ignored. The technological level of today's electrical engineering progress enables us to develop special instruments for scanning and mapping vast areas of landscapes to reveal potentially harmful factors. Geo-pathogenic zones (GPZ) are a major cause of natural impact on humans. Interaction of Earth's electromagnetic fields with local electro-physical heterogeneities are considered as a base of GPZ. Extremely low frequency electric fields, ELFEF, influencing the human brain, have been experimentally confirmed. The spinning electric field, another important phenomenon which can affect humans, has been revealed and established experimentally. The instruments depicting negative influence of GPZ can also be employed for water prospecting due to their capability to detect ELFEF and spinning fields. The results of this research are shown as electro-physical mechanisms of GPZ. [C1363]

#### "Netted sensors for higher-dimensionality performance"

Many sensors that are in service today were designed for locating objects in two dimensions. Air-traffic-control (ATC) radars, for example, are often circular-scan radars that can provide range and azimuth measurements, which can be used to locate an airliner's latitude and longitude. Radars such as these typically do not have the capability to locate an object in three dimensions, thereby providing information regarding the object's altitude. Knowledge of aircrafts' altitudes, however, is highly desirable given the demands put on ATC by the crowded skies of modern aviation. Previous work has shown how two-dimensional target-location accuracy can be

improved within the same dimensionality by combining multiple sensors. More recent work is revealing how, by netting multiple two-dimensional sensors such as circular-scan radars, three-dimensional object-location can be achieved. In this paper the concept of networking multiple two-dimensional sensors will be described. A scenario including multiple two-dimensional sensors will be presented, and analytic performance results will be provided for various sensor combinations and geometries. [C1364]

#### "Detection for signal in ELF atmospheric noise interference"

Extremely low frequency (ELF) atmospheric noise is non-Gaussian, consisting of the sum of a Gaussian background and narrow pulses caused by lightning strokes. Therefore, the conventional detection method for signal in Gaussian noise gets worse. In this paper, a new structure for signal detection in the ELF atmospheric noise is proposed. First, the ELF atmospheric noise is modeled as a symmetric  $\alpha$ -stable (S $\alpha$ S) process. Then the performance of optimum linear detector, matched filter, and locally optimum detector are examined. The FFT-based algorithm is used for calculating the probability density function (PDF). Finally, the probability of error (Pe) of each detector is compared by extensive Monte-Carlo simulation. [C1365]

#### "A velocity estimation method for Multi Carrier Phase-Coded radar"

Due to good balance among spectrum efficiency, ambiguity function and peak-to-mean envelope power ratio (PMEPR), wideband Multi-Carrier Phase-Coded (MCPC) radar has caught much attention from researchers recently. Based on separation of sub carriers from multi-frequency structure, this paper provides velocity estimation method for such radar signal. After detecting the peak Doppler spectrum of each sub carrier, the unambiguous velocity can be obtained by Least-Squared (LS) algorithm. The simulation results show that these methods can estimate the velocity of fast-moving target efficiently and guarantee the accuracy against low SNR. [C1366]

#### "Automatic target recognition of SAR images based on the fuzzy neural networks"

ATR (automatic target recognition), based on SAR (synthetic aperture radar) image, is crucial to the success of battlefield awareness and has become a very hot research topic. But many problems, which are caused by a great deal of missing, polluting, and superimposing of the signals, still generally exist in practical application, such as the low recognizing rate. How to recognize the useful signals from badly polluted images has become a difficult point in remote sensing image process. Thus, this paper will provide a way to recognize radar signal automatically by using the fuzzy neural networks. [C1367]

#### "Small target detection in SAR image using the Alpha-stable distribution model"

The Constant False Alarm Rate (CFAR) algorithm is most commonly used for small target detection in SAR images. As the goodness-of-fit of distribution model to SAR clutter has great effect on the performance of algorithm, after a comprehensive statistical analysis of background clutters of different SAR data, a modified CFAR algorithm based on the Alpha-stable distribution is proposed for detecting small targets in SAR images, especially under the extremely inhomogeneous background clutter. Considering for the complexity of Alpha-stable distribution model, the parameter estimation and threshold determining steps of the modified algorithm are introduced in detail. Performance of the algorithm is assessed by experiments on ADTS data. Compared with typical two-parameter CFAR (TP-CFAR) algorithm based on Gaussian distribution and K-CFAR algorithm based on K distribution, the proposed method is demonstrated to be most suitable for detecting small target in extremely inhomogeneous regions. [C1368]

#### "Blind separation of instantaneous linear mixtures of cyclostationary signals"

Blind separation of signals, which consists of recovering signals only from observed instantaneous linear mixtures without a priori information about the mixing matrix, is an important problem in many practical applications including radar, sonar, wireless communication and so on. For blind separation of cyclostationary signals, proposed a novel approach (PM) which dropped a pre-whitening stage usually required by many second-order statistics based methods such as AMUSE and SOBI algorithms. However, the PM algorithm has a fatal disadvantage in that it cannot fully separate all signals in the circumstance of more than two sources. To overcome this drawback, we proposed an improved PM algorithm in this paper. Several numerical simulations are also provided to illustrate the effectiveness of the proposed method. [C1369]

#### "Radar mosaic based on the explicit radar ray paths"

In radar observation, different ray paths, which influence the three-dimensional gridding process, is due to the different gradients of reflectivity. The earth's radius model, which could not describe the radar ray path in a

certain atmospheric thermodynamic condition, is the average condition of the radar ray pathway. In order to get the mosaic data of a certain thermodynamic condition, we need an arithmetic that could produce mosaic data based on the explicit radar ray paths. In this paper, we propose a method enable us to get the mosaic data based on any certain thermodynamics profiles of atmosphere. And the results are compared to the products of radar mosaic scheme based on the fixed earth's radius model in a certain atmospheric thermodynamic condition. [C1370]

#### **"Detecting and tracking of small moving target in avian radar images"**

A sequence of plane position indicator (PPI) images containing a small moving target is collected using an experimental avian radar surveillance system, which is constructed by modifying a standard marine radar. Smoothing trajectory of a small moving target is separated from the image sequence after background subtraction, clutter suppression, measurements extraction and tracking. The background image is generated by Fast Independent Component Analysis (FastICA). Low segmentation value is set in clutter suppression to improve detecting rate at the cost of introducing a great deal of clutters. Therefore, false alarm rate need to be reduced by tracking. Meanwhile, a modified Hough transform method is applied for track initiation. Monte Carlo data association is proposed for track maintenance and Kalman filtering is adopted for target state prediction and update. Finally, the trajectory is smoothed and then fused with a satellite map for further observation. [C1371]

#### **"Accurate time interval measurement method based on Vernier caliper principle"**

An accurate method by using main clock and vernier clock is introduced to measure time interval. Vernier clock is used to count the time interval. The corresponding count results are sampled by the main clock. The relationship between the sum of sampling sequence and time interval is investigated. By utilizing the sampling sequence, we can calculate the precise time difference easily. The implementation steps are listed and the resolution is analyzed. [C1372]

#### **"A new method based on the BP neural network to improve the accuracy of inversion of the vegetation height"**

The error in the estimation of the ground interferometric phase will reduce the accuracy of the inversion of the vegetation height in three-stage vegetation inversion method. Aiming at this problem, the new vegetation height inversion method based on the BP neural network is proposed. The new method directly fits the nonlinear mapping relationship between the complex correction coefficients and the vegetation height, so it reduces the height inversion error caused by the error in the estimated ground interferometric phase. The new method has better performance than the three-stage vegetation height inversion method, and the experiment results validate the superiority of the new method. [C1373]

#### **"Blind adaptive beamforming algorithm based on cyclostationary signals"**

The design of beamformer is an important aspect in array signal processing applied in several fields including radar, sonar, wireless communication and so on. The Capon beamformer, which has been used widely because of its many advantages, requires a priori knowledge of array manifold which sometimes it is difficult to obtain in some applications. Thus, the techniques of blind adaptive beamforming which don't need this information became of interest in recent years. For the cyclostationary signals encountered in numerous applications, a blind adaptive beamforming algorithm, which has a low computation complexity and fast convergence performance, is presented in this paper. [C1374]

#### **"Study on a method of compensation for the range profile of high velocity spatial targets"**

For wideband LFM signal, the paper presents a mathematical model of echo from spatial maneuvering targets and analyzes the impact of high acceleration and maneuvering on range profile quantitatively. According to invariable chirp rate, a range profile compensation algorithm based on difference is proposed. It can estimate the chirp rate accurately by FFT without acceleration and velocity estimation, so the influence of high-order coefficient is eliminated. Due to its no phase estimation, this algorithm has good anti-noise performance. In addition, the sample rate does not need to be higher than the bandwidth of LFM signal, so the processing speed is improved. The analysis is proved by simulation results. [C1375]

#### **"Study on adaptive monopulse with reduced dimension STAP technique"**

For airborne radar, the estimation performance of moving target parameters is greatly affected by the residuals of ground clutter after space-time adaptive processing (STAP). The non-homogeneity of environment, which

results in the lack of available secondary data, will make this problem worse. In this paper, a novel method, which utilizes small amount of secondary data, is proposed for getting more accurate estimation under non-homogenous environment. In this method, the spatial and temporal dimensions are reduced properly for the benefit of low secondary data support and exact clutter covariance matrix estimation; additionally, by combining a STAP processor with monopulse technique, target parameters will be obtained. The simulation results are shown this method is more accurate and adaptable than the previous adaptive monopulse with STAP method under the non-homogeneous environment. [C1376]

#### "Angle estimation of coherent multi-target for MIMO bistatic radar"

The angle estimation algorithm of coherent multi-target for MIMO bistatic radar is presented. In the algorithm, the virtual array data from multi-target in MIMO receiver is firstly decorrelated, then special matrix based on the ESPRIT method is constructed, finally the eigenvalues and the eigenvectors of the matrix are used to estimate direction of departures and direction of arrivals. In this algorithm, the parameters can be directly paired by the relationship between the eigenvalues and eigenvectors. The correctness and performance of the proposed method are verified by the computer simulation. [C1377]

#### "Contact-free measurement of heartbeat signal via a doppler radar using adaptive filtering"

It has been proven that the cardiopulmonary signs, including respiration and heartbeat signal, can be contact-free measured via a Doppler radar. However, the heartbeat signal cannot be identified when the human subject does not hold his or her breath. To resolve the problem, the adaptive noise canceller (ANC) based on recursive-least square (RLS) algorithm is presented to simultaneously measure the heartbeat and the respiration signal. Experimental results showed that not only can the heartbeat signal be well identified, but the heart rate also strongly correlated with that derived from the electrocardiogram (ECG). [C1378]

#### "Feature extraction and soft segmentation of texture images"

In this paper, we propose an efficient method for texture image segmentation. First we extract four feature channels smoothed with the total variation (TV) flow. Then we propose a soft segmentation model based on the Chan-Vese model by adding a weight in the arc length term and using a soft membership function in stead of level set function to represent the region. We derive a fast algorithm using the Additive Operator Scheme (AOS) and Chambolle's fast dual projection method. Experimental results on texture and Synthetic Aperture Radar (SAR) images show the effectiveness of our algorithm. [C1379]

#### "Parameters analysis for polarimetric SAR Based on classification accuracy"

As a multi-channel microwave remote sensing imaging radar system, polarimetric Synthetic Aperture Radar (SAR) enhances the information extraction ability for material scene in the observation area, in which the design and state monitoring for parameters play an important role in polarimetric SAR system and equipments management. This paper presents an analysis method for three typical polarimetric SAR system parameters: channel noise, polarization imbalance, and polarization isolation. We explore the polarimetric SAR image classification accuracy ratio and the relationship with three parameters above, review the statistic model of each parameter, and propose an analysis model between each parameter and the classification accuracy ratio measurement. By the polarimetric SAR image experiment, the comparative curve between each parameter and the influence on classification performance is obtained, which shows an application reference for polarimetric SAR system design and management. [C1380]

#### "Improved PGA algorithm based on adaptive range bins selection"

Phase gradient autofocus (PGA) algorithm has been proved to be a superior method for higher order phase error correction in SAR/ISAR image post processing. However, the accuracy of phase error estimation using traditional PGA algorithm is usually not guaranteed especially when there are several strong adjacent scatterers in a range bin. In this paper an improved iterative PGA approach based on adaptive range bins selection is presented. Results of real data experiments show that the improved PGA algorithm outperforms the traditional one. [C1381]

#### "SAR image despeckling using directionlet transform and Gaussian scale mixtures model"

In this paper, a novel despeckling method based on Gaussian scale mixtures (GSM) model in the directionlet domain is proposed. Before despeckling, we define a measurement of directivity of texture to calculate the directivity of texture according to the edge map. After directionlet transform, neighborhoods of coefficients at adjacent scales are modeled as GSM model. Under this model, a Bayes Least Squares (BLS) estimator is

adopted to reduce speckle noise. Quantitative and qualitative experimental results show that the proposed method is an effective despeckling tool for SAR images. The method can suppress the speckle noise and, in the meantime, preserve the scene features as much as possible. [C1382]

#### "Universal coupling curve for coupled resonators and transmission lines"

Coupled resonators and coupled transmission lines are described with the same universal curve. Resonant frequencies of coupled resonators and impedances of coupled transmission lines reveal the same dependence on coupling coefficient. This can be used to select, adjust or create the models of coupled structures. [C1383]

#### "Investigations of multilayer three-strip coplanar lines with the ferrite material"

In this paper the investigations of a multilayer coplanar line consisting of three strips located on a longitudinally magnetized ferrite are presented. In the analysis of proposed structure the coupled mode and mode matching methods are applied. Using proposed approach the ferrite coupled line junction is designed. For this junction the transmission parameters are calculated. The numerical results are verified via experiment. [C1384]

#### "Application of hybrid approach to the analysis of resonators loaded with axially symmetrical posts"

In this paper a new hybrid method is applied to the analysis of circular cavity resonators loaded with arbitrary configuration of axially-symmetrical posts. The method is based on a combination of finite difference frequency domain method and mode matching technique. In our approach each scatterer is treated as an effective circular cylinder represented by impedance matrix defined in its local coordinate system. In order to obtain the scattering parameters of an arbitrary configuration of objects in global coordinate system an analytical iterative scattering procedure (ISP) is utilized. The proposed technique is applied to determine the resonant frequencies of three different configurations of resonators. The validity of the proposed approach is verified with the analytical approach and commercial software. [C1385]

#### "Receiver Antenna Array"

Our aim is to develop a microwave receiver antenna system, which can form its radiation pattern (main lobe direction, null-point direction, structure of the side lobes), measure the direction of the RF source in milliseconds. In this paper we will show the theoretical background of the antenna system, the build-up of the realized system and some measurement results. [C1386]

#### "A new method for refractive index measurement of isotropic and anisotropic materials in millimeter and submillimeter wave range"

Based on patented by us interferometer-turning method the experimental set-up for refractive index measurement of parallel plates from isotropic and anisotropic materials in ranges millimeter-submillimeter (mm-submm) wave length have been created and described. The process of interference fringe shift measurement that based on created software has been analyzed, necessary working correlations have been given and experimental accuracy of refractive indexes measurement has been appraised. [C1387]

#### "Multi-frequency approach to the coaxial multilane through-reflect-line calibration"

We present an improved coaxial multilane through-reflect-line calibration method which allows to correct for errors in the description of calibration standards. Our approach is based on the multi-frequency formulation of the vector-network-analyzer calibration problem which accounts for the physical relationships between calibration standard S-parameters at different frequencies. We illustrate our approach with experimental results for the coaxial multilane through-reflect-line calibration with type-N airlines. We show that our calibration method significantly improves the measurement accuracy as compared with the classical multilane through-reflect-line calibration method. [C1388]

#### "Discrete shape optimization method for the non-uniform transmission line directional couplers"

In this paper a new method for a non-uniform directional couplers design is presented. It is modeled on the cascade connection of a large number of short, equal length sections of a uniform coupled transmission line. The coupling coefficient vector is optimized with the non-smooth sub-gradient algorithm. The performance of the optimization algorithm is surprisingly good. The algorithm generates many, close to optimal, solutions, with a variety of shapes. Initial profiles are almost smooth. However, at the end of optimization, shape tends to converge to a technological constraint. The optimal structure consists of a cascade connection of uniform coupled transmission line sections (of maximal coupling), separated by sections of a non-coupled transmission line.

[C1389]

#### **"Modeling of integrated microstrip bend structures on silicon substrates up to 110 GHz"**

This work describes an equivalent circuit model for microstrip bend structures on silicon substrates targeted for integrated millimeter wave circuits. The values of the lumped elements are extracted from 3D electromagnetic simulations for three different bend shapes and strip widths in the range of  $W=5-50\text{ }\mu\text{m}$  up to 110 GHz. The width dependence of the element values are derived using curve fitting algorithms and the integration of the model equations in circuit simulation environments is demonstrated. The developed model is compared with measurement results of several bend test structures fabricated in a high performance  $0.25\text{ }\mu\text{m}$  SiGe BiCMOS technology. Excellent agreement has been obtained. [C1390]

#### **"Photonic structures in the microwave band and their applications"**

The possibility to utilize microwave photonic structures for measurement parameters of nanometer films and for creating on their base functional devices of microwave electronics has been shown. A wideband waveguide matched load on the base of waveguide photonic crystal has been described. Microwave filters with transmittance controlled from -1.5 dB to -25 dB by changing the PIN-diodes bias voltage from 0 to 700 mV have been constructed. [C1391]

#### **"Analytical study and simulation of distributed phase shifter"**

This paper presents the modeling of phase shifter based on distributed CPW transmission lines combined with SMD components. It presents an analytical study of the phase shifting, the insertion loss and the return loss of proposed phase shifter. The expression of phase shifting is obtained through a global ABCD matrix of 9-sections of proposed phase shifter. [C1392]

#### **"Tuning properties of irregular posts in waveguide junctions-tunable filter application"**

In this paper the authors' hybrid method of electromagnetic wave scattering is applied to investigate the tuning properties of rectangular posts in waveguide junctions. As an example a basic waveguide filters employing several conducting cylindrical posts with rectangular cross section are considered. The size and location of the posts in a waveguide junction are optimized to obtain the required frequency response characteristic of the structures. Since, the posts are inhomogeneous, they can be used as tuning elements. In this work it is shown, that a simple rotation of rectangular posts allows one to correct any inaccuracies created during fabrication of the filter structure. A good agreement is obtained between the results of this method and own measurements of the fabricated structure. [C1393]

#### **"Design of UWB uniplanar $180^\circ$ hybrid employing ground slots and microstrip-slot transitions"**

The paper describes the design of a uniplanar  $180^\circ$  hybrid with an ultra wideband (UWB) performance. The device uses a single substrate and all its four ports are of microstripline type. Its construction is accomplished by first designing separately the out-of-phase and in-phase dividers. To merge the two devices into the hybrid, the input port of the in-phase power divider is split into two lines to overpass a ground slot in the out-of-phase divider. The proposed design strategy results in the  $180^\circ$  hybrid exhibiting a well-balanced power division between the output ports and good quality return losses of the out-of-phase (difference) and in-phase (summation) ports across the band from 3 to 11GHz. The isolation between the difference and signal ports is excellent and the differential phase shift is also close to the ideal case of  $180^\circ$  and  $0^\circ$  across this band. [C1394]

#### **"Performance and characterization of MMIC phase shifter with wire bonds interconnections"**

This paper presents some aspects of bond wire interconnections and its affect on the performance of a 6-bit phase shifter. The phase shifter operates in S-band and was connected to Rogers RO4003 substrate by the means of ball bonds. Discontinuities introduced by the interconnections were modeled as a low pass network. This non-optimal bonding worsened scattering parameters of the phase shifter by  $\sim 15\%$ . [C1395]

#### **"Line-length optimization of offset-short standards for broadband VNA calibration"**

The paper introduces a novel method for selecting optimal line lengths of multiple offset-short standards that are applied to broadband calibration of vector network analyzers (VNAs). The method is based on the design of experiments (DOE) approach and analysis of the determinant of the Fisher information matrix. To interpret results of the analysis, new terms, adopted from the filter theory, are suggested. The analysis reveals a tradeoff between solutions that provide low uncertainty and broad bandwidth of the VNA calibration. Both aspects are

vital at millimeter wavelengths, when using calibration standards based on 1.85 or 1 mm coaxial lines. The length optimization, using the DOE criterion of D-optimality, enables expanding the calibration frequency range much over that provided by the offset shorts currently available in commercial calibration kits. [C1396]

#### "Adaptive signal acquisition and wireless power transfer for an implantable prosthesis processor"

This paper describes an ADC array and wireless power transfer link for an implantable prosthetic processor which digitizes neural signals sensed by a microelectrode array. The ADC array consists of 96 variable resolution ADC base cells. The base ADC has been implemented in 0.13 $\mu$ m CMOS as a 100kS/s SAR ADC whose resolution can be varied from 3 to 8-bits with corresponding power consumption of 0.23 $\mu$ W to 0.90 $\mu$ W. The resolution of each ADC cell is adapted according to neural data content of the signal from the corresponding electrode, this reduces power consumption by a factor of 2.3 whilst maintaining an effective 7.8-bit resolution across all channels. A wireless power transfer system for implanted medical devices which uses antenna area 100 times smaller than previous designs has also been realized. Adaptive simultaneous conjugate matching and a high efficiency rectifier and regulator in 0.13 $\mu$ m CMOS together with a 4mm<sup>2</sup> antenna deliver 140 $\mu$ W at 1.2V DC from a 4cm<sup>2</sup> transmit antenna and a 0.25W 915MHz source through 15mm of tissue to power the implanted device. [C1397]

#### "Low-power low-complexity carrier-based UWB transmitter in 90nm CMOS for wireless biomedical radar sensing applications"

This paper presents a low-power low-complexity ultra-wide band (UWB) transmitter designed in 90nm CMOS technology for UWB radar sensing applications. The proposed design is carrier-based and is targeting for motion detection, biomedical imaging, and short range data communications. This non-coherent UWB transmitter, generates on-off modulated signals at different carrier frequency within the 3-10 GHz band. A voltage controlled oscillator generates a modulated pulse consisting of multiple cycles of sinusoidal waves with smaller bandwidth. The carrier frequency can be adjusted over the whole UWB frequency band by changing the capacitance of a capacitor bank. The transmitter driver controls the output power and matches the 50 $\Omega$  antenna load. The average power consumption of the transmitter is 1.85mW at a carrier frequency of 9GHz using 1V supply. [C1398]

#### "Active beamforming with interpolated FIR filterin"

The interpolated FIR (IFIR) radar was recently introduced in the context of MIMO radar theory. It was shown that this system has a signal to clutter ratio intermediate between those of the SIMO and MIMO radars. This paper considers the optimal design of the active IFIR beamformer in presence of jammers. It is shown that this beamformer can achieve beamwidths as sharp as those of colocated MIMO radars with full-length virtual arrays. At the same time, the extra complexity of MIMO radars, which arises from use of multiple transmitter waveforms and several sets of receiver matched filter banks, is not present in the IFIR realization. Design examples for IFIR radars which optimize the receiver beamforming weights in presence of jammers for fixed transmitter are also presented. [C1399]

#### "A joint block diagonalization approach to convolutive blind source separation"

This paper is concerned with blind separation of convolutive sources. The main idea is to make an explicit exploitation of block Toeplitz structure and block-inner diagonal structure in autocorrelation matrices of source signals at different time delays as well as of inherent relations among these matrices. With implementation of joint block diagonalization, a tri-quadratic cost function is introduced so that the mixture matrix can be extracted from a set of the correlation matrices of the observed vector sequence without pre-whitening. In this novel one-stage algorithm, every iteration step involves finding the closed solution to the corresponding least squares problem. Once the estimate of the mixing matrix is obtained, the source signals are retrieved by the classical least squares methods. The performance of the proposed algorithm is illustrated by simulation results. [C1400]

#### "A W-band LNA in 0.18- $\mu$ m SiGe BiCMOS"

This paper presents the design and implementation of a W-band LNA. Fabricated in a 0.18- $\mu$ m SiGe BiCMOS technology, the five-stage LNA achieves a peak power gain of 19 dB with a 3-dB bandwidth from 70-97 GHz and a minimum noise figure of 9 dB. The LNA exhibits more than 10-dB gain and input return loss  $< -12$  dB across the entire W-band (75-110 GHz). The SiGe LNA is suitable for several W-band applications including 77/79-GHz automotive radars and passive imaging in the 80-110 GHz window. [C1401]

#### "Auditory speech processing for scale-shift covariance and its evaluation in automatic speech

### recognition"

The syllables of speech contain information about the vocal tract length (VTL) of the speaker as well as the phonetic message. Ideally, the pre-processor used for automatic speech recognition (ASR) should segregate the phonetic message from the VTL information. This paper describes a method to calculate VTL-invariant auditory feature vectors from speech, using a method in which the message and the VTL are segregated. Spectra produced by an auditory filterbank are summarized by a Gaussian mixture model (GMM) to produce a low-dimensional feature vector. These features are evaluated for robustness in comparison with conventional mel-frequency cepstral coefficients (MFCCs) using a hidden-Markov-model (HMM) recognizer. A dynamic, compressive gammachirp (dcGC) auditory filterbank is also introduced. The dcGC provides a level-dependent spectral analysis, with near instantaneous compression, and two-tone suppression. [C1402]

### "Ambiguity function analysis for MCPC radar signal"

The MCPC signal using Orthogonal Frequency-Division Multiplexing structure has caught much attention of researchers recently since it has good anti-jamming capability, high spectrum efficiency and simple digital processing. This paper deduces ambiguity function expression of MCPC radar signal analyses its performance and discuss the influence of individual parameter on ambiguity function in both range and Doppler domain. Derived conclusion can provide theoretical basis for the waveform design and signal processing of the MCPC signal. [C1403]

### "A novel DOA estimation technique for coherent real-valued sources"

This paper proposes a new DOA estimation technique for coherent real-valued signal sources which is named Modified Covariance AR spectrum estimation of Modified Cross Correlation Sequence (MCCS-MC) algorithm. Firstly, we introduce the basic principle of the new technique: transform the DOA of the sources into frequency of a modified sequence, and get the arrival angles by power spectrum estimation of the sequence. Then we focus on the performance analysis of the proposed technique. Simulation results show that the algorithm not only solves the angle ambiguity problem in the DOA estimation of real-valued signals, but also precisely and stably estimates the arrival angles of coherent sine signals without spatial smoothing or matrix rebuilding. [C1404]

### "A novel method for extraction of in-pulse feature of LFM signal"

Aiming at the shortly SNR capability of wavelet-ridge in extracting in-pulse features of LFM signal, in this paper, a time-frequency associated analyzed method based on wavelet transform and time-frequency reassignment is proposed. The method is based on LFM's wavelet scalogram, and combined with time-frequency reassignment and time-frequency ridge. With the help of time-frequency reassignment in improving the time-frequency agglomeration of representations, the SNR capability of wavelet-ridge is enhanced. The result of the emulation experiments approved the feasibility of this method. [C1405]

### "Complex dielectric permittivity of composites based on dielectric matrixes with inclusions of carbon nanotubes"

Complex dielectric permittivity of composites based on two-component epoxy adhesive with different volume concentration of inclusions of multilayer carbon nanotubes and particles of fine-dispersed graphite was determined from the transmission spectra of the microwave radiation interacting with the sample under investigation. Complex dielectric permittivity of multilayer carbon nanotubes and particles of fine-dispersed graphite was determined as a result of reverse problem solving with utilization of the dependency of complex dielectric permittivity of composites on the inclusions volume fraction. It was shown that in creating composites based on dielectric matrixes with inclusions of particles of fine-dispersed graphite and carbon nanotubes the last ones provides the greater of the real part of dielectric permittivity and the lesser of the imaginary part of dielectric permittivity. [C1406]

### "Some MIMO radar advantages over phased array radar"

MIMO radar is a new radar technique developed recently. It can achieve better detection performance than conventional phased radar. In this paper, we investigate some advantages of MIMO radar on the non-ideal factor of transmitting signal such as the instability in signal phase and the spur in transmitting signal etc. And then, a simulation system was established, some simulation shows the advantage of MIMO radar over its conventional counterpart. [C1407]

### "The application of chaotic signal in MIMO radar"

Multiple Input Multiple Output (MIMO) radar is a new radar technique. It has many advantages over conventional phased radar in many ways such as anti-intercept of radar signal, low velocity target detection, and resolution. The signal design is a chief problem for radar. In this paper, we analyze the chaotic signal for MIMO radar.

[C1408]

#### "Fast Hough transform algorithm for radar detection"

In this paper, a fast algorithm for radar detection based on line Hough transform is presented. Unlike the traditional method, the idea of our proposed is that the point of data space should be mapped into the Hough parameter space of slope and intercept, where the relative position of the points in the data space is preserved. Then, only one time transformation of coordinate is employed to get the position of a batch points in parameter space. Therefore, the computation burden is significantly reduced. In addition, the detector performance is investigated. Finally, we illuminate the reduction of computation in details. [C1409]

#### "Aggregate type identification in concrete compounds using microwave transmission line and ANN"

Growing concrete market, increasing variety of concrete products and requirements for higher quality calls for a fast and accurate moisture measurement technology. A fast and accurate method for aggregate type identification in concrete compounds is presented in this paper. A transmission line and time domain sampling method for data acquisition is used. In order to find the relationship between material type and signal spectrum curve an artificial neural network classifier (ANN) is used. A total of 13 mixtures of three materials (sand, crushed granite stone and dolomite) mixed in different proportions were identified using the proposed method. Experiments have confirmed the possibility to use transmission line combined with ANN in material independent moisture measurement systems. [C1410]

#### "Dynamic mode of radiosystem with spatial structure optimization in presence of interferences"

Increase of radiosystem interference immunity is reached by application of its optimal spatial structure. In order to overcome algorithm implementation difficulties, connected with hypersensitivity to deviations from suppositions of non-stationary signal parameters and interferences parameters, the regularized algorithm of calculation robust spatial structure is offered. The solution of extreme problem, which belongs to the class of ill-conditioned problems, is searched on basis of representation of spatial structure as element of metric space. The comparative analysis of system efficiency with optimal spatial structure in static and dynamic operating modes is carried out. [C1411]

#### "Lithuanian experience of evaluation on radar antenna radiation"

A method for calculating intensity of electromagnetic fields radiated by powerful radars equipment is proposed in this paper. Taken attention that in calculations it is necessary to use average radiated power. The results of calculations show that an antenna of height 5 m radiates a power flux density at the height of a man's head less than the level permitted by Lithuanian law-20.0  $\mu\text{W}/\text{cm}^2$ . [C1412]

#### "Investigation of susceptibility of routers to high power microwave pulse radiation"

A susceptibility of different types of computer network routers to high power microwave pulse radiation was investigated. Experiments have been performed for different microwave power level, frequency band, pulse duration, and repetition rate. Experimental results were described using electronic fault models of thermal heating and parasitic charging. [C1413]

#### "Magnetic antenna for near-field UHF RFID tag"

In this paper, we propose a method of the improvement of performance of UHF RFID Tag antenna in near field. Currently, near-field UHF RFID receives a lot of attention as a possible solution for item level tagging in various applications. [C1414]

#### "RF identification and localization-recent steps towards the internet of things in metal production and processing"

This paper gives an overview on recent radio frequency local positioning and identification techniques applied in steel production and processing. It is shown that it is required to combine different radio technologies in order to track and trace the goods involved in the manufacturing processes reliably and continuously. In addition the applied components must be carefully adapted to the given application area. The presented RF technologies are key components for the future internet of things and the presented applications illustrate both, the huge potential

as well as the challenges involved with applying modern radio systems in harsh manufacturing processes.

[C1415]

### "Hybrid RFID System"

Continuous development in RFID and microcontrollers technologies gives new possibilities to create systems that are able to integrate a lot of sensors based on different technologies. This integration brings us closer to realize the Ubiquitous Network Society vision. However, many problems must be addressed before we will benefit from such systems. In this paper we describe concept of integrating RFID technology with other sensors technologies to develop a hybrid RFID system. Security issues on each level of communication are also addressed. [C1416]

### "EGSM and CDMA collocation and near field antenna estimation"

This article presents a typical collocation methods which provides an acceptable level of interference between two radio systems placed in close proximity. In particular, the importance of near field estimation was indicated as an essential element of effective isolation distance calculation for collocation purposes. [C1417]

### "Optimization parameters of dielectric in aperture-coupled stacked patch antenna on bandwidth"

The present paper described a method of analysis that can be applied to these geometries, as well as related configurations. The paper presents a model of the antenna on which the simulation was conducted on the impact parameter on bandwidth. The influence of the changes of the value of these parameters of individual layers on the bandwidth was talked over. Paper shows the analysis of multilayer microstrip antennas process is very complex and time consuming and compare between calculation and measurements. One of the most important parameters which have been calculated is the bandwidth. The paper describes a clear advantage of multilayer antennas over monolayer ones, where the bandwidth is significantly narrower. [C1418]

### "A compact double-ridged horn antenna for ground penetrating radar applications"

A compact double-ridged horn antenna for ground penetrating radar applications in the frequency range of 1-7 GHz will be presented in this work. Within this contribution the design, simulation and fabrication of such an antenna will be considered. Among the varying design parameters are linear and exponentially tapered walls as well as variations of the curvature of the dielectric waveguide between the two ridges. In addition an absorber structure and a complex shaped metallic back plate have been introduced to further improve the return loss. The primary design goal is a broad bandwidth while maintaining compact dimensions. Two modifications have been introduced in this antenna design in contrast to the standard TEM horn. By protruding the ridges from the aperture plane and filling the space between the ridges with dielectric material it is possible to lower the operating frequency without increasing the size of the original setup. The proposed design has been applied to subsurface radar application in both, field simulations by means of CST Microwave Studio and measurement in a GPR test scenario. The fabricated antenna has been verified by anechoic chamber measurements. The performance of the antenna with respect to the detection of subsurface objects will be verified by various experiments. [C1419]

### "Study of effect of corrugated edges on the radiation characteristics of GPR antenna"

This paper presents some results of studying the effect of the size of the corrugated edges of the tapered slot antenna (TSA) with elliptical taper on its radiating characteristics. Planar antennas with dimensions of 235 to 120 mm have been simulated in the free space and in the presence of dielectric medium in the near field. The modeling and near field monitoring has been performed using numerical method implemented in CST Microwave Studio software. The effect of the width of the corrugated area on the antennas edges in the range of 5 to 50 mm has been studied by computer simulations and experiments. [C1420]

### "Broadband microstrip patch antenna with reduced transversal size"

In the paper we present the proposal of broadband patch antenna with reduced transversal size. The broadband operation is obtained by means of application of thick substrate and electromagnetic coupling made of two slots. The nonresonant dimension of the antenna is reduced by using H-type slot instead of simple rectangular slot. The antenna has been designed and fabricated and 29% bandwidth for  $WFS < 1.5$  has been achieved. The broadband matching has been confirmed by the measurement of the reflection coefficient of fabricated antenna. However, the radiation pattern in E-plane shows some irregularities and needs additional research. [C1421]

### "A design and adjustment method for ultrawideband microstrip antenna design"

This paper presents a combined theoretical and experimental design and adjustment method for ultra-wideband (UWB) microstrip antennas with new geometries on the radiofrequency printed circuit board (PCB) with the permittivity  $\epsilon_r=2.3$  and the thickness  $h=1\text{mm}$ . The first theoretical design is made by using a standard 3D electromagnetic software package. The antenna specifications are measured and adjusted by the equipment Microwave Test Set IFR 6203B. The obtained antenna has the bandwidth of 600 MHz and very good impedance matching at the resonant frequency 7.2GHz ( $S_{11} = -55.7\text{dB}$ ). This method can reduce time for antenna design in the laboratory conditions. Using it with other initial antenna structures and adding other resonant strips, we can obtain other antennas with smaller dimensions on keeping their large bandwidth and small return loss. [C1422]

#### "Compact Tapered Slot Antennas for UWB microwave imaging applications"

This paper presents the design of compact Tapered Slot Antennas (TSAs) for application in an Ultra Wide Band (UWB) microwave imaging system. In the initial step, a conventional size-reduced TSA with an exponential taper for 3.1-10.6 GHz band is designed. From the radiation pattern analysis, it is found that this antenna exhibits poor directivity in the lower part of UWB. To overcome this shortfall, two modifications are investigated. One includes corrugations and the other one elliptical cuts on sides of the initial TSA. It is shown that the modified TSAs feature improved directivity while their UWB impedance characteristics are similar to the original TSA. The TSA with corrugations exhibits an almost constant directive radiation pattern across UWB. However, its gain oscillates with frequency leading to a pulse distortion. Therefore the size-reduced TSA with elliptical cuts in conducting sides looks to be the most attractive choice with respect to both directive properties and distortionless pulse transmission. [C1423]

#### "A 5.8 GHz RFID-based data transmission system as an energy efficient solution for on-board monitoring"

This paper presents a wireless data transmission system based on the RFID concept designed initially for an environment typical in aeronautics. As a response to a growing interest into wireless monitoring of various parameters onboard of modern aircraft, the author performed several experiments that were aimed at verifying to what extent a low-complexity RFID-based data transmission solution can meet basic requirements related to the expected distance between sensors, as well as the possibility to realise an efficient data link when the sensors are not installed in the line-of-sight and the transmission must rely solely on wall reflections. The paper concludes with a description of the results of the performed measurements. [C1424]

#### "Wavelets on nonuniform triangular meshes for fast basis transform"

Fast method of moment (MoM) solvers implement advanced algorithms like the fast multipole method (FMM) or wavelet transform (WLT). Applying wavelet transform yields a sparsely populated matrix and enables fast iterative solvers. However, the effort of performing the transform itself may significantly add to the overall computational complexity. Traditional methods like multiplying with a change of basis matrix are very inefficient concerning time and memory demands. In this paper, new wavelet functions are considered enabling a fast wavelet transform that uses in-place operations and has low computational complexity. [C1425]

#### "3D vector electric field distributions and dispersion characteristics of open rectangular and circular metamaterial waveguides"

Here we present the 3D vector electric field distributions of the main and the first higher modes propagating in the open metamaterial rod and hollow-core waveguides. [C1426]

#### "Advanced macromodel matrix structure cloning for FDTD"

We propose an improved macromodel-based technique for efficient analysis of the structures based on Photonic Crystals (PhC). The technique involves a new structure of the coupling matrix and advanced cloning of not only the macro-model  $\Gamma$  matrices, but also the coupling matrices SE and SH. The method allows one to shorten considerably the preprocessing time, the RAM usage and also the iterating speed of performing FDTD. With this scheme, it is possible to simulate efficiently up to several thousands of macromodels. [C1427]

#### "UWB microwave imaging system including circular array antenna"

The paper describes the design of an ultra wideband (UWB) microwave imaging system employing a 12-element circular array antenna. The array uses compact tapered slot antenna (TSA) elements operating over 3.1-10.6 GHz band. The elements of the array are activated by two coaxial SP6T switches that are connected to a vector network analyser (VNA) to achieve monostatic or multi-static radar modes of operation. In addition, the array is moved using a mechanical cylindrical scanning subsystem. This electronic/mechanical sub-system allows a fast

highresolution scan of an imaged object. The paper describes the reasons for choosing this particular imaging system configuration and provides full construction details. Also shown are the imaging results of a circular plastic container filled with a vegetable oil and small diameter circular cylindrical targets using a novel image reconstruction algorithm. [C1428]

#### "Dispersion dependencies of glass pipe waveguides filled with lossy biological liquids"

Here we present dispersion characteristic dependencies of the main mode of open cylindrical hollow-core glass waveguides filled with blood and lymph at three different internal waveguide radii and two waveguide materials when the frequency range is of 0.1 GHz to 100 GHz. The pipe waveguides were made of acrylic-glass with the permittivity 4 and glass-ceramic with the permittivity 6.9 materials. The thickness of glass was always 0.5 mm and internal radii of waveguides were 1.5, 1 and 0.5 mm. We also show here the real part of propagation constant of two empty waveguides with the internal radius equal to 0.5 mm for the four hybrid modes at the frequency range of 0.1 GHz to 300 GHz. [C1429]

#### "Millimeter wave application for non-destructive homogeneity characterization of semiconductor and dielectric wafers"

Millimeter wave technique for non-destructive material homogeneity characterization is described. The idea of this technique is the local excitation of the millimeter waves in the testing plate shape material and the measurement of the transmitted (reflected) wave amplitude and phase in different places of it, i.e. the material plate is scanned by the beam of the millimeter waves. Results of the homogeneity measurements for some semiconductor and dielectric wafers are presented. The measurement technique sensitivity is discussed. [C1430]

#### "Reduced-order models in the finite element analysis"

A novel technique of incorporating macromodels into finite element electromagnetic analysis of waveguide components is presented. Macromodels are generated by using a model order reduction algorithm (ENOR), which results in significant decrease of the number of variables, that describe the computational region. Proposed technique allows for using a few independent macromodels as well as to duplicating one macromodel in many subregions of analysed structure. Reduction of the numerical costs is obtained without sacrificing solution accuracy. Furthermore, proposed approach leads to reduction of the overall simulation time. [C1431]

#### "Verification of the mutual coupling compensation technique in small planar antenna arrays"

In this paper the quality of a technique to compensate for mutual coupling (and other phenomena) in small linear antenna arrays is investigated. This technique consists in calculation of a coupling matrix, which is then used to determine corrected antenna array excitation coefficients. Although this technique is known for more than 20 years, there is still very little information about how different phenomena existing in real antenna arrays influence their performance. In this paper the effect of mutual coupling is separated from other undesired effects, e.g. aperture edge diffraction, and its influence on coupling compensation is determined. It is shown that mutual coupling itself can be compensated very well and an ultralow sidelobe level could be achieved in practice. [C1432]

#### "A printed RFID Tag antenna for metallic objects operating in UHF band"

A design of RFID antenna for metallic object is presented. The antenna was fabricated by means of printing technique with electro conducting ink. Input impedance of designed structure was measured with network analyzer and compared to results obtained from numerical calculations. [C1433]

#### "Analysis, design and measurement of a low sidelobe level lightweight array antenna for surveillance radar applications"

This paper describes a design and a realization of a low sidelobe level lightweight array antenna in X-band. The array antenna utilizes Taylor magnitude distribution in its aperture as a sidelobe level reduction technique. The measured sidelobe level of the antenna is -22 dB in its wider dimension plane and -18 dB in its narrower dimension plane. The radiating elements of the array are cavity backed patches electromagnetically coupled to microstrip excitation stubs. The feed distribution network of the antenna is realized as a low cost microstrip corporate feed. The array antenna has been produced by means of a low cost conventional PCB technology. Measurements of a prototype unit has been presented and compared with the theoretical calculations. [C1434]

#### "Matrix analysis of antenna array for MIMO UWB systems"

The paper presents theoretical matrix analysis of antenna structure consisting of two double-element planar antennas for ultra-wideband (UWB) application in MIMO (2x2) indoor communication systems. A new approach to full electromagnetic analysis of MIMO spatial antenna array is described. Mathematical model of functional power parameters for whole MIMO UWB transmit-receive antenna structure is introduced. Results of computer simulations of different matrices describing whole antenna system and power parameters are presented. [C1435]

#### "The analysis of textile antenna array radiation pattern"

In the paper the results of investigation on the textile antenna array radiation are presented. The FDTD computer simulation method is used to simulate the radiation of textile antennas located close to the human body. The results obtained for different configurations of antenna location are presented [C1436]

#### "Multiband omnidirectional communication antenna"

In that paper design and performance of multiband omnidirectional communication antenna is presented. The antenna is fabricated in technology based on teflon laminate with metallization on both sides. It allows to implement developed solution in various commercial applications. Measured antenna covers common free of license WLAN communications frequency bands: 2.4-2.5GHz, 5.15-5.9GHz and also WiMax 3.63.8GHz band. [C1437]

#### "Enhanced direction of arrival estimation via reassigned space-time-frequency methods"

Two new space-time-frequency direction of arrival estimation algorithms are presented that decrease the estimation variance under specific conditions of narrow differential direction of arrival when multiple signals impinge upon the sensor array. The first algorithm, called Wide-Lane, provides a modest extension of existing space-time-frequency (STF) techniques by integrating a wide path along the signal's instantaneous frequency track through the time-frequency (TF) plane. The second algorithm, called Reassigned STF, utilizes the TF reassignment method to increase the signal's localization within the TF plane prior to estimating the direction of arrival with MUSIC. The performance variation of space-time MUSIC to a variety of signal structures is also presented. [C1438]

#### "Measurement and performance of digital monopulse radar array antenna"

A base band sum-difference scenario used in digital monopulse end-guidance radar system is introduced in this paper. A method used to measure the microstrip array antenna pattern at base band is presented. The result shows that the antenna pattern in this design has much better performance at null-depth of difference beam than the traditional design. The angle measurement performance based on the antenna patterns is also recommended. [C1439]

#### "Integrated Millimeter-wave passive devices based on Silicon substrate for SoP application"

In this paper, a process to fabricate BCB/Au multilayer stack on low resistivity Silicon (Si) based on the embedded package structure is developed, especially for the first time spin coating of the dielectric material on the Si substrate. Transmission lines, including micro-strip transmission lines and coplanar waveguide (CPW) lines are designed, fabricated and characterized, which performs excellently: insertion loss and return loss of the standard 50 ohm micro-strip lines are less than 0.08 dB/mm and better than 32 dB/mm respectively during the band from 20 GHz to 30 GHz. Additionally, a power divider is fabricated using the thin film micro-strip lines, which applied in the front end of a traffic flow detecting radar. This power divider has such a wonderful performance, such as insertion loss less than 0.45 dB and return loss better than 25dB with an intrinsic size of 1.6 Ч 0.84 mm<sup>2</sup>. [C1440]

#### "Minimized Ku band microstrip circulator design"

Double Y-junction is a traditional central conductor shape for microstrip circulator. In order to minimize the dimension, An improved double Y-junction microstrip circulator design in Ku band is described in this paper. In addition, a simple principle of how to select a proper kind of ferrite is introduced. The experimental model and test results are given proved the efficiency of the design. [C1441]

#### "An improved High-Frequency-Raised inversion algorithm for radar imaging"

The synthetic aperture technique can not be used to improve azimuth resolution in forward-looking mode or real aperture radar systems. In this paper, an improved High-Frequency-Raised (HFR) algorithm is introduced to enhance the azimuth resolution of radar systems. The super-resolution performance of the proposed algorithm

depends on the raise coefficient and is different for different equivalent antenna patterns. Simulation and experimental results validate the capability of the improved HFR algorithm. [C1442]

#### "Millimeter wave beam tilting array for radar system"

A new kind of millimeter wave beam tilting array is designed and validated in this paper, the array is composed of four sub arrays to acquired high gain. Beam tilting radiation pattern is realized by the quasi-traveling wave operating structure. Absorbing patch is arranged at the end of every sub array for avoiding using matching resistor to improve the radiation efficiency of the array. The beam tilting radiation pattern forming theory is researched firstly and then a model is constructed and optimized with HFSS, a 32-elements array which operates in Ka band is fabricated and measured. The performance of the array is validated by good simulation and measurement results. [C1443]

#### "A transceiver for Ku band digital monopulse radar system"

A transceiver which includes four transmitting channels, four receiving channels and four calibration channels used for Ku band digital monopulse radar system is introduced in this paper. This design may improve the performance of transmitters and receivers. The channel calibration can be carried out easily with the built-in calibration path. The amplitude and phase consistency between different channels maintains good and stable in wide frequency span as well as large power range. Relevant test results are recommended. [C1444]

#### "Design and simulation of ultra-wideband double-ridged horn antenna"

It is known to us, double-ridged horn antenna is one of common and important antenna types, it has been widely used in the EMC, measurement, radar and communication system. A 118GHz double-ridged horn antenna that possesses high performance is designed with the HFSS. VSWR, Gain and radiation pattern of the antenna can fulfill engineering demands based on the simulation of HFSS. Further, this paper shows a new comparatively method of post-cavity treatment in antenna. [C1445]

#### "Calculation of the characteristic impedance of TEM horn antenna using support vector machine"

A method based on support vector machine (SVM) is presented to calculate the characteristic impedance of transverse electromagnetic (TEM) horn antennas. The method can be used for computer aided design (CAD) of TEM horn antennas. The results obtained from the SVM model are in very good agreement with the analytical and numerical result. [C1446]

#### "Scattering characteristic of soot aggregation particles randomly distributed"

The generation multiple Mie theory (GMMT) is introduced to investigate the scattering characteristic of a soot aggregation particles randomly distributed. Computes of the Muller matrix elements are carried out at two wavelengths (0.6328 $\mu\text{m}$  and 1.06 $\mu\text{m}$ ). Some selected results are given by the equivalent medium method (EMM) and compared the results given by GMMT. The results are expected to provide useful insights into the formation mechanism and structural characteristics of randomly distributed cluster agglomerates. [C1447]

#### "A compact quasi-lumped LTCC diplexer for radar application"

An integrated quasi-lumped diplexer based on low temperature cofired ceramic (LTCC) technology is presented. The diplexer is made of L-band low pass filter (LPF) formed by lumped element and X-band band pass filter (BPF) adopting step impedance resonator (SIR). The diplexer's performance has been simulated and optimized by EM simulator. An experimental diplexer has been made and measured. The measured result of the frequency response agrees very well with the simulated one, the LPF's insertion loss is less than 1dB, and 1dB cut-off frequency is 1.46GHz; the BPF's insertion loss is less than 3.5dB, and 1dB bandwidth is about 0.6GHz at the center frequency 8.3GHz. Its good performance, small size and relatively simple structure make it a good candidate as an integrated diplexer for various LTCC systems. [C1448]

#### "Application of parallel integer coded differential evolution strategy on ultra-wide band TEM horn antenna"

With the application of global optimization algorithm, the research of parallel optimization algorithm and its realization become very important. In this paper, two kinds of parallel models of parallel integer coded differential evolution strategy, such as master-slave model, coarse-grained model, are proposed and simply evaluated. For engineering problems, the integer coding is efficient, and automatically filters unsteady solutions. They are combined with finite-difference time-domain (FDTD) method to optimize time-domain ultra-wide band (UWB)

transverse electromagnetic (TEM) horn antenna. As for the TEM horn antenna to each model, the optimization results are illustrated in order to evaluate them. [C1449]

#### **"Integrated design of wide-band wide-scan phased array antenna and couple line"**

A novel phase array antenna with integrated couple line is designed and measured in this paper. This kind of structure assures the stability of monitor system in active phased array radar system. The relative frequency band of the phased antenna array antenna is larger than 25% and it can electrical scan 60 degree both in E-plane and H-plane. The couple coefficient between the ports of different antenna elements in 8-ele structure and the couple port of couple line are in good consistence. Curve of the couple coefficient in the whole frequency band is flat. [C1450]

#### **"Edge diffraction effects on the RCS analysis of antenna array"**

Diffraction effects of the edge region within the antenna array aperture have been discussed with the numerical simulation and measurement in the antenna array monostatic Radar Cross Section (RCS) analysis. Research illustrates that the edge of array presents dominant diffraction effects on the antenna mode RCS character evaluation in a wide frequency range, and bistatic RCS character proposes Radar Absorbing Material (RAM) is an effective approach for the shielding the edge diffraction. [C1451]

#### **"The research of broadband millimeter-wave Vivaldi array antenna using SIW technique"**

A compact millimeter wave Vivaldi antenna array printed on thick substrate and fed by a substrate integrated waveguide (SIW) structure was proposed in this paper. It consists of a compact SIW binary divider, which has minimize significantly the feed structure insertion losses and achieve a broadband performance in millimeter wave range, and four-elements printed Vivaldi array. The whole antenna array was designed, fabricated, and thoroughly investigated. The whole antenna and feed net were designed, fabricated on single substrate, which takes the advantages of small size, low profile, low cost and high performance etc. The simulation results show that the design is effective and right. [C1452]

#### **"Analysis of wide-band aperture-coupled microstrip antenna array by CN-FDTD"**

The Finite Difference Time Domain (FDTD) method is widely used for radiation and scattering problems in electromagnetics due to its ability to model heterogeneous and complex geometries. And a single wideband simulation results can be provided. In this paper a three-dimensional implementation of the lumped-element by Crank-Nicolson finite-difference time-domain (CN-FDTD) algorithm has been presented to simulate a wide-band aperture-coupled microstrip antenna array with an "hour glass" shape aperture. The difference equations allow arbitrary lumped elements to be inserted into one FDTD cell, preserving the full explicit nature of the CN-FDTD scheme. As a validation of the results by the proposed method, the results by commercial software are also reported. Compared with the results of the two methods, the reasonably good agreement is found. Consequently, the accuracy of CN-FDTD application for antenna design with lumped elements in this paper is verified. [C1453]

#### **"A novel frequency scanning monopulse microstrip antenna array"**

A novel frequency scanning monopulse microstrip antenna array is proposed in this paper. The array has the frequency scanning performance in one dimension and has the monopulse performance in another dimension. The miniaturized slow-wave structure has been used to achieve the compact structure. Compared with the conventional slow-wave structure, this miniaturized slow-wave structure reduces its height to 45% of the conventional one. The 444 frequency scanning monopulse microstrip array has been designed as an example. The 444 microstrip antenna, the slow-wave structure and monopulse comparator are placed on the same layer, resulting in a very compact structure. The simulated results show that the range of the scanning angles is  $(-38^\circ, -6^\circ)$ , the gain is above 12dBi at the working bandwidth and the peak gain is 14.09dBi. [C1454]

#### **"Wide-band and low cross polarization conformal array with microstrip parasitic-dipole antenna"**

In this paper a microstrip parasitic-dipole antenna is proposed and an array is constructed by the proposed antenna on conformal conical surface. The proposed antenna has a good impedance bandwidth, lower cross-polarization. The proposed array exhibits excellent impedance bandwidth of 28.5% and can scan its patterns with lower cross-polarization compared with a conventional conformal microstrip patch array. [C1455]

#### **"Surveillance and inversion of regional atmospheric duct from multiple radar stations"**

The atmospheric duct is an anomalous refractivity structure which often occurs over large ocean surface. A surveillance and inversion method for regional atmospheric duct from multiple radar stations is introduced here. It has 1) a larger surveillance area for atmospheric ducts and 2) more accurate inversion results due to more inputted clutter information. In order to describe the M-profile for evaporation ducts more freely, an improved two-parameter M-profile is used. [C1456]

#### "Scattering characteristic from a cylindrical Salisbury screen with 1rad"

This paper presents radar cross section results from a MLFMM model of scattering from a cylindrical Salisbury screen with 1 rad. Different from some previous researches, this study is concentrated on the results at high radar frequencies such as in I and J bands (9-11 GHz). Both normal and off-normal incidence is considered. According to our calculated results by MLFMM, it exhibits better scattering performance than the same size plate. In addition, we find that in the angle range of 70-90°, a few data of the latter are smaller slightly than those of the former. However, we believe it may not affect the application in fact. Finally, in order to study the interaction between incident wave and the cylindrical Salisbury screen, the distribution of surface current and charges at 9.8 GHz are presented. [C1457]

#### "Grid-cell combination in 3D-FDTD modeling of ELF propagation of the earth"

In this paper, we have developed a model of extremely low frequency (ELF) wave propagation based on an advanced three-dimensional finite difference time-domain (3D-FDTD) method. We have studied the Schumann Resonances (SR) of the earth and three different altitude profiles of conductivity in the lossy Earth-Ionosphere Cavity. The eigen-frequencies of the model have been obtained, and the global averages of the vertical Erand tangential E $\theta$  components for these three different conductivity models have been investigated. [C1458]

#### "An efficient splitting the plane-wave FDTD method"

The paper presents a new efficient method of introduction of plane wave source into finite difference time domain (FDTD) grids: the method of splitting the plane-wave FDTD (SP-FDTD). The new equations for the 1-D propagator are based on splitted-field Maxwell's equations, and the propagator makes the 1-D and 2-D dispersion equations identical. The technique virtually eliminates numerical dispersion, filed location and polarization mismatches between propagator and main grid, for a plane wave propagating at an angle forming an integer grid cell ratio, which can represent almost any angle in theory. Through the leak test of the different incident angles of the Gauss pulse plane wave source in 2-D, it shows that, the technique can achieve a perfect total-field scattered-field separation, making leakage down to -340 dB levels. [C1459]

#### "The method of microwave power amplifier model parameter test based on the larger-signal scattering function"

Concentrating on vector network analyzer with nonlinear calibration software, this paper establishes the test systems of microwave power amplifier scattering function, introduces the essential calibration method of the test systems, and validates the correctness of calibration method. And the scattering function is acquired by testing power amplifier which has been designed, and nonlinear characteristic under practical working condition is analyzed based on the scattering function. [C1460]

#### "A Ka-band T/R front-end for phased array radar"

In this paper, a Ka-band transmitter/receiver (T/R) front-end for a phased-array radar is proposed. The transceiver includes a receiver channel and a transmitter channel. A function link shared with the receiver channel and the transmitter channel is comprised of a 5-bit phase shifter and a variable gain amplifying circuit including an attenuator and a low noise amplifier. Connection to either the final power amplifier on transmitter or the LNA on receiver is accomplished by using two single-pole double-throw switches (SPDTs). Experimental results of the front-end verify the validity of the design. A noise figure of 4.9 to 5.6 dB, a receiver gain of 24.4 to 29.4 dB and a output power from 0.74 W to 1 W are obtained within a frequency range from 34.5 GHz to 35.5 GHz. The digital phase shift provides 10.2° root-mean square(RMS) phase shift error at 35 GHz. [C1461]

#### "Illumination method for millimeter wave imaging indoors"

This paper presents an effective illumination method for millimeter wave imaging indoors based on multi-phase diversity principle. Though limited to its ability to do the image recognition accurately, it still gives a good performance for millimeter wave imaging indoors. The results from a real-time indoor millimeter wave imaging are presented, clearly showing the hidden metal objects. [C1462]

### "Acceleration of Time-Domain Finite-Element Method in electromagnetic analysis with OpenMP"

Paralleled Time-Domain Finite-Element Method (TDFEM) is developed based on OpenMP for 2-D electromagnetic scattering analysis in this paper. The matrix-vector multiplication in conjugate gradient (CG) solver is parallelized with OpenMP. As a result, the efficiency of TDFEM algorithm is accelerated dramatically with multi-processor PC. The bistatic radar cross sections (RCSs) of some typical 2-D objects are computed with paralleled TDFEM. High speedup ratio and high parallel efficiency are obtained, which provides a practical and effective acceleration method for TDFEM analysis on multi-CPU computers. [C1463]

### "Research on Si-based MEMS process in development 3D millimeter-wave multi-chip module package"

A low cost & feasible system on package solution on the basis of BCB and silicon wafer (10 Ohm-mm)-Si-Based 3D MMCM package solution is presented in this paper. What is more, a standard Si-Based MEMS process is employed to achieve package and revision of a GaAs-Based Monolithic Amplifier circuit. The measured results show that input return loss is less than 20 dB; moreover, small signal gain is more than 17 dB across 21 GHz to 26 GHz. The excellent measured results make the Si-based 3D-MMCM package solution a very attractive and feasible candidate for millimeter-wave 3D system level package applications. It is a step towards achievement of 3D system level package meeting excellent millimeter-wave performance. [C1464]

### "Design and implementation of a LTCC-based receiver front-end module"

A S-band receiver front-end module using Low Temperature Co-fired Ceramic technology is presented to be small and reliable with the main passive components such as splitter, coupler, bandpass filter, resistors and capacitors embedded in LTCC substrates. The MCM-level module with a dimension of 27mm×25mm×1.9mm, realized in interconnecting the active chips by micro-assembly technology, is shown to meet the requirements quite well in experimental test. [C1465]

### "An ultra wide band power divider/combiner based on Y-structure waveguide"

In this paper, an improved power divider/combiner based on Y-structure waveguide is proposed at ka-band (26-40 GHz). To widen the bandwidth of the divider/combiner, a stepped-impedance waveguide transformer is used, and a vertical resistive card is inserted into the divider/combiner to realize high isolation. According to EM simulations, the power divider/combiner illustrates a 42.4% effective bandwidth (ranging from 26 to 40 GHz), the return loss is better than -24 dB, and the isolation is better than -21 dB. This structure has properties of not only a wide band, low insertion loss and high output power, but also a small size, a high power combining efficiency and efficient heat sinking, and has potential for millimeter-wave broad-band high power combination. [C1466]

### "Parameter Identification Method for Ship Swaying Motion Differential Equations"

This paper introduces a solution method for ship swaying motion differential equations—maximum likelihood parameter identification method. To evaluate its data processing effects, we have taken the real-time measurement data as a research object and computed with several algorithms, at the same time compared their prediction results. The results show that parameter identification method for differential equation is reliable in calculation, whose accuracy can satisfy the demand for shipboard equipments to accurately track space targets, which is recommended to use for ship swaying measurement data processing. [C1467]

### "A Comparative Study of the DGTD Algorithm and the FVTD Algorithm in Computational Electromagnetics"

By calculating some typical electromagnetic problems, the performances of the FVTD algorithm and the DGTD algorithm for computational electromagnetics are compared systematically, including the choice of the time step, the numerical accuracy, the CPU time and the memory requirement. The FVTD algorithm is more efficient for electrically small structure and is more accuracy for the structure with curved surface, but is not suitable for large scale electromagnetic phenomenon simulating. The DGTD is more resource consuming, but it is more accurate and has the potential ability to handle electrically large structure. [C1468]

### "Design of an alpha-beta filter by combining fuzzy logic with evolutionary methods"

The  $\alpha$ - $\beta$  filter based on the Kalman-like estimation scheme has been recognized as a outstanding tool for estimating the position and velocity signals of moving objects. Nevertheless, the performance of estimation heavily depends on the parameters  $\alpha$  and  $\beta$ . In general, the choice of parameters is a trade-off optimization problem between the tracking accuracy and noise reduction capability. In order to obtain the suitable design of

$\alpha$ - $\beta$  filter for some specifications, a combined fuzzy logic and evolutionary optimization method is proposed for determining the parameter values. The simulation results are employed to illustrate the developed  $\alpha$ - $\beta$  filter which is capable of tracking the desired signals accurately and, at the same time, reducing the noise disturbance remarkably. [C1469]

#### "Notice of Violation of IEEE Publication PrinciplesExtended target tracking using an IMM based nonlinear Kalman filters"

Notice of Violation of IEEE Publication Principles"Extended Target Tracking Using an IMM Based Nonlinear Kalman Filters,"by Yucheng Zhou, Jiahe Xu, Yuanwei Jing, Georgi M. Dimirovskiin the Proceedings of the 2010 American Control Conference, July 2010, pp. 6870-6875After careful and considered review of the content and authorship of this paper by a duly constituted expert committee, this paper has been found to be in violation of IEEE's Publication Principles.This paper contains significant portions of original text from the paper cited below. The original text was copied without attribution (including appropriate references to the original author(s) and/or paper title) and without permission.Due to the nature of this violation, reasonable effort should be made to remove all past references to this paper, and future references should be made to the following article:"Extended Target Tracking Using an IMM based Rao-Blackwellised Unscented Kalman Filter,"by Zhiwen Zhong; Huadong Meng; Xiqin Wangin the Proceedings of the 9th International Conference on Signal Processing, October 2008, pp.2409-2412The unscented Kalman filter (UKF) and ensemble Kalman filter (EnKF) are developed to extended target tracking problem for high resolution sensors. The nonlinear Kalman filters are based on an ellipsoidal model, which is proposed to exploit sensor measurement of target extent. The ellipsoidal model can provide extra information to enhance tracking accuracy, data association performance, and target identification. In contrast to the most commonly used extended Kalman filter (EKF), the UKF and EnKF provide more accurate and reliable estimation performance, due to the presence of high nonlinearity of the model. Correspondingly, the EnKF has lower computational complexity than the UKF. An interacting multiple model (IMM) technique is combined with the filters to adapt the target maneuver and motion mode switching problem which is vital for nonlinear filtering. The developed IMM-UKF and IMM-EnKF algorithms on extended target tracking problem are validated and evaluated by computer simulations. [C1470]

#### "Speckle Reduction with Multiresolution Bilateral Filtering for SAR Image"

Synthetic aperture radar (SAR) images are inherently affected by multiplicative speckle noise, which requires despeckle before many other image processing and analysis applications. In this paper, a new speckle reduction method based on wavelet and bilateral filtering is proposed. Bilateral filtering is applied to the low frequency subbands of a signal obtained by wavelet transform. The new method preserves edges and protect details. Experimental results tested on real SAR images demonstrate the performance of the proposed method. [C1471]

#### "Novel Space-Time Processing Method for Airborne SAR to Detect and Image the Slowly Moving Targets"

In the paper the problem of the ground clutter rejection for airborne SAR is discussed. The features of space-time clutter filtering and clutter spectrum of airborne SAR imaging are analysed. It is pointed out that there exist some problems such as Doppler ambiguity and blind speed band expansion when STAP filtering is applied to the ground clutter cancellation. Aiming at the solving of difficulties in detecting and imaging the slowly moving target with single-channel airborne SAR, a new method suitable for multi-channel airborne SAR to detect and image the slowly moving target is proposed, which can effectively avoid the blind speed and Doppler ambiguity and keep the processed data rate lower. Computer simulation results show that this method is valid. Compared with other method for detecting and imaging the slowly moving targets, the improvement factor obtained by the proposed method is narrower than that. [C1472]

#### "Universal test bench of diesel hydraulic governor based on hardware-in-loop simulation"

The universal test bench for diesel hydraulic governor using hardware-in-loop simulation technology is established. The problems of common in use, variable-speed drive, simulation model, data acquisition and analyzing are solved. The structure of the test bench, along with the hardware and software meeting the requirement of deterministic real-time performance are introduced. Some experimental results are provided to prove the effect of the test bench, which providing a facility for a technician to conduct a general check and calibration for governor assembly. [C1473]

#### "Beamforming using passive nested arrays of sensors"

A novel approach to beamforming using a new class of sensor arrays is proposed, which can increase the

achievable degrees of freedom significantly beyond the conventional limits obtained from uniform linear arrays (ULA). This class of arrays is named as "nested arrays" since they are obtained by nesting two or more ULAs with increasing inter-sensor spacing. Using the second order statistics of the signal received by such an array in a novel way, it is possible to perform beamforming with  $O(N^2)$  degrees of freedom using only  $O(N)$  physical elements. This kind of beamforming will be shown to be essentially non linear in nature and theoretically, it is capable of nulling the effect of noise provided enough snapshots are available. [C1474]

#### "Reduced memory architecture for CORDIC-based FFT"

In this paper, a new pipelined, reduced memory CORDIC-based architecture is presented for any radix size FFT. A multi-bank memory structure and the corresponding addressing scheme are used to realize the parallel and in-place data accesses. The proposed memory-reduced CORDIC algorithm eliminates the need for storing twiddle factors and angles, resulting in significant area savings with no negative impact on performance. As a case study, the radix-2 and radix-4 FFT algorithms have been implemented on FPGA hardware. The synthesis results match the theoretical analysis and it can be observed that more than 20% reduction can be achieved in total memory logic. [C1475]

#### "Improved method for blind estimation of the variance of mixed noise using weighted LMS line fitting algorithm"

The paper addresses blind evaluation of the parameters of mixed noise in images. The conventional approach is based on line fitting in the scatter-plot of local variance estimates using LMS algorithm. This does not utilize the fact that the points in the scatter plot typically appear in clusters that depend on the image. It is shown that the use of weighted LMS algorithm that takes into account the number of points in clusters provides considerable improvement in the accuracy of line fitting and, thus, better estimation of the parameters of mixed noise. [C1476]

#### "Multi-sensor data fusion via federated adaptive filter"

The aim of this paper is to present a federated adaptive filter for use of multi-sensor data fusion systems for target tracking. The computational architecture of the filter consists of several local processors and a global processor. Each local processor incorporates a scheme of Bayesian decision theory into the multiple-model filter to develop a switching capability to react against the same target dynamics, inclusion of both maneuver and non-maneuver phases. The global processor combines the local estimates via a weighted least squares estimator for generating a global estimate. Simulation results show that proposed filter has better tracking performance than the information matrix filter. [C1477]

#### "Multi-network video streaming in a campus visit scenario"

Mobile computing devices are increasingly making use of multiple network technologies to provide seamless connectivity across changing operational contexts. Reliable delivery of video to mobile devices is particularly challenging in these dynamic and multi-network environments. This paper provides a report on our experience in applying Partially Reliable Stream Control Transmission Protocol (PR-SCTP) in a multi-network campus visit scenario. We provide a large scale evaluation of PR-SCTP along with specific site data. Our results show that PR-SCTP is a promising platform for supporting multi-network video delivery. [C1478]

#### "The design and analysis on the small-scale antenna of spread frequency radio lifesaving system"

Radio lifesaving system which is based the spread frequency system works at the MW & SW band, uses the ground wave to orientation with the characteristics of high orientation precision, short responding time and large working bound. However, as the large signal wavelength of the band, the receiver usually adopts a large whip antenna as the signal receiving equipment, which is so large that to become a technical difficulty of equipment miniaturization. To solving this problem, this paper proposes a new-designed angle reflector antenna based on the Hilbert fractal curve as the system antenna which is simulated based on the finite-difference time-domain method (FDTD). Shown as the simulation result, the antenna with the size of 30 mm Ч 30 mm can work in the band of 1.5~10 MHz has the characteristics of high gain, low VSWR, and omni-direction, meets the system requirements. [C1479]

#### "Passive RFID-based Indoor Positioning System, An Algorithmic Approach"

Radio Frequency Identification, RFID technology having been realized of its potential usages only in recent years is now widely used in multiple disciplinary industries and applications. Major of which include SCM, logistics and retail as well as manufacturing. Another key application area of RFID is its use for localisation or positioning of items and people indoors. However, signal propagation in indoor environments is error prone and make

localisation challenging. With RFID being one of the most promising technologies for indoor location awareness applications, this paper presents an algorithmic approach to locate an unknown RFID tag with the use of multiple passive RFID tags. A number of experimental results indicate a general reduction of linear positioning error mean from 3.41m to 0.61m with respect to decreasing inter-tag spacing from a maximum of 7m to a minimum of 1m, respectively. The main advantage of this technique is the reduction in number of expensive RFID readers; instead multiple inexpensive passive RFID tags placed at calculated positions provide essential data to position an unknown tag. [C1480]

#### "A thermal design methodology for power SiGe HBTs with non-uniform emitter finger spacing"

As an effective and feasible method, the technology of non-uniform emitter finger spacing has been used to alleviate the thermal effects and improve the uneven temperature profile in multi-finger power SiGe HBTs. However, for the HBT with dozens of emitter fingers, designing multiple finger spacing values becomes trivial and time-consuming. In the paper, a new thermal design methodology namely Grouping and Adjusting (GA) method is proposed to shorten design time of non-uniform spacing values. Taking a 30-finger HBT for example, the detailed design procedure of non-uniform spacing values is presented, which shows that the peak temperature is lowered by 8.3K, and the maximum temperature difference is improved by 23.5% when compared with the uniform one. Furthermore, three types of the formulas for designing the spacing values are proposed to meet the different requirement of the temperature profile. [C1481]

#### "High-repetition and -stability all-solid state pulsers based on avalanche transistor Marx circuit"

Ultra-wide spectrum (UWS) pulser, in which avalanche transistor is used as its switch, can generate high-repetition and -stability short-pulse, but its power is sharply lower than that of SOS and Tesla generators. Marx circuit is used to increase the power of this type of pulser. Different charged-capacitance and class of Marx circuit determines different waveform and peak-power of output pulse. 20-class and 30-class avalanche transistor Marx circuit pulsers are designed, and the charged-capacitance is 100 pF and 470 pF, then 4 types of waveform are get. The highest output peak-voltage is 2.9 kV, the highest repetition can reach 70 kHz, and keep a better pulse stability, jitter is less than 40 ps. [C1482]

#### "Analysis of electromagnetic scattering of cavities with nonuniform plasma coating"

The radar cross section of cavities coated with nonuniform plasma is analyzed by using the shooting and bouncing ray (SBR) method in this paper. The curvilinear triangular patches are adopted to model the surface of arbitrarily shaped cavities, so that it can meet the practical needs of engineering. The nonuniform plasma slab used to coat cavities is modeled by a series of subslabs, in which the plasma parameters are assumed to be constant. Then the reflection coefficients of the rays to coated cavity are calculated and then applied in calculating the RCS of cavities. The numerical results of the cavities coated with nonuniform plasma indicate that the parameters of the plasma slab can affect the RCS effectively. [C1483]

#### "Application of AMC on mini ultra-near radar detecting system"

To solving the isolation problem of transmitting-receiving antenna in very-near anti-missile system, this letter analyses the equivalent model of AMC, which is made of high-impedance electromagnetic surface, and shows the relationship between its reflectance and phase offset. Then a novel method is brought to improve the isolation by the AMC and the experiments show that this method is able to make the isolation reach -80 dB in a 200 M band. So it has a very huge application value because of its simple structure and low cost. [C1484]

#### "4H-SiC bipolar junction transistors for UHF and L-band long-pulse radar applications"

This paper reviews the current status of 4H-SiC RF npn bipolar junction transistors (BJT's). Process developments including precise and uniform SiC etch and low resistance p-type ohmic contact formation on a two inch SiC wafer will be presented. The high temperature operation up to 500°C and radiation hardness up to 1.6 Mrad, as well as RF performance promising for long-pulse UHF and L-band radar applications will be reported. Rationale and approaches to the further improvement to S-band will be discussed. [C1485]

#### "Classification of radar signals using time-frequency transforms and fuzzy clustering"

A method based on Smoothness Pseudo Wigner-Ville distribution and kernel principle component analysis is proposed to extract features of radar emitter signals. Then, these discriminative and low dimensional features achieved were fed to the classifier which is designed based on fuzzy Support Vector Machines (SVMs). In simulation experiments, the classification of two-class LFM signals was compared with four kernel functions. And the classifier attains over 83% overall average correct classification rate for five radar signals. Experimental

results show that the proposed methodology is efficient for complex radar signals detection and classification. [C1486]

#### **"FDTD analysis of three-dimensional target covered with inhomogeneous unmagnetized plasma"**

A normalized RC-FDTD algorithm is applied to study both the bistatic and monostatic radar scattering of perfectly conducting sphere covered with inhomogeneous unmagnetized plasma. The effects of electron density distributions and plasma collision frequencies on the radar cross section (RCS) are discussed respectively. The simulations confirm that plasma cladding can be successfully used to reduce the RCS of a conducting sphere at almost all scattering angles, although the RCS could increase at some other angles. And the back scattering results indicate that plasma cladding can reduce the RCS of the conducting sphere in a very wide frequency range. Reasonable selection of the plasma parameters can enhance the effectiveness of plasma stealth. [C1487]

#### **"Analysis of image fusion and classification for high resolution SAR data on-line"**

SAR and optical remote sensing image, with highly complementary characteristics, can enhance the integration of information utilization of remote sensing data. Adopting the new Cosmo-SkyMed SAR high-resolution image data, we inhibit speckle impact using enhanced Lee filtering. Then we fused this image with a CBERS image using local use standard deviation based on wavelet packet method. Because of fully integrating the characteristics of each image, it can retain the spectral characteristics and details of properties to the maximum extent, improve signal-to-noise ratio, and be conducive to information extraction. The experiments show that the automatic classification accuracy significantly increased and classification Kappa coefficient increased from 0.47 to 0.93 after fusion of Cosmo-SkyMed and CBERS02 data. Meanwhile, This paper employ a geospatial information processing concept model complied interoperable system framework and an implementation approach for accessing geospatial information openly by chaining individual service module to assemble complex geospatial processing and executing the processing model to deliver information. [C1488]

#### **"The innovation on the education model of the engineering management-based on the viewpoint of WSR methodology"**

Education is a system, so a well defined fostering goal is the precondition for carrying out systematically education activities for the innovation on the education model of the engineering management. Based on the WSR methodology, this paper analyzed the roots of the problems currently existed in the fostering model from three aspects, namely Renli, Shili and Wuli and proposed a new model on engineering management education. The goal is to foster forthcoming engineers with high creativity and social responsibility. [C1489]

#### **"Intelligence analysis in early warning air roster training"**

The paper introduces a new simulation system for training early warning air roster, which uses data mining technology on the massive accumulation training information for intelligence analysis. In the system, the model of association rules are established. Using this model, the system provide ability that arrange much more reasonable training plan for each early warning air roster. Furthermore, it can support an optimized decision of how to make up the team of rosters. [C1490]

#### **"EM scattering by conductor plate coated with multilayered medium having metamaterials"**

The electromagnetic scattering of conductor plate coated with multilayer medium is investigated based on the physical optics (PO) theory and the principle of equivalent impedance boundary condition (IBC). Compared with the multilayered plate coated with right-handed medium, the radar cross section (RCS) of plate composed of metamaterial and right-handed medium has a reduction of 5.76dBsm in the mirror direction. It shows that metamaterials can become a candidate of the radar absorbing material (RAM), which offers a new idea for the development of stealth technology. [C1491]

#### **"Application of VSIE method to scattering problem involving conducting and anisotropic bodies"**

Evaluation of electromagnetic scattering by anisotropic media may be of interest in many military and civil applications. This paper presents the hybrid volume and surface integral equation(VSIE) based scheme to analyze scattering from conducting and/or inhomogeneous dielectric bodies with anisotropic electromagnetic properties. The Rao-Wilton-Glisson (RWG) basis functions are used to discretize those unknowns of the matrix equations. The method of moments(MOM) technique is augmented with the fast multipole which enable large scale analysis. Finally, several numerical results are presented to demonstrate the stability and accuracy of the proposed method. [C1492]

### "Multi-target scattering analysis based on generalized higher-order finite-difference time-domain method"

A generalized higher-order finite-difference method (in which the time difference utilizes the symplectic integrator propagator and the spatial difference utilizes the discrete singular convolution) is proposed to analyze electromagnetic scattering from multiple targets. Numerical test results have demonstrated the higher stability and enhanced effectiveness of the proposed method when compared with the standard FDTD procedure. In addition, there are significant reductions in CPU time and memory space requirements when used with suitable meshes. [C1493]

### "Supporting omni-directional communications capability in variable attitude spacecraft"

This paper describes the work undertaken to provide omni-directional communications on Sapphire, a variable attitude spacecraft. Several options to solve the problem are considered and two chosen; analysis is presented to show that mission objectives can be met. [C1494]

### "Multi-objective optimization of an isoflux antenna for LEO satellite down-handling link"

A multi-objective optimization approach has been applied to the synthesis problem of the geometrical structure of antenna with complex set of requirement specification. This methodology is a promising tool for new development and application for several kind of microwave structure. [C1495]

### "Criteria for phase shifter operation of an azimuthally magnetized coaxial ferrite waveguide"

Three criteria: a physical, a mathematical and a functional one for operation of the coaxial waveguide, completely filled with azimuthally magnetized ferrite, under for normal TE<sub>01</sub> mode excitation, as a digital nonreciprocal phase shifter, are established. The first of them is deduced from the phase characteristics of configuration and determines the limits of the interval in which it provides differential phase shift for a specific value of the off-diagonal ferrite permeability tensor element. The second criterion associates the structure parameters with certain roots of its characteristic equation, expressed by complex confluent hypergeometric functions and with the related to them positive real  $L(c, \rho, n)$  numbers ( $c=3D/3$ ,  $0 < \rho < 1$ ,  $n=3D/1$ ). The third one specifies the limits of the domain of phase shifter operation. These are functions, representing in normalized form the dependence of phase shift at the cut-off frequencies and at the envelope lines, marking the end of the phase curves for negative ferrite magnetization from the side of higher frequencies, on the guide radius for a fixed central conductor thickness. [C1496]

### "Principles of the electromagnetic modelling of some microwave components, based on the circular waveguides with azimuthally magnetized ferrite"

The principles of electrodynamic analysis of the characteristics of the ferrite control components (nonreciprocal digital phase shifters, cut-off switches and isolators) which use circular waveguides, entirely filled with azimuthally magnetized ferrite or containing a coaxial disc- or ring-shaped area of the medium alluded to and a dielectric one, surrounding it or taking up its hollow, resp., and work in the normal TE<sub>01</sub> mode, are enunciated: i) employment of complex confluent hypergeometric and eventually also of real cylindrical functions; ii) indispensability of inventing of numerical methods for evaluation of some special functions of the mathematical physics: the Euler gamma function, its logarithmic derivative and the confluent functions in the complex field, as well as of the cylindrical ones in the real domain; iii) elaboration of techniques for numerical solution of complicated transcendental equations, involving complex confluent and possibly real cylindrical functions, too; iv) introduction of a new class of real numbers, called  $L$  numbers, connected with the purely imaginary roots of the equations mentioned; v) development of numerical schemes for computation of the phase curves of geometries regarded and of iterative procedures for finding the differential phase shift provided by them; vi) laying down of criteria for the operation of configurations as phase shifters, magnetically controlled cut-off switches and isolators. Each of the maxims pointed out is elucidated in detail. [C1497]

### "A design of beam forming network integrated in multilayer microstrip structure for applications in airborne SAR"

This paper presents the design, arrangement and components of multilayer microstrip beam forming network manufactured in multilayer PCB technology for application in airborne synthetic aperture radar antenna. The network has been designed for easy integration with the array of radiating elements operating in L and C bands. [C1498]

### **"Resonator techniques for reflectivity and surface resistivity at high temperature: Methodology and measurements"**

Two different methodologies based on resonator techniques are presented. The first has been realized for wide band reflectivity characterization at high temperature while the second has been developed to verify surface resistivity including roughness, surface contamination and other undesired effect. Both methods have been developed for characterization over a large temperature range. Measurement results on Ti6Al4V samples, Copper and AlBeMet ® are presented. [C1499]

### **"Control and diagnostic system for the demonstrator of S Band active antenna"**

In the paper, a Control and Diagnostic System designed for the Demonstrator of S Band Active Antenna is presented. Transmit and receive antenna radiation pattern is steered and controlled by a central computer. Diagnostic system is focused on transmit part of the demonstrator with solid state T/R modules. The key elements of diagnostic, amplitude and phase meters integrated with each transmit channel are presented. The system works in pulse condition. Real, transmit signal as reference for diagnostic system is used. Independent, built-in system of diagnostic for T/R modules are presented as well. It enables safe modules operation and failure location in service mode. The Control and Diagnostic System is based on CAN 2.0 bus what allows to operate with very high reliability and baud rate up to 1 Mb/s. [C1500]

### **"Inter-period compensation of the unambiguity range degradation in polarimetric FMCW radar with time-shifted dual-orthogonal signals"**

This paper describes a new type of sounding signals for polarimetric FMCW radar and the corresponding signal processing technique. This technique coordinates continuous transmission of two bi-cyclic LFM-signals on orthogonal polarizations and applies an advanced de-ramping processing on receive. The first signal consists of two identical LFM-signals; the second one has time shift relatively first and is composed by the same LFM-signal and its copy having negative sign. The time between the components of sounding signal prevents the frequency overlap between polarimetric components of scattered signal in the branches of every polarimetric radar channel. Thanks to this frequency gap between the signals in every time instant, a high-isolation level in polarimetric FMCW radar channels can be provided. However, the use of two LFM-signals having the same form but a relative time shift can decrease the unambiguity range, because the delayed signals scattered by far-located objects (interfering signals) can be determined as useful signals scattered by close-located objects in a cross branch in a polarimetric radar channel. The use of the proposed bi-cyclic LFM-signals and the additional summation units in the de-ramping filter allows the suppression of these interfering signals due to the phase sign change of the beat signals. As result, the developed de-ramping processing technique can be used in polarimetric FMCW radar receiver providing high-level cross-channels isolation without unambiguity range degradation for estimation of all elements of the radar target scattering matrix. [C1501]

### **"Minimizing of influence of synchronization lack between short LMF signal and filter on its compression"**

As researches show, the compression in the time domain of short single chirp (LMF) signals with low BT depends significantly on both matching the signal and matched filter (MF) impulse response (IR) parameters to a specific window and using non-linear operations on convolutions. These ways are effective only when a synchronization between those signal and MF is obtained. This work depicts as the above mentioned methods as a way of minimizing of influence of the synchronization lack. The proposed matched filtering method with the use of  $n$  parallel MFs and the other techniques allows only one sample to be obtained in the main lobe with position located in the appropriate sampling period  $T_{\text{sw}}$  with accuracy  $T_s/n$ . These approaches are expedient for use in radar and sonar array processing. [C1502]

### **"Interaction of thin conductive sheets with TE<sub>10</sub> electromagnetic wave in rectangular waveguide"**

Numerical investigation of a thin conductive layer, interacting with TE<sub>10</sub>electromagnetic field mode in rectangular waveguide, was performed. A finite-difference time-domain method with subcell technique was applied to perform the modelling. The distribution of the electric field in the layer and the reflection coefficient from it have been calculated for different length, shape and conductivity structures. These investigations can be useful for the development of high frequency microwave sensors, the operation of which is based on a non-uniform carrier heating effect in the layer. [C1503]

### **"Patch antennas setups for omnidirectional pattern to provide TTC links onboard small spacecraft"**

Advancements in patch antennas made feasible their applications in hard to sustain environments, such as

space or sea and oceans. These applications are often quite new and often represent maturing broadband communication. In many instances one of the main design objectives is to ensure omnispherical or omniazimuth coverage with patch antennas placed onboard a specific platform. With use of numerical CAD tools and with application of near-field antenna measurements, we have carry on extensive research into relevant design guidelines for ten years. In this paper we present some of our findings. [C1504]

#### **"FPGA based IF digital receiver for the PARSAX-Polarimetric agile radar"**

An FPGA-based digital receiver has been developed to perform real-time processing for the PARSAX radar. It is a fully polarimetric FMCW radar with dual-orthogonal sounding signals, which has the possibility to measure all elements of the radar targets polarization scattering matrix simultaneously, in one sweep. This paper presents the design principles including the range profile interpretation, optimal parameters selection and processing gain analysis. A novel parallel deramping processing architecture suitable for FPGA implementation is introduced; the overall digital de-ramping processing has been implemented in one chip of FPGA and verified by experimental results. [C1505]

#### **"The multiposition passive satellite system for the terrestrial radiation sources monitoring"**

We proposed an iterative algorithm for radio sources coordinates estimating by the range-difference method using the multiposition passive satellite system. We simulated the coordinates estimating algorithm. We defined requirements to the satellite orbit altitude and to the distance between the satellites for the small satellites group. We estimated time of arrival estimation accuracy, which is necessary to achieve the required coordinates estimation accuracy. [C1506]

#### **"A novel approach applied for the internal and semi-external calibration of the PARSAX dual-channel polarimetric agile radar system"**

Polarimetric agile radar is able to measure all elements of the polarization-dependent backscattering matrix (BSM) simultaneously. Polarimetric calibration is an important issue to determine the BSM accurately. This paper focuses mainly on the internal and semi-external calibration of the dual-channel polarimetric agile radar system. The paper presents a novel approach based on very up to date methods used for cross-validation between simulations and measurements. Error models of all parts of the radar system will be derived from the approach and implemented in the radar system calibration. After calibration, the good matching performance for relative measurement between two channels demonstrates the validity of the here-proposed calibration approach. [C1507]

#### **"Monopulse direction finder for harmonic radar system"**

This paper presents first results of experimental amplitude comparison monopulse direction finder for harmonic radar. Aperture coupled patch antenna arrays are used for operation in 1.5 GHz band with 10% operation bandwidth. Antennas with leaf characteristic enable 50° sector of operation in azimuth. Problems with common (circular) polarisation are discussed. [C1508]

#### **"Comparative numerical analysis of the slot antenna arrays the energy and finite element methods"**

It is described the results of numerical simulation of liner and planar antenna arrays, obtained using the program designed by the article authors. In the program are used the analytical expressions which describe the main array characteristics. The results are compared with the results obtained using HFFS. [C1509]

#### **"Simulation of direction of arrival and beamforming algorithms used in smart antenna system for software-defined radio"**

The demand for mobile communication systems with global coverage, interfacing with various standards and protocols, high data rates and improved link quality for a variety of applications has dramatically increased in recent years. The Software-Defined Radio (SDR) is the recent proposal to achieve these. In SDR, new concepts and methods, which can optimally exploit the limited resources, are necessary. Smart antenna system is one of those, which combats the co-channel interference and maximizes the user capacity of mobile communication system. The paper presents the analysis of the beamforming and direction of arrival (DOA) algorithms used in the smart antenna systems. The analysis is carried out for the MULTiple Signal Classification (MUSIC) algorithm and The Multiple Sidelobe Canceller and the Maximum SINR Beamformer algorithm using MATLAB as a simulation tool. [C1510]

### "Wideband aperture coupled microstrip array antennas for radar applications"

A new 1x2 and a 1x4 wideband aperture coupled microstrip array antennas, to work in Ku and K bands, are presented in this paper. The array antennas have VSWR < 2 from 11.4-23.8 GHz. The gain of the 1x2 array antenna is above 10 dB from 11.4-17.8 GHz and the 1x4 array has more than 12 dB gain within 11.3-17.3 GHz. Additionally, by using a 2x4 array antenna more than 16 dB gain is obtained at the frequency range of 11.5-17.2 GHz. The 1x4 array antenna was fabricated in which, good agreement is obtained between simulation and experimental results. [C1511]

### "Investigation into a folded wideband monopole antenna for use in portable devices"

This paper presents investigations into a compact antenna for use in portable devices to access almost all modern wireless services from about 800MHz to 6GHz. Initially, a microstrip-fed planar monopole of quarter-elliptical shape on FR-4 substrate is designed to generate a wide impedance bandwidth. This radiating element is augmented with a parasitic microstrip stub and a ground-plane cut to improve wideband performance. To reduce its projection area, the planar monopole is folded. The folded antenna occupies a volume of 13mm x 50mm x 5.6mm. It operates over two wide bands between 0.85 and 3.8GHz, and 4.9 and 6GHz, with reference to 6dB return loss (VSWR 3:1). Its radiation patterns are omnidirectional in the lower band and deteriorate at higher frequencies. The corresponding gain varies between 1.5 and 7dBi. [C1512]

### "Microstrip monopulse array antenna"

The new construction of microstrip monopulse array antenna is described. It consists of four radiating elements in a row. Such row is supplied by ring coupler connected at its two sides using of coaxial cable jacks. This gives possibility to get relative high radiation power that is needed in radar or radio-transmitters. Proposed array antenna construction is simple, and its measurements results show that obtained frequency band is relatively wide. [C1513]

### "On multiport antennas for MIMO-systems"

A very promising method to enlarge the radio channels capacity is the use of MIMO (Multiple Input Multiple Output) systems. The need to deploy more than one antenna leads to the problem of the restricted available space reserved for the antennas, especially on the terminals. Another fundamental problem is the evaluation of the MIMO performance in a realistic propagation environment. Only a global view will bring up a realistic picture about the improvements using multiple antenna technologies. At the beginning of the presentation basics on MIMO-technology will be given. The second part will show in a very fundamental way the realisation of a compact 4-port antenna, which provides a sufficient decoupling between the ports. Finally the system performance of this antenna is investigated. Based on the analysis of the diagram correlation coefficient and the mutual coupling of the elements a basic idea of the antenna performance is evaluated. Measured and simulated correlation coefficients of typical channel matrixes taking the antenna into account will give finally an idea of the real MIMO performance. [C1514]

### "Model order selection of the target doppler spectrum"

The information about shape and geometrical dimensions of the moving target can be extracted using Doppler spectrum. The short observation time interval corresponds to constant speeds of target scatterers as well as low resolution by Doppler frequency shift. Methods of spectral estimation are applied to identify the scatterer parameters. Two methods of a target Doppler spectrum model order selection based on information criteria are presented. [C1515]

### "Target detection in Doppler radar with PSK signals"

The aim of this article is to test the effectiveness of the known structures of radar signal processing (RSP) that employ CFAR processors in order to detect moving targets in the frequency domain, depending on the chosen width of velocity channels (the number of FFT). The Doppler radar is radar with continuous transmission of PSP (Phase Shift Keying) signals. Real records that have been produced by Doppler radar for the case of moving people or cars on the background of trees are used in the study. The results obtained lead to believe that detection of targets with CA CFAR processors provides the required effectiveness in case when the velocity channel width is correctly defined. [C1516]

### "Antenna activities in support to future candidate earth explorer core missions with a SAR"

Three candidate Earth Explorer Core Missions have been selected for Phase-A study, namely BIOMASS, CoReH2O and PREMIER. Two of the candidates are Synthetic Aperture Radar (SAR) missions: BIOMASS

operating in P-band and CoReH2O operating in Ч and Ku-band. Antenna development activities have been initiated to reduce technological risks and in support to Phase A studies. The paper describes the latest results from those activities. [C1517]

#### "Field Effect transistors for fast terahertz detection and imaging"

We present recent results on detection of terahertz radiation with nanometer size GaAs FETs and Si MOSFETs at room temperature. We demonstrate that the detection sensitivity and speed allows application of the transistors in terahertz imaging systems. At low temperatures the transistors can act as magnetic field tunable detectors. [C1518]

#### "Calibration of a 220-325 GHz vector-network-analyzer with multiple rectangular-waveguide sections"

We study the performance of the multiline through-reflect-line method in the calibration of a 220-325 GHz vector-network-analyzer with WR-03 rectangular-waveguide test-ports. The calibration method is based on multiple uniform-waveguide sections with unknown propagation constant and different lengths, a reflect standard which is assumed to be identical on both vector-network-analyzer ports but otherwise unknown, and a direct thru connection of the test ports. Experimental verification demonstrates that the multiline through-reflect-line technique yields repeatable and physically meaningful results. [C1519]

#### "PARSAX: High-resolution Doppler-polarimetric FMCW radar with dual-orthogonal signals"

The article describes the IRCTR PARSAX radar system. It is an S-band high-resolution Doppler polarimetric FMCW radar utilizing dual-orthogonal sounding signals. The signals allow for measuring in one sweep all elements of the radar targets polarization scattering matrix simultaneously. PARSAX characteristics are: modular system set-up, highly-optimised linearity and sensitivity of the RF front-end receiver, use of a flexible multi-channel arbitrary waveform generator as sounding waveforms source, high-resolution analogue to digital conversion of the received signals at sufficiently high intermediate frequency and FPGA-based programmable digital multi-channel receiver. The paper shows that PARSAX is a unique radar research platform for studying arbitrary sounding waveforms with bandwidth up to 50 MHz and processing algorithms in Doppler-polarimetric radar. [C1520]

#### "Gyrotropic waveguides analysis based on the neural networks"

The paper addresses the problem of the cylindrical gyrotropic waveguide analysis by an electrodynamical model. The technique of semi-automatic extraction of the dispersion characteristics by the use of single-layer perceptron neural network is proposed. Presented waveguide analysis algorithm is divided in four stages: initialisation of system parameters, evaluation of transcendental linear dispersion equation system, extraction of dispersion characteristics and waveguide broadband width evaluation. [C1521]

#### "Artificial neural network algorithm for automated filter tuning with improved efficiency by usage of many golden filters"

This paper shows how to improve the efficiency of the Artificial Neural Network (ANN) method for the cavity filter tuning. It was proved that the usage of many golden filters in the process of collecting the learning vectors, used in ANN training, has the significant influence in decreasing the ANN generalization error. Thus, the algorithm efficiency is increasing. The generalization error value of ANN, trained on samples from two different filters, as a norm of the filters similarity is proposed. The tuning experiment for the 6-cavities RX filters of GSM diplexer has been demonstrated. In the experiment the ANNs were trained based on the vectors collected from up to five different filters, showing the significant influence of the number of "known filters" on the ANN generalization error. [C1524]

#### "GaN class E wideband microwave power amplifier"

The simulation and experimental investigation of wideband class E power amplifier using GaN MESFET NPTB00025 was carried out. Special multi-resonant microstrip output network was used to obtain required load impedance. In addition, a single-frequency class E power amplifier was simulated and experimentally investigated for adjust values of parasitic elements of transistor's model in switching-mode power amplifiers. In the bandwidth of 500-600 MHz output power of 9.2 W with power-added efficiency of 65 % and DC supply voltage of 18 V was obtained. [C1525]

#### "Via interconnection structures for x-band surface mount circulators"

A method for modeling and designing various via interconnection structures for surface mount circulators is presented. The circulator-via assembly and the interconnection methods are described. The microstrip-via-microstrip structure is divided into parts, each part is treated separately. The background of empirical methods and microwave network theory is shown as a basis of the design steps. Interconnections including single and double vertical via structures are compared by means of the FDTD method. Based on a previously designed X-band circulator, the effects of the via connections on the circulator performance are investigated. [C1528]

#### "The Method of Designing Ultra Low Phase Noise Dielectric Resonator Oscillators"

In this paper a method of designing ultra low phase noise Dielectric Resonator Oscillators (DRO) is presented. The design procedure is described basing on an exemplary 1.3 GHz Voltage Controlled DRO realized in the negative resistance oscillator configuration. Issues of the resonator and the active circuit design important for achieving a good phase noise performance are described. Described method was used for designing a 2.85 GHz oscillator with very good results. [C1535]

#### "High temperature stability of nitride-based power HEMTs"

The temperature stability of InAlN/GaN heterostructure FETs has been tested by a stepped temperature test routine under large signal operation conditions. Devices have been successfully operated up to 900 °C for 50 hrs. Failure is thought to be contact metallization related, indicating an extremely robust InAlN/GaN heterostructure. [C1536]

#### "Metal contacts to wide bandgap semiconductor structures for RF power applications"

The increasing demand for electronic transistor with the cut-off frequency 100 GHz devices capable of function at high power and have been demonstrated this year. frequency levels, high temperatures, and harsh In order to take the full advantage of their environment is one of the most significant issue superior inherent properties several challenges of modern information society, especially in the in material processing are to be overcome. One field of RF systems for telecommunication and of the most important issue is the quality of wireless communication. Moreover, energy metal-semiconductor contacts. This is problems and environmental concerns due to especially true for both, for Schottky barriers global warming have generated the need for to be used in Schottky rectifiers and for ohmic novel semiconductor devices for active contacts being a part of any semiconductor electrical power management in areas such as device. The ohmic contacts are primarily energy generation and distribution, and important because a potential barrier of high transport where efficiency and/or high energy is inclined to form at an interface temperature operation are of the essence. Wide between metal and wide-band-gap bandgap semiconductor devices, particularly semiconductor, which consequently results in those using SiC and GaN-based materials, are low-current driving, slow switching speed, and key candidates for power-control and high- increased power dissipation. This paper speed communication devices, owing to their provides a comprehensive and critical excellent intrinsic properties, which involve assessment of fundamentals and practice of large breakdown electric field, in the 54106metal contacts to wide bandgap Vcm-1range, together with high electron semiconductors with an emphasis on high saturation drift velocity, strong hardness, and power/temperature handling capability. The good thermal conductivity. GaN is already topics covered in this paper-- are grouped in five used in high-frequency circuits and is subsections. First, deals with carrier transport attracting increasing attention as a material to mechanisms in metal-semiconductor contacts, play a leading role in the next generation of which are applicable to any metal-power electronics. On the other hand, much semiconductor system. In the next section, effort have been already put in SiC technology points specific to metal/SiC and metal/GaN and first SiC power devices have already been contacts are discussed. Then, there is a place commercialised. Moreover, SiC is the favourite for a discussion of ohmic contacts, their substrate for GaN-based high-power and high- fabrication and characterisation methods. In frequency applications. SiC also appears as particular, the issue of determining properly enabling platform for large area graphene ohmic contact resistivity is discussed in detail. electronics, while a radio-frequency graphene The main part of the paper presents most significant results concerning thermally activated reactions between metal and properties of interface and its role in formation semiconductor and formation of intermediate of Schottky barriers and ohmic contacts. For layers in metal/SiC and metal/GaN contacts. GaN-based materials experimental results on For SiC, attention focuses on the effect of an the use of MAX phases for thermally stable intermediate graphite layer on electronic metallization systems receive major interest. [C1537]

#### "Modeling of metal/insulator/GaN ultraviolet photodetector by finite element method"

A metal/insulator/GaN ultraviolet photodetector has been studied by computer simulations using finite element method. The equations of drift-diffusion model have been solved numerically in the illuminated structure taking into account electronic states at the insulator/GaN interface with a continuous U-shaped energy distribution in the GaN bandgap. The capacitance of the structure has been calculated versus the light excitation intensity and the gate voltage. The influence of the interface states on the photodetector characteristics has been discussed. [C1538]

#### "A novel multi-band frequency selective surface design and its application in a compact 60-GHz folded dipole array"

This paper describes some basic theories about the frequency selective surface (FSS). For the first time we demonstrate a novel design of a multi-band FSS to the best of our knowledge. It consists of a periodic array of concentric-square-shaped elements. Like traditional FSSs, the surface of the proposed FSS can simply be fabricated using printed circuit technology on the substrate. Simulation results show a clear dualband and possible performance variation with relevant parameters. We integrate this FSS into a compact 60-GHz folded dipole antenna array package in order to test its application. Results show that it successfully converts a single-band antenna to a multi-band one and specific resonant bands can be easily adjusted for the practical purposes. [C1539]

#### "Third harmonic generation in silicon with a 118 GHz gyrotron"

Third harmonic generation in n-type Si crystals is experimentally studied using 118 GHz gyrotron. The results are treated using new approach of the dynamical non-uniformity of the non-linear medium. [C1540]

#### "Microwave power capabilities of InAlN/GaN HEMTs"

This paper reports on microwave power results of InAlN/GaN HEMTs on silicon carbide substrate. It is shown a

power density higher than 10W/mm up to 10GHz. Investigations based on diamond substrate or heat spreaders on top of the device to improve the thermal dissipation are also described. [C1541]

#### "Microwaves reflection of centimeter wavelength range of two-dimensional square symmetry plasma photonic crystals"

In this paper, an exact approach, uniting several modern methods, to the theory of multiple scattering of wave fields in two dimensional inhomogeneous media, the so called transfer relations' method with the technique of matrix Riccati equation, is applied in a quantitative analysis with given accuracy of reflection spectra of plasma photonic crystals with square lattice symmetry. [C1542]

#### "Control system for high power solid State microwave generators 2.45 GHz band"

The paper presents development and implementation of the four high power microwave sources system used for testing phased 2.45 GHz antenna array. Each module has maximum output power of 200 watts and covers frequency band between 2.35 and 2.6 GHz. System provides possibility of independent setup of frequency, amplitude and phase of each generator (depends on mode of operation). [C1543]

#### "Design of a 54 to 63 GHz differential common collector SiGe Colpitts VCO"

The design of a 60 GHz differential common collector Colpitts VCO in SiGe HBT technology with 180 GHz ftis presented. The impact of parasitics on the negative resistance is evaluated and an extension regarding existing design equations is derived. Within a wide tuning range from 54.1 to 62.7 GHz, a phase noise performance between -98 and -90 dBc/Hz is measured at 1 MHz offset. To the knowledge of the authors this is the best phase noise performance of a 60 GHz VCO in silicon yielding such a high tuning bandwidth. At a dc voltage of 2 V and a dc current of 14 mA, the output power amounts to  $-5 \pm 1$  dBm. [C1544]

#### "Talbot effect supported millimeter wave generation"

The temporal Talbot effect enables the flexible and cost-effective generation of microwave signals. We demonstrate the generation of frequencies up to 90 GHz using an optical pulse source with a 10 GHz repetition rate. Time- and frequency domain measurements were performed. The phase noise of the generated RF tones was assessed. [C1545]

#### "Achievement and perspective of GaN technology for microwave applications"

This paper give an overview of some recent results obtained by Alcatel-Thales III-V Lab using emerging AlGaIn/GaN HEMT technology. This technology is very suitable up to Ku-Band and offer impressive power performances. The second part of the presentation will give an overview of results obtained using new InAlN/GaN heterostructures, which is expected to offer similar output power but with improved efficiencies and to cope with higher working frequencies. [C1546]

#### "InP HBT demultiplexing ICs for over 100 Gb/s optical transmission"

In this paper we present the design and optimization of decision and DEMUX circuits fabricated in a 0.7  $\mu$ m InP HBT technology. Full-rate characterization at 50 Gb/s shows CPM of 13 ps and excellent 3R capabilities. Circuits are compatible with positive and negative signal to ease high-speed interface with different types of photodiode in the photoreceiver. The decision circuit copackaged with the pin-photodetector was used as photoreceiver in 107 Gb/s optical experiment. Error-floor free demultiplexing operation with 231-1 PRBS signal was demonstrated. [C1547]

#### "Periodic FDTD modeling of 3D photonic crystals"

In this paper application of FDTD method supplemented with periodic boundary conditions to the analysis of three-dimensional photonic crystals is presented. For that purpose, a model of body-centered cubic dielectric lattice is introduced and investigated. Complex-looped FDTD algorithm is applied for the computation of a photonic bandgap diagram in the first irreducible Brillouin zone revealing dispersive properties of the lattice. [C1548]

#### "Inexpensive helical antenna for global navigation satellite systems"

In this paper theoretical and practical study of an inexpensive L-band helical antenna is presented. The geometrical parameters of the antenna were calculated using standard formulas. The frequency shift resulting

from the winding of the wire on a polyurethane (PU) core was also taken into account. Numerical analysis of the sensitivity of antenna parameters to the manufacturing process had been provided. After manufacturing the antenna an appropriate impedance matching section was designed and fabricated. Measured return loss was below -18 dB in the frequency range 1.48-1.67 GHz. Radiation patterns and axial ratio of the antenna in the direction of maximum radiation are also presented in this research. [C1549]

#### **"Tunable filters based on metal-dielectric resonators"**

A method of metal-dielectric resonator's frequency tuning is proposed. The method is suitable for electromechanical control using piezoelectric or MEMS actuator. The two-resonator and three-resonator tunable filters based on metal-dielectric structures are developed. [C1550]

#### **"A 2 W GaAs doherty amplifier for 5.5-5.6 GHz applications"**

In this paper the design of a 2 W uneven C-band Doherty power amplifier is presented. The Doherty PA is designed to achieve high efficiency for digitally modulated signals with high peak to average power ratio (PAR) used in wireless local area network (WLAN) systems around 5.6 GHz. The Doherty amplifier has been designed using two equal sized GaAs devices for the main Class- AB and peaking Class-C amplifiers. An uneven power divider is used at the input to deliver more input power to the peaking PA. The measured maximum output power of the realized uneven Doherty PA is 34 dBm with 50 % peak drain efficiency (43 % of power added efficiency). The power added (drain) efficiency is higher than 25 % (30 %) up to 6 dB of back-off. Moreover, an adjacent channel power ratio (ACPR) of -30 dBc has been measured using a digitally modulated signal of 10 MHz bandwidth. [C1551]

#### **"GaAs MMIC Doherty Power Amplifier with asymmetrical drain bias voltage"**

This paper presents a 3.4x2.3mm<sup>2</sup> MMIC Doherty Power Amplifier in pHEMT GaAs technology, designed for X-Band applications (9.6 GHz). The obtained results shown 31dBm maximum output power with a 47.6% associated drain efficiency. Moreover, in the designed 6dB of output power back-off, from 25dBm to 31dBm output power, the efficiency is higher than 30% with a related gain compression lower than 1.5dB. As will be detailed, such a performance are maintained almost constant in a frequency bandwidth greater than 10% (9.1-10.1 GHz). [C1552]

#### **"Doherty power amplifiers for handset applications"**

The efficiency and linearity are enhanced by a direct input dividing and an uneven power drive. An optimized envelope tracking (ET) operation of Doherty power amplifier (PA) is presented. The PA and the supply modulator are realized using a 2  $\mu$ m InGaP/GaAs HBT and 0.13  $\mu$ m CMOS processes, respectively. For WiMAX application, it shows a PAE of 38.6% and an EVM of 3.64% at an output power of 24.22 dBm with a gain of 24.62 dB. [C1553]

#### **"A diplexer design method using an augmented channel filter approach"**

A new method of microwave diplexer design is presented. The new technique does not require a final diplexer tuning. The method is a modification of the technique based on accurate channel filters synthesis using surrogate models of coupling coefficients in order to obtain initial structure dimensions [1]. Here the structure optimized during channel synthesis is modified to assure correct loading of the junction. By doing so, the diplexer response after channels synthesis agrees with design specification and diplexer tuning is not needed. [C1554]

#### **"Design of a dual-band GaN Doherty amplifier"**

In this paper, the design, realization and test of a dualband Doherty power amplifier (DPA) will be presented. The design has been realized in hybrid technology using a packaged GaN HEMT as active devices. A special attention will be focused on the passive structures involved in the DPA design (input power splitter, impedance transformer network, impedance inverter network and phase compensation network) showing several possible implementations and the related tricky aspects. The DPA has been designed to operate simultaneously at 2.14GHz and 3.5GHz with 6 dB of output power back off (OBO) at both frequencies. [C1555]

#### **"Design of broadband complex impedance-matching networks and their applications for broadbanding microwave amplifiers"**

In this paper design a method is presented for broadband matching of complex impedances using distributed

circuit elements. The method is a combination of the classical analytic network theory approach for lumped element matching networks and of the numerical optimization techniques. The aim is to create distributed element matching networks for Rf transistors in order to design broadband amplifiers in a systematic way. The design method is demonstrated by several realized and tested microstrip matching circuit in the 1.5...2.5GHz frequency range, which are well applicable for amplifier design. A microwave amplifier example operating in the 1...2GHz band is shown as well. [C1556]

### "Innovative maritime communications technologies"

Current maritime systems are to a large extent based on legacy analog VHF radios for ship-to-shore communications near port waters, and relatively low bandwidth digital satellite communications (SatCom) for long-range ship-to-ship/shore communications. The cost of bandwidth for SatCom networks is expected to remain high due to the cost of launching satellites into orbit and also due to the stabilizers required for presently available on-board antennas. On the other hand, the legacy VHF system comprises low bandwidth radios incapable of supporting applications requiring high data rates. Unlike the terrestrial networks, advancement in maritime communication means is severely lagging behind its land counterpart. MARINTEK is the principle investigator of the MarCom project, a joint initiative between several national and international R&D institutions, Universities and Colleges, Public Authorities and Industry, funded by the industry itself and The Norwegian Research Council's MAROFF program, which is aiming at developing a novel digital communication system platform to ensure the proliferation of innovative mobile network applications presently being widely implemented on land-based wireless systems [C1557]

### "A 27 dBm microwave amplifier with varactors-controlled matching networks"

In this paper design and development of 27dBm medium-power amplifier with varactor-based input/output matching networks is presented. The frequency tunable range of 1.3GHz to 2.6GHz was obtained for input matching  $|\Gamma| \leq 0.3$  and power gain higher than 13dBm. Adaptive impedance matching networks provide frequency adjustment and output power level optimization by means of two voltages control. The amplifier was fabricated using surface mounted technology and conventional low-cost GaAs transistor and hyperabrupt varactors. Main parameters of the implemented amplifier with nonlinear behaviour of varactors are investigated. The device can be applied to operation with constant envelope multi-standard and multi-band radio-communication systems. [C1558]

### "On BER of STBC coded MIMO systems in different indoor environments"

The spatial diversity is known to overcome the multipath propagation effects and to increase the spectral efficiency in multi antenna systems. Under IEEE 802.11n specifications channel modeling, we evaluate the error performances of WLAN employing STBC (Space Time Block Codes) with and without CSIT (Channel State Information at Transmitter) for 2x1 and 2x2 MIMO (Multiple Input Multiple Output) cases when different antenna spacing is used at transmitter and receiver. [C1559]

### "Doherty power amplifier and GaN technology"

In this paper, the features of GaN HEMT technology and Doherty Power Amplifier architecture will be investigated, as a possible answer for the stringent requirements of the next generation of wireless systems. In particular, the attention will be focused on the capabilities and the relevant drawbacks of a GaN HEMT technology when designing DPAs. The discussion of the most important DPA's design aspects will be done through the presentation of several hybrid prototypes. Experimental results will be also given to support the theoretical aspects. [C1560]

### "3 GS/s S-Band 12 bit MuxDAC on SiGeC technology"

In advanced applications such as digital radar, Ultra Wide Bandwidth communications and software defined radio, the need for instantaneous bandwidth often drives system design decisions. Access to high speed data converters enabling up and down conversion directly in the L Band and S Band removes the limit imposed by bandwidth scarcity and allows the design of flexible and simplified system architectures. Broadband DAC's (Digital to Analogue Converters) are key enabling components which open up new design opportunities for digital Synthesizer systems. In this regard, this paper describes a new 12 Bit 3GS/s DAC, based on a 200 GHz SiGeC bipolar Technology, which enables direct synthesizing of 1GHz arbitrary waveforms directly in the high IF (S\_Band) region closer to the Antenna. [C1561]

### "Asymmetric mechanisms of second-order intermodulation in downconversion mixers"

This paper addresses the issue of second-order intermodulation mechanisms with memory effects in downconversion mixers. In particular, an attempt is made to explain asymmetries in generated distortion caused by interferers situated below and above the local oscillator frequency. The analysis is carried out on a circuit level using Volterra-series techniques and provides an insight into underlying frequency-dependent mechanisms. [C1562]

#### "ADI-FDTD method for physical simulation of semiconductor devices"

This paper describes an alternating-direction implicit finite-difference time-domain method for the two-dimensional time-dependent simulation of semiconductor devices. This approach leads to the significant reduction of the semiconductor simulation time. We can reach over 80% reduction in the simulation time by using this technique while maintaining the same degree of accuracy achieved using the conventional approach. As the first step in the performance investigation, we use the electrons flow equations in the absence of holes and recombination in this paper. [C1563]

#### "Integrated cylindrical horn antenna array"

In this paper the integrated ultra wide band antenna cylindrical array consisting of eight double ridged horn antennas is presented. The mechanical and electromagnetic properties of that antenna array and their relations to its functionality in different systems are also presented. [C1564]

#### "Magnetic properties of the finemet alloys in the microwave frequency range"

In the paper measurements of the magnetic properties of powdered nanostructured alloys-Fe<sub>73,5</sub>Cu<sub>1</sub>Nb<sub>3</sub>Si<sub>13,5</sub>B<sub>9</sub>(Finemet) were presented. Measurements were realized in the coaxial line in the frequency range 0, 2-10, 2 GHz. The new technique for measuring of permittivity and permeability of powdered materials was developed. The obtained data was compared with data of powder received from milling of well known ferrite-Yttrium Garnet YIG class ferrite, named G-175. [C1565]

#### "Method of dynamic parameters measurement of high-speed D/A converters"

Developed sampling device and algorithm of digital signal processing for automated measurement of settling times of fast D/A converters is represented. The new sampling device with numerically controlled oscillators allows realizing of the different types of the time scale transformation. Using of  $\Sigma\Delta$  A/D converter and FIFO memory allows significant simplification of the device. The equations of time scale transformation ratio and sampling step are presented. A method of using of an ideal comb filter in frequency domain to filter measurement signal has been developed. It is shown that such filtering allows significant reduction of noises of measurement signal. Results of the research of developed digital signal processing algorithm are submitted. [C1566]

#### "Slotted Waveguide Antenna Arrays for Airborne Radars"

This paper presents a review of recent activities on the development of X-, Ku-, and Ka-band slotted waveguide antennas. Potential applications of the antennas include various airborne radars systems. We illustrate the implementation of the antennas into a helicopter collision avoidance and weather radar, a surveillance and tracking radar, and an airborne SAR system. The corresponding design solutions, antenna and radar characteristics are discussed as well. [C1567]

#### "A dual reflector antenna for point-to-point system applications"

In this paper design and realization of a dual reflector antenna for receiving Internet signal in the point-to-point system is presented. Three different configurations of dual reflector antenna have been considered to obtain the antenna operating in 5.2-5.8 GHz band and having small dimensions. The results of computer simulations and measurements are shown. The design was based on electromagnetic simulations using QW-V2D package (an axisymmetrical version of FDTD software). [C1568]

#### "Invited paper"

The paper provides an overview of the state of the art the area of reconfigurable antennas as the devices the most quickly developing during in recent years. This article brings together in a review manner a comprehensive summary of high quality research contributions across basic and applied sciences. As a result a broad spectrum of topics is covered reflecting the areas in which Institute of Radioelectronics's expertise is a worldwide recognized. The transdisciplinary nature of most areas aims to stress a sense of purpose in the work developed.

[C1569]

#### "FDTD modelling of plain susceptors for microwave oven applications"

A new approach for numerical modelling of microwave susceptors used as an active element in packaging of microwaveable food products were investigated. The accuracy of the method was validated in the case of estimation of reflected, absorbed, and transmitted power for the susceptor in free space, where the exact solution is known. Further, the amount of power absorbed by the susceptor was calculated for the case of the susceptor attached to the cylinder made of water. The influence of the position and size of the cylinder was considered. The amount of power absorbed by the susceptor and the cylinder were calculated. [C1570]

#### "Composite dielectric-loaded resonators for highly-stable bandstop and bandpass filters"

Use of composite-dielectric resonators, in both direct coupled and capacitively-coupled implementations, enables realization of both bandstop and bandpass filters, with similar construction, high power capability and unique, temperature-stable properties. Improving temperature stability allows for reduction in filter order by elimination of tuning guardband, while lumped element substitution for transmission line lengths provides suppression of periodic distributed element responses and thus wide stopbands for bandpass filters. [C1571]

#### "Improving the accuracy of subgridding scheme in finite differences method based on Legendre polynomials expansion"

In this article the Legendre polynomials have been used to interpolate the field at the boundary of the meshes of different densities. The numerical verification of the proposed technique has been carried out in frequency domain. It has been shown that the accuracy of the presented method is very high and stable-the error monotonically decreases as a function of the refinement factor. [C1572]

#### "On the synthesis of coupled-lossy resonator filters with unloaded quality factor control"

A technique for fast synthesis of coupling matrix low-pass prototypes of generalized Chebyshev bandpass filters with lossy resonators is presented in this paper. The coupling matrix is found by solving a nonlinear least squares problem based on zeros and poles of filter's transfer functions. Additional constraints are introduced that allow one to control the level of unloaded quality factor of resonators. [C1573]

#### "Measurements of the complex permeability of yttrium iron garnet substrates near ferromagnetic resonance"

This paper describes a simple method of measurements the complex permeability of yttrium iron garnet (YIG) substrates. The permeability of YIG is measured near a ferromagnetic resonance. The method is based on the measurements of resonant frequencies and Q-factors of YIG substrate placed into two structures: single post dielectric resonator and split post resonator. The obtained results are presented. [C1574]

#### "Krylov space iterative solvers on graphics processing units"

CUDA architecture was introduced by Nvidia three years ago and since then there have been many promising publications demonstrating a huge potential of Graphics Processing Units (GPUs) in scientific computations. In this paper, we investigate the performance of iterative methods such as cg, minres, gmres, bicg that may be used to solve large sparse real and complex systems of equations arising in computational electromagnetics. [C1575]

#### "Measurements of complex dielectric permittivity and magnetic permeability of carbon-coated Ni capsules"

With advance of multiferroic composites it becomes increasingly interesting to measure both complex dielectric permittivity and magnetic permeability simultaneously and preferably at high frequencies. In this work both of these parameters in case of carbon-coated nickel nanocapsules (Ni@C) embedded into organic matrix were measured in a waveguide set-up in 26-36 GHz frequency range. [C1576]

#### "Analysis of a new approach for tunable and reduced size balanced amplifier using thin-film BST varactors"

A new approach for tunable balanced power amplifier (PA) using barium-strontium-titanate (BST) varactors is presented and analyzed. Tunable PA utilizes the idea of reduced size tunable branch-line couplers, comprising of

BST Varactors. The simulation results indicate the feasibility of balanced amplifier from 1500 to 2500 MHz in terms of gain, reflection coefficients, and stability. The key features of the presented design are the stability of traditional balanced PA, frequency agility and 50% size reduction due to the use of reduced size branch-line couplers. [C1577]

#### "Analysis of rectangular microstrip structures by the method of moments"

Rectangular microstrip structures (RMS) are widely used in various microwave devices. Using the method of moments and principle of partial images, various techniques are created to determine charge distribution in 2D models of microstrip structures (their cross-section). In this paper, a technique for calculating surface charge distribution and total capacitance of complex 3D rectangular microstrip structures is proposed using the mentioned method and principle. To demonstrate feasibility of the proposed technique, three RMS were investigated. Obtained results are compared with the data published by other researches. Total error is typically less than 5%. [C1578]

#### "The method of improving performance of the GPU-accelerated 2D FDTD simulator"

In this paper, several methods of optimizing parallel implementation of 2D FDTD algorithm are presented. Some practical problems occurring in real simulations are taken into consideration. Moreover, the presented methods are supported with appropriate tests and practical examples. [C1579]

#### "A Comparative analysis of two wide-band rational approximations for input impedance of antennas"

Asymptotic waveform evaluation technique and the Neville-type Stoer-Bulirsch algorithm are investigated and compared as the tools for efficient performance evaluation of antennas with emphasis placed on their input impedance over a wide frequency band. Numerical results are given for a helical antenna with a truncated-cone reflector. [C1580]

#### "Design of Wilkinson power divider using stubs"

Design of Wilkinson Power Divider with open stub which has better isolation and minimal return loss is presented. The proposed device distributes the power without unbalancing its amplitude and phase, while providing constant 50 ohm impedance. Comparing with conventional Wilkinson power divider, it takes less area on substrate board. The simulated and measured results are presented and discussed. [C1581]

#### "Electromagnetic wave trapping in the split-ring-cavity system"

The single split-ring magnetic and/or electric dipole moments attaining large values at resonance ensure trapping electromagnetic wave energy in the near-field space of the ring, and in the cavity created by the ring and a reflecting wall. The self-formation of coupled resonators system manifests in sharpening the resonance. Resonance broadening to a forbidden band is proved to arise in the array of split rings ensuring bandstop filter applications. Simulation data on the field amplitude distribution and frequency domain are proved to be in reasonable agreement with experiments. [C1582]

#### "Numerical modeling in wave scattering problem for small particles"

A numerical solution to the problem of wave scattering by many small particles is studied under the assumption  $ka \ll 1$ ,  $d \gg a$ , where  $a$  is the size of the particles and  $d$  is the distance between the neighboring particles. Impedance boundary conditions are assumed on the boundaries of small particles. The results of numerical simulation show good agreement with the theory. They open a way to numerical simulation of the method for creating materials with a desired refraction coefficient. [C1583]

#### "Fresnel formulas for nondiffracting electromagnetic waves"

The generalization of Fresnel equations for non-diffracting waves are presented. The obtained equations determine refraction and reflection coefficients in case of plain interface between different media. Brewster's angle analogue and total reflection condition are obtained, as well. These equations reduces to the classical Fresnel equations in case of plane wave limit. As an application of the obtained equations, electromagnetic field distribution in a plane dielectric wave guide is examined in the new way. The obtained dispersion relations are independent of the nondiffracting wave electromagnetic field distribution. This implies, that an infinite number of electromagnetic field configurations may exist at a fixed frequency in the plain dielectric wave guide. [C1584]

### "Optimal sidelobes reduction and synthesis of circular array antennas using hybrid adaptive genetic algorithms"

In this article, a hybrid optimization method has been proposed consisting of Adaptive Genetic Algorithms (AGAs) and Constrained Nonlinear Programming (NLP) to solve the problems of performance optimization of circular array antenna consist of parallel center feeding short dipoles elements with two complex nonlinear optimization problems. In the first problem, the hybrid optimization algorithm is used to reduce the value of sidelobe level in the circular array radiation pattern by finding the optimal values of the excitation coefficients of each element in the circular array. In the second problem, a synthesis of circular array with different forms of the desired radiation pattern is considered. Several examples are considered here to verify the validity of this method. The results obtained by this method show that it is possible to obtain an array radiation pattern with low sidelobe level of -40dB in the first problem. In the second problem, it is shown that it is possible to obtain a wide flat main lobe of 60beam width, and two nulls on both sides of the main lobe with 10width for each. Comparisons were made between the results of this method and the results obtained by Standard Genetic Algorithm (SGA), and it is clearly shown that this method is more efficient and flexible in solving the problems of performance optimization of circular array antenna. [C1585]

### "Automated method of antenna factor measuring"

The antenna is an essential part of a test system. In some applications, selecting the best antenna may be very important. Unfortunately, selecting the right antenna can be a difficult task, because of variation in the way manufacturers specify and describe them. This article explains the specific method of the antenna factor (AF) as one of the main antenna parameters definition by measurement in an electromagnetic field. Automated method of antenna factor measurement (AMAFM) in anechoic chamber is described. [C1586]

### "Microwave radar for express testing of semiconductor materials"

The microwave radar for express testing of semiconductor materials consisting of pulsed magnet, transmitting and receiving antennas, HF generator, pulsed modulator and digital oscilloscope are described. In semiconductor specimen put in pulsed magnetic field a magnetoplasmic wave is excited and propagated through a specimen signal and reference signal delay is measured to find a value of concentration of free charge carriers in semiconductors. Experimental data of testing of InSb, CdHgTe specimens are presented and an acceptable correspondence of results was achieved. [C1587]

### "Efficiency of the IE-MoM approach in the analysis of dielectric bodies embedded in a cavity"

This paper presents the analysis of dielectric bodies embedded in cavities made of perfect conducting metal using numerical approaches. For a case study of resource requirements a Dielectric Resonator Filter has been designed. Different numerical approaches were presented: FEM, FDTD, FIT, MoM and they were compared due to their computational effectiveness. Two of those method FIT and MoM showed a much higher efficiency than others. Their resource requirements were compared using simulations of a case study device. This paper shows that our Method of Moment with use of Green's function for stratified media has the best performance in solving dielectric bodies embedded in metal cavity. Therefore, there is a need to develop this method. [C1588]

### "Utilization of RFID technology for fixed assets inventory process improvement"

Article describes utilization of radio frequency identification method for improvement of fixed assets inventory. It propose the solution for labor cost reduction in execution of annual company legal activities through usage of mobile RFID reader and dedicated application for handheld device and desktop computer. [C1589]

### "Vortical electromagnetic waves with a stationary power flow"

We show analytically that in source free medium vertical electromagnetic wave can be derived from electromagnetic field, described by electric and magnetic Hertz vectors. To characterize the wave's vorticity we examine moment values of the real Poynting vector versus various directions of Hertz vectors in respect of wave propagation. This enables us to distinguish pure circular polarized transverse waves, possessing constant modulus orbital angular momentum and time and space invariant Poynting vector, from those of vortical, consisting of two time invariant and two vortical time dependent components. Poynting vectors of vortical components depend on time and have opposite directions while the time unvarying components have the same direction towards the wave propagation. The result of interaction of two vortical components is time invariant orbital angular momentum and time independent power flux, which is directed perpendicular to the common power flux of unvarying components. [C1590]

### "Wideband microstrip phase shifters"

The paper presents wideband, microstrip phase shifters. Some types of the phase shifters are described. Experimental results of electrical parameters are obtained. Features of the phase shifters are discussed and showed. [C1591]

### "Planar MS-CPS bypass balun for CPS-fed textile antennas"

This paper presents the design, numerical analysis and measurements of a planar bypass balun that provides 1:4 impedance transformations between the unbalanced microstrip (MS) and balanced coplanar strip line (CPS). This type of balun is suitable for operation with small antennas fed with balanced a (parallel wire) transmission line, i.e. wire, planar dipoles and loop antennas. The balun has been applied to textile CPS-fed loop antennas, designed for operations below 1GHz. The performance of a loop antenna with the balun is described, as well as an idea of incorporating rigid circuits with flexible textile structures. [C1592]

### "Three dimensional magnetic field distributions and dispersion characteristics of rectangular and circular SiC waveguides"

Here we present the 3D vector magnetic field distributions of the main mode and the first higher modes propagating in lossy SiC rod waveguides at different temperatures and the dispersion characteristics of the SiC rectangular and circular rod waveguides. [C1593]

### "The performance of the IFM receiver in a dense signal environment"

The capabilities of multichannel IFM system for working in dense and complex signal environment have been presented in the paper. The present electromagnetic environment in microwave frequency band is filled by the complex simultaneous or overlapped signals. High performances are required from microwave receivers worked in these difficult conditions. The IFM receiver is possible to fulfill these requirements. The analysis and measurement results for simultaneous signals have been presented in the paper. The measurements for varied frequency and signal power of two simultaneous signals using multichannel IFM receiver was done and measurements results have been presented. The instantaneous frequency measurements for complex signals using dual channel IFM receiver have been done. The measurements results for LFM and FSK signals have been presented in the paper. The frequency measurement errors depend on the structure of the frequency discriminators, especially on the delay line length and microwave detectors parameters. [C1594]

### "Localization in wireless sensor networks using switched parasitic antennas"

A switched parasitic monopole antenna for 2.4 GHz ISM applications is design and investigated in this paper. One of the most promising applications for such switched-beam antennas is localization in wireless sensor networks (WSN). It is demonstrated that the use of this antenna improves accuracy of localization algorithms and allows for reduction of the number of reference nodes in localization system. [C1595]

### "Modulation-mode and power-assignment for SVD-assisted downlink multiuser MIMO systems"

Multiuser multiple-input multiple-output (MIMO) downlink (DL) transmission schemes experience both multiuser interference as well as inter-antenna interference. However, instead of treating all the users jointly as in zero-forcing (ZF) multiuser transmission techniques, the investigated singular value decomposition (SVD) assisted DL multiuser MIMO system takes the individual user's channel characteristics into account. The performed joint optimization of the number of activated MIMO layers and the number of bits per symbol along with the appropriate allocation of the transmit power shows that not necessarily all user-specific MIMO layers has to be activated in order to minimize the overall BER under the constraint of a given fixed data throughput. [C1596]

### "Optimisation of resistive sensor for ridge waveguide"

Finite-difference time-domain simulations of electromagnetic field distribution in double ridge or H-type waveguide segment with a semiconductor structure were performed. The structure serves as a resistive sensor for high power microwave pulse measurement within the working frequency range of the waveguide. As a result of the investigation, conditions for the optimal sensor with the "flattest" frequency response were determined. The best calculated sensitivity variation for the sensor was roughly  $\pm 21\%$  for WRD-250 waveguide and  $\pm 6\%$  for WRD-750 waveguide. [C1597]

### "Development strategy for GaN-based high-efficiency hybrid medium-power RF amplifiers through

### **low-cost substrate prototyping"**

Two high-efficiency power amplifiers have been designed, fabricated, and tested using a commercially available GaN HEMT transistor and a low-cost hybrid microstrip PCB. The designed hybrid modules are a "tuned load" Class B amplifier and a Class F amplifier. The simulated performances show a peak efficiency of 72 and 78 % with an output power of 5 and 4.5W respectively. The measured performance, although still satisfactory, exhibits an efficiency of 60 and 55 %, respectively, for the two stages. The paper presents a discussion on the design approach, on the intrinsic/extrinsic load to be presented to the active device, and on the cause of the efficiency drop occurring between the simulated and measurement performances. [C1598]

### **"Computer aided microstrip circulator design"**

A method for taking the advantages of electromagnetic simulation software for the design of microwave ferrite device will be presented in this paper. The design steps will be shown through the design process of a microstrip circulator working at 10 GHz. The key point of the design is using quarter-wave transformer for achieving good quality impedance matching between the 50 Ohm system and the circulator. [C1599]

### **"Design and simulation GaN based class-S PA at 900MHz"**

A Class-S Power Amplifier architecture seems to be an attractive alternative for classical PAs due to offered very high efficiency operation. Switching mode PA principle assumes combined operation based on digital, single-bit Delta-Sigma ( $\Delta\Sigma$ ) modulated signals and RF analog signals, what complicates design and analysis procedures. However the Class-S PA topology is known, there are not any universal design methods which can be unambiguous applied to considered architecture. Presented work defines and describes design method for Class-S PA based on GaN HEMT transistors. Moreover main simulation results for Class-S architecture based on Current Switching Class-D (CSCD) configuration at the carrier frequency of 900 MHz have been performed. [C1600]

### **"Compensated broadband five-section directional coupler for application in butler matrices"**

A broadband five-section symmetrical 3 dB directional coupler has been designed. In order to improve the frequency characteristic of the coupler a recently proposed compensation technique has been used. The developed coupler operates in 2-12 GHz frequency band and can be applied in a broadband 4x4 Butler matrix. [C1601]

### **"L-Band Electron Paramagnetic Resonance (EPR) spectrometer"**

The paper describes the general concept as well as potential applications of the EPR L-Band spectrometer. The latter part of the article presents the detailed construction of the L-Band microwave unit with the Loop-Gap cavity of the spectrometer. The spectrometer is mainly developed for testing irradiated food. [C1602]

### **"A 100W SiC MESFET amplifier for L-band T/R module of APAR"**

In the paper, a 100 W SiC MESFET amplifier design for especially L-band T/R module of APAR is presented. The output power higher than 100 W has been achieved by combining in a balanced configuration two single stages with Cree's 60 W CRF24060 SiC MESFETs. The amplifier design methodology is based on the small-signal model and DC characteristics of SiC MESFET. The model is extracted using the transistor S-parameters at three operating points for On-state, Off-state and normally bias. The measurements and simulations prove usefulness of the proposed method. The amplifier were excited both pulsed and cw signals for the case temperature from 60°C to 140°C. The As result of the case temperature changes the output power drop was lower than 0.5 dB on the level of 150 W. [C1603]

### **"Advanced switch-mode concepts using GaN: The class-S amplifier"**

Efficiency of power amplifiers for the wireless infrastructure is presently a hot topic. Switch-mode type amplifiers and/or more complex concepts, e.g. Doherty or envelope tracking (ET) are being explored intensively, exploiting the potential of GaN technology. This paper contributes recent results on a related approach, the class-S concept, which offers also compatibility with digital baseband processing. Its potential is evaluated based on realizations for the 450 MHz frequency band with GaN MMICs. [C1604]

### **"Path planning based on fluid mechanics for mobile robots using unstructured terrain models"**

Mobile robots using a 360° field of view LIDAR ranging sensor can generate enormous 3D point clouds. To reduce the quantity of data in memory a compression can lead to unstructured environment models such as

irregular meshes. This kind of structure can contain deformed cells and the path planning can be cumbersome. This paper presents a path planning method based on fluid mechanics able to deal with unstructured terrain models. The algorithm uses the finite element method to compute a velocity potential function free from local minima. Then, several streamlines are computed as a road map and the optimal path is selected among the candidate paths. The approach is implemented on the Canadian Space Agency (CSA) Mars Robotics Testbed (MRT) rover and tested at the CSA Mars Emulation Terrain (MET). To confirm the feasibility of the method, the path planner has been tested on 284 LIDAR scans collected in a realistic outdoor challenging terrain. [C1605]

### "Extracting general-purpose features from LIDAR data"

The detection of features from Light Detection and Ranging (LIDAR) data is a fundamental component of feature-based mapping and SLAM systems. Existing detectors tend to exploit characteristics of specific environments: corners and lines from indoor (rectilinear) environments, and trees from outdoor environments. While these detectors work well in their intended environments, their performance in different environments can be very poor. We describe a general purpose feature detector for LIDAR data that is applicable to virtually any environment. Our methods adapt classic feature detection methods from the image processing literature, specifically the multi-scale Kanade-Tomasi corner detector. Our resulting method is capable of identifying stable features at a variety of spatial scales and produces uncertainty estimates for use in a state estimation algorithm. We present results on standard datasets, including Victoria Park and Intel Research Center (both 2D), and the MIT DARPA Urban Challenge dataset (3D). [C1606]

### "Robust vehicle localization in urban environments using probabilistic maps"

Autonomous vehicle navigation in dynamic urban environments requires localization accuracy exceeding that available from GPS-based inertial guidance systems. We have shown previously that GPS, IMU, and LIDAR data can be used to generate a high-resolution infrared remittance ground map that can be subsequently used for localization. We now propose an extension to this approach that yields substantial improvements over previous work in vehicle localization, including higher precision, the ability to learn and improve maps over time, and increased robustness to environment changes and dynamic obstacles. Specifically, we model the environment, instead of as a spatial grid of fixed infrared remittance values, as a probabilistic grid whereby every cell is represented as its own gaussian distribution over remittance values. Subsequently, Bayesian inference is able to preferentially weight parts of the map most likely to be stationary and of consistent angular reflectivity, thereby reducing uncertainty and catastrophic errors. Furthermore, by using offline SLAM to align multiple passes of the same environment, possibly separated in time by days or even months, it is possible to build an increasingly robust understanding of the world that can be then exploited for localization. We validate the effectiveness of our approach by using these algorithms to localize our vehicle against probabilistic maps in various dynamic environments, achieving RMS accuracy in the 10cm-range and thus outperforming previous work. Importantly, this approach has enabled us to autonomously drive our vehicle for hundreds of miles in dense traffic on narrow urban roads which were formerly unnavigable with previous localization methods. [C1607]

### "Boundary detection based on supervised learning"

Detecting the boundaries of objects is a key step in separating foreground objects from the background, which is useful for robotics and computer vision applications, such as object detection, recognition, and tracking. We propose a new method for detecting object boundaries using planar laser scanners (LIDARs) and, optionally, co-registered imagery. We formulate boundary detection as a classification problem, in which we estimate whether a boundary exists in the gap between two consecutive range measurements. Features derived from the LIDAR and imagery are used to train a support vector machine (SVM) classifier to label pairs of range measurements as boundary or non-boundary. We compare this approach to an existing boundary detection algorithm that uses dynamically adjusted thresholds. Experiments show that the new method performs better even when only LIDAR features are used, and additional improvement occurs when image-based features are included, too. The new algorithm performs better on difficult boundary cases, such as obliquely viewed objects. [C1608]

### "Human detection and tracking via Ultra-Wideband (UWB) radar"

This paper presents an algorithm for human presence detection and tracking using an Ultra-Wideband (UWB) impulse-based mono-static radar. UWB radar can complement other human tracking technologies, as it works well in poor visibility conditions. UWB electromagnetic wave scattering from moving humans forms a complex returned signal structure which can be approximated to a specular multi-path scattering model (SMPM). The key technical challenge is to simultaneously track multiple humans (and non-humans) using the complex scattered waveform observations. We develop a multiple-hypothesis tracking (MHT) framework that solves the complicated

data association and tracking problem for an SMPM of moving objects/targets. Human presence detection utilizes SMPM signal features, which are tested in a classical likelihood ratio (LR) detector framework. The process of human detection and tracking is a combination of the MHT method and the LR human detector. We present experimental results in which a mono-static UWB radar tracks human and non-human targets, and detects human presence by discerning human from moving non-human objects. [C1609]

#### "On the global optimum of planar, range-based robot-to-robot relative pose estimation"

In this paper, we address the problem of determining the relative position and orientation (pose) of two robots navigating in 2D, based on known egomotion and noisy robot-to-robot distance measurements. We formulate this as a weighted Least Squares (WLS) estimation problem, and determine the exact global optimum by directly solving the multivariate polynomial system resulting from the first-order optimality conditions. Given the poor scalability of the original WLS problem, we propose an alternative formulation of the WLS problem in terms of squared distance measurements (squared distances WLS or SD-WLS). Using a hybrid algebraic-numeric technique, we are able to solve the corresponding first-order optimality conditions of the SD-WLS in 125 ms in Matlab. Both methods solve the minimal (3 distance measurements) as well as the overdetermined problem (more than 3 measurements) in a unified fashion. Simulation and experimental results show that the SD-WLS achieves performance virtually indistinguishable from the maximum likelihood estimator, and significantly outperforms current algebraic methods. [C1610]

#### "Global rover localization by matching lidar and orbital 3D maps"

Current rover localization techniques such as visual odometry have proven to be very effective on short to medium-length traverses (e.g., up to a few kilometres). This paper deals with the problem of long-range rover localization (e.g., 10km and up). An autonomous method to globally localize a rover is proposed by matching features detected from a 3D orbital elevation map and rover-based 3D lidar scans. The accuracy and efficiency of the algorithm is enhanced with visual odometry, and inclinometer/sun-sensor orientation measurements. The methodology was tested with real data, including 37 lidar scans of terrain from a Mars-Moon analogue site on Devon Island, Nunavut. When a scan contained a sufficient number of good topographic features, localization produced position errors of no more than 100m, and as low as a few metres in many cases. On a 10km traverse, the developed algorithm's localization estimates were shown to significantly outperform visual odometry estimates. It is believed that this architecture could be used to accurately and autonomously localize a rover on long-range traverses. [C1611]

#### "Ground plane identification using LIDAR in forested environments"

To operate autonomously in forested environments, unmanned ground vehicles (UGVs) must be able to identify the load-bearing surface of the terrain (i.e. the ground). This paper presents a novel two-stage approach for identifying ground points from 3-D point clouds sensed using LIDAR. The first stage, a local height-based filter, discards most of the non-ground points. The second stage, based on a support vector machine (SVM) classifier, operates on a set of geometrically defined features to identify which of the remaining points belong to the ground. Experimental results from two forested environments demonstrate the effectiveness of this approach. [C1612]

#### "Estimation of DOD and 2D-DOA and polarizations for bistatic MIMO radar"

Multi-parameter estimation is investigated for target discrimination and localization in multiple-input multiple-output (MIMO) radar system. With an M-element uniform linear array in the transmitter and a square array consisting of  $N_2$  pair of crossed-dipoles in the receiver, a novel method is proposed for joint estimation of direction-of-departures (DODs), two-dimensional direction-of-arrivals (2D-DOAs) and polarizations of multiple targets for bistatic MIMO radars. Its signal model is described, and the algorithm is given by exploiting rotational invariance property of ESPRIT and polarization sensitive array processing technology in transmit and receive arrays. To discriminate and localize targets in a 3-D plane, more information than those of traditional bistatic MIMO radar algorithms is provided using the proposed method. Also, by making use of polarization diversity, its resolution capability is greatly improved when two targets are closely spaced. [C1613]

#### "DOA estimation for wideband sources using cross correlation transformation"

In this paper, we consider the problem of estimating directions-of-arrival (DOAs) of wideband source signals. A new class of focusing matrices is proposed for use in the coherent signal subspace method. The new method does not require any preprocessing for initial values through using the cross correlation transformation (CCT). Numerical results show that when the DOAs fall within more than one group of one beamwidth each and there are closely spaced sources, the CCT method outperforms the methods requiring preprocessing in terms of root-

mean-square error (RMSE). [C1614]

### "All-weather perception for man-portable robots using ultra-wideband radar"

Autonomous man-portable robots have the potential to provide a wide range of new capabilities for both military and civilian applications. Previous research in autonomy for small robots has focused on vision, LIDAR, and sonar sensors. While vision and LIDAR work well in clear weather, they are seriously impaired by rain, snow, fog, and smoke. Sonar can penetrate adverse weather, but has limited range outdoors, and suffers from specular reflections indoors. For the Daredevil Project, we have investigated the use of ultra-wideband (UWB) radar to provide obstacle detection capabilities for man-portable robots. Our research shows that UWB radar can effectively penetrate adverse weather, including dense fog, and detect obstacles that would be undetectable by vision or LIDAR under the same conditions. We have developed filtering algorithms that process the raw radar returns to eliminate reflections from ground clutter and make obstacles easier to detect. We have tested this system on an iRobot PackBot equipped with both UWB radar and LIDAR, and we have demonstrated how UWB radar can be used for obstacle detection in obscured environments. [C1615]

### "On-line calibration of multiple LIDARs on a mobile vehicle platform"

In this paper, we examine the problem of extrinsic calibration of multiple LIDARs on a mobile vehicle platform. To achieve fully automated and on-line calibration, the original non-linear calibration model is reformulated as a second-order cone program (SOCP). This provides an advantage over more standard linearized approaches in that a priori information such as a default LIDAR calibration, calibration tolerances, etc., can be readily modeled. Furthermore, in contrast to general non-linear methods, the SOCP relaxation is convex, returns a global minimum, and can be solved very quickly using modern interior point methods (IPM). This enables the calibration to be estimated on-line for multiple LIDARs simultaneously. Experimental results are provided where the approach is used to successfully calibrate a pair of Sick LMS291-S14 LIDARs mounted on a mobile vehicle platform. These showed the SOCP formulation yielded a more accurate reconstruction and was 1-2 orders of magnitude faster than the traditional non-linear least-squares approach. [C1616]

### "Towards marine bloom trajectory prediction for AUV mission planning"

This paper presents an oceanographic toolchain that can be used to generate multi-vehicle robotic surveys for large-scale dynamic features in the coastal ocean. Our science application targets Harmful Algal Blooms (HABs) which have significant societal impact to coastal communities yet are poorly understood ecologically. Bloom patches can be large spatially (in kms) and unpredictable in their extent. To understand their ecology, we need to be able to bring back water samples from the 'right' places and times for lab analysis. In doing so, we target hotspots representative of intense biogeochemical activity for such sampling. Our approach uses remote sensing data to detect such hotspots using ocean color as a proxy, and advectively projects these patches spatio-temporally using surface current data from HF Radar stations. Experiments with satellite and Radar data sets are promising for large, coherent blooms. We show how these predictions can be used to select an appropriate sampling trajectory for an AUV. [C1617]

### "A hybrid SLAM representation for dynamic marine environments"

We present a hybrid SLAM system for marine environments that combines cubic splines to represent the trajectories of dynamic objects, point features to represent stationary objects and an occupancy grid to represent land masses. This hybrid representation enables SLAM to be applied in environments with moving objects, where solutions using point features alone are computationally prohibitive or where dense objects e.g. landmasses can not be represented correctly using point features. Estimation is achieved using a sliding window framework with reversible data-association and reversible model-selection. Our main contributions are: (i) a hybrid representation of the environment; (ii) occupancy grid fusion is continually refined for the duration of the sliding window; (iii) the trajectories of dynamic objects are represented using cubic splines and (iv) radar scans are re-rendered at a sub-scan resolution to compensate for the egomotion during the scan acquisition period. We show that the continual refinement of the occupancy grid greatly improves the quality of the resultant map, leading to a better estimate of the egomotion and therefore better estimates of the trajectories of dynamic objects. We also demonstrate that the use of cubic splines to represent trajectories has two major advantages: (i) the state space is compressed i.e. many vehicle poses can be represented using a single spline section and (ii) the trajectory becomes continuous and so fusing information from asynchronous sensors running at multiple frequencies becomes trivial. The efficacy of our system is demonstrated using real marine radar data, showing that it can successfully estimate the positions/velocities of objects and landmasses observed during a typical voyage on a small boat. [C1618]

### "Planar landmark detection using a specific arrangement of LIDAR scanners"

All terrestrial applications which depend on a GPS receiver for a precise position fix suffer in the urban environments. A Terrestrial Mobile Mapping System is one such application. We have been working on a Terrestrial LIDAR (Light Detection and Ranging) scanner (or Laser scanner) based Mobile Mapping System (MMS) in our laboratory. To aid the localization of our moving mapping platform (a land vehicle), we opted to use the technology similar to SLAM (Simultaneous Localization and Mapping). Our primary focus is on the urban canyons where the GPS signal perturbations are highly likely to occur. The main characteristic of an urban canyon is the planar sections of the man made buildings. In this paper, we present a specific arrangement of the LIDAR scanners tailored to extract the planar landmarks. This is the first important step in improving the localization functionality. Here we discuss about our new LIDAR system configuration and the design justifications along with the obtained results of planar landmark extraction. [C1619]

### "An obstacle-edging reflex for an autonomous lawnmower"

We developed a controller that allows our prototype lawnmower, CWRU Cutter, 1st place winner of the 2009 ION Autonomous Lawnmower Competition, to follow pre-defined paths and reflexively edge around obstacles before returning to the path. CWRU Cutter is equipped with localization sensors (GPS) and obstacle detecting sensors (LIDAR and camera). [C1620]

### "Lightweight efficient and feasible IP multimedia subsystem authentication"

In IP Multimedia Subsystem (IMS) of UMTS, IMS information is delivered through the general packet radio service (GPRS) transport network, before a user equipment (UE) can access the IMS service, it must perform both packet-switch domain and IMS authentication. It is inefficient that almost all involved steps in IMS authentication are duplicated. Hence, some one-pass IMS authentications were proposed to increase the efficiency of the IMS authentication. Unfortunately, these protocols have some problems which make them unfeasible. Therefore, we proposed a lightweight one-pass IMS authentication protocol to reduce signaling traffic. Through analysis, we found that it has minimal impact on the network functionality and will not influence the succeeding IMS re-authentication, which makes it more feasible. [C1621]

### "Relating local vision measurements to global navigation satellite systems using waypoint based maps"

Roughly 50% of all the traffic fatalities are due to lane departures [2]. There is great interest in advanced driver assistance systems that prevent unintended lane departure. Currently there are passive lane detection systems that warn the driver of unintended lane departure known as lane departure warning (LDW) systems which rely on cameras to track lane markings. LDW systems based solely on camera measurements are prone to failures due to poor environmental lighting or poor lane marking coverage. Combining the measurements from multiple sensors will create a much more robust LDW system that is not prone to failures. [C1622]

### "Lidar attitude estimation for vehicle safety systems"

This paper presents two techniques for determining vehicle pitch and roll with a 3-D lidar which will first auto-calibrate itself to the vehicle's axes. The first method presented is based on Euler angles and the second on Gaussian Processes. A 3-antenna Septentrio GPS receiver is used to assess system performance. [C1623]

### "Combine draft detector with GPS receiver to monitor barge's loadage"

In order to maintain channels and harbors at safe depths, periodic dredging is required. With increasing environmental awareness and tightening legislative control, licenses and approvals are required to dispose of dredged material. For the sake of supervision of loaded barges, this article introduces a Barge's Loadage Monitoring System (BLMS). The applications utilized in Xiamen waterway authority can display various information needed for supervising barges on electronic chart platform visually and comprehensively. The main feature of its innovation is combining draft detector with GPS and on-board transponder technologies. [C1624]

### "A spectral space-variant approach for structure indexing in Spotlight TerraSAR-X data"

Modern space missions equipped with SAR instruments provide high spatial resolution data. In such data features of urban objects, man-made structures, as well as natural targets can be identified. We propose a descriptive model based on the frequency spectra of the complex signal, that integrates the radiometric, geometric, and texture features, for scene and target indexing, to cope with the problem of large database queries and information retrieval. Considering the properties of the Spotlight imaging mode in particular, a phase

correction algorithm is applied to the data, prior to feature extraction. The assignation of a particular scene to a certain class is done using a Bayesian Support Vector Machine classifier. The method allowed for the recognition of more than thirty targets and structures in the scenes. [C1625]

#### "High-quality HRR ATR system using an improved neural recognition chain"

One of the most recent technique to design an efficient ATR system is to use high-resolution radar (HRR) imagery as input information flow. To increase the quality of such system, an interesting approach is to use powerful artificial neural networks inside of its recognition chain. Consequently, an improved neural recognition function based on modified feature extraction and selection methods and respectively, on genetic optimized RBF network architecture is described. Finally, to confirm the broached theoretical aspects, a real HRR image database was also used. [C1626]

#### "A communication waveform for radar"

This paper discusses some opportunities created by using Orthogonal Frequency Division Multiplexing signals for radar and communication at the same time. Two examples of opportunities in radar are proposed, i.e. solving the unambiguous radial speed in a single transmission and improving the signal-to-background contrast. The performance of the data link is analyzed and shown to be useful. [C1627]

#### "A potential field approach to finding minimum-exposure paths in wireless sensor networks"

A novel artificial-potential approach is presented for planning the minimum-exposure paths of multiple vehicles in a dynamic environment containing multiple mobile sensors, and multiple fixed obstacles. This approach presents several advantages over existing techniques, such as the ability of computing multiple minimum-exposure paths online, while avoiding mutual collisions, as well as collisions with obstacles sensed during the motion. Other important advantages include the ability of utilizing heterogenous sensor models, and of meeting multiple objectives, such as minimizing power required, and reaching a set of goal configurations. The approach is demonstrated through numerical simulations involving autonomous underwater vehicles (AUVs) deployed in a region of interest near the New Jersey coast, with ocean currents simulated using real coastal ocean dynamics applications radar (CODAR) data. [C1628]

#### "Self-Organizing Networks: State-of-the-art, challenges and perspectives"

In this paper, a general overview of Self-Organizing Networks (SON), and the rationale and state-of-the-art of wireless SON are first presented. The technical and business requirements are then briefly treated, and the research challenges within the field of SON are highlighted. Thereafter, the relation between SON and Cognitive Networks (CN) is covered. At last, the application of Algorithmic Information Theory (AIT) as a possible theoretical tool to support SON in addressing the growing complexity of networks is discussed. [C1629]

#### "ICA-based information extraction method for PolSAR images"

Identifying and characterizing objects in PolSAR images rely on proper backscattered signal models, correct segmentation algorithms and on exploiting the connections between the physical structure of the considered objects and their radar echos. The paper presents an ICA-based approach for characterizing physical properties of the objects on the Earth surface. Segmentation of PolSAR image is based on stochastic models. Each segment is assimilated to an object or surface type and pixels of the segment are treated like realizations of the underlying target scattering mechanism. This scattering mechanism is characterized through ICA-based approach, thus providing information about the corresponding target. The TSVM decomposition is used to analyze the mixing matrix issued from ICA and to link its values to physical properties of the target. [C1630]

#### "The generated curve in symmetrical plane for double curved antenna reflector with Cosec2 pattern beam, illuminated by a Cos4 pattern beam for primary radiator"

The paper presents a method to generate the symmetrical plan curve for a Cosec2 radiation pattern double curved antenna reflector, for the case when the primary radiation source has a Cos4 radiation pattern. There is also shown the diffraction calculus for the antenna having the reflector generated by using the calculated vertical profile. [C1631]

#### "A novel spectrum reconstruction algorithm based on FrFT for multiple azimuth beam SAR"

In this paper, we consider the problems of reconstructing the spectrum based on Fractional Fourier Transform (FrFT) from periodic non-uniformly sampled signal in multiple azimuth beams SAR system. First, based on the

theory of the paired echoes, the influence of periodic non-uniform sampling for SAR imaging has been derived. Second, signal model of non-uniformly sampling in azimuth direction has been established. Finally, detailed analysis of spectrum reconstruction algorithm in the fractional Fourier domain has been performed. In addition, the simulations are carried out to verify the correctness of the results. [C1632]

### "Meshless RPIM modeling of open-structures using PMLs"

Meshless methods are emerging as a new class of numerical techniques for modeling complex electromagnetic problems. To apply them to open structures, effective absorbing boundaries need to be developed. In this paper, the perfectly matched layer (PML) absorbing boundary condition is implemented into the meshless radial point interpolation method (RPIM) for accurate meshfree modeling of electromagnetic radiation problems in time-domain. Two benchmark radiating structures, a parallel waveguide and a conical unipole antenna, are presented to validate the effectiveness of the implementation. Comparisons are made between the numerically computed results and the measured results from previous reports and good agreements are found. In contrast to conventional FDTD technique, the RPIM modeling with the PML condition requires much less computational efforts for antenna radiation problems, thanks to its capability of conformal modeling and multi-scale solutions. [C1633]

### "High-phase-resolution 77-GHz-band radar module for near-field millimeter-wave imaging"

Near-field millimeter-wave (MMW) imaging is a unique approach for inspecting cracks in covered concrete surfaces to assess the deterioration of concrete structures. We have developed a 77-GHz-band radar module with in-phase and quadrature detection which is superior to measuring both of the amplitude and phase of MMW in a near-field range. A monostatic radar system is hybrid integrated into the module with a constant-width antipodal tapered slot antenna with an antenna gain of 14.5 dBi which is connected to a microstrip-line coupler with an isolation of higher than 26 dB using a leakage cancellation technique. In distance measurements in free space, the phase resolution is less than 8 degrees corresponding to the distance resolution of smaller than 0.01 mm, which is high enough to distinguish MMW signals scattered by the cracks from multiple reflection of the concrete surfaces and inside aggregates. [C1634]

### "Earth observation instruments with e-scan antennas state-of-the-art and outlook"

Spaceborne radars with electronically scanned antennas are in use on European satellites since the launch of Envisat in March 2002. Despite the higher complexity and consequently cost, electronically scanned antennas are more and more attractive for spaceborne radar. The return materialises either in significantly better system performance or in newly gained system feasibility. The paper will discuss firstly state-of-the-art phased array technology as used for the European Sentinel 1 C-band SAR and explore secondly the capabilities of full digital beam forming implementation for the next generation of SAR systems. Thirdly phased arrays as a feasibility prerequisite in quasi bi-static radar for future ocean altimetry, exploiting GNSS signals will be discussed. Lastly reflector based e-scan antennas will be discussed which form a good compromise between complexity and flexibility as needed for SAR systems requiring high gain antennas. A Ka-band SAR application will be presented. [C1635]

### "Commercial manufacturing practices applied to phased array radars"

Transmit/Receive Modules for Phased Array Radar are often identified as a key cost driver for the system. The cost structure of the module is driven by both the performance specifications and the choices made in design and manufacturing of the module. Seeking a path to dramatically lower the cost of T/R modules for phased array systems, commercial processes and practices have been adopted for the MMIC design, MMIC packaging and module construction. These new manufacturing approaches offer a path to cost reduction while maintaining a high level of performance. [C1636]

### "Extremely Low Frequency Electric Field Induced Mutations in Escherichia Coli K12 Strains"

Escherichia coli K12 W3110 was treated by extremely low frequency electric field (ELF EFs) 10min with the field intensity of 100, 200, 300, 400kV/m. The mutant frequency reached  $31.2 \times 10^{-6}$  at field intensity of 100kV/m, which was about 26-fold over the background ( $1.2 \times 10^{-6}$ ) and 12-fold over the controls ( $2.5 \times 10^{-6}$ ). This result indicated that the ELF EFs could act as a mutagen. The results also show that base pair (bp) substitutions were the main type of ELF EFs induced mutations. Although all types of base pair substitutions were observed, 30% of the bp substitutions were G:C → A:T transitions, 70% of the bp substitutions were A:T → T:A, G:C → T:A, A:T → C:G, G:C → C:G transversions. When the spontaneous and the ELF EFs exposure group were compared, base-pair substitutions, deletions and additions of the ELF EFs exposure group were significantly increased, and the deletion or the addition of a 5'-TGGC-3' sequence at hot spot was decreased from 82 to 26%. But the

remarkable increase in absolute Mutation Frequency (MF) of the deletion or the addition of a 5'-TGGC-3' sequence at hot spot in the ELF EFs exposure group suggested that ELF EFs did induce the mutations of this type. The spectra of our ELF EFs exposure group with increasing G:C to A:T transitions and A:T to T:A transversions indicate that ELF EFs exposure may induce SOS response. [C1637]

#### "Advanced architecture for a low cost multifunction phased array radar"

MIT Lincoln Laboratory and M/A-COM are jointly conducting a technology demonstration of affordable Multifunction Phased Array Radar (MPAR) technology for Next Generation air traffic control and national weather surveillance services. Aggressive cost and performance goals have been established for the system. The array architecture and its realization using custom Transmit and Receive Integrated Circuits and a panel-based Line Replaceable Unit (LRU) will be presented. A program plan for risk reduction and system demonstration will be outlined. [C1638]

#### "Waveguide transition to feed a fully PCB integrated dielectric rod antenna"

A microstrip line-to-circular waveguide transition is described which operates at a nominal design frequency of 77 GHz. In order to improve the transmission characteristics, an additional periodically structured shield is used. The transition is capable of exciting a dielectric rod antenna, thus enabling the realization of radar modules on a PCB substrate with a dielectric rod antenna interface. [C1639]

#### "Fast subspace decomposition null extension for two-dimensional array antenna"

A multiple null algorithm that can adjust the number, width and depth of multiple nulls in accordance with the environment requirements is proposed for the improvement of the interference cancellation capability of two-dimensional array antennas. The Fast Subspace Decomposition (FSD) and cyclic-Jacobi algorithms are employed to robustly simplify the computation of inverse interference covariance matrix and to determine the optimal weighting matrix of the multiple null digital beam former (DBF). Finally, the numerical simulations of the multiple null DBF are used to demonstrate its anti-jamming capability for the two-dimensional array antennas. The number of multipliers for computing the inverse of interference covariance matrix between FSD algorithm and Eigen value decomposition (EVD) algorithm is also compared. [C1640]

#### "Miniature radio frequency ion trap mass spectrometry"

RF ion traps are useful in chemical analysis and have added benefits when scaled to smaller dimensions. For a miniature ion trap it is ideal to be able to predict the performance of the ion trap prior to fabrication in order to save time and optimize parameters. We have developed both the simulation and fabrication of scaled ion traps. The simulation tool allows us to model miniature ion traps in order to predict how the frequency and amplitude of the RF voltage could be scaled in order to optimize the performance of the ion trap. We demonstrate the performance of a scaled ion trap array fabricated through the integration of stereolithography on circuit board and compare its performance with our ion trajectory simulator. [C1641]

#### "Piggyback modulation for UHF RFID sensors"

We introduce the technique of "piggybacking" sensor data onto existing commercial passive UHF RFID tags. Sensor data fed into a PIN diode modulator is coupled onto the tag and transmitted along with the tag ID via backscatter. The radar cross section (RCS) of the tag antenna is a function of the input impedance of the tag ASIC, coupling S-parameters, and the input impedance of the PIN diode modulator. Both analog and digital sensor signals coexisting with identification data are presented. [C1642]

#### "Novel image reconstruction algorithm for a UWB cylindrical Microwave Imaging System"

A theoretical and experimental study of a novel image reconstruction algorithm for an Ultra Wideband (UWB) Microwave Imaging System aiming at detecting and locating small targets in a homogenous circular cylindrical dielectric body is presented. The system uses a double circular scan in which the second scan is achieved after rotating by a small angle the antenna sub-system or the imaged body. The obtained two sets of data serve the purpose of subtracting the background that masks the target. Assuming that the target is asymmetric with respect to the axis of rotation, the difference data includes the original target and its negative "ghost". In order to eliminate the "ghost" only the positive valued difference data is extracted. This data is scaled and mapped to show the original target location. The validity of the proposed image reconstruction algorithm is demonstrated in an example of a cylindrical plastic container filled with a vegetable oil and small cylindrical targets. [C1643]

### "Multi-PC FDTD: Solving large scale EM problems"

After giving historical data on FDTD speed and problem sizes, the state of the art approach to fast and efficient FDTD simulations is explained for large scale structures. Future challenges include the simultaneous simulation of the RF device or antenna and its surrounding environment, increasing the modeling effort by at least an order of magnitude. An intelligent hierarchical concept exploiting the different size and speed levels of data storage (CPU-cache, RAM, hard-disc and Multi-Machine computing) is presented and analyzed to face the challenges.

[C1644]

### "A forest fire monitoring system based on GPRS and ZigBee wireless sensor network"

The significance of forest fire monitoring was determined by the importance of forest resource and the destructive of forest fire. In the paper, according to the limitation of traditional forest fire monitoring schemes, a new wireless network implementation scheme oriented to forest fire monitoring was presented based on GPRS communication technology and ZigBee technology. The related hardware schemes and software program flows were given. The forest environmental information was collected by ZigBee network and transmitted to FTP server with public network IP on the internet through GPRS network by GPRS module which was controlled by coordinator node. The monitoring center got the data, which was provided for relative experts and decision maker, from FTP server to implement the achievement of remote data from monitoring region. Through the analysis of historical data and real-time data, correct judges and decisions were made. It had strategic significance to improve the level of modernization of forest fire monitoring. [C1645]

### "A path planning achievement of car following in motion control via LiDAR sensing"

This paper presents a new car following system to track a preceding car and maintain a desired safe distance based on a laser imaging, detection, and ranging (LiDAR) sensor. The proposed system has the ability of lane change, including longitudinal and lateral control. To accomplish the car following sensing task, environment information provided by in-vehicle Lidar and monocular vision is used. A camera is an auxiliary device to map Lidar data into the output image and verify the detection ability of LiDAR. The LiDAR and camera sensors are installed on a demonstrated vehicle, and the LiDAR sensor which has one-dimensional scanning ability can measure the relative distance of the vehicle from a preceding vehicle by scanning the horizontal plane with laser beams. The relative position is processed and estimated by random sample consensus (RANSAC) method and geometry relation, and then the heading and speed of vehicle are automatically operated by an embedded processor. The speed variation tracking is implemented by fuzzy-PI algorithm, and the pure pursuit method is applied as the steering control strategy to keep up with the trajectory in lateral control. Environmental clutter becomes the main challenge in data processing when LiDAR tries to track the desired vehicle. Besides, a comfortable requirement of vehicle control is also considered and complied with the rule of ISO 2631. Thus, the proposed system integrates engine vacuum connected to throttle and active steering system with embedded ahead control algorithms into a powerful car following system in practice, which has been verified in experiments using two vehicles. The mobile hardware are built with three embedded systems using X86 processor in Linux system, and furthermore the sensing data collection is accomplished by Ethernet interface. The proposed system is carried out with theoretical application and hardware integration, and the result shows car following approach applicability. [C1646]

### "A method for determining the number of signals based on modified K-means clustering"

Determining the number of signals impinging on an array of sensors is one of the hot and important problems in array processing field. Research on estimation method which is available in colored noise field has important theoretical and practical meaning. A new method is proposed based on K-means clustering algorithm, we construct a distinguishing criteria in reason according to the difference between the signal and noise eigenvalues, and then the signal and noise eigenvalues are classified into two kinds using K-means clustering method. The method is valid in colored noise field. Computer simulation results and the available measured data confirmation prove the effective performance of the method. [C1647]

### "Resolutions of some overlap signals based on MUSIC algorithm"

In order to reduce resolution angle in direction finding system, a method based on MUSIC algorithm is proposed. According to the receiving characteristic of pulse signals in actual direction finding system, the method is proposed on the condition of some overlap signals. Because of the some overlap characteristic of signals, we can obtain a new covariance matrix by means of subtracting between two covariance matrixes which can be got from received data easily. One of the two covariance matrixes is got from the data of only one signal and the other one is from the data of two overlapped signals. It is known that we can estimate the direction of arrival from the covariance matrix of only one signal using MUSIC algorithm. Likewise, we can estimate another

direction of arrival from the new covariance matrix which is obtained by the new method. Thereupon, we get the directions of arrival of two signals. Both simulation and the test based on actual direction finding system proved that the proposed method can get smaller resolution angle with well performance. [C1648]

#### "High-dimensional Matched Subspace Detection when data are missing"

We consider the problem of deciding whether a highly incomplete signal lies within a given subspace. This problem, Matched Subspace Detection, is a classical, well-studied problem when the signal is completely observed. High-dimensional testing problems in which it may be prohibitive or impossible to obtain a complete observation motivate this work. The signal is represented as a vector in  $\mathbb{R}^n$ , but we only observe  $m$  of its elements. We show that reliable detection is possible, under mild incoherence conditions, as long as  $m$  is slightly greater than the dimension of the subspace in question. [C1649]

#### "A research on the robust digital watermark of color radar images"

Color images play a more and more important role in actual life, and the wavelet transformation technique is effective in image analyzing and processing. Thus the color-image watermark algorithm based on discrete wavelet transformation (DWT) begins to draw an increasing attention. This paper puts forward a robust watermarking algorithm based on wavelet transformation, which takes the masking of Human Visual System (HVS) in color images into full consideration, and color images are transferred from RGB space to YCbCr space. By means of the fine independence of YCbCr space, the contents and information of host images in every independent color channel can be fully excavated and then embedded in color images after being Arnold scrambled. The experimental results show that watermark embedded by this algorithm is of better robustness and invisibility. [C1650]

#### "New detection algorithm for weak target signal embedded in direct path interference using Signal Phase Matching Principle"

A detection method for weak signals embedded in direct-path interference is discussed. This method is based on FM radio signals as the illuminator of passive radar. On the basis of Signal Phase Matching Principle, a new algorithm for suppressing the direct-path interference is proposed in wave-beam domain. To improve the declining performances of the algorithm when the amplitude fluctuates, a compensatory factor is presented. The simulation results show the validity of the algorithm and the compensatory method. [C1651]

#### "Localization performance enhancement using IMM fusion in cricket sensor network"

In this paper, we propose an approach for estimating a location of moving-target over a sensor field via distributed IMM estimator with multiple pseudo measurements using trilateration positioning algorithm. Pseudo measurement which indirectly measures the position of target is defined by results of trilateration positioning coordinates. As a single node only can measure the distance to the target in Cricket sensor network, the nodes need to form groups of three to be able to perform trilateration. Also, since trilateration method ignores distance sensing error, adequate error covariance information is estimated in pseudo measurement model using self tuning method. Each distinct group can make local pseudo measurements and these data are fused with local IMM estimates. With these algorithms, localization performance enhancement of moving target is achieved.

[C1652]

#### "Robust waveform design for MIMO radars"

The problem of robust waveform design for multiple-input, multiple-output radars equipped with widely-spaced antennas is addressed here. Robust design is needed as a number of parameters are unknown, e.g., the target scattering covariance matrix and, possibly, the clutter covariance matrix. A min-max approach is proposed, so that the code matrix is designed to minimize the worst-case cost (or equivalently maximize the corresponding figure of merit) under all possible target (or target and clutter) covariance matrices. Surprisingly, the same min-max solution applies to many commonly adopted performance measures, such as the average signal-to-clutter-plus-noise ratio, the mutual information between the received signal echoes and the unknown target response, and the approximation of the detection probability in the high- and low-signal regimes. [C1653]

#### "High isolation lange-ferrite circulators with NF suppression for simultaneous transmit and receive"

This paper presents a new type of circulator that consists of three Lange couplers and two ferrite circulators for broadband, high isolation, transmit noise suppression and simultaneous transmit and receive (STAR). The operation principal of the circulator is based on quadrature phase cancellation and combination techniques. Preliminary results show that the isolation between the transmit and receive port is  $>24$  dB in frequency range of

5-12 GHz without optimization and 60 dB isolation with 800 MHz bandwidth with optimization. The NF data at the receive port show significant suppression of transmit noise for Gain-NF product that exceeds 21 dB. [C1654]

### "Research of Portable Community-Oriented Health Monitoring"

A new kind of wrist-worn health monitoring terminal is developed to realize multi-parameter measurement, wearing facilitates and reliable data transmission. The physiological parameters includes body temperature, pulse rate, breath rate and waveform, blood pressure, electrocardiograph(ECG), electroencephalogram(EEG) and the level of blood glucose real-timely. This terminal is designed by modules, which includes intelligent processing module based on MSP430, electrodes for collecting the physiological signals and electric circuit module for signal preprocessing, wireless data transmission module based on GPRS. The terminal is able to analyze the above signal. The terminals can be formed as a network based on wireless transmission. Credible and portable terminal for life indication is realized by developing micro-sensor and integrated modules for signal detecting and processing. Amounts of clinic tests have been done and the results have been approved by the doctors in hospitals and patients. [C1655]

### "A compact self-similar power combining topology"

A compact, modular 16-way combiner is presented which is based on a self-similar combiner topology. The combiner achieves a simulated passive efficiency of 38% at 77 GHz in a standard 90nm process with 1.49 $\mu$ m thick Al top metal. A 77 GHz power amplifier is built based on the combiner, combining the output power of 16 stages to achieve a Psatof 11.4dBm, small signal gain of 9.4dB, and a 3dB bandwidth of more than 11 GHz on a 0.7V supply, with the optimal MAG for the technology being approximately 5dB at 77 GHz. The power amplifier is unconditionally stable with the K factor exceeding 3.8 between 50-90 GHz. The entire architecture is based on a modular power splitting and combining network that makes the design flexible and scalable. To the best of the authors' knowledge, this is the highest Psatreported at 77 GHz in CMOS with a sub 1V quiescent Vds. [C1656]

### "Decentralized multihypothesis sequential detection"

This article is concerned with decentralized sequential testing of multiple hypotheses. In a sensor network system with limited local memory, raw observations are observed at the local sensors, and quantized into binary sensor messages that are sent to a fusion center, which makes a final decision. It is assumed that the raw sensor observations are distributed according to a set of  $M \geq 2$  specified distributions, and the fusion center has to utilize quantized sensor messages to decide which one is the true distribution. Asymptotically Bayes tests are offered for decentralized multihypothesis sequential detection by combining three existing methodologies together: tandem quantizers, unambiguous likelihood quantizers, and randomized quantizers. [C1657]

### "A new class of ternary and quaternary sequences with two-level autocorrelation"

Pseudorandom sequences with good correlation properties are widely used in communications and cryptography. The search of new sequences with two-level autocorrelation has been a very interesting problem for decades. In 2002, Gong and Golomb proposed the iterative decimation-Hadamard transform (DHT) which is an useful tool to study two-level autocorrelation sequences. They showed that for all odd  $n \leq 17$ , using the second-order decimation-Hadamard transform, and starting with a single binary m-sequence, all known two-level autocorrelation sequences of period  $2n-1$  which have no subfield factorization can be obtained. In this paper, we present a new class of ternary or quaternary sequences with two-level autocorrelation using the second-order decimation-Hadamard transform. The period of such sequences is  $2n-1$ . [C1658]

### "Nonbinary sequences with perfect and nearly perfect autocorrelations"

The design of pseudorandom sequences with optimal correlation properties forms a crucial part of communications and radar engineering. Perfect autocorrelation sequences are however exceedingly rare. We discuss a technique that yields examples of such designs over enlarged PSK (PSK+) alphabets. We also design nearly perfect autocorrelation sequences over enlarged QAM (QAM+) alphabets, compatible with contemporary wireless transmission standards. [C1659]

### "Performance analysis of an optical beam-forming network with custom microwave CAD tools"

Next generation wideband and ultra-wideband radar antenna arrays need efficient true-time delay networks for array control. Optical beam-forming networks have been considered as a promising solution in such arrays. Performance analysis of optical beam-formers is thus quiet necessary. In this paper signal to noise ratio and dynamic range of simple optical beam-forming structures are investigated with a custom microwave CAD tool. Two structures with optical and RF power combining methods are discussed. With the proposed devices'

parameters, the optical combining method shows better performance for low and moderate optical powers.

[C1660]

#### "77 GHz automotive digital beamforming radar with SiGe chipset"

In this paper, we describe the design and layout of an automotive radar sensor demonstrator for 77 GHz with a SiGe chipset and a fully parallel receiver architecture which is capable of digital beamforming and superresolution direction of arrival estimation methods in azimuth. Additionally, we show measurement results of this radar sensor mounted on a test vehicle. [C1661]

#### "Detection of weak moving targets based on 2-D range-Doppler FMCW radar Fourier processing"

This paper deals with a FMCW radar measurement scheme and a 2-D range-Doppler FMCW radar Fourier processing that is especially suited to detect very weak moving targets. A 2-D Fourier transform is applied to a larger set of consecutively measured FMCW radar beat signals. By this a phase coherent evaluation of a very long measuring time and a highly sensitive target separation in range and Doppler dimension is feasible. Applications of the proposed method are for example live sign detection of trapped or buried people, intruder detection or level measurements to organic fluids. The practical application of the described method is illustrated with a 24 GHz FMCW radar sensor system. The signal evaluation was implemented on a field programmable gate array (FPGA) to facilitate real time processing. Exemplary measurement results are presented to illustrate the capability of the applied method. [C1662]

#### "Enhanced drift in RF-power LDMOS transistors under pulsed stress conditions"

This paper presents an experimental evaluation of the reliability of LDMOS transistors with possible use in radio base station PA or for pulsed S-band Radar applications. Alternative device layouts have been investigated in a stress-test measurement system capable of generating pulses in the nanosecond range. The investigation shows that pulsed operation accelerate device drift. For the most sensitive parameter RON, pulsed operation at low supply voltage increase the drift with a factor 3 compared to constant operation. The investigation indicates that the stress is affecting the overlap or the field region but not the channel region. RESURF designed devices with decreased field in this region therefore show less RONdrift. [C1663]

#### "Considerations for future automotive radar in the frequency range above 100 GHz"

Within the last years automotive radar sensors became more and more important. Started with comfort systems like adaptive cruise control (ACC) and parking aid, the safety aspect increasingly came to the fore. In the near future not only upper class cars will be equipped with various radar applications like pre crash, collision warning and collision avoidance to increase traffic safety. Therefore many high performance radar sensors have to be integrated in the car. This paper describes the demands on future radar sensors. It is discussed how the step to higher operating frequencies could be beneficial particularly for urban situations with high traffic density. Furthermore the paper will provide and discuss design considerations for future mmW-Radar sensors in automotive safety applications. [C1664]

#### "Specification and design of a fast-tuning stepped-frequency synthesizer for a short-range-SAR-system in the K-Band"

We developed a stepped frequency synthesizer for short-range wide-beam radar applications. It is shown how a direct digital synthesizer (DDS) can be used as signal source for low-range applications. Attention was put on the tuning speed as well as on high bandwidth, frequency resolution and costs of the system. For high resolution the system was designed in the K-Band at 24 GHz. [C1665]

#### "A novel motion compensation algorithm for automotive SAR: Simulations and experiments"

In this paper a novel motion compensation algorithm for automotive SAR is presented. Aiming at automotive applications, the motion compensation algorithm utilizes only one 1-axis MEMS accelerometer instead of a 6 Degrees of Freedom inertial sensor. A complete motion compensation procedure is presented and its performance is analyzed quantitatively. The critical system parameters are designed with the help of a fully characterized simulator and Monte Carlo simulations. The experiment results demonstrate that the motion compensation algorithm together with a standard low-cost accelerometer can yield very useful images for automotive applications. [C1666]

#### "LTR analysis and signal processing for concealed explosive detection"

This paper presents the methodology for Concealed Weapon and Explosive (CWE) detection using Ultra Wideband (UWB) radar. The framework of the approach is based on the study of the Late Time Response (LTR) of the complex human-explosive object which occurs when the illuminating signal is characterised as UWB. The LTR is analysed using methods for extraction of its natural resonant frequencies which constitute a unique signature. Therefore it is investigated if the explosive or grenade resonant frequencies can be retrieved by the human-grenade LTR. [C1667]

#### **"Absolute distance measurement with asynchronous-optical-sampling terahertz impulse radar"**

We proposed a method to determine the absolute distance of a distant target using asynchronous-optical-sampling terahertz impulse radar. The determined distance was good agreement with the actual distance measured by a scale. [C1668]

#### **"Ppb standoff detection of nitric oxide in air"**

We demonstrate standoff detection of NO in air with ppb resolution. The weakly ionized plasma produced by picosecond UV laser pulses via REMPI is detected remotely by a microwave scattering technique. [C1669]

#### **"Darker than black: radiation-absorbing metamaterial"**

Taking advantage of the broadband "super-singularity" in the density of states of hyperbolic metamaterials, we develop a new approach to radiation-absorbing systems and present an experimental realization of this concept. [C1670]

#### **"Ultra wideband radar for water detection in the human body"**

In this paper an Impulse Radio Ultra Wideband (IRUWB) radar for detecting water accumulation in the human body is proposed. The method of On-body water detection is investigated both in a simulator with a bladder model and measurement system with a phantom. The Vivaldi antenna is used in the measurement system. The simulation and measurement results show the feasibility of water detection in the bladder through the reflection from the boundary of muscle and urine. The proposed concept offers also potential for continuous, wireless detecting and monitoring of the human organs ( heart, lung and bladder) and vital functions. [C1671]

#### **"Iterated simplified multiple model filters for target tracking in the presence of glint"**

The problem of target tracking in the presence of glint is investigated in the paper. Traditional interactive multiple model filters for tracking with target glint were first summarized and then simplified multiple model filters were developed in full detail according to a Gaussian assumption in the interactive multiple model structure. Novel iterated filters based on unscented Kalman filter and extended Kalman filter were put forward and then combined with simplified multiple model algorithms in order to improve tracking performance. Compared with the standard simplified multiple model filter, the proposed filters has higher estimation accuracy plus faster convergence speed. Simulation results demonstrate the conclusion above. [C1672]

#### **"Application of the combinatorial models for innovative design techniques"**

Application of the Perfect Combinatorial Sequences Theory, namely the concept of Ideal Ring Bundles (IRBs), for improving the quality indices of engineering devices or systems based on combinatorial technique is proposed in the paper. For example, resolving ability of radar is known to be of very dependent from positioning of elements in antenna array; high-performance technology of information coding and design of communication signals with favorable correlation properties demands an optimal placement of the signals in spatially and temporally distributed systems, and other examples of technological problems relating to the optimal placement of spatially or temporally distributed systems can be cited. However, a lot of well-known engineering devices, technologies or systems with non-uniform structure are very distant from perfect fulfillment of the design with respect to performance reliability, resolving ability and the other significant operating characteristics of the system. An ordinary IRB is ring-like sequence of positive integers, which form perfect partitions of a finite interval  $[1, S]$  of integers. The sum of connected subsequences of an IRB enumerate the set of integers  $[1, S]$  exactly once. This property makes IRBs useful in applications, which need to partition sets with the smallest possible number of intersections. [C1673]

#### **"77 GHz radar transceiver with dual integrated antenna elements"**

A complete radar transceiver for 77 GHz with two integrated antenna elements is presented. Based on a previously published design [1], two of the transmit and receive channels of the transceiver are supplemented

with integrated antenna elements. The antennas exhibit a well defined antenna pattern with an efficiency of better than 50%. [C1674]

#### "Particle filters for beam-space high resolution DOA estimation"

This paper addresses the application of particle filter (PF) schemes to tracking Direction-Of-Arrival (DOA) in beam-space, using a passive array of sensors with single snapshot. This proposed technique has significant ability to estimate the DOAs of multiple sources at arbitrary times throughout the observation period, and that the requirement for quasi-stationarity over a limited interval may be relaxed. According to the State-Space Model of beam-space narrowband array signals, the importance function is established. Sampling from the importance function, the algorithm estimates the bearings of sources by sequential Monte Carlo methods. Based on DOAs estimation and the observation in each snapshot, the proposed algorithm estimates the amplitudes of the sources and the variances of noise, using a maximum posteriori estimator simultaneously. Computer simulations are presented to show the performances of the algorithms. [C1675]

#### "Design of elevator audio player controlled by wireless communication"

The objective of elevator audio playing system mainly concerns the device installed in elevator to provide music, advertisement and notifications. In this paper, GPRS is utilized for mode control and wireless instruction sequence update. As the core of the whole system, STM32 Microcontroller unit can browse and manage the catalog of files in SD card. Additionally, through building-up FAT 16 File System (FS), MCU will manage sound files in player flexibly and conveniently. Thus, the device supports enables three playing modes, namely, by category, by designated order or by random order. Laboratory Experimental result proves that the designed audio playing system is of flexible and stable maneuverability. This system will bring comfortable up-and-down experience to passengers, increase efficiency of elevator management and bring gains to advertiser and elevator service provider. [C1676]

#### "Decision-making model for mobile blind compensation in jamming"

In order to solve the problem of the blind region for radar netting in jamming, based on the analysis of anti-jamming capability; this paper uses the highly mobile radar to compensate the blind region to upgrade the anti-jamming capability holistically. It defines the conception of the blind compensation gain, constructs the decision-making model and designs the genetic algorithm. The result of simulation indicates the model is effective. The model provides the decision-making evidence for mobile blind compensation and lays a foundation for reserve and application of highly mobile radars. [C1677]

#### "Research on fault monitoring for railway automatic blocking and continuous transmission lines"

The characteristics of railway automatic blocking and continuous transmission lines are studied. On this basis, a fault monitoring system is designed. Monitoring units installed on lines can detect the short fault directly (when earth fault happens, "S-injection method" is applied), and send out this information to adjacent GPRS units via Radio Frequency (RF). Then adjacent GPRS units send the data to the server. Through analyzing the gathered data, the server can locate the fault section. The test and field operation indicates that this system can identify fault section accurately and rapidly, increasing both of economic and social benefits. [C1678]

#### "Implementation of handheld remote sense image calibration system software"

This paper based on 4S(GPS, GPRS, GIS and RS technology in a integrated system) and designed a remote sense image calibration system by using a high precise GPS module which is integrated in the handheld client device. This article designed and realized a software architecture and a data storage and transfer model though the GPRS real-time network. The handheld devices based on 4S changed the poor efficiency way of the original remote sense image of the manual data acquisition, post-mapping and other operations. The efficiency of original system is also greatly enhanced by implement the digitization of external work system which is constituted on a collaborative platform within the inner work system. [C1679]

#### "An efficient nonuniform channelizer based on Adjacent Channel Merging"

An efficient nonuniform channelization method based on ACM (Adjacent Channel Merging) is proposed to extract large amount of radar signals with different band widths. The neural networks based on cosine basis functions are used to train the LP prototype filter coefficients in order to satisfy the ACM condition. Use this LP prototype filter to form windowed FFT uniform channelizer, then simply add the outputs of the adjacent channels and the nonuniform channelizer can be achieved. The proposed channelizer is simply composed of an FFT component and a few adders, so it has a smaller number of computations than DDC and TPFT channelizers. The computer

simulation results given at last shows that the proposed method also has a good channelizing performance.

[C1680]

#### "A new evidence combination method"

Considering that the Dempster rule of combination in evidence theory has disadvantages while dealing with highly conflicting evidence, a novel two-level combination method for fusing conflicting evidence is proposed in this paper. Distinguishing between highly conflicting evidence and lowly conflicting evidence, the method adopts the PCR6 rule based on DS<sub>m</sub>T in the first level of combination to solve high conflict and in the second level uses Dempster rule to keep fast convergence speed and good calculation capability, which can manage conflicting evidence with various degrees effectively and reasonably. The validity of the method proposed is demonstrated by calculation examples. [C1681]

#### "Automotive radome design-fishnet structure for 79 GHz"

Metamaterials are considered as an option for quasi-optical matching of automotive radar radomes, lowering transmission loss and minimizing reflections. This paper shows a fishnet structure design for the 79 GHz band which is suitable for this type of matching and which exhibits a negative index of refraction. The measured transmission loss is 0.9 dB at 79 GHz. A tolerance study concerning copper plating, substrate permittivity, oblique incidence, and polarization is shown. Quasi-optical measurements were done in the range of 60-90 GHz, which agree with simulated results. [C1682]

#### "Switchable power combining network for 35GHz"

Power combining networks are a key component for most radar systems. In combination with micromechanical switches the network can be used for multi-beam lens systems, filter bank etc. The main disadvantage of such a switchable power combining network are high losses. In a Doppler beam sharpening system (DBS) for 35 GHz a power combining network with Micro-Electro-Mechanical-Systems (MEMS) switches was realized. [C1683]

#### "Bistatic scattering center models for the simulation of wave propagation in automotive radar systems"

Deterministic radio channel simulations for large and complex environments at very high frequencies are a challenging task. In this paper an approach is presented in which the computational complexity is significantly reduced by using scattering center models for the most complex objects. The scattering centers are described in form of directional, bistatic scattering intensities and can be computed for the isolated complex object in advance without considering the complete environment. Thus, the simulation performance benefit is due to a significant reduction of the complexity of the geometrical representation of the scene. The parameterization of the scattering centers itself is based on an efficient high frequency asymptotic field prediction tool incorporating Geometrical Optics and other techniques. The models are designed to study deterministically the wave propagation for vehicle based radar systems operating near 80 GHz. An example for a bistatic three-dimensional parameterization is given. Furthermore, a fast Inverse Synthetic Aperture Radar (ISAR) imaging technique is applied that can be used to find the most relevant scattering center positions on the objects. [C1684]

#### "Analysis and research of proportional conflict redistribution rules in identity identification"

The research on identity identification of high conflicting evidence is a popular and difficult problem. Proportional conflict redistribution rules are a kind of effective method for dealing with high conflicting evidence. The series of proportional conflict redistribution rule (PCR1 to PCR6) are introduced and analysed in this paper. Experiments show that the six rules obtain an available conclusion which provide s reasons to the engineering application and improvement of identity identification. [C1685]

#### "Time allocation in cognitive radar for multitarget detection with dynamic programming"

The radar performs three main functions: search, tracing and weapon engagement. Each of functions occupies amount of time, energy and computation resource of the radar system. For cognitive radar, it should have the basic function which is learning. The radar needs to manage its resources dynamically and interactively between the setting of radar parameters to optimize the tasks to be carried out and perceive environment highlights the role in which knowledge and intelligence will be central in cognitive radar performance. The problem discussed here is the time allocation of cognitive radars in a multitarget environment. In this paper, we develop the optimization criterion based on the detection probabilities based on dynamic programming algorithm(DPA).

[C1686]

### **"Design and optimization of amplitude-modulated microwave backscatter transponders"**

In the current paper design rules and exemplary optimized designs for microwave backscatter transponders are presented. The overall goal of the proposed transponder design is to achieve a maximum signal to noise ratio in the radar signal of a given base-station that interrogates the transponder. To accomplish this task, it is important not only to consider the transponder modulation factor, i.e. the values of modulated/switched antenna loads, but also the resulting radar cross-section of the loaded transponder antenna. Unfortunately, both aspects are partly opposing and optimization is not straightforward. The design method presented and applied in this paper allows selecting the optimal relation between the antenna parameters and the load parameters. To prove the proposed method, exemplary designs and measurement results of 5.8 GHz backscatter transponders are shown. [C1687]

### **"Direct measurement of electron loss rate in air"**

We present direct local measurements of electron attachment and recombination rates in atmospheric air. Using a microwave scattering based resonantly enhanced multi-photon ionization scheme we monitor the electron density dynamics with nanosecond resolution. [C1688]

### **"Optimal waveform selection for software defined data acquisition system"**

This paper describes specific digital beamforming methods and prototype of the data acquisition system. Moreover, the detailed description of the beamforming and reception algorithms would explain the possible estimation criteria for given system. The modelling results and software radar prototype performance are presented. Concerning the use of spread spectrum waveforms with wideband beamforming methods, possible modes of data acquisition applications will be discussed. [C1689]

### **"Partial treatment of wind turbine blades with radar absorbing materials (RAM) for RCS reduction"**

The application of radar absorbing materials (RAM) in order to reduce the interference of wind farms with radar systems is considered as a possible mitigation solution. This paper will address the key challenges when trying to efficiently apply RAM to certain parts of the wind turbine blades to significantly reduce the scattering of radar signals. Modeling of the radar cross-section (RCS) is presented for a generic 40 meter blade wind turbine before and after applying RAM to different parts of the blade. The results of modeling possible solutions of partially RAM treated blades are compared. [C1690]

### **"Stroke detection using a broadband microwave antenna system"**

In this paper we describe a microwave based measurement setup and a signal processing algorithm for stroke detection and diagnostics. [C1691]

### **"Millimeter-wave integrated waveguide antenna arrays and beamforming networks for low-cost satellite and mobile systems"**

This paper overviews the state-of-the-art of the substrate integrated waveguide (SIW) techniques in the design and realization of innovative and low-loss millimetre-wave antenna arrays and beamforming networks for low-cost satellite and mobile systems. Novel classes of SIW-based antenna and beamforming techniques on the basis of this concept of substrate integrated circuits (SICs) are demonstrated to offer unprecedented performances and opportunities. Different structures and architectures are theoretically and experimentally studied and discussed for specific space- and ground-based applications. High-density integration and high-volume manufacturing issues are addressed. [C1692]

### **"Mutual coupling and platform effects in the synthesis of Passive Coherent Location radar array"**

Introduction and main concepts: An increasing interest in passive surveillance systems can be observed in last period. The key idea, which is also common to other non-radar applications, is to conveniently exploit opportunity signals, as analogue FM transmitters or Digital Video Broadcasters to detect and/or tracking targets [1-3]. [C1693]

### **"Vital signs monitoring with a UWB radar based on a correlation receiver"**

In the first part of this publication, vital signs detection observing small amplitude changes due to the movement of a target in front of the radar is shown. In the context of vital signs monitoring the target is the chest of human beings. This basic principle is also used in continuous wave (CW) radars, but the presented impulse-based UWB radar has moreover a range gating capability. Consequently, the target distance can be obtained and different

targets (persons) can be monitored. Several measurement results using this measurement principle for respiration and in particular for heart beat monitoring are presented and discussed. Furthermore, the shortcomings of this method are depicted. In the second part, advanced signal post-processing by deconvolution with a Wiener filter is presented, leading to an improved resolution performance for the realized UWB radar system. Promising results of this method show that small targets can be identified in a multi-target scenario. Therefore, the movement of small targets, e. g. the heart muscle within the human body, could be tracked directly. [C1694]

#### "Antenna front-end concepts of a low-cost coherent radar demonstrator for S-band application"

Some of the concepts of an AESA antenna front-end for a low-cost coherent radar system demonstrator intended for maritime applications in the S-band are presented in this contribution. Manufacturing and maintenance cost reduction with respect to present commercial systems is achieved by replacing the conventionally used magnetron RF power generation and the mechanically rotated antenna by a semiconductor transmitter and an AESA antenna with custom-developed mixed-signal integrated circuits as core components of its T/R-modules. The operation with coherent signals facilitates the application of modern signal processing techniques in order to compensate for the heavily reduced peak transmit power. [C1695]

#### "A Least-Squares Algorithm for Multipath Estimation Using an UWB-IR Link"

This paper introduces a modified complex to real amplitude least-squares (CRALS) algorithm for the estimation of dense multipath in an UWB-IR channel. The traditional CRALS is ineffective for UWB-IR signal due to its wide bandwidth and large off period. This algorithm is modified to resolve three closely spaced paths in a correlation window. One novelty of the modified algorithm is that region-based processing is used for the initial estimate in place of coordinate descent processing used in traditional algorithm, and so the long iteration due to large off period is saved. The other novelty is that the procedures are simplified because of no necessity to increase the penalty term to infinity in UWB-IR case. Its efficiency is compared to the generalized maximum-likelihood estimator (GML) by simulation in different signal to noise ratios (SNR). The reason for its efficiency improvement comes from fewer effective spectrum samples and region-based processing of correlation results. Real measurement is conducted to verify this algorithm's performance. Its estimation error of time difference of arrival (TDOA) is about 0.18ns. [C1696]

#### "Distributed Localization for Wireless Sensor Networks Using LFM Waves"

A novel distributed localization method for wireless sensor networks (WSN) is proposed in this paper. Linear frequency modulation (LFM) waves are emitted from two anchors simultaneously to create an interference field. Through the frequency measurement of local RSSI (Received Signal Strength Indication) signal, the TDoA (Time-Difference-of-Arrival) is estimated independently at each sensor to detect range difference from the sensor to the two anchors, by which the position can be determined. Furthermore, an extended method applied to mobile sensors is also presented. The proposed method only relies on radio transceivers and requires no time synchronization for sensors. Simulations results demonstrate the effectiveness of our method. [C1697]

#### "ISAR rotational motion compensation using entropy metric"

Inverse Synthetic Aperture Radar (ISAR) is an efficient tool for providing image from moving targets. When the target's maneuverability is not too serious, conventional FFT imaging algorithm is enough for providing focused image. But the target being imaged is often engaged in complicated maneuvers. So autofocusing techniques are needed. We can classify these techniques into two main categories: Parametric and nonparametric algorithms. Minimum entropy method is one of the nonparametric autofocusing methods. In this paper we present a new algorithm for autofocusing ISAR images based on entropy criterion. Simulation results show the effectiveness of the proposed algorithm. [C1698]

#### "Retrodirective array based radar (invited)"

This paper will demonstrate recent work at Queens University of Belfast as well as review the small body of literature on the new topic of Retrodirective Radar. Details are presented on the core capabilities of Retrodirective antenna arrays for near field target acquisition and pulsed far field tracking in Radar applications. [C1699]

#### "Synthetic Structural Imaging (SSI): A new ultrasound method for tracking breast cancer morphology"

A new signal interrogation concept, based on Synthetic Structural Imaging (SSI) physics, has been developed to

guide therapies. The SSI method was previously successful in radar and sonar imaging; here it is demonstrated for acoustic scattering from penetrable biological targets. Operating at ultrasonic frequencies of several hundred kilohertz, SSI trades the higher resolution of typical B-mode ultrasound imaging for a significantly stronger correlation to target shape and volume, which are among the primary tissue classifiers. Tissue phantom models were fabricated with embedded spheroidal inclusions ranging from 2.41 mm through 6.3 mm in diameter. The phantom medium was 10 wt% porcine gelatin and the inclusions were 28 wt% porcine gelatin. The inclusion dimensions were measured with calipers. The phantom was interrogated with two impulse-excited Panametrics transducers: a model V301 with a peak frequency of 0.50 MHz and a -6 dB bandwidth of 81%, and a model V314 with a peak frequency of 0.99 MHz and a -6 dB bandwidth of 77%. The backscattered RF data were digitized, recorded, and digitally bandpass-filtered. The experimental profile functions were computed. Volumes were estimated by integrating the experimental profile functions. SSI-determined volume ratios were demonstrated to be within 7% to 18% of caliper-determined volume ratios. [C1700]

### "Improving Service Availability in 3GPP Generic Access Network (GAN) by Adaptive Keep-Alive Interval (AKI)"

The Generic Access Network (GAN) developed by 3GPP extends services to unlicensed spectrum. A mobile station with multiple air interfaces can access 3GPP services through GAN and roam seamlessly between different radio access networks. However, resource management is a critical issue in GAN. To allocate GAN resources efficiently, we propose Adaptive Keep-alive Interval (AKI). By using AKI, an MS can send less signaling messages. In addition, AKI can increase system utilization by releasing unused resources. The proposed AKI is evaluated by extensive simulations. The results show that the proposed AKI can reduce signaling overhead and increase GAN utilization significantly. [C1701]

### "A Traffic Information Service-Broadcast model for mixed-equipage Aircraft Simulation"

The use of new Air Traffic Management (ATM) concepts built upon the capabilities afforded by the Automatic Dependent Surveillance-Broadcast (ADS-B) system in NextGen airspace aims to provide substantial improvements in system capacity and throughput without compromising safety relative to today's ground-directed ATM based on Secondary Surveillance Radar (SSR). These concepts rely on airborne based surveillance and include the use of airborne systems and procedures to perform traffic monitoring, self-separation, and merging and spacing. The Traffic Information Service-Broadcast (TIS-B) system is intended to provide the crucial bridge for ADS-B aircraft to employ some of these concepts during the transition phase. Although TIS-B surveillance is not expected to be of the same quality as ADS-B surveillance, it still provides aircraft state and velocity information required so that airborne systems can provide airborne separation assistance/assurance and airborne spacing capabilities (with increased separation margins). While simulation studies of these NextGen concepts in the end-state system are already underway, additional simulation models will be needed to represent the intermediate state system where not all aircraft will be equipped with ADS-B. The suitability of new ATM concepts for use in the transitional NextGen airspace with mixed equipage (Mode C, Mode S, and Mode S Extended Squitter (ES)) aircraft can be studied using simulation tools such as NASA Langley's Airspace and Traffic Operations Simulation (ATOS) enhanced with the TIS-B model described in this paper. ATOS is a distributed, Human in the Loop (HITL) simulation consisting of multiple, mid-fidelity, desktop cockpit simulators called ASTOR (Aircraft Simulation for Traffic Operations Research). This paper describes the RTCA standards-based design of the TIS-B model developed for use in ATOS. This model consists of ground and aircraft subsystems with a focus on the models of TIS-B system functional elements such as Ground Surveillance Processing (GSP), TIS-B Target Report Distribution Function (DF), Ground Link Specific Processing (GLSP), Airborne Link Specific Processing (ALSP), and Target Tracking and Report Assembly (RA). The modeling of SSR data processing functions in the GSP, including position and altitude measurement, state estimation, radar tracking, and computation of Navigation Accuracy Category (NAC) and Navigation Integrity Category (NIC) of aircraft position is discussed at length. This paper also describes how Target reports are extrapolated (to account for data latency), generated, and distributed by the DF model. A Ground Based Transceiver (GBT) model implements the GLSP functions that include generation of TIS-B messages and suppression of TIS-B messages corresponding to aircraft producing ADS-B signals being received by the GBT. Modeling of the reception of ADS-B transmissions by the GBT is included using the ADS-B reception model developed for ASTOR air-to-air reception modeling. Finally, this paper describes the modeling of the ALSP and RA functions within the ASTOR. The paper also presents and discusses the preliminary model validation test results obtained from the simulation by comparing truth and TIS-B message derived track data and provides insights into how the TIS-B model can be used to support NextGen concept studies. [C1702]

### "Angle-resolved thz time domain reflection spectroscopy of rough surfaces"

The use of a fiber-coupled terahertz TDS system offers new possibilities for angle-resolved reflection

spectroscopy. We put the focus especially on angle-resolved scattering from roughened surfaces of both dielectric and metallic surfaces. [C1703]

#### "THz fiber-based swept-source imaging radar"

We demonstrate an all-THz fiber-based swept-source imaging radar system. Our experiment shows that this radar can be used in real time to nondestructively detect and locate the concealed living objects with high stability and sensitivity. [C1704]

#### "Automatic recognition of diverse 3-D objects and analysis of large urban scenes using ground and aerial LIDAR sensors"

We describe a learning-based 3D object recognition pipeline developed under the DARPA URGENT program for analyzing a large LIDAR dataset collected by both airborne and ground platforms for an extended urban area. Our approach utilizes a novel strip-based cueing approach that incorporates the properties and context of urban objects. Strip-based cueing segments potential objects and assigns them to appropriate classification stages. Our learning-based recognition pipeline successfully recognized 17 3D object classes in LIDAR data collected in and over Ottawa, Canada with high efficiency and average accuracy of 70%. [C1705]

#### "3D optical Yagi-Uda nanoantenna array"

We fabricated three-dimensional arrays of optical Yagi-Uda nano-antennas. Due to the high directivity of the array structure the incoming light is received efficiently at the resonant wavelength in the near-infrared (around  $\lambda = 1.3 \mu\text{m}$ ). [C1706]

#### "Linearization of ultra-broadband optical chirps for precision length metrology"

We demonstrate precise active linearization of ultra-broadband ( $>5 \text{ THz}$ ) laser frequency sweeps using a self-heterodyne technique. Frequency errors less than 170 kHz relative to linearity were observed enabling very high resolution ranging over large distances. [C1707]

#### "90ps tunable true-time delay line based on photonic crystals"

A photonic crystal waveguide delay line is reported with 90ps of tunable delay over a 20GHz bandwidth. This corresponds to a maximum phase shift of  $600^\circ$ . The true-time delay characteristics are evidenced using a vector network analyzer. [C1708]

#### "High pulse-energy atmospheric aerosol lidar at 1.5-microns wavelength: Opportunities for innovation from a meteorologist's perspective"

Laser and optical engineering challenges and recent progress in the area of high pulse-energy direct-detection atmospheric lidar near 1.5 microns wavelength are described. [C1709]

#### "On Time Varying Channel Estimation Using Sparse Models"

We consider the design of sufficiently informative inputs for estimating the parameters of a time-varying linear system. Specifically, we assume the output of the system may be modeled as linear combinations of known time-varying elements whose parameters are points in an appropriately chosen grid for the parameter space, such that these parameters are sparse in comparison with the grid size. The sufficiently informative inputs we study are signals that guarantee a unique sparsest solution thereby satisfying minimum requirements for numerically solving the estimation problem. Since in practice the parameters of interest may not lie on the grid constructed for the parameter space, we discuss how our input designs can be modified to provide robustness in the presence of modeling error and noise. [C1710]

#### "SiGe BiCMOS Chip Sets for Use in an X-Band Multi-function Chip"

SiGe Radio Frequency Integrated Circuits have been designed and fabricated for use in the X-band Si-based multi-function chip, which is known as a core-chip for a Transmit/Receive module of a phased array radar systems. In this paper, six kinds of Radio Frequency Integrated Circuits will be presented such as a power amplifier, a digital serial-to-parallel converter, a Single-Pole-Double-Throw switch, an 8 dB attenuator, a 16 dB attenuator, and a 45 degree phase shifter. The power amplifier based on a cascode configuration using SiGe HBTs shows the Radio Frequency performance of the 12 dB gain and 19 dBm P1dB. The other five chips have been designed using 0.25  $\mu\text{m}$  Complementary Metal-Oxide Semiconductor technology. The digital serial-to-

parallel converter shows the perfect functional operation to 20 MHz clock. The Single-Pole-Double-Throw switch, the 8 dB and 16 dB attenuations, and the 45 degree phase shifter show good Radio Frequency performances. The most of chip sizes are very small to be lower than 1 mm<sup>2</sup>. These chip sets may make an attractive solution for a high power X-band multi-function chip for a T/R module of a phased array radar system. [C1711]

### "A Novel Homogeneous Mesh Grouping Scheme for Broadcast Cognitive Pilot Channel in Cognitive Wireless Networks"

With the irreversible trend of the convergence and cooperation among heterogeneous wireless networks, the need for network information awareness of user equipments (UEs) becomes increasingly imperative in the Cognitive Wireless Networks (CWN). As one of the candidate solutions for network information delivery for UEs, the Cognitive Pilot Channel (CPC) concept has been brought forward recently, providing UEs with the necessary network information for network selection by using the public signaling channel. Besides, both broadcast and on-demand CPC modes have been proposed for the network information delivery under the assumption that the geographical region is divided into meshes. In this paper, a novel homogeneous mesh grouping (HoMGP) scheme based broadcast CPC mode is designed to improve the efficiency of broadcast CPC mode in the CWN. The homogeneous meshes are selected and grouped based on the frequency occupancy graph, which is obtained by using the image processing techniques. By grouping the homogeneous meshes together, both the frame format and flow of the HoMGP broadcast CPC mode are designed to deliver heterogeneous network information to the UEs efficiently, which is verified by numerous simulation results. [C1712]

### "Quantum Cascade laser for elastic-backscattering LIDAR measurement"

We present an experimental demonstration for an elastic-backscattering LIDAR system measurement using a Quantum Cascade laser (QCL). The laser emits a peak power of above 13W at 80K and with a wavelength of 4.5μm. [C1713]

### "Lifetime Maximization of UWB-Based Sensor Networks for Event Detection Applications"

Ultra wideband (UWB) technology is well suited for communication in wireless sensor networks, in which low power consumption for data transmission and the availability of precise ranging information are highly desirable. In this paper, we consider the application of UWB in an event-detection sensor network, and we are interested in maximizing the network operational lifetime while satisfying requirements on the detection and false alarm probabilities. Towards the goal of lifetime maximization we (i) jointly find the optimal routes from multiple events to the sink, to avoid the bottleneck-node phenomenon which often limits lifetime, and (ii) allow adjustment of the data rate that each sensor generates to contribute to event detection, in order to balance the energy consumption among the nodes in the network. Using the UWB signal characteristics, we present a convex optimization model to solve the lifetime maximization problem. The numerical results show that the proposed framework leads to significant improvements in network operational lifetime compared to benchmark approaches. [C1714]

### "Performance of Downlink Schedulers with Superposed or Orthogonal Transmissions"

This work looks into the extension of the proportional fair (PF) scheduler to the multi-user case, where the source is transmitting several messages under the superposition coding (SC) strategy in a Gaussian Broadcast channel. Jointly with the weighted sum-rate (WSR) scheduling criterion, we derive guidelines for 2-user pairing, based both on SNR and user priority. We compare superposition coding access with frequency division multiple access, while time division is obtained naturally as a result of the user pairing. Results elucidate that the 2-user SC PF always improves the single-user PF in terms of average throughput and delay reduction, and we compare its performance with the 3-user SC PF. Finally, the WSR shows throughput gains similar to the 2-user SC PF for certain configuration of the scheduler. [C1715]

### "A target polarization recognition method for radar echoes"

This paper distinguishes ship target from chaff by their difference in depolarization characteristics using fully polarized dual-channel radar which transmits vertical and horizontal polarization wave alternately and receives co-polarization and cross-polarization components simultaneously with two channels. It recognize the target by taking advantage of the difference of the vertical and horizontal depolarization characteristic parameters of the target and chaff in radar echoes, after enlarging the difference between the cross-polarization component and co-polarization component of the radar echoes involving both target and chaff. furthermore, non-linear polarization transformation is adopted to increase the chaff and targets separability and to improve the recognition rate in result. In the end, the recognition result is proved to be more desirable by processing information in polarization domain than in time and frequency domain. [C1716]

### "A novel analytical method and error criterion of the synthetic range profile"

In this paper, a novel method to analyze the distortion of a synthetic range profile (SRP) is put forward, which is simpler and more effective, and more importantly it can be available for the present existing any synthetic wideband waveform (SWW) forms. At the same time, since the traditional error criterion of the SRP for the stepped frequency waveform (SFW) is the quadratic phase error criterion, which has some inherent faults for any synthetic wideband waveforms, a modified error criterion is proposed to overcome such shortcomings. Specific conclusions are investigated with some simulations. [C1717]

### "Research of LTCC millimeter-wave T/R module"

Low-Temperature Co-fired Ceramic (LTCC) technology is one type of Co-fired ceramic multi-chip module (MCM-C), which is a high-integration and multilayer- printed packaging technology. In this paper, a millimeter-wave T/R module was presented with a very compact module size of 55 $\times$ 13 $\times$ 10mm<sup>3</sup> and an extremely low weight of only 31 grams by this technology, its output power was greater than 30dBm. Besides, the optimum EMC design and technology of embedded passive components were used. [C1718]

### "Radar anti-jamming application of solid-state noise source"

Jamming reconnaissance receiver (JRR) is an important anti-jamming equipment of radar. In this paper, we propose a compensation method based on solid-state noise source to against the performance degradation of JRR caused by long-term aging, which can compensate all channels simultaneous and accomplish by JRR itself. First, presented the structure of JRR, analyzed the principle and structure of solid-state noise source. To reduce the influence of ambient temperature on compensation performance, then we given and compared two solutions: constant temperature mode and table lookup mode. At last, advanced a method using attenuator to simulate the influence of long-term aging, and carried on a contrast test. The test results show that, the aging process has no effect on the performance of JRR after the compensation based on solid-state noise source, the long-term stability of JRR has been improved greatly. [C1719]

### "Design of velocity radar for railway"

The main velocity-measuring methods for train are analyzed and the relative merits of these methods are given. Through the analysis, Doppler radar for train's velocity measurement stands out for its distinctive features. The design plan for velocity radar's key components was introduced, and a pre-industrial prototype was finished. Finally, the test results verified the radar's high performance. [C1720]

### "Optimum design of jamming reconnaissance receiver"

This paper presents a channelized jamming reconnaissance receiver, and analyzed false response, amplitude response and temperature drift, which influence the performance of channelized receiver. For the sake of interchangeableness, we divided the receiver into RF assembly and IF assembly, then compensated each assembly independently and estimated system error. At last, we tested the receiver under assemblies (spare parts) interchanged situations at different temperatures. The results show that both absolute and relative accuracy reach  $\pm 2$  dB. The purpose of cutting down spare parts and improving maintainability, supportability, reliability has been achieved. [C1721]

### "An approach research to segmentation of the SAR image based on the Markov random field"

Markov random field method is a very active research field in image segmentation. In this paper, a new approach to the segmentation of SAR target chip image based on the Markov random field (MRF) and Maximum a Posteriori (MAP) rule is proposed. By statistical analysis of the different regions in the SAR target chip image, the valid segmentation algorithm for choosing the iteration initial value is obtained. Compared with other segmentation algorithms such as Simulate Annealing algorithm and the Iterative Conditional Model (ICM) algorithm by the synthetic image and operational SAR image, the proposed approach in the paper can accelerate the convergence speed, reduce the iterative numbers and improve the segmentation speed. [C1722]

### "A method of over cosec square-beam shaping with sharp cut off"

Cosec square beam have receiving uniform echo performance at the same height but different distances. The level exceeds that of traditional cosec square beam. In order to restrain interfere of multipath reflect, the beam must be cut sharply on the ground. Through setting appropriate fitness functions and choosing optimal optimization algorithm, a method of over cosec square-beam shaping with sharp cut off is presented in this

paper, which can obtain result that satisfies the designed requirements of engineer. [C1723]

#### "Analysis on the refraction stealth characteristic of cylinder plasma envelopes"

The refraction stealth characteristic of two dimensional cylinder plasma envelopes is studied. Firstly, an electromagnetic (EM) problem model of EM-wave propagating through cylinder plasma envelopes is set up. Then EW-wave traces equation in cylinder plasma is derived and a novel concept of plasma refraction deviation angle is presented out. Furthermore, the relation between refraction deviation angle and incidence angle of EM-wave is yielded and the relation between refraction deviation angle and plasma density distribution is made out as well. It is shown that cylinder plasma envelopes could make distinct refraction stealth. [C1724]

#### "PMCHW-AMCBFM for analysis of electromagnetic scattering by 3-D homogenous dielectric objects"

In this article, we present a novel approach based on PMCHW integral equation formulation in conjunction with the adaptively modified characteristic basis function method (AMCBFM) to solve the scattering from homogenous dielectric bodies. In the new method, equivalent electric and magnetic currents on the surface of object are needed and expanded using RWG basis functions. AMCBFM is subsequently used into the former matrix equation. The studied object is partitioned into distinct blocks with some overlapped-domains between neighboring ones. The matrix equation is solved by direct solution instead of iterative methods. The compatibility, accuracy and efficiency of this novel approach are demonstrated by a variety of scattering problems. [C1725]

#### "Analysis of ELF attenuation rate using the geodesic FDTD algorithm"

This paper is analyzed the attenuation rate of extremely low frequency (ELF) electromagnetic waves propagating in the Earth-ionosphere system, using the geodesic FDTD model. In the simulation both the classical two-exponential model and the "Knee" model of ionosphere are used. The resulting difference among using different algorithm are also explained. [C1726]

#### "Anisotropic scattering for a magnetized cold plasma sphere"

The transformation of parameter tensors for anisotropic medium in different coordinate systems is derived. The electric field for a magnetized cold plasma sphere and the general expression of scattering field from anisotropic target are obtained. The functional relations of differential scattering cross section and the RCS for the magnetized plasma sphere are presented. Simulation results are in agree with that in the literatures, which shows the method used and results obtained are correct and the results provide a theoretical base for anisotropic target identification etc. [C1727]

#### "Performance analysis for angle measurement of monopulse radar with non-consistent amplitude-phase features"

Monopulse radar is widely used for its high angle measurement and great anti-interference performance. In this paper, a classical signal processing method of sum and difference patterns for anti-symmetrical monopulse radar using digital beam forming (DBF) technique is proposed. Effects on angle measurement performance caused by amplitude-phase non-consistency are analyzed and its corresponding simulation results are verified. These results can be used in practical engineering implementation. Furthermore, the method proposed in this paper can also be applied in other tracking radar systems which include DBF. [C1728]

#### "Engineering design of the rain mode on an ocean-dedicating radar altimeter"

Satellite radar altimeters are fundamental tools in microwave remote sensing, but traditionally they were regarded as unsuitable for rain measurement. This paper designs a rain mode on an ocean-dedicating altimeter, taking China's forthcoming HY-2 ALT as a typical example. In rain mode the altimeter receives the surface and rain echoes simultaneously, so it can estimate the rain layer structure without losing surface topography information. The variable system parameters are designed to fulfill the task with very low hardware expenses. Some key issues are discussed in detail. To achieve the compatibility of measuring both surface and rain, an adaptive digital i/q demodulator is proposed, and receiver weighting is implemented to suppress the side-lobes. Constrained by echo power, altimeter can detect rains heavier than 6 mm/hr. [C1729]

#### "GaN technology for microwave and millimeter wave applications"

After many years of development to improve the material and devices, GaN technology is now in production and poised to revolutionize many of today's Radar and Communication systems. In this paper we present an

overview of GaN development, focusing on reliability, affordability, and defense applications. [C1730]

### "Special session in honor Dr. Kiyo Tomiyasu"

This session is dedicated to the career of Dr. Kiyo Tomiyasu. His career includes technical accomplishments in microwaves, lasers, and remote sensing of the earth using satellite-borne radiometers, scatterometers, and synthetic radars. He has contributed much to MTT-S, and to IEEE, including awards and contributions to the IEEE Foundation. This special session will include invited speakers to recall activities associated with Dr. Tomiyasu, his contributions to the MTT-S AdCom and his technical accomplishments as witnessed by the speakers. Dr. Tomiyasu will receive the Thomas Alva Edison Medal at the IMS 2010 Plenary Session. This special session in honor of Dr. Kiyo Tomiyasu will be recorded and CD-ROMs made available to the session attendees. [C1731]

### "Improving estimation algorithms based on field data for a hybrid energy system"

The production of green energy is a topic of great importance nowadays and of wide interest throughout the world. The system described in this paper allows an in-depth evaluation of the energetic efficiency of the green power solution proposed to power a remote location. Our goal is to study the difference between the values proposed with the aid of theoretical algorithms for energy production estimation and the field data. By studying this differences new solutions can be proposed to optimize the algorithms. [C1732]

### "The SAR/GMTI airborne radar PAMIR: Technology and performance"

PAMIR, a multifunctional SAR/GMTI imaging radar, combines the tremendous research potential of an experimental active broadband phased array system with the wide area of imaging procedures of mono- and bistatic systems. With its two different reconfigurable antenna frontend configurations operating a very high simultaneous bandwidth of 1.8 GHz in X-band, a variety of controversial requirements can be investigated and experimentally explored. The broadband beamforming together with azimuth wide scan capabilities ( $\geq \pm 45^\circ$  @ 1.8 GHz bandwidth of the antenna aperture) requires a switchable true time delay network with time increments equivalent to a fraction of a wavelength. The subarray structure including its time delay components are described. PAMIR serves as an ideal airborne platform for broadband SAR/GMTI research activities including interferometric image formation. [C1733]

### "Development of a multi-frequency airborne radar instrumentation package for ice sheet mapping and imaging"

We have developed improved versions of three different radar systems and integrated them as an airborne instrumentation suite for sounding and imaging Polar ice sheets. The first instrument consists of a multi-channel, coherent, pulsed radar operating at VHF with up to 20 MHz bandwidth. This instrument is capable of sounding a few-kilometer thick ice while flying at altitudes up to 10 km above mean sea level. The second instrument is designed to operate at UHF using a burst of narrow-bandwidth signals to digitally synthesize a bandwidth of in excess of 300 MHz. This apparatus is used to measure internal layers of the ice sheet to a depth close to 100 m. The third component to the instrumentation package is based on a frequency-modulated continuous wave (FMCW) radar, which operates at microwave (Ku band) frequencies with up to 1 GHz of instantaneous bandwidth. This radar set is used to measure the ice sheet surface elevation profile with centimeter accuracy. We are presenting a description of each system, with emphasis on the VHF depth sounder. We also present sample field test results obtained during the 2009 austral summer season in Antarctica, as a validation of the performance of the instrument package. [C1734]

### "High-phase-resolution 77-GHz-band radar module for near-field millimeter-wave imaging"

Near-field millimeter-wave (MMW) imaging is a unique approach for inspecting cracks in covered concrete surfaces to assess the deterioration of concrete structures. We have developed a 77-GHz-band radar module with in-phase and quadrature detection which is superior to measuring both of the amplitude and phase of MMW in a near-field range. A monostatic radar system is hybrid integrated into the module with a constant-width antipodal tapered slot antenna with an antenna gain of 14.5 dBi which is connected to a microstrip-line coupler with an isolation of higher than 26 dB using a leakage cancellation technique. In distance measurements in free space, the phase resolution is less than 8 degrees corresponding to the distance resolution of smaller than 0.01 mm, which is high enough to distinguish MMW signals scattered by the cracks from multiple reflection of the concrete surfaces and inside aggregates. [C1735]

### "Laser and vision based map building techniques for mobile robot navigation"

We presents some preliminary results of the ongoing research with the final goal of building an autonomous mobile robot. To achieve this scope the mapping problem is an ineluctable one. This paper presents a visual mapping system which detects the same Speeded Up Robust Features (SURF) on the stereo pair images in order to obtain three dimensional point clouds at every robot location. The algorithm tracks the displacement of the identical features viewed from different positions to get back the robots positions. The Iterative Closest Point (ICP) algorithm is used to register the obtained landmarks in the feature based map of the entire environment. Also a mapping algorithm based on the laser system is presented which can detect the dynamic objects that are present in the robots field. The results of an indoor office environment experiments are shown. [C1736]

#### "Space Registration Algorithm Based on Constrictive Total Least Squares"

The precision of space registration is generally low with the situation of a big random error in radar network. In the case of neglecting model linearization errors, this shortcoming is due to the fact that the coefficient matrix of measurement equation exists errors. This paper presents the constrictive total least squares algorithm based on the Earth-centered Earth-fixed (ECEF) coordinates, which exploits the correlation among coefficient matrix errors. Simulation results show that the method has higher registration accuracy and faster convergence speed, compared with least squares and generalized least squares algorithm. [C1737]

#### "A Parameter Estimation Method for Moving Target in Stepped Frequency Radar"

The impact of moving target on the one-dimensional coherent imaging in stepped radar is analyzed in this paper. A cross-correlation-based estimation method of radial velocity is proposed. It is proven by analytical derivation that the cross-correlation analysis on adjacent pulses yields the quantity related to the radial acceleration and velocity of moving target, based on which the radial motion parameters of targets can be precisely estimated. The simulation results demonstrate that this approach can estimate the radial acceleration and velocity with high precision at high signal-to-noise ratio, and compensate for the raw data effectively. As a result, good high-resolution one-dimensional image could be gotten. [C1738]

#### "Adaptive Threshold for Fast Signal Detection in Multi-target Tracking"

An adaptive threshold algorithm is used for frequency-shift keying (FSK) demodulation in multi-targets and radar communication system. The special algorithm is needed because of the radar burst signal in this system. The selection of the threshold is generally a tradeoff between the goals of maximizing the probability of detection while minimizing false alarm. It replies radar pulse immediately without carrier synchronization, so the threshold is calculated by the priori knowledge of the signal amplitudes. CIC filter can save resource and is used after first down-conversion, but its performance of detection is not as good as FIR filter. Simulation results show that the adaptive threshold algorithm can reduce the probabilities of miss detection and false alarm. [C1739]

#### "Visible-infrared fusion in the frame of an obstacle recognition system"

In this article we propose different fusion schemes using information provided by visible and infrared images for road obstacle SVM-based classification. Three approaches for the fusion of VIS and IR information are presented. The early fusion yields a feature vector integrating at the feature level both visual and infrared information. The obtained bimodal feature vector is used as input to an SVM-based classification scheme. The intermediate fusion, which is performed at the kernel level combines different simple kernels of the SVM classifier in order to obtain a multiple kernel (MK). The late fusion combines matching scores of individual obstacle recognition modules in order to improve the system's final decision. In this late fusion case two methods have been considered to calculate the optimum weighting parameter: an Adaptive Fusion of Scores (AFScores) and a non-Adaptive Fusion of Scores (nAFScores). Comparative results showed that fusion-based obstacle recognition systems outperform monomodal visual and infrared obstacle recognizers. An important advantage of these fusion-based systems is their possibility to adapt to the environmental illumination conditions due to the weighting parameter which can contribute to the adjustments of the system's final decision. [C1740]

#### "Application of Kalman filtering to acoustic sound diagnostic measurement"

Application of Kalman filtering theory to data processing is a well-known. Many books and articles is devoted to radar targets tracking, as classic example we introduce, as a book more different applications can by introduced. The development theory and practice continues and we would like present one possible new application. The paper deals with problems of Kalman filter application to acoustic sound diagnostic measurement. The approaches are aimed to measurement data processing. There are results of application to the real acoustic signals of car engine are presented. [C1741]

### "The possibilities of utilization of mobile pulsed radar sensors"

The risk of collision between birds and aircrafts has been known since the time when birds and aircrafts started to occupy the same airspace. The majority of bird strikes today occur at or around airports. The paper analyses a possibility of bird and other object detection in airfields using pulsed radar sensor. The paper deals with the possibilities of utilisation of mobile pulsed radar sensor. There are analyzed possibilities of small object detection by pulsed radar sensor. The results of detection possibilities of small objects and real raw digitized radar data are presented. In the paper there are derived formulas for probability of object detection focusing on small objects. There are presented some results of radar cross section analyses. The paper presents some results achieved in the project of applied research. [C1742]

### "Design of an X-band high power solid state power amplifier based on GaN HEMT"

Based on GaN HEMT's high output power, low power loss and efficient heat dissipation, an X-band, 50W solid state power amplifier is designed. Slotted-waveguide directional coupler is designed as a 2-way power divider/combiner. At last, the output power, 165W, is combined through three power combiners by four 50W solid state power amplifiers. [C1743]

### "Design and analysis of double negative binary diffractive lens"

For a compact millimeter wave imaging system it is very important to design every component into small size, for the components in a millimeter wave system are usually much larger than those in an optical imaging system due to relatively long wave lengths. In this paper, we suggest a kind of binary diffractive lens (BDL) designed using double negative materials (DNG) as the objective lens for a millimeter wave imaging system. The DNG-BDL has not only the advantage of low profile but also small f number, which will be benefit for constructing a compact millimeter wave imaging system. Several DNG-BDL are designed and analyzed using the FDTD method. The numerical results of the focal plane field of the DNG-BDL are presented, which show that the DNG-BDL with small f number has relatively better focusing characteristic than that of a double positive BDL with same f number. [C1744]

### "Quasi-optical duplexer in 220GHz"

Recently, system designers have looked toward the higher frequency, shorter wavelength (to THz), consequently the device requires smaller and more precision. Many methods in microwave band are not feasible to THz. This paper describes a duplexer (Its main components is polarizing beam splitter and polarization converter.) works in the radar system set-up at 220GHz. After simulations, the exact model size is confirmed and the calculated data show a good result. These components have an advantage is easy to machining. At last, the main components have been fabricated and tested. And the experiment results show the feasible of this duplexer. [C1745]

### "Bistatic Synthetic Aperture Radar imagery simulation of sea surface"

A bistatic Synthetic Aperture Radar (Bis-SAR) imagery simulation of an extended sea surface is presented which is based on a facet scattering model. A semi-deterministic approach is developed to calculate high frequency bistatic raw data from the model of large sea surface. An effective method of modified nonlinear chirp scaling (NLCS) algorithm is presented to handle a general case of bistatic raw data and generate the simulation imagery of sea surface. This algorithm solves the inefficient problem for some time-domain algorithms and extends the limited number of bistatic cases to general for some frequency-domain methods. The concrete models and imagery results are illustrated. [C1746]

### "Millimeter-wave integrated waveguide power dividers for power combiner and phased array applications"

In this paper, we will propose integrated power dividing/ combining networks for power combiner and phased array applications. The design procedures for a Ka-band 4-port power combining network will be presented, together with the simulated and tested results. It has a total insertion loss lower than 0.25dB and phase difference less than  $\pm 3^\circ$  in a relative bandwidth of 4% around center frequency of 35.8GHz. The isolation between any two output ports is better than 20dB. The design and tested results for a 10-port 2-layer power combining network will also be included. Finally, we will propose a 200W Ka-band power combiner based on the integrated waveguide networks. [C1747]

### "A design of stripline-coaxial vertical transition with ultra-broadband"

A vertical transition of stripline-coaxial is presented in this paper. The discontinuousness between the stripline

and coax is decreased by increasing the diameter of the coaxial inner conductor and changing the width of the stripline at the connecting location. The simulation results indicate the vswr and insertion loss are below 1.1 and 0.1dB from 1 GHz to 18 GHz, respectively. A prototype 4 ways power divider is also developed with the proposed vertical transition, whose measured vswr is below 1.3 with 40% bandwidth. And the measured insertion loss is less than 0.5 dB. The whole performance is equivalent to the horizontal transition, even better in a certain band. The rationality and practicability of this design are confirmed. [C1748]

#### **"Intermediate frequency circuit design for a 60GHz LFM CW radar"**

This paper describes an intermediate frequency (IF) circuit design in a 60 GHz linear frequency-modulated continuous-wave (LFMCW) radar system. The IF circuit includes a preamplifier stage, an auto-gain amplifier stage and an analog-to-digital (ADC) stage. Totally the IF circuit has a gain of more than 120 dB, which helps the system to have the ability of detecting target with distance of 150 m. The details of the IF circuit design are presented and the experimental results of the whole radar prototyping system are given. [C1749]

#### **"Predesign of the wind field measuring radar for FengYun-3E meteorological satellite"**

Spaceborne microwave scatterometers have successfully provided global ocean surface wind field for two decades. Ocean wind data have become as a critical tool utilized daily by operational weather forecast and warming centers around the world. However current scatterometers still can not satisfy the requirement of achieve ocean wind vectors in nearly all weather and all wind conditions. The wind field measuring radar (WIFIR) onboard Chinese FengYun-3E meteorological satellite is being developed to attempt to overcome their shortcomings. This paper describes the predesign of the WIFIR, including the mission requirements, system design, and performance analysis. [C1750]

#### **"Fast two-dimensional imaging of scattering centers using the nonuniform FFT"**

Radar imaging of target scattering centers can be of great diagnostic utility. Conventionally, the radar image has been produced by a technique widely used in computer-aided tomography (CAT), e.g. the filtered backprojection (FBP) algorithm. FBP reconstruction produces high quality images by handling the measured data directly in polar format. However, the FBP algorithm is more computationally complex than the direct Fourier methods. This paper develops fast two-dimensional (2-D) imaging of scattering centers using a nonuniform fast Fourier transform (NUFFT) algorithm. The proposed method is first compared to the conventional FBP approach on simulated data and then applied to real data sets measured on the RCS test range. Results suggest that the NUFFT method can produce more precise images and requires much less computational time than the FBP algorithm. [C1751]

#### **"An efficient technique for extracting singularity arising in RCS computation of cylindrical antenna"**

Analysis of electromagnetic scattering characteristics from wire antennas using method of moments has been performed over the past decades. In this paper, an efficient technique is adopted to evaluate the potential and reaction integrals arising in radar cross section (RCS) computation of cylindrical antenna by method of moments. The singularity of potential and reaction integrals is extracted through the semi-analytical method. The induced current on the surface and RCS of cylindrical antenna are calculated. Numerical examples are presented to illustrate the computational accuracy and efficiency of the proposed technique. [C1752]

#### **"Scattering-based I/Q signal simulation of sea clutter returns"**

A fast Slope Summation Facet Model (SSFM) that derived from the original Bass and Fuks' two scale model (BFTSM) is proposed to describe the sea scattering including both the coherent and diffused incoherent features. This kind of facet implement can readily change the average line budget of sea return locally corresponding to the facet returns, so that it can be used to find the amplitude of each scatterer. Moreover, with the help of the approximate phase extraction procedure, the coherent radar sea clutter could be readily obtained, which easily leads to the final realization on the modeling of the radar return data of I/Q signal. [C1753]

#### **"The requirement of range sidelobe for dual-frequency precipitation radar on FengYun-3 precipitation measurement satellite"**

Pulse compression as one of the key technologies for the dual-frequency precipitation radar (DPR), which will be installed on Chinese FengYun-3 (FY3) Precipitation Measurement Satellite, is being studied. Since the backscattered echo of the sea surface is much stronger than the rain echo, the surface clutter can also contaminate the rain echo through the range sidelobe. In this paper, the model of surface clutter interference with the FY3 DPR is built, and the formulations of computing sea clutter with considering the effect of range

weighting function are deduced. Based on the analysis of sea clutter, the requirements for range sidelobe level of the FY3 DPR are proposed. [C1754]

#### "A broad-band analog phase shifter design on I-Q vector modulator"

Phase shifter is widely applied in some area, including communication and radar. In the study, the principle of broadband analog phase shifter on I-Q modulating is introduced, which is validated by the theory design using Ansoft serenade. The microwave phase shifter on I-Q modulating broadband is simulated and the corresponding entity is designed. Finally, some test are done to the phase shifter, and we sum up the design experience, all those can provide some design experience with the engineers. [C1755]

#### "Research on the one-dimensional randomly gradient index coating"

The randomly gradient index coating could create diffuse reflections in front of conducting objects, which is beneficial to suppressing their scattering main lobes. In this paper, we have made some preliminary investigations on the influence of geometry parameters and distribution mode of index gradient on the scattering characteristic and diffuse reflection performance of the randomly gradient index coating. [C1756]

#### "A novel wide beam UWB antenna design for Through-the-Wall radar"

This paper presents a novel wide beam UWB antennae design for Impulse Radio-Ultra Wide Band (IR-UWB) Through-the-Wall detection radar. The design is based on a typical bowtie slot antenna structure with an added reflector in order to achieve unidirectionality and wide beam. The effects of different parameters of the added reflector on the impedance and radiation characteristics are analyzed. The different structural parameters of antenna are optimized by numerical simulations. Simulated and measured results show that the front-to-back ratio is great than 10 dB and the beam width is approximately  $120^\circ \sim 145^\circ$  within operation band for  $|S_{11}| < -10\text{dB}$  (0.8GHz~2.3GHz). [C1757]

#### "A new hybrid-frequency radar system based on compressed sensing theory"

Inspired by compressed sensing theory, a novel radar system, called hybrid-frequency radar is proposed. It transmits multiple carrier-frequency modulated by random amplitude in each pulse, and can use much fewer pulses than that of stepped-frequency radar to achieve the same non-ambiguous range interval while the target is sparse spatially. [C1758]

#### "Angle estimation for two unresolved Swerling I targets in monopulse radar"

Most methods of angular estimation for unresolved targets are based on Swerling II targets model. These methods rely upon the use of pulse-to-pulse frequency agility. In this paper we consider the case that the fluctuation of targets observed are slow, research how the RCS fluctuation of targets affects monopulse radar system and then we address a method of resolving two unresolved targets based on the statistical feature of monopulse angular estimation for slow fluctuation targets. The result of simulation demonstrates that this method is effective. [C1759]

#### "Oblique projection polarization filtering and its performance in High Frequency Surface Wave Radar"

A novel polarization filtering method based on the oblique projection operator is proposed to improve the target detection performance for High Frequency Surface Wave Radar (HFSWR) system in this paper. The performance of the proposed oblique projection polarization filter (OPPF) is detailedly analyzed in presence of additive Gaussian white noise and the desired signal's Mean Square Error (MSE) with the estimation error of the interference polarization parameter is discussed in detail. Numerical simulation results show that the proposed OPPF can enhance the target while mitigate the interference perfectly. [C1760]

#### "Design variations of HVVFET™ transistors for high-efficiency class-AB L-band power amplifiers"

HVVFET™, with its proven RF performances, such as high power gain, high peak power density and superior ruggedness, represents a major step forward in realizing compact high-power modules for ground-based and airborne radars. In this paper, the dependence of the HVVFET's RF performances on process-related parameters-including Si epilayer thickness and top-surface gold-bump thickness (Hbump)-is examined. The packaged device with a 2mil-thick bump results in a total Cgd of 0.49pF and 0.38pF at Vds=10V and 30V respectively, from which an extrinsic component (Cgd, ext) of 0.29 pF is extracted. Independently, on a 1mil-bump sample, a Cgd, ext of 0.58 pF is obtained, doubling the value of the 2mil sample. The Cgd, ext-to-

Hump proportionality suggests that  $C_{gd}$ , which predominantly arises from the parallel-plate, air-dielectric capacitor between the gate metal trace on the package and the exposed Si bulk. When operated at 1.03GHz with  $V_{dq}=36V$  in class-AB mode, the 2mil and 1mil samples exhibit an output power of 41.2W and 42.4W at 1dB compression, with a peak power gain of 20.1dB and 19.4dB, respectively. [C1761]

### "Design of a dual-feed orthogonal polarized patch antenna array"

A dual-feed orthogonal polarized patch array with high polarized isolation has been designed in this paper. A very foundational rectangular patch is adopted to be array elements which provide desirable isolation between two feeding ports for orthogonal polarizations, and desirable axis ratio for circular-polarized array. The feed network is designed as a planar structure which can be extended to construct the larger array conveniently. Two 4 × 4 arrays are designed and fabricated to investigate the isolation performance between two feeding ports for orthogonal polarizations and the axis ratio performance for circular-polarized arrays. Simulated and measured results show that desirable performance of isolation below -40 dB and bandwidth of axis ratio less than 3 dB of 6% can be achieved. [C1762]

### "Self-adaptive frequency estimation algorithm of improving liquid level measurement precision of LFMCW radar"

Based on the Fast Fourier Transform(FFT) of sine signal sampling sequence, this article proposed a self-adaptive frequency estimation method using multi-spectral line information which is near the peak of spectral map. To solve the interpolation direction error of rectangular windows Rife ratio method, combining with triangular method, the new method self-adaptively selects different methods according to the different frequency. Experimental simulation results show that the new method has high estimation accuracy and small calculation amount, and is less affected by the signal-to-noise ratio (SNR), and is suitable for real-time signal processing in the low SNR. [C1763]

### "Detection of human targets using ultra-wide band through-the-wall radar"

In this paper, an ultra-wide band (UWB) through-the-wall radar (TWR) prototype is described, and experiments are performed on detecting human targets behind wall. An adaptive background subtraction method is applied to signal processing to reduce clutter and antenna couplings. Range-time histories of an adult male person behind wall are presented for different locomotion states such as standing, marking time, and walking along cross-range direction. [C1764]

### "FM interference suppression for PRC-CW radar based on STFT and median filtering"

The influence of FM interference on correlation detection performance of the pseudo random code continuous wave (PRC-CW) radar is analyzed. It is found that the correlation output deteriorates greatly when the FM interference power exceeds the anti-jamming limitation of the radar. According to the fact that the PRC-CW radar return signal is a wideband pseudo random signal occupying the whole TF plane, whereas the FM interference signal is well concentrated in the TF plane, a new method is proposed based on STFT and median filtering for FM interference suppression. This method implements the filtering of the received signal by substituting the median filter output for only a portion of the TF plane corrupted by the interference. The echo signals corrupted by two types of interferences including linear FM (LFM) and sinusoidal FM (SFM) forms under different signal-to-jamming ratio (SJR) situations are simulated. It is shown that the method can effectively suppress the FM interference and improve the performance of target detection significantly. [C1765]

### "Azimuth variant bistatic SAR imaging algorithm based on physical optics method"

Recently, a new bistatic point target reference spectrum, which is called extended Loffeld's bistatic formula (ELBF) is proposed. The point target simulation shows that this method can work well in the general bistatic configuration. In this paper, physical optics (PO) method is introduced to calculate the echo data from three dimensional targets for bistatic SAR. Then the original LBF and ELBF are tested for the bistatic SAR imaging by using electromagnetic simulation data. Experiment results demonstrate that compared with the conventional LBF, the ELBF has better imaging quality for azimuth variant configurations. [C1766]

### "Study on measurement model for radar electromagnetic compatibility analysis"

This paper proposes a new measurement model of electromagnetic compatibility(EMC) based on the attenuation coefficient of radar maximum range. First of all, the traditional measurement model of interference measure is introduced, and its disadvantage is pointed out. Then, the measurement model of stand-off jammer(SOJ) is analyzed, the attenuation coefficient of radar maximum range is proposed, and the relationship of the attenuation

coefficient of radar maximum range ( $\mu$ ) and several main parameters of the victim radar is established. Finally, simulation results indicate that increasing range between radars and decreasing sidelobe gain can achieve better radar EMC. This model can illuminate the interference condition between radars quantitatively and objectively.

[C1767]

#### "Optimizing polyphase signals for orthogonal netted radar"

Orthogonal netted radar systems (ONRS) can fundamentally improve radar performance by using a group of specially designed orthogonal polyphase code signals. However, the existing numerical solutions only address autocorrelation and cross-correlation properties with the result that the signals degrade severely in the presence of small Doppler shifts. In the context of these problems, a new set of polyphase sequences is presented with good correlation properties as well as resilience to Doppler shifts. These sequences are built using numerical optimization based on correlation properties as well as the Doppler effect on matched filter output, which maintains Doppler tolerance. The statistical simulated annealing algorithm and the greedy code search method are used to optimize the sequences. Correlation and Doppler results are compared with best-known sequences and shown to be superior. [C1768]

#### "Variable structure multiple model particle filter for maneuvering radar target tracking"

This paper presents two methods for maneuvering radar target tracking, one is called variable structure multiple model particle filter (VSMMPF), which combines the variable structure multiple model (VSMM) filter with a Sampling-Importance Resampling (SIR) particle filter (PF); The other one is called modified adaptive grid multiple model (AGMM), which is suitable when model parameter scope is unknown beforehand. PF is used to deal with problems with arbitrary nonlinearities and non-Gaussian noise. Thus the combination of VSMM and PF is able to deal with problems of nonlinearities, non-Gaussian and maneuvering. As one of the VSMM algorithms, Grid adaptation (GA) is unique one which can produce new model-set that are not predefined and model parameter can be any value within continuous model space. However, it only used to tracking maneuvering target in 2D coordinate turn system. Our modified AGMM could track generic planar maneuvering target. Simulation results indicate that performance of the algorithm VSMMPF outperforms interacting multiple model (IMM) PF and the AGMM PF which combines AGMM with PF runs well especially when model scope is unknown in advance.

[C1769]

#### "The design of cancellation unit against radiofrequency interference in life-detection radar"

When the life-detection radar detects the human-life existence, echoes from stationary barriers are generally so strong that make the post-amplifier saturated and submerge the useful life signal. In this paper, a method of interference suppression is discussed. To restrain strong interferences, a reference signal deriving from emission signal is used to cancel the clutters. This paper designs a cancellation system using Microcontroller Unit and the amplitude and phase modulation unit to produce the reference signal. The searching algorithm is proposed to find out the best digital values that respectively control the amplitude and phase of reference signal. To improve the efficiency of algorithm in the searching process, searching procedures of phase and amplitude are discussed. Simulation results are shown in a three-dimensional diagram. [C1770]

#### "Highly integrated 79, 94, and 120-GHz SiGe radar frontends"

This paper reflects on design aspects for multichannel frequency-continuous wave (FMCW) radar frontends from conception to application on board. In the 79-GHz domain, multi-channel applications are recapitulated, and in the 94-GHz domain, a broadband transceiver is presented along with a voltage-controlled oscillator (VCO) that covers a tuning range of 12 GHz. The functionality of the 94-GHz chipset was verified by means of a four-channel multiple-input multiple-output (MIMO) radar prototype. Finally, a highly integrated 120-GHz transceiver with on-chip signal generation is presented. [C1771]

#### "Non-Air Conducted Speech Enhancement Based on Iterative Spectral Subtraction Method"

A novel non-air conducted speech detecting method has been developed in our laboratory by using millimeter wave radar technology. Because of the special attributes of the millimeter wave, this method may considerably extend the capabilities of traditional speech detecting methods. However, radar speech is substantially degraded by additive combined noises that include radar harmonic noise, electrocircuit noise, and ambient noise. This study, therefore, proposed an iterative spectral subtraction method which can be adaptive estimate noise spectrum at every iteration time, and reduce the musical noise remained in the previous spectral subtraction process. Results from simulations as well as evaluations confirm that enhanced non-air conducted speech is more pleasant to listeners than speech produced by traditional spectral subtraction algorithms. This suggests that the proposed method satisfactorily reduces whole-frequency and musical noises and produces good speech

quality. [C1772]

### "Advanced system level simulation of UWB three-dimensional through-wall imaging radar for performance limitation prediction"

A system level framework has been developed to simulate the UWB three-dimensional through-wall radar system and accurately predict its performance limitations. Only through a novel simulation model where Agilent ADS Ptolemy simulation is used combined with its Matlab co-simulation, is it possible to accurately simulate the UWB radar system. The developed simulation model has been validated experimentally using our UWB radar prototype. The system model can be easily extended to other UWB radar systems by simply changing the input pulse shape, UWB channel environment, wall characteristics, transceiver topology, etc. Various effects such as signal quality, pulse shape, wall characteristics can be easily investigated and re-optimized for high performance 3-D imaging using our developed model. [C1773]

### "Fast response Retrodirective Radar"

This paper shows the ability of an all analogue Retrodirective Radar, the first of its type, to provide continuous surveillance and near instantaneous target acquisition while automatically beam steering in real time onto a target which is presented to it. Assessment of the phase conjugation unit shows that the Radar is capable of operating either in CW or in pulsed mode. Test results are presented which show that Retrodirective tracking of targets travelling at speeds in excess of 780 m/s is possible. To confirm tracking ability bistatic results of a small near field target are presented, and the capability is also shown to extract the position of the near field target with only very simple calculations, with no DSP circuitry required. [C1774]

### "Towards high-performance 100 GHz SiGe and CMOS circuits"

This paper presents SiGe and CMOS circuits with 100 GHz operation. The goal is to show that SiGe can be used for imaging systems due to its low  $1/f$  noise properties. A W-band SiGe imaging chip is presented with performance which is nearly as good as the best InP chips. Another goal is to show that deep-scaled CMOS can result in high performance amplifiers, detectors, and doublers at 90-110 GHz and at 180-220 GHz. The applications areas are in high data-rate communications, 100 GHz automotive radars (140 and 220 GHz) and mm-wave imaging systems. [C1775]

### "Session-WE1"

{no data available} [C1776]

### "High isolation lange-ferrite circulators with NF suppression for simultaneous transmit and receive"

This paper presents a new type of circulator that consists of three Lange couplers and two ferrite circulators for broadband, high isolation, transmit noise suppression and simultaneous transmit and receive (STAR). The operation principal of the circulator is based on quadrature phase cancellation and combination techniques. Preliminary results show that the isolation between the transmit and receive port is 24 dB in frequency range of 5-12 GHz without optimization and 60 dB isolation with 800 MHz bandwidth with optimization. The NF data at the receive port show significant suppression of transmit noise for Gain-NF product that exceeds 21 dB. [C1777]

### "Development of a multi-frequency airborne radar instrumentation package for ice sheet mapping and imaging"

We have developed improved versions of three different radar systems and integrated them as an airborne instrumentation suite for sounding and imaging Polar ice sheets. The first instrument is a multi-channel, coherent pulsed chirp radar operating at VHF with up to 30 MHz bandwidth. This radar set is capable of sounding a few-kilometer thick ice while flying at altitudes up to 10 km above mean sea level. The second instrument is designed to operate at UHF using a burst of narrow-bandwidth signals to digitally synthesize a bandwidth in excess of 300 MHz. This apparatus is used to measure internal layers of the ice sheet to a depth close to 100 m. The third component to the instrumentation package is a microwave frequency-modulated continuous wave (FMCW) radar, which is used to measure the ice sheet surface elevation profile with centimeter accuracy. We are presenting a description of each system along with field test results that validate the performance of the instrument package. [C1778]

### "System of locating and recognizing characters in complex background"

In this paper we propose a locating and recognizing character method in complex background, a system based

on this method is built. First, through color reduction to reduce the color to some main colors, then decompose the image into a series of binary images according to the representative colors. After the image decomposition, connected component analysis and combination of character area are used to locate the character area. Finally, the characters are recognized on the basis of feature extraction. The experimental results show that the method can quickly locate character area and has a high positioning accuracy; therefore, the final recognition rate is high. [C1779]

#### "A fast clutter cancellation method in quadrature doppler radar for noncontact vital signal detection"

A fast clutter cancellation technique is proposed for quadrature Doppler radar to robustly detect the vital signals when clutters enter the test environment. The dc offset at baseband varies with the change of test environment, dramatically reducing the accuracy of vital signal detection. To solve this problem, a clutter cancellation generator is employed in the radar receiver. Based on the detected dc offset values in I and Q channels, the generator produces an output signal, anti-phase to the received clutter signal, such that the clutter signal is cancelled at RF frontend. Therefore the time-varying dc offset at baseband is eliminated. The clutter cancellation method is described and the experiment was conducted to demonstrate the proposed method. [C1780]

#### "A highly integrated heterogeneous micro- and mm-wave platform"

A highly integrated platform for micro- and mm-wave frequency applications is introduced. The platform utilizes heterogeneous process modules with integrated passive and tunable devices together with silicon and GaAs MMIC technology to achieve outstanding flexibility. The different process modules are accounted for and their feasibility is proven through a number of application demonstrators from 23 GHz telecom backhauling and 77 GHz automotive radar indicating excellent performance. [C1781]

#### "Calibration of a Digital phased Array for polarimetric Radar"

When an active phased array is used for polarimetric radar applications, the system must be calibrated to reflect the fact that polarization of the transmitted and received fields is dependent on the scan angle. This paper discusses the challenges of polarimetric phased array calibration, and demonstrates these techniques using a linear array of eight S-band dual-polarized antennas connected to an active Digital Array Radar (DAR) pro-totype system. The ability to accurately measure polarimetric scattering matrices is demonstrated after using direct far-field measurements to compensate for polarization errors on receive and target reflection measurements to compensate for transmit polarization errors. [C1782]

#### "A fast clutter cancellation method in quadrature doppler radar for noncontact vital signal detection"

A fast clutter cancellation technique is proposed for quadrature Doppler radar to robustly detect the vital signals when clutters enter the test environment. The dc offset at baseband varies with the change of test environment, dramatically reducing the accuracy of vital signal detection. To solve this problem, a clutter cancellation generator is employed in the radar receiver. Based on the detected dc offset values in I and Q channels, the generator produces an output signal, anti-phase to the received clutter signal, such that the clutter signal is cancelled at RF frontend. Therefore the time-varying dc offset at baseband is eliminated. The clutter cancellation method is described and the experiment was conducted to demonstrate the proposed method. [C1783]

#### "Design and implementation of the low-power tracking system based on GPS-GPRS module"

The purpose of the research proposed in this paper is to develop a Low-Power Tracking System, which can meet the special needs of the security of a mobile device. The system contains two parts: the GPS terminal in the module receives the locating information of the tracked device, and the control center. This paper discusses both hardware and software design of the tracking system. In the end, the future research of the positioning and tracking system is discussed. [C1784]

#### "Highly integrated 79, 94, and 120-GHz SiGe radar frontends"

This paper reflects on design aspects for multi-channel frequency-continuous (FMCW) wave radar frontends from conception to application on board. In the 79-GHz domain, multi-channel applications are recapitulated, and in the 94-GHz domain, a broadband transceiver is presented along with a voltage-controlled oscillator (VCO) that covers a tuning range of 12 GHz. The functionality of the 94-GHz chipset was verified by means of a four-channel multiple-input multiple-output (MIMO) radar prototype. Finally, a highly integrated 120-GHz transceiver with on-chip signal generation is presented. [C1785]

### "Cable imaging with an active W-band millimeter-wave sensor"

A system that can detect wires and cables suspended in the air and give fair warning of such obstacles on approach is highly desirable for both commercial and military helicopter pilots alike, given the recent increase in wire strike accidents. This paper discusses the recent development of a flight capable active millimeter-wave imaging system as a candidate and potential solution for such a system. The development methodology and flight test results presented validate the functionality of this flight system as a useful development platform for advanced system concept applications even beyond cable detection and imaging. [C1786]

### "Narrowband frequency scanning array antenna at 5.8 GHz for short range imaging"

We present a frequency scanning array antenna for radar applications. A high angular range is obtained while requiring only a small frequency band. This is achieved by using a band-pass filter feed structure that increases the frequency-dependent phase difference between the individual array elements. An angular range of  $\pm 50$  degrees is obtained while using only 150 MHz bandwidth with 5.8 GHz center frequency corresponding to the ISM Band. This antenna type can be applied for detecting covered objects or for short range imaging. [C1787]

### "Cable imaging with an active W-band millimeter-wave sensor"

A system that can detect wires and cables suspended in the air and give fair warning of such obstacles on approach is highly desirable for both commercial and military helicopter pilots alike, given the recent increase in wire strike accidents. This paper discusses the recent development of a flight capable active millimeter-wave imaging system as a candidate and potential solution for such a system. The development methodology and flight test results presented validate the functionality of this flight system as a useful development platform for advanced system concept applications even beyond cable detection and imaging. [C1788]

### "THz for space: The golden age"

Over the past three decades interest in the unique spectral measurements offered by terahertz instruments operating outside the Earth's atmosphere has grown enormously. Since the historic flight of Cosmos 669 in 1974, and the first THz telescope with cryo-cooled detectors operated on board Salyut 6 in 1978, satellite instruments have performed both direct detection and heterodyne spectroscopy measurements in the interstellar medium, in external galaxies, in the atmospheres of planets and comets and in the Earth's stratosphere. Seventeen orbital instruments containing THz sensors or sources have either completed their mission objectives or are currently operational. They originate in Russia, Japan, Europe and the US and cover applications in astrophysics and cosmology; planetary and small solar system body science; and pollution, ozone and climate monitoring on the Earth. At least a dozen serious future mission proposals are under consideration, including new areas of meteorology, terrestrial planet finding and planetary radar spectroscopy. It is truly a golden age for THz space science and applications. This talk will review past, present and future space instruments carrying infrared, millimeter wave and terahertz components and their science objectives. [C1789]

### "Interferometric detection of the angular velocity of moving objects"

This paper presents a new method of detecting the angular velocity of moving objects using passive interferometry. The new technique is presented using a millimeter-wave correlation interferometer to measure the angular velocity of a moving target directly, without the need for multiple looks. As the object passes through the interferometer beam pattern the frequency of the signal output is dependent on the angular velocity of the object, and a simple time-frequency analysis visually displays the angular velocity of the target. The basic theory is presented and experimental results showing the detection of a walking person are presented. [C1790]

### "Time-domain calibration technique for ultra-wide instantaneous-bandwidth vector waveform generation using parallel I/Q channels"

An architecture for generating ultra-wide instantaneous-bandwidth vector waveforms by combining the spectra of multiple I/Q sub-channels is described. Each sub-channel consists of an I/Q modulator driven by a pair of digital-to-analog converters. A time-domain calibration technique is described that uses the measured channel response to equalize the sub-channels. The overall response of the combined system is realized by properly controlling the phases of the corrected I/Q sub-channels. Examples of wideband vector waveforms generated using the combined system will be given. [C1791]

### "A heterodyne receiver for harmonic doppler radar cardio-pulmonary monitoring with body-worn passive RF tags"

Summary form only given. Harmonic Doppler radar can be used to isolate a subject's respiratory motion from environmental clutter. In this paper, a heterodyne receiver is used to detect tag motion and human cardiopulmonary activity, with the results compared with a that using a homodyne receiver. The heterodyne system is shown to work at a greater distance from the subject (more than 160 cm) with greater sensitivity to tag motion (more than 10 dB), using the same transmitted power (10 dBm). Both homodyne and heterodyne receivers are also used to successfully detect a human heartbeat by attaching a passive harmonic tag over a subject's chest. [C1792]

### "Environmental Monitoring System Based on GIS and Wireless Communications"

To solve the problems in environmental monitoring arising from remote data acquisition, real-time transmission and analysis, this paper researched the principle of wireless communications SMS / GPRS and the technology of seamless integration with GIS. The system architecture was designed and key technical solutions were implemented. Based on the SMS / GPRS technology, the wireless real-time transmission of the remote monitoring data was achieved, and GIS visualization technology was carried out to visualize the monitoring data. Geographic affected areas were analyzed by GIS spatial analysis. The system is applicable to the environmental protection departments to realize applications such as monitor data acquisition, communication transmission, GIS management and analysis and decision-making. [C1793]

### "Session-TH3"

{no data available} [C1794]

### "Second generation transceivers for D-band radar and data communication applications"

A single chip, dual-functionality radio and FMCW radar transceiver, operating at 140 GHz is described. Doppler, loop-back and 4Gb/s NLOS radio link demos, over the air and distances exceeding one meter, are demonstrated. The second part of the paper presents novel, sub-1.8 V circuit topologies intended for a low power, high resolution 120 GHz radar transceiver with self-calibration capabilities. The measured receiver noise figure, gain and phase noise are 7.5 dB, 20 dB and -100 dBc/Hz@1MHz offset respectively. [C1795]

### "Towards high-performance > 100 GHz SiGe and CMOS circuits"

This paper presents SiGe and CMOS circuits with > 100 GHz operation. The goal is to show that SiGe can be used for imaging systems due to its low  $1/f$  noise properties. A W-band SiGe imaging chip is presented with performance which is nearly as good as the best InP chips. Another goal is to show that deep-scaled CMOS can result in high performance amplifiers, detectors, and doublers at 90-110 GHz and at 180-220 GHz. The applications areas are in high data-rate communications, > 100 GHz automotive radars (140 and 220 GHz) and mm-wave imaging systems. [C1796]

### "Analog type millimeter wave phase shifters based on MEMS tunable high-impedance surface in rectangular metal waveguide"

Possibility of compact low loss analog type millimeter wave phase shifter was demonstrated. The phase shifter is controlled by a MEMS tunable high-impedance surface placed, e.g., as a backshort or as sidewall inclusions of a rectangular metal waveguide. Reflection type phase shifter can provide differential analog phase shift from  $0^\circ$  to up to  $240^\circ$ . Reliable and tunable MEMS based high-impedance surface has been demonstrated for the first time. The insertion loss of the fabricated MEMS tunable high-impedance surface varies from 0.7 dB to a maximum of 3.5 dB (at a resonance frequency), which is a dramatic improvement over our previous non-tunable prototype. [C1797]

### "Piggyback modulation for UHF RFID sensors"

We introduce the technique of "piggybacking" sensor data onto existing commercial passive UHF RFID tags. Sensor data fed into a PIN diode modulator is coupled onto the tag and transmitted along with the tag ID via backscatter. The radar cross section (RCS) of the tag antenna is a function of the input impedance of the tag ASIC, coupling S-parameters, and the input impedance of the PIN diode modulator. Both analog and digital sensor signals coexisting with identification data are presented. [C1798]

### "THz electronics projects at DARPA: Transistors, TMICs, and amplifiers"

Revolutionary THz transmitter and receiver demonstrations are the ongoing focus of a portfolio of programs within the DARPA. Through the sponsorship of the Terahertz Electronics and related programs, a technology

base is being established to effectively generate, detect, process, and radiate sub-MMW frequencies to exploit this practically inaccessible frequency domain for imaging, radar, spectroscopy, and communications applications. Transistors, integration technologies, power amplification, and their precision metrology are the key elements under active investigation. THz InP transistors have been achieved that have enabled the world's fastest 0.48 THz monolithic integrated circuits. Compact THz high power amplifiers using micro-machined vacuum electronic devices will enable radiation sources at 1.03 THz with 15 GHz of instantaneous bandwidth. Ultimately, low-loss interconnects and integration techniques will couple TMICs with HPAs to enable THz coherent heterodyne transceivers. [C1799]

#### "Session-Wednesday-detail"

{no data available} [C1800]

#### "A light weight 8-element broadband phased array receiver on Liquid Crystal Polymer"

In this paper we present a light weight broadband phased array hybrid receiver module on a multi-layer Liquid Crystal Polymer (LCP) substrate. The phased array module has 8 channels and is designed to operate in the Ka-band, from 32-37 GHz. A broadband linear tapered slot antenna array with a corporate power combiner, chip-on-board MMICs, and all control chips necessary for beam steering are all integrated on a multi-layered near-hermetic LCP substrate. The phased array antenna has a measured bandwidth of 5 GHz with  $\pm 30^\circ$  beam steering capability from boresight, and shows less than  $6.75^\circ$  of beam squint across the full bandwidth of operation. The total size of the array is 100 mm  $\times$  100 mm with a board thickness of only 16 mils and weighs only 12.3 grams. [C1801]

#### "Spaceborne SAR Systems and technologies"

With the launch and operation of Europe's first remote sensing satellite ERS-1 in the 90's, the usefulness and need of spaceborne SAR Systems has become obvious. Meanwhile, affordable 'state of the art' technology in modern active phase array antennas has drastically improved the SAR system agility and its image performance, such that also commercial and military application is of highest interest. [C1802]

#### "A heterodyne receiver for Harmonic Doppler radar cardiopulmonary monitoring with body-worn passive RF tags"

Harmonic Doppler radar can be used to isolate a subject's respiratory motion from environmental clutter. In this paper, a heterodyne receiver is used to detect tag motion and human cardiopulmonary activity, with the results compared with a that using a homodyne receiver. The heterodyne system is shown to work at a greater distance from the subject (more than 160 cm) with greater sensitivity to tag motion (more than 10 dB), using the same transmitted power (10 dBm). Both homodyne and heterodyne receivers are also used to successfully detect a human heartbeat by attaching a passive harmonic tag over a subject's chest. [C1803]

#### "Waveguide transition to feed a fully PCB integrated dielectric rod antenna"

A microstrip line-to-circular waveguide transition is described which operates at a nominal design frequency of 77 GHz. In order to improve the transmission characteristics, an additional periodically structured shield is used. The transition is capable of exciting a dielectric rod antenna, thus enabling the realization of radar modules on a PCB substrate with a dielectric rod antenna interface. [C1804]

#### "Sidelobe level reduction in wide-angle scanning array system using pattern-reconfigurable antennas"

A technique aimed at peak sidelobe level (SLL) reduction for wide-angle scanning arrays is presented in this work, based on the use of a newly designed pattern-reconfigurable antenna (PRA). The proposed antenna consists of a monopole antenna and two parasitic strips, where each strip can be reconfigured into either a reflector or a director via PIN diode switches, leading to the beam deflection. A 2.45 GHz PRA was implemented and the measured results demonstrate three reconfigurable patterns, radiating toward two end-fire and one broadside directions, respectively. When this PRA is used in a 14 linear array, the SLL is -7.5 dB at end-fire directions and -11.8 dB at broadside. The SLL at end-fire is 7.4 dB enhancement compared to the linear array with the conventional monopole. The design principle was discussed and a Butler-matrix-fed linear array with four PRAs was implemented for demonstration. [C1805]

#### "FS-5, paper 5: Earth observation instruments with e-scan antennas state-of-the-art and outlook"

Spaceborne radars with electronically scanned antennas are in use on European satellites since the launch of Envisat in March 2002. Despite the higher complexity and consequently cost, electronically scanned antennas are more and more attractive for spaceborne radar. The return materialises either in significantly better system performance or in newly gained system feasibility. The paper will discuss firstly state-of-the-art phased array technology as used for the European Sentinel-1 C-band SAR and explore secondly the capabilities of full digital beam forming implementation for the next generation of SAR systems. Thirdly phased arrays as a feasibility prerequisite in quasi bistatic radar for future ocean altimetry, exploiting GNSS signals will be discussed. Lastly reflector based e-scan antennas will be discussed which form a good compromise between complexity and flexibility as needed for SAR systems requiring high gain antennas. A potential application in Ka-band SAR will be presented. [C1806]

#### "THz Electronics projects at DARPA: Transistors, TMICs, and amplifiers"

Revolutionary THz transmitter and receiver demonstrations are the ongoing focus of a portfolio of programs within the DARPA. Through the sponsorship of the Terahertz Electronics and related programs, a technology base is being established to effectively generate, detect, process, and radiate sub-MMW frequencies to exploit this practically inaccessible frequency domain for imaging, radar, spectroscopy, and communications applications. Transistors, integration technologies, power amplification, and their precision metrology are the key elements under active investigation. THz InP transistors have been achieved that have enabled the world's fastest 0.48 THz monolithic integrated circuits. Compact THz high power amplifiers using micro-machined vacuum electronic devices will enable radiation sources at 1.03 THz with 15 GHz of instantaneous bandwidth. Ultimately, low-loss interconnects and integration techniques will couple TMICs with HPAs to enable THz coherent heterodyne transceivers. [C1807]

#### "2D transformation optics using anisotropic transmission-line metamaterials"

In this contribution we propose a two-dimensional metamaterial unit cell which synthesizes equivalent material parameters needed for 'transformation optics', as introduced in. The proposed metamaterial consists of a grid of reactively loaded transmission-line segments and is a variation of the unit cell presented in, synthesizing also the required off-diagonal elements of the permeability tensor. The application of cloaking of the 'transformation optics' approach is taken as a test case for the novel metamaterial. The cloak we present is different from the structure presented in in that it synthesizes not only  $\mu$  and  $\epsilon$  but also  $\mu$ . [C1808]

#### "UWB array antenna utilizing novel electrical scanning system with tapped delay lines"

In this paper, we present a newly developed UWB array antenna adopting a novel electrical scanning system. This antenna was realized by introducing two new technologies. First, each antenna element is equipped with an impulse generator. Second, the phase control between the antenna elements is realized by tapped delay lines and transmitting trigger signals. An experimental UWB array antenna with 16 elements has been designed and fabricated. The measurement results showed excellent performance of the antenna. Thus, it is expected that this UWB antenna system will contribute to performance improvement, compact size and cost reduction of UWB radar systems such as obstacle detectors and anticollision sensors. Index Terms-UWB radar, array antenna, electrical scanning antenna, beam steering, phased array, delay line. [C1809]

#### "Narrowband frequency scanning array antenna at 5.8 GHz for short range imaging"

We present a frequency scanning array antenna for radar applications. A high angular range is obtained while requiring only a small frequency band. This is achieved by using a band-pass filter feed structure that increases the frequency-dependent phase difference between the individual array elements. An angular range of  $\pm 50$  degrees is obtained while using only 150 MHz bandwidth with 5.8 GHz center frequency corresponding to the ISM Band. This antenna type can be applied for detecting covered objects or for short range imaging. [C1810]

#### "Second generation transceivers for d-band radar and data communication applications"

A single chip, dual-functionality radio and FMCW radar transceiver, operating at 140 GHz is described. Doppler, loop-back, and 4Gb/s NLOS radio link demos, over the air and at distances exceeding one meter, are demonstrated. The second part of the paper presents novel, sub-1.8 V circuit topologies intended for a low power, high resolution 120 GHz radar transceiver with self-calibration capabilities. The measured receiver noise figure, gain, and phase noise are 7.5 dB, 20 dB, and -100 dBc/Hz@1MHz offset, respectively. [C1811]

#### "Calibration of a digital phased array for polarimetric radar"

When an active phased array is used for polarimetric radar applications, the system must be calibrated to reflect

the fact that polarization of the transmitted and received fields is dependent on the scan angle. This paper discusses the challenges of polarimetric phased array calibration, and demonstrates these techniques using a linear array of eight S-band dual-polarized antennas connected to an active Digital Array Radar (DAR) prototype system. The ability to accurately measure polarimetric scattering matrices is demonstrated after using direct far-field measurements to compensate for polarization errors on receive and target reflection measurements to compensate for transmit polarization errors. [C1812]

#### "Commercial manufacturing practices applied to phased array radars"

Transmit/Receive Modules for Phased Array Radar are often identified as a key cost driver for the system. The cost structure of the module is driven by both the performance specifications and the choices made in design and manufacturing of the module. Seeking a path to dramatically lower the cost of T/R modules for phased array systems, commercial processes and practices have been adopted for the MMIC design, MMIC packaging and module construction. These new manufacturing approaches offer a path to cost reduction while maintaining a high level of performance. [C1813]

#### "The SAR/GMTI airborne radar PAMIR: Technology and performance"

PAMIR, a multifunctional SAR/GMTI imaging radar, combines the tremendous research potential of an experimental active broadband phased array system with the wide area of imaging procedures of mono- and bistatic systems. With its two different reconfigurable antenna frontend configurations operating a very high simultaneous bandwidth of 1.8 GHz in X-band, a variety of controversial requirements can be investigated and experimentally explored. The broadband beamforming together with azimuth wide scan capabilities ( $\pm 45^\circ$  @ 1.8 GHz bandwidth of the antenna aperture) requires a switchable true time delay network with time increments equivalent to a fraction of a wavelength. The subarray structure including its time delay components are described. PAMIR serves as an ideal airborne platform for broadband SAR/GMTI research activities including interferometric image formation. [C1814]

#### "A highly integrated heterogeneous micro- and mm-wave platform"

A highly integrated platform for micro- and mm-wave frequency applications is introduced. The platform utilizes heterogeneous process modules with integrated passive and tunable devices together with silicon and GaAs MMIC technology to achieve outstanding flexibility. The different process modules are accounted for and their feasibility is proven through a number of application demonstrators from 23 GHz telecom backhauling and 77 GHz automotive radar indicating excellent performance. [C1815]

#### "Recent Microwave Nondestructive Measurement in Biomedical Engineering"

Recent microwave nondestructive measurement in biomedical engineering are reviewed. A novel method for non-contact monitoring of stress-induced autonomic activation through the back of a chair is developed, using a compact 24 GHz microwave radar (8 4 5 4 3 cm), without large scale equipment and placing a heavy burden on the monitored individual. This method appears to be promising for future monitoring of stress induced autonomic activation of operators and may reduce stress induced accidents. A novel in vitro test of blood analysis based on the measurement of the dielectric properties at microwave frequencies is reported. The measurements were made using rectangular cavity perturbation technique at the S-band of microwave frequency with the different samples of blood obtained from healthy donors as well as from patients. The measurements are in good agreement with clinical analysis. Novel planar type probes were developed to demonstrate the possibility of replacing the existing high cost open-ended coaxial probes. Three probes are developed. The measurement results of each probe showed excellent compatibility with those of the open-ended coaxial probe up to almost 40 GHz. The proposed planar type probes have great potentials for practical medical applications in view of low cost, disposability, and monolithic integration capability with the driving circuits. Finally the technical challenges of microwave nondestructive measurement in biomedical engineering are discussed. [C1816]

#### "Status and trends in AESA-based radar"

Radar technology, predominantly in the area of defence applications, is in a continuous process of extending its present capabilities. Especially Active Electronically Scanned Array (AESA) radars, with their unprecedented degree of operational flexibility, are currently about to revolutionise the performance of air- and spaceborne, naval and ground radars. The current status of AESA radar and the trends in system and technology advances are discussed. Trends on system level will be the use of MIMO-architectures and shared antenna apertures. [C1817]

### "Advanced system level simulation of UWB three-dimensional through-wall imaging radar for performance limitation prediction"

A system level framework has been developed to simulate the UWB three-dimensional through-wall radar system and accurately predict its performance limitations. Only through a novel simulation model where Agilent ADS Ptolemy simulation is used combined with its Matlab co-simulation, is it possible to accurately simulate the UWB radar system. The developed simulation model has been validated experimentally using our UWB radar prototype. The system model can be easily extended to other UWB radar systems by simply changing the input pulse shape, UWB channel environment, wall characteristics, transceiver topology, etc. Various effects such as signal quality, pulse shape, wall characteristics can be easily investigated and re-optimized for high performance 3-D imaging using our developed model. [C1818]

### "The new generation of European E-scan fighter radars"

Two European programmes towards an airborne E-scan radar have obtained major attention: AMSAR, a generic demonstrator for developing the technology required for an AESA radar and for proving its operational capabilities, and CAESAR that paves the way to the next generation of radar for Eurofighter. Future sub-array AESA architectures and multi-channel receivers will enable efficient jammer suppression by use of Adaptive Beam Forming. The technology basis of T/R-Modules will move to Gallium-Nitride, promising improvements in efficiency, output power and miniaturisation. [C1819]

### "Spaceborne SAR systems and technologies"

Design and development of Spaceborne Synthetic Aperture Radar Systems is one of the major activities at EADS Astrium, Friedrichshafen, Germany. Examples of recent and current developments are the TerraSAR-X and the TanDEM-X Satellites, both operating at X-band with multi-polarization capability. At C-Band, the Sentinel-1 SAR Instrument is a further example for active phased array radar currently under development in our company. In addition to the design and manufacturing of 'state of the art' active phased array SAR sensors, new techniques and technologies are under preparation. The overall objective is to upgrade significantly the image performance, to enlarge the capabilities of spaceborne SAR and to improve the performance to cost ratio. For this, digital beamforming is a key element. [C1820]

### "Fast response Retrodirective Radar"

This paper shows the ability of an all analogue Retrodirective Radar, the first of its type, to provide continuous surveillance and near instantaneous target acquisition while automatically beam steering in real time onto a target which is presented to it. Assessment of the phase conjugation unit shows that the Radar is capable of operating either in CW or in pulsed mode. Test results are presented which show that Retrodirective tracking of targets travelling at speeds in excess of 780 m/s is possible. To confirm tracking ability bistatic results of a small near field target are presented, and the capability is also shown to extract the position of the near field target with only very simple calculations, with no DSP circuitry required. [C1821]

### "GaN technology for microwave and millimeter wave applications"

After many years of development to improve the material and devices, GaN technology is now in production and poised to revolutionize many of today's Radar and Communication systems. In this paper we present an overview of GaN development, focusing on reliability, affordability, and defense applications. [C1822]

### "Advanced architecture for a low cost Multifunction Phased Array Radar"

MIT Lincoln Laboratory and M/A-COM are jointly conducting a technology demonstration of affordable Multifunction Phased Array Radar (MPAR) technology for Next Generation air traffic control and national weather surveillance services. Aggressive cost and performance goals have been established for the system. The array architecture and its realization using custom Transmit and Receive Integrated Circuits and a panel-based Line Replaceable Unit (LRU) will be presented. A program plan for risk reduction and system demonstration will be outlined. [C1823]

### "The new generation of European E-scan fighter radars"

Two European programmes towards an airborne E-scan radar have obtained major attention: AMSAR, a generic demonstrator for developing the technology required for an AESA radar and for proving its operational capabilities, and CAESAR that paves the way to the next generation of radar for Eurofighter. Future sub-array AESA architectures and multi-channel receivers will enable efficient jammer suppression by use of Adaptive

Beam Forming. The technology basis of T/R-Modules will move to Gallium- Nitride, promising improvements in efficiency, output power and miniaturisation. [C1824]

#### "UWB array antenna utilizing novel electrical scanning system with tapped delay lines"

In this paper, we present a newly developed UWB array antenna adopting a novel electrical scanning system. This antenna was realized by introducing two new technologies. First, each antenna element is equipped with an impulse generator. Second, the phase control between the antenna elements is realized by tapped lines and transmitting trigger signals. An experimental UWB array antenna with 16 elements has been designed and fabricated. The measurement results showed excellent performance of the antenna. Thus, it is expected that this UWB antenna system will contribute to performance improvement, compact size and cost reduction of UWB radar systems such as obstacle detectors and anticollision sensors. [C1825]

#### "Status and trends in AESA-based radar"

Radar technology, predominantly in the area of defence applications, is in a continuous process of extending its present capabilities. Especially Active Electronically Scanned Array (AESA) radars, with their unprecedented degree of operational flexibility, are currently about to revolutionise the performance of air- and spaceborne, naval and ground radars. The current status of AESA radar and the trends in system and technology advances are discussed. Trends on system level will be the use of MIMO-architectures and shared antenna apertures. [C1826]

#### "An Improved Peak Extraction Algorithm in PHD Based Multi-Target Tracking Algorithm Applied to Passive Radar"

To extract the target location correctly in PHD based multi-target tracking algorithm, an improved peak extraction algorithm was proposed. This new algorithm stemmed from the CLEAN technique in radar signal processing. By finding the highest peak in every iteration, the assumed target was extracted and its corresponding location information was obtained. Simulation results prove the efficiency and correctness of this new algorithm. [C1827]

#### "Ice sheet anisotropy measured with polarimetric ice sounding radar"

For polar ice sheets, valuable stress and strain information can be deduced from crystal orientation fabrics (COF) and their prevailing c-axis alignment. Polarimetric radio echo sounding is a promising technique to measure the anisotropic electromagnetic propagation and reflection properties associated with COFs. In this paper, fully polarimetric P-band data acquired with the airborne POLARIS system near the ice divide of the Greenland ice sheet are analyzed. Based on a simple electromagnetic model, these data are interpreted, and a pronounced birefringence is found. [C1828]

#### "Passive infrared localization with a Probability Hypothesis Density filter"

In passive infrared localization (PIL) humans are located based on their thermal radiation. Thus, an active tag is not required and privacy is guaranteed due to non-identifying sensors. However, in case of multi-target tracking, the non-identifying sensors result in missing associations between targets and measurements. As additionally the number of humans in the surveillance region is unknown and varying, conventional localization approaches like the JPDA or MHT filter cannot be applied since they require a fixed number of targets or are not tractable. The Probability Hypothesis Density (PHD) filter, on the other hand, that propagates only the first order moment of the multitarget probability distribution offers an efficient and elegant way to handle the aspects of missing association and varying target number. Furthermore, false measurements as well as missed detection are considered implicitly. In this paper we present an implementation of this filter for PIL that allows an accurate and reliable tracking of several humans. The accuracy and reliability are evaluated under the influence of noise. Thus, several simulations and real measurements are carried out that reveal a mean error of less than 30 cm in case of three humans. Moreover, efficiency tests show that on standard PCs update rates of more than 50 Hz are achievable. [C1829]

#### "A tracking algorithm for GNSS reflected signals on sea surface"

The observation of the ocean surface using electromagnetic sources of opportunity (GNSS signals for instance) has been a green research topic for several years. The Global Navigation Satellite System (GNSS) presents a powerful and useful technology for remote sensing, ocean surface monitoring and oceanography. Many experiments have been conducted to show the efficiency of the Global Positioning System (GPS) in applications such as ocean surface altimetry, wave height, surface current measurements, and current direction estimation

[1]. Considering the GPS link as a passive sensor for ocean monitoring, we study in this paper the possibility of tracking GPS signal reflection footprints on the sea surface to improve the acquisition and the extraction of this signal. As an analogy to the classical problem of moving targets Radar tracking, we develop a tracking algorithm based on Kalman filtering. [C1830]

#### "An integrated approach to determine parameters of a 3D volcano model by using InSAR data with metamodel technique"

In this paper, an integrated approach is presented to determine the suitable parameters of a magma-filled dyke, which causes observable deformation at the ground surface. By this approach, the finite element method (FEM) and metamodel techniques are combined. FEM is used to establish the numerical model of the dyke and to produce the data required to identify metamodel parameters. Parameter identification problems are also known as parameter estimation or inverse problems. The metamodel technique is employed to make the whole procedure efficient in the identification phase. The identification approach is carried out by a systematic routine based on particle swarm optimization (PSO) algorithm. The approach is tested with synthetic data generated by analytic models. Moreover, it has been also applied to Stromboli Volcano (Italy) as an example, and the ground deformation data is acquired by using interferometry SAR technique. With the approach, the parameters can be successfully estimated with acceptable degree of accuracy. The results also indicate that only one kind of geophysical data are not sufficient for solving such a complex problem. [C1831]

#### "A CHMT model based DE-speckling method for SAR image"

A coarse-classification based tying method for the Contourlet-domain Hidden Markov Tree model (CHMT) solution algorithm is proposed to speed up the parameters estimation; and a general SAR image filtering framework, to which any kind of shift-variant transform can be applied, is generated by applying together with the LOG Transform, mean rectification and cycle-spinning, etc. The proposed coarse classification based tying method for CHMT is applied to de-speckle the SAR image in the general framework, and the result is compared with those of some commonly-used filters. The visual effects and the statistical parameters indicate that the coarse-classification based tying method for CHMT is much faster than the other tying methods, and the CHMT based de-speckle method can achieve better result than some commonly-used filters. [C1832]

#### "Roll invariant target detection based on PolSAR clutter models"

Based on the Kennaugh-Huynen decomposition, the Target Scattering Vector Model (TSVM) allows to extract four roll-invariant parameters. Those parameters are necessary for an unambiguous description of the target scattering mechanism. The proposed method consists in applying the TSVM prior to the GLRT-LQ detector for the detection of any oriented target. [C1833]

#### "PolSAR images characterization through Blind Sources Separation techniques"

Since the backscattered signal in PolSAR images is intrinsically linked with the physical characteristics of the objects in the image, valuable information may be extracted therefrom. The paper focus is to propose a new physical characterization of the scattering target, inspired by the Blind Sources Separation techniques. [C1834]

#### "Processing of bistatic TanDEM-X data"

On June 21st, 2010, the German radar satellite TanDEM-X was launched and successfully placed in an orbit approaching the TerraSAR-X satellite until both systems will fly in close formation and will establish the only available bi-static interferometer in space. The primary TanDEM-X mission goal is to generate a global Digital Elevation Model (DEM) with a relative point-to-point height accuracy of 2 meters for moderate terrain at 12 m posting. For that purpose interferometric SAR data will be acquired over a period of 3 years in parallel to the operational running TerraSAR-X mission. Systematic processing of SAR raw data to so-called Raw-DEMs is performed by one single processing system, the Integrated TanDEM Processor (ITP). The final global DEM is then calibrated and mosaicked by a second system, the Calibration and Mosaicking Processor (MCP). The scope of this paper is to present an overview of ITP functionalities and to summarize the first processing results. [C1835]

#### "Peatland subsurface water flow monitoring using polarimetric L-band PALSAR"

The potential of L-band PALSAR for monitoring water flow beneath the peat surface is demonstrated on a bog near Lac Saint Pierre (Canada). Two polarimetric ALOS acquisitions collected at spring and fall under different water conditions are used. The Touzi decomposition, which was shown to be very promising for peatland characterization using the C-band Convair 580 SAR, is applied. Like in, the information provided by the multi-

polarization (HH, HV, and VV), the scattering type magnitude (the Cloude  $\alpha$  or the Touzi  $\alpha_s$ ), the single scattering eigenvalues and the entropy, cannot detect the presence of water underneath the peat surface. The Touzi scattering phase is shown to be the only target scattering decomposition parameter that can detect water flow variations beneath the peat surface. The fall acquisition that took place after two days rain permits demonstrating that the wave can penetrate deep into the acrotelm layer to detect the rain water that has sunk rapidly into the peat layer of high hydraulic conductivity. The spring acquisition at dry conditions permits better discrimination of poor fen from bog. The wave, which cannot detect deep water flow in the bog sublayer of low hydraulic conductivity (the catotelm), is more sensitive to the shallower fen subsurface water and this makes possible the separation of poor fen from shrub bog. The requirement for polarimetric PALSAR acquisition during summer is brought out for more effective exploitation of PALSAR unique long wavelength penetration capabilities in monitoring arctic peatland transformations related to climate change stress. [C1836]

#### "Texture estimation in sar images: The impact of scale and model order"

This paper discusses methods and parameter settings that help to estimate texture in SAR images. In general, this is a difficult task for SAR images that are characterized by speckle noise and which span a wide range of pixel magnitudes. We applied Gauss Markov Random Field (GMRF) models and Enhanced Model Based Despeckling (EMBD) to 1 meter resolution amplitude images of the German TerraSAR-X mission. The results demonstrate that one can find appropriate parameter combinations that allow robust texture estimation even for different types of target areas. [C1837]

#### "Accuracy of the engineering calibration of weather radars"

This paper provides a synopsis of the accuracy calculation for the engineering calibration of a weather radar system. The underlying meteorological radar equation is optimized in order to reduce the total uncertainty of the calibration. Special emphasis is given to the determination of the different uncertainties of the various measurements which are required for a system calibration. A spreadsheet for the calculation of the total uncertainty of the calibration is presented. [C1838]

#### "Fine structure of the upper ocean from high-resolution Terrasar-X imagery and In-Situ measurements"

We investigate small-scale features using SAR imagery, including sharp frontal interfaces, slicks of artificial and natural origin, and wakes of surface ships. Collection of the ground truth data helps in the understanding of the physical mechanisms behind the patterns visible in the image. [C1839]

#### "Polarisation and mode combinations for ship detection using RADARSAT-2"

RADARSAT-2 provides new opportunities for spaceborne monitoring of vessel traffic and fishing activities. A series of RADARSAT-2 data has been collected and analysed over Norwegian waters. ScanSAR and Standard Quad-pol images have been used in the analyses. The Norne field is used as a test site, because it is possible to image the same vessel under different conditions. The different polarisations and polarisation combinations are analysed. [C1840]

#### "Assessment of airborne lidar data for instream flow type classification"

The information of instream biotype, i.e., types, location, distribution, etc, are important for estuary environment management. Field observations carry out by ecology surveyor is the standard procedure to gather that information, which is time consuming and difficult to be applied to a large spatial extend. In this research, we propose using airborne for instream biotype classification. Texture of point clouds is the key to distinguish between flow types, and semi-variogram was employed for texture measurement of different flow types. The principle component analysis is then used for classification and data compression. The results show that the first principle components are closely related to the flow types considered in this study. [C1841]

#### "Ground topography estimation over forests considering Polarimetric SAR Interferometry"

The work detailed in this paper analyzes the topographic phase retrieval process on forested areas by means of Polarimetric Interferometric SAR data. On the basis of the Random Volume over Ground scattering model, an alternative implementation for the retrieval of the topographic phase, avoiding the bias introduced by the volumetric scattering components is presented. [C1842]

#### "SAR mapping technology and its application in difficulty terrain area"

In western China, there is a large area perennially covered by cloud, fog, ice, and snow. It is very difficult to acquire optical image for mapping in this area, so high resolution spaceborne synthetic aperture radar (SAR) images have to be used to make topographic maps. A scheme of SAR mapping technology is proposed in this paper. Digital elevation model (DEM) was extracted with stereo radargrammetry (StereoSAR), and topographic map was created with ideal SAR stereoscopic image pairs. Due to the difficult terrain, parallax edit under stereoscopic observation is used for improving matching result from stereo images. Ideal SAR stereoscopic image pairs generated with image simulation based on DEM are used for stereoscopic observation to extract topographic features. Ascending and descending image data were combined to solve the problem of lack of information caused by shadow and layover. Mapping experiment in western China shows that SAR data with resolution of 3-8 meters can be used to make topographic map at scale of 1:50,000 by the scheme of SAR mapping introduced in this paper. [C1843]

#### **"Building detection and height estimation from high-resolution insar and optical data"**

State-of-the-art satellite SAR sensors acquire data of one meter geometric ground resolution, airborne sensors achieve even higher resolutions. Nonetheless, layover and occlusion hamper interpretability of such data particularly in urban scenes. In order to overcome this drawback, we use additional information from aerial photos to detect buildings. Features are extracted from both data sets and introduced to a common feature vector followed by a classification into building sites and non-building sites with Conditional Random Fields (CRF). Furthermore, we show that the different sensor geometries of the SAR and the optical sensor may be used to estimate building heights. [C1844]

#### **"Radar observations of wave field in littoral zone"**

The dissipation of the wave energy in the littoral zone is significant for the coastal hydro- and sediment dynamics. In this presentation, a recently developed method is presented about the separate, simultaneous measurements of wave propagating field and of wave breakers' velocity, based on ground based, Doppler, X-band Radar observations. The kinetic energy of the wave field is calculated for the last 2 km of the N. Sea towards the shore, with high spatial resolution (7.5 m) and the rate of the dissipated is estimated. [C1845]

#### **"Status of the Metop ASCAT soil moisture product"**

Since December 2008 the European Organisation for the Exploitation of Meteorological Satellites (EUMETSAT) has been disseminating global 25 km ASCAT surface soil moisture data in near real-time (within 135 minutes after sensing) over its broadcast system EUMETCast. The ASCAT surface soil moisture product is thus the first truly operational satellite soil moisture product that may be used for Numerical Weather Prediction (NWP), flood forecasting and other time-critical applications. In this paper we provide information about the status of the ASCAT Level 2 soil moisture processor, review first published validation and application studies and discuss plans for further improvements. [C1846]

#### **"Spaceborne sar imaging of coastal ocean phenomena"**

Synthetic aperture radar (SAR) observes the large-scale ocean surface wind field. With SAR instruments, we can actively monitor phenomena in the coastal ocean and marine atmospheric boundary layer at very high spatial resolution (on the order of tens of meters) in all weather conditions day and night. SAR observations are particularly useful in coastal regions where clouds are usually present, causing observation problems for visible and infrared sensors. SAR sensors onboard the RADARSAT-1/2, ENVISAT, ALOS, and other satellites can provide swath coverage of about 100 to 450 km, wide enough to cover oceanic and atmospheric meso-scale features. SAR has long been used to monitor the ocean surface wind field, vessel locations, oil spills, sea state, and sea ice at NOAA. In this paper, we present several case studies. [C1847]

#### **"SAR and optical images registration using shape context"**

Image registration is the process of overlaying two or more images of the same scene taken at different times, from different view points, and /or by different sensors. A novel feature-based multi-sensor image registration system is developed. The system consists of two new points: first, edge features are extracted from images, and the features are dilated to suppress some certain kinds of noise arising from groves; second, the preprocessed features are matched using the improved shape context. The shape context has been found to be robust in hand written digit and object recognition, and now it is introduced into remote sensing image matching after some adjustments. The developed system is successfully applied to register airborne optical and C-band SAR images in our experiments, and the results demonstrate its robustness and accuracy. [C1848]

### "Filtering and segmentation of polarimetric SAR images with Binary Partition Trees"

A new multi-scale PolSAR data filtering technique, based on a Binary Partition Tree (BPT) representation of the data, is proposed. Different alternatives for the construction and the exploitation of the BPT for filtering and segmentation are presented. Results with simulated and experimental PolSAR data are presented to show the capabilities of the BPT-filtering strategy to maintain both spatial details and the polarimetric information. [C1849]

### "A novel approach for redundant integration of finite differences and phase unwrapping on a sparse multidimensional domain"

Phase unwrapping and integration of finite differences are key problems in several technical fields, among which SAR interferometry. In this paper we propose a general formulation for robust and efficient integration of finite differences and for phase unwrapping, which includes standard techniques methods as sub-cases. The proposed approach allows obtaining more reliable and accurate solutions by exploiting redundant differential estimates (not only between nearest neighboring points) and multi-dimensional information (e.g. multitemporal, multi-frequency, multi-baseline), or external data (e.g. GPS measurements). The method requires the solution of linear or quadratic programming problems, for which computationally efficient algorithms exist. The validation tests performed confirm the validity of the technique. [C1850]

### "Insar time-series analysis for management and mitigation of geological risk in urban area"

This work shows the capabilities of InSAR time series analyses to support civil protection activities in the framework of geological risk management and mitigation. We discuss the outcomes from an integrated analysis of conventional in situ investigations and observations with advanced InSAR analyses carried out for the test sites of Agrigento and Naro (Italy), affected by ground instability respectively due to landsliding and tectonic forces. The study of past ground deformations provided valuable insights into the spatial and temporal patterns and behaviors of these phenomena, helping local civil protection authorities to focus resources on the areas of maximum need and to identify the most appropriate mitigation measures to reduce the impacts on elements at risk. [C1851]

### "Radargrammetric improvements: A multi-window approach"

This paper deals with the relevance of using stereoscopic radar images in order to retrieve the relief of terrain. Firstly, the basic characteristics of the radargrammetry are described. Thus, we present the results of the radargrammetric processing using the ZNCC procedure and applied to radar images. These images are recorded by the SIR-C mission over the French Alps. The results show that the image matching can fail, especially in foreshortened areas. So, we expose two different improvement methods using several correlation windows in order to cancel the reconstruction errors. The first improvement take advantage of a multi-window approach to combine information multiplying the correlation surfaces obtained for each correlation window size. The second improvement is based on another multi-window approach that makes it possible to get correlation windows adapted to the foreshortened areas. Finally, we combine these two improvement methods to show that it's possible to make the disparity map more reliable for the first step of the pyramidal scheme. [C1852]

### "Visual tracking of multiple interacting objects through Rao-Blackwellized Data Association Particle Filtering"

A multiple object visual tracking framework is presented, which is able to manage complex object interactions, missing detections and clutter. The main contribution is the ability to deal with complex situations in which the interacting objects can change their dynamics while they are occluded. This is achieved by explicitly estimating putative locations of the occluded objects. The tracking is modeled by a Rao-Blackwellized Data Association Particle Filter (RBDAPF), which has a tractable substructure that allows to analytically compute the object positions, while the object-measurement associations are approximated by Particle Filtering. Besides improving the accuracy, this filter decomposition reduces the computational cost, since the complexity with the number of objects becomes linear instead of exponential. The Particle Filter efficiently manages the measurements from visible and occluded objects, the clutter, and missing measurements to estimate the correct data associations that lead to a robust tracking. Experimental results on surveillance videos show that the proposed RBDAPF framework is able to track multiple interacting objects in complex situations. [C1853]

### "Aspects of multivariate statistical theorywith the application to change detection"

This paper proposes a new method for change detection measurement including whole SAR imaging modes such as PolIn- SAR, partial PolInSAR and InSAR in a set of multi-temporal multidimensional SAR images. The method is based on the special case of Kullback-Leibler (KL-divergence) test, known as Mutual Information. In

order to develop an algorithm, firstly the joint distribution of PolInSAR data set, based on the second order statistics has been derived. Such a derivation accounts for the whole multi-temporal SAR images. Then the mutual information is used to measure the difference between the joint density of multi-temporal PolSAR data sets and their marginal density known as complex Wishart distribution. A comparison between the proposed and the other well-known change detection (e.g. cross correlation) technique is shown by means of real data, describing the advantages due to the fact that the proposed change detector involves almost every facet of the applied change detection. [C1854]

#### "POLSAR image classification using BP neural network based on Quantum Clonal Evolutionary Algorithm"

POLSAR image classification plays an important role in remote sensing. POLSAR data are a type of mass data and have more independent features which can represent different physical significances than optical image. Therefore, POLSAR image classification is actually a high dimensional nonlinear mapping problem. Because of the nonlinear mapping function of BP neural network, it can be used to classify POLSAR image. But BP neural network classifier is sensitive to initial weights and thresholds. Quantum Clonal Evolutionary Algorithm (QCEA) can converge to an optimal value quickly and can be used to optimize the initial weights and thresholds of BP neural network. Therefore, in this paper, BP classifier based on QCEA was used for POLSAR image classification. Firstly, optimize the initial weights and thresholds of BP neural network using QCEA. Secondly, train the optimized BP neural network classifier by gradient descent algorithm. Finally, classify the POLSAR image using the trained classifier. The validity test is demonstrated using Danish EMISAR L-band fully polarimetric data of Foulum Area (DK), Denmark. The preliminary result indicates that this method can classify most of the areas correctly. [C1855]

#### "Automatic registration of sar and optical image based on multi-features and multi-constraints"

This paper proposes a two-stage registration method for SAR and optical images based on multi-features and multi-constraints. In the first stage, closed regions are extracted automatically to achieve the coarse mapping parameters as geometrical restriction. In the second stage, Harris corner points and cross-road features are extracted, and then correlation analysis and mutual information are utilized to match the corresponding control points. After that, multi-constraints are used to delete the false matched points. The retained ones are served as ground control points for registration. The experimental results show that the method can reduce the possibility of false matching effectively and the registration error is within one pixel. [C1856]

#### "Beamwidth analysis for SAR processing of airborne depth-sounder data over ice sheets"

Information on the bedrock topography below the Greenland and Antarctic ice sheets is vital to developing models of future sea-level rise. To measure the topography, advanced data acquisition and processing techniques, including Synthetic Aperture Radar (SAR), are required. This work investigates the optimal beamwidth that would enable SAR processing to maximize the signal to noise ratio of the target. Platform height above the ice surface and bedrock roughness determine the optimal beamwidth. We found that for data collected at a "typical" altitude of 867 m, the optimal beamwidth is about 8°. In the high-altitude case, we found that beamwidth did not have a significant effect on the signal-to-noise ratio. This is probably related to scattering from the ice surface. [C1857]

#### "DSM generation from very high optical and radar sensors: Problems and potentialities along the road from the 3D geometric modeling to the Surface Model"

The availability of new high resolution optical and radar spaceborne sensors offers new interesting potentialities for the acquisition of data useful for the generation of Digital Surface Models (DSMs). The accuracy level of DSM is strictly related both to the image orientation and to the matching process. As regards the image orientation, remote sensing community usually adopts two different types of models for High Resolution Satellite Imagery (HRSI): the physical sensor models and the generalized sensor models also called rigorous and Rational Polynomial Functions (RPFs) models respectively. In a scientific software developed by the research group of Geodesy and Geomatic Area of the University of Rome "La Sapienza" both rigorous and RPFs models are implemented, with a specific tool for the terrain-independent Rational Polynomial Coefficients (RPCs) generation; the software manages the imagery acquired by several optical sensors (EROS A, Ikonos, QuickBird, Cartosat-1, WorldView-1, GeoEye-1) and by the Italian SAR constellation COSMO-SkyMed. In the same software a facility for image matching is embedded. The Area Base Matching (ABM) is used, combined with the orientation model re-parametrized in terms of RPCs. In the present work some examples of models application and DSM generation are analyzed and discussed. [C1858]

### "A new Bayesian source separation approach to blind decorrelation of SAR data"

In this paper, a novel approach for performing blind decorrelation of SAR data is proposed. A patch-wise computation of the point-spread function (PSF) is performed directly from the SAR data to account for spatial nonstationarities present in SAR. The problem of estimating the PSF is formulated as an additive source separation problem in the frequency domain, and is subsequently solved using a Bayesian least squares estimation approach based on a Fisher-Tippett log-scatter model. Experimental results using both simulated SAR data and real RADARSAT-2 SAR sea-ice data showed that the proposed decorrelation approach can successfully learn the correct PSF and significantly reduce the correlation in SAR data. [C1859]

### "Sparsity-driven focused SAR image formation"

Most imaging systems are adversely affected by the errors in the observation model. One significant example is encountered in synthetic aperture radar (SAR) imaging. Inexact measurement of the distance between the SAR sensing platform and the scene center or random delays on the transmitted signal result in model errors. These errors appear as phase errors in the SAR data and they cause defocusing of the reconstructed image. Mostly, phase errors vary only in the cross-range direction. However, in many scenarios, it is possible to encounter 2D phase errors, which are both range and cross-range dependent. In this study, a sparsity-driven method for joint SAR imaging and phase error estimation is proposed. This method is able to correct 1D as well as 2D phase errors. Experimental results show the effectiveness of the proposed method. [C1860]

### "SAR complex image analysis: A Gauss Markov and a multiple sub-aperture based target characterization"

In this paper we discuss Gauss-Markov Random Field (GMRF) based on multiple sub-aperture decomposition method for the analysis of targets in complex-valued high-resolution SAR data. Gauss-Markov Random Field (GMRF) model with a quadratic energy function as a parametric analysis parameterizes the spectrogram of the signal, whereas sub-aperture decomposition method exploits the holographic property of the spectrum at the cost of reducing resolution. This analysis helps to understand, characterize and analyze complex-valued SAR data and provides temptation to use complex-valued SAR data over detected data. [C1861]

### "Polarimetric decomposition for forest biomass retrieval"

In this paper, the decomposition of fully polarimetric SAR data into three canonical scattering mechanisms is investigated with respect to forest biomass retrieval. It is demonstrated that the dominant backscattering contribution depends strongly on the frequency, incidence angle, and stand condition. The relation between in-situ biomass measurements and the individual decomposition components is examined. [C1862]

### "Realization of the NASA Dual-Frequency Dual-Polarized Doppler Radar (D3R)"

This paper describes some of the novel technologies adopted in the realization of the NASA Dual-frequency Dual-polarized Doppler Radar (D3R) system for to be used by the GPM ground validation program. A description of the transceivers and major trades that lead to a solid-state architecture is presented. Other aspects enabling the design such as the waveform design and generation and the digital receiver is also described. Data measured from a similar power amplifier was used to estimate the expected range side lobe performance. An estimate of the expected sensitivity based on the transceiver parameters also presented. [C1863]

### "Polarimetric SAR estimation based on non-local means"

During the past few years, the non-local (NL) means have proved their efficiency for image denoising. This approach assumes there exist enough redundant patterns in images to be used for noise reduction. We suggest that the same assumption can be done for polarimetric synthetic aperture radar (PolSAR) images. In its original version, the NL means deal with additive white Gaussian noise, but several extensions have been proposed for non-Gaussian noise. This paper applies the methodology proposed in to PolSAR data. The proposed filter seems to deal well with the statistical properties of speckle noise and the multi-dimensional nature of such data. Results are given on synthetic and L-Band E-SAR data to validate the proposed method. [C1864]

### "An application of reciprocity to the numerical modeling of a GPR system"

In this paper, a technique is developed to model ground penetrating radar interactions. It combines reciprocity with the results from a full numerical model and allows one to compute a large number of scattering responses simultaneously, provided the scatterers are small. The results of an example calculation are shown and compared with a full numerical model and a possible application is demonstrated. [C1865]

### "Eigen decomposition parameter based forest mapping using Radarsat-2 PolSAR data"

In this paper, a set of polarimetric eigenvalue and eigenvector based parameters, e.g. entropy and anisotropy, are investigated for forest application. The correlation terms of the eigenvectors,  $\mu_1$  and  $\mu_2$ , are found to be better for forest mapping in both summer and winter using Radarsat-2 quad-polarimetric space borne SAR data. These are used to automatically identify forest class pixels from the volume scattering category of a Freeman-Durden Wishart unsupervised segmentation map. The algorithm scheme was developed and implemented using fully polarimetric Radarsat-2 SAR (PolSAR) data acquired in July and October and the validity was evaluated using the ground reference data created from SPOT5 K-clustering classification map. [C1866]

### "Polarimetric SAR tomography of natural environments using hybrid spectral estimators"

SAR tomography is the extension of conventional two dimensional SAR imaging principle to three dimensions. In order to improve the vertical resolution with respect to classical Fourier-based methods, high resolution approaches are used in this paper to perform SAR tomography. Both nonparametric spectral estimators, like beamforming and Capon and parametric ones, like MUSIC, maximum likelihood, are applied to real data sets and compared in terms of scatterer location accuracy and resolution. This paper addresses the discrimination of coherent scatterers presented in the natural environment and a joint approach of estimation and detection is proposed. [C1867]

### "Mean-shift and hierarchical clustering for textured polarimetric SAR image segmentation/classification"

Image segmentation and unsupervised classification are difficult problems. We propose to combine both. A clustering process is applied over segment mean values. Only large segments are considered. The clustering is composed of a mean-shift step and a hierarchical clustering step. The hierarchical grouping is based upon a powerful segmentation technique previously developed. The approach is applied on a 9-look polarimetric SAR image. Textured and non-textured image regions are considered. The K and Wishart distributions are used respectively. The unsupervised classification results can be very useful for image analysis and further supervised classification. The obtained region groups constitute an important simplification of the image. [C1868]

### "On the use of Support Vector Machines for land cover analysis with L-band SAR data"

This study investigates a new technique for land cover analysis by means of the Support Vector Machines. Intrinsic spatial variability within SAR images, beyond that caused by speckle, is of high interest for land cover characterization and classification. However, its use is still an ongoing issue due to its complex multi-scale nature. On the other hand, classification algorithms based on statistical learning methods such as the supervised Support Vector Machines (SVM) approach are implemented in a wide range of data mining applications. SVM can also be used as a technique for feature selection. In this paper, a new tool using the Recursive Feature Elimination SVM-based process (SVM-RFE) and the textural Haralick's parameters is introduced. The real contribution of textures within the land cover classification can be understood. A small set of textural parameters is determined at local scale while being optimal for the land cover discrimination. In this study, orthorectified 50m resolution data acquired by the L-band PALSAR/ALOS sensor are used. [C1869]

### "An improved CSA for one-stationary BiSAR squint mode"

The purpose of this paper is to solve the imaging problems of one-stationary bistatic synthetic aperture radar (BiSAR) squint mode. Through the analysis of the target's two-dimensional spectrum, an improved chirp scaling algorithm (CSA) is got. It can deal with the space variability of this kind of BiSAR and the simulation is done to verify the validity and feasibility of this algorithm. [C1870]

### "Coherent marine radar measurements of properties of ocean waves and currents"

Marine radars offer the capability to image ocean wave propagation by virtue of repetitive coverage of the same scene. With a typical 1.25-s rotation period, ocean wave frequencies of 0.4 Hz can be measured unambiguously. Imaged areas of the order of ten square kilometers, allow the dynamics and kinematics of ocean wave fields to be measured with higher azimuthal resolution than traditional oceanographic instruments, such as buoys or pressure sensors. Using the dispersion relation for shallow waves in coastal regions, ocean wave spectra and bathymetry can be estimated using non-coherent marine radars. The derivation of wave height or wave height spectra from marine radar imagery has had some success by relating the radar echo intensity imagery of waves to wave height using an empirically derived modulation transfer function (MTF). More recently, using a radar scattering model's dependence of the radar scattering cross section on long wave slope, good results are

reported in deep water for shipboard experiments, where winds and waves are typically in the same direction. However, in coastal waters, offshore winds blowing in a direction other than that of the incoming wave field can produce enhanced roughness on the front face of waves, resulting in a modulation of the radar wave field image that is not wave height dependent. A coherent radar can overcome these limitations using the direct measurement of the radial component of orbital wave velocity, accounting for Bragg scatter velocity. Radial orbital velocity will maximize and minimize at similar locations on long wave profiles as do radar echo intensity, so wave patterns should look very similar for the two. Thus, analysis methods similar to those used in non-coherent radar studies should be applicable to coherent radar data as well. We present recent experimental results on the retrieval of coastal ocean wave and current properties due to a storm over the Outer Banks of North Carolina in November of 2009. [C1871]

#### "Ship detection and measurement using the TerraSAR-X dual-receive antenna mode"

The detection of ships and the retrieval of parameters like vessel velocity, heading and size are important techniques for ocean and shore surveillance systems. Space borne SAR along-track interferometry (ATI) can detect ships for large areas and measure their velocity at the same time by means of interferometric phase. In this paper we report about first results of automatic ship detection using TerraSAR-X ATI. [C1872]

#### "RPC modeling for spaceborne SAR and its application in radargrammetry"

The RPC (Rational Polynomial Coefficient) model can be used as a replacement sensor model for geo-coding spaceborne SAR data. A hybrid method, combining the L-curve and the IMCCV (Iteration method by correcting characteristic value) method, for solving ill-conditioned equations in the RPC model is proposed. The hybrid method can get higher accuracy at low cost of calculation time. Based on an example in Malaysia, the application for fast RPC geocoding for stereo radargrammetry is shown. [C1873]

#### "Data acquisition of vessel ISAR data with assistance of automatic identification system"

In the past, imaging of moving vehicles using the principle of inverse synthetic aperture radar (ISAR) has typically been applied to ground moving vehicles or air and space borne objects. Nowadays, demands to image moving vessels on sea come along for both military applications and coastal surveillance. New processing algorithms have to be developed to focus ISAR data of vessels because of the complicated three-dimensional rotational motion and the sea clutter. Experimental data have to be available for the development process. To be able to acquire these data, the airborne radar sensor PAMIR of Fraunhofer FHR has been extended by integrating a receiver for automatic identification system (AIS) messages, which supports the system with position information of the vessels on sea. The paper shows the hardware integration and software implementation. Benefits of the information gained from the received AIS messages are discussed and results of first acquired data are presented. [C1874]

#### "A new SAR sensor designed for micro-satellites"

Micro Satellites ( $\mu$ SATs) are good opportunities for small countries. This paper describes a new design of a SAR for a  $\mu$ SAT. The centre frequency and the SAR processing were optimized in a way to allow the realization of a simple but capable system that provides many interesting opportunities for researchers and allows participating to international environmental monitoring and control activities. The major points of the design are a frequency that allows some penetration through vegetation and a relative small antenna in length and width. A new SAR processing concept allows a medium swath-width and an acceptable resolution. A patent is pending. [C1875]

#### "Morphological filtering of SAR interferometric images"

This paper proposes a new morphological filter for SAR interferograms. It is based on a modified version of alternate sequential filters with reconstruction (MASF), in which the structuring elements are adaptively defined according to the fringe directions. This provides a good fidelity to the fringe information while efficiently removing noise. Another feature of the proposed approach is to apply the filter on the original interferogram and on shifted version, to overcome the wrapping of the phase, and to combine the two results. The proposed filtering technique is then tested on both simulated and real data with different levels of noise. It is also compared to previous techniques according to simplicity and noise reduction. [C1876]

#### "Relations between SAR tomography and full-waveform LIDAR for structural analysis of forested areas"

Active remote sensing techniques, like SAR tomography and full-waveform LIDAR, are able to capture the 3D reflectance function at or inside objects. They are therefore of special interest for analyzing forest environments.

Research goals are the derivation and characterization of the different physical measurement aspects of data taken over forested areas, as well as establishing mutual relations in such a way that LIDAR data can be used to calibrate and correct 3D density data of SAR tomography. The paper outlines the phenomenology of forested areas in SAR tomograms and full-waveform LIDAR data and sketches a simple mathematical methodology for linking SAR and LIDAR reflection density profiles. [C1877]

#### **"Optimal algorithms for spaceborne altimeter"**

This paper is dedicated to new methods of space altimeter altitude and sea surface significant wave height (SWH) measuring. These methods are based on the fundamentals of Bayesian optimal measure method of a parameter. Optimal discriminators of the parameters are developed using the least square error of the estimate criteria, apart from others papers which mostly minimize the least square error of altimeter waveform fitting function. Potential measurement accuracy calculation results are also presented. [C1878]

#### **"Development and experiments of a passive SAR receiver system in a bistatic spaceborne/stationary configuration"**

In this paper, the development of a stationary SAR receiver system using TerraSAR-X as transmitter is described. First the bistatic geometry and expected resolution are considered. After giving an overview of the hardware setup, the expected performance of the system is evaluated. The paper ends with the processed results of a measurement campaign performed in summer and fall 2009, and a comparison with the monostatic data acquired by the TerraSAR-X satellite. [C1879]

#### **"Detection of salient features in surface current maps from dopplerized X-band radar"**

The mapping of the near surface currents and their interaction with the spatial and temporal varying bottom topography is of high significance for the experimental analysis of morphodynamic processes in coastal areas and the monitoring the effectiveness of coastal protection actions. An efficient application is also the real-time monitoring of currents in harbours to pilot large vessels [8]. The next steps of this inquiry are the application of image processing methods to extract also, together with the orientation, length scales and spatial shifts of salient current features. The correlation with salient features of the bed topography will be analyzed further together with sea state images that can also be deduced from radar data. [C1880]

#### **"Quasar SBK accurate internal calibration"**

A new compact fully polarimetric Ku band SAR system (SBK) is being developed by INTA radar Laboratory as an advanced payload for QUASAR project, which involves INTA new SAR developments for small platforms and UAV's. As an operative system, SBK shall allow precise calibration of the obtained data in order to achieve high products quality. The present paper shows SBK internal calibration concept focusing on internal calibration facility description, on ground characterization task overview and in flight calibration method. Furthermore, internal calibration accuracy estimation based on first prototypes measurements is also presented. [C1881]

#### **"Extraction of typhoon-damaged forests from multi-temporal high-resolution polarimetric SAR images"**

The purpose of this study is to extract the forests destroyed by typhoons and to quantitatively estimate the damage levels by using high-resolution polarimetric synthetic aperture radar (SAR) data. The study area is located in Tomakomai, Hokkaido, Japan. Two sets of data were acquired before and after the typhoon by the L-band airborne Pi-SAR (Polarimetric-interferometric SAR) with 3m Ч 3m resolution (4-look in azimuth direction). It was found that the values of RCS (Radar Cross Section) averaged over the whole image after the typhoon damage changed by -0.47 dB, 0.05 dB, and 0.64 dB at HH-, HV-, and VV-polarization respectively in comparison with those before the damage. To fully utilize the data, a scattering model of the linear combination of the cross- and co-polarization RCS changes was developed to estimate the damage levels. Similar analytical approaches were also applied using the three-component decomposition analysis. The changes in RCS of double-, volume- and surfacescattering mechanisms after the damage were respectively 27.5 dB, -0.20 dB and -20.3 dB. Finally, by comparing the results with the ground survey data, the accuracies of 64.1% and 77.7% were obtained for the RCS and decomposition analyses respectively. [C1882]

#### **"Rice areas mapping using ALOS PALSAR FBD data considering the Bragg scattering in L-band SAR images of rice fields"**

The objective of this paper is to assess the use of ALOS PALSAR FBD data to map rice growing areas. Image enhancement in backscattering in rice fields as a result of Bragg resonance scattering was found only at HH

polarization since double-bounce scattering is a prerequisite to Bragg resonance scattering for radar backscatter from bunches of rice plants. A rice mapping method using HV images was developed and applied to Haian test site. Validation showed that rice mapping using L-band SAR is promising when cross-polarized data are available to cope with the Bragg resonance scattering effects. [C1883]

#### **"Bistatic SAR based on Terrasar-X and ground based receivers"**

The paper presents the development of a ground based bistatic receiver using TerraSAR-X as a transmitter. The receiver subsystems like antennas, low-noise amplifiers, mixers, filters, synthesizers, etc. have been developed using low-cost monolithic devices in order to allow affordable deployment and at the same time offer final year students a challenging SAR engineering project. First raw data have been acquired on the Barcelona harbor area that has been focused producing geocoded images well matched with existing maps. A preliminary interferogram have been also produced. [C1884]

#### **"Designing an Illegal Mining Detection System based on DinSAR"**

Satellite Differential Radar Interferometry (DInSAR) has demonstrated its ability for monitoring mine-induced ground subsidence. However, it is still a challenging task to routinely identify all mining activities from the large-scale coverage interferogram, especially the illegal mines. In response to this challenge an underground mining detection system based on DInSAR is described. The system is tested over a dense mining area in Asia. With such a system it is hoped that the detection efficiency of illegal underground mining using DInSAR can be improved. [C1885]

#### **"Effect of squint imaging on beam position design of space borne SAR"**

Range migration of space borne SAR at large squint angle is much greater than the side-looking SAR, and longer echo receiving window is needed. Thus, the traditional beam position design method is invalid. In this paper, the method of drawing zebra map is improved by taking the range migration into consideration. The maximum and the minimum slant ranges during the synthetic time are derived. This paper also analyses the relation between the effective swath width and the range beam width at large squint angle. Simulation for X-SAR system proves that a given azimuth resolution limits the squint angle. STK and echo simulation are used to verify the validity of the improved beam position design method. [C1886]

#### **"Dual-polarized, coherent microwave backscatter from rough water surfaces at low grazing angles"**

We show that at low grazing angles, breaking wave effects are very important in HH polarized microwave backscatter from the ocean but less so at VV polarized backscatter. When the ocean surface is disturbed only by wind, breaking wave effects in VV backscatter are much smaller than Bragg scattering, even at low grazing angles. For HH polarization, on the other hand, breaking wave effects are very important at low grazing angles. In the presence of surface current gradients set up by internal waves, HH cross sections can exceed those at VV by as much as 10 dB near internal wave crests, indicating enhanced breaking wave effects that cannot be described as specular. Breaking effects are nearly as strong as Bragg effects in VV backscatter under these conditions. Spectral comparisons confirm these conclusions. [C1887]

#### **"Quikscat backscatter sensitivity to landscape freeze/thaw state over ALECTRA sites in Alaska from 2000 to 2007: Application to SMAP validation planning"**

The mapping of freeze/thaw state of the landscape is one of the main objectives of NASA's upcoming SMAP (Soil Moisture Active and Passive) mission. This study applies ALECTRA (Alaska Ecological Transect) biophysical network and QuikSCAT scatterometer data to evaluate some of the validation issues regarding the SMAP freeze/thaw measurements. Although the QuikSCAT data is at Ku-band frequency, rather than the L-band of the SMAP instrument, the data is utilized due to its uniquely high temporal resolution over the ALECTRA sites. The results show that multiple temperature measurements representative of individual landscape (soil, snow cover, vegetation and atmosphere) elements and spatial heterogeneity within the satellite field-of-view are important for understanding the radar backscatter process and aggregate freeze/thaw signal. The backscatter temporal dynamics and relative contribution of these landscape elements to the freeze-thaw signal varies with land cover type, seasonal weather and climate conditions. [C1888]

#### **"Road surface quality measurement using inexpensive radar"**

The near surface dielectric characteristics of pavement can indicate the overall health of roadways and bridge decks. By performing simple and fast reflectometry measurements of the near surface, it may be possible to efficiently monitor large amount of critical civil infrastructure, and provide early alerts of the initial stages of

damage. We demonstrate the variation with moisture content of surface reflected waves using a commercial-off-the-shelf 24 GHz FMCW radar. Initial experiments show that detectable amounts of water is absorbed in asphalt and concrete. The amount of absorbed water increases with micro- and macro-cracking, and this measurement will correlate with quantifiable changes in the observed return signal. [C1889]

#### "A shadow percentage estimation method for Radar look angle selection in spaceborne INSAR application"

Spaceborne INSAR (Interferometric Synthetic Aperture Radar) is an important remote sensing tool for topographic mapping, while there are inevitably shadow areas in Radar images. Shadow area has no radar echo signal or low coherence SNR (signal noise ratio). In this paper, Shadow area percentage estimation according to Radar look angle is proposed. Digital elevation model of natural terrains and ascending and descending orbits are used in simulation. This estimation method is suitable for incidence angle considerations in the phase of INSAR system design. [C1890]

#### "Doppler processing of coherent radar backscatter for ocean surface wave measurements"

The technique for extracting wave period and wave direction from a navigation radar backscattering intensity is well developed but the determination of spectral density or wave height is hindered by the complex nature of the modulation transfer function. In contrast to backscattering intensity, Doppler velocity from coherent radar is the radial velocity of the scattering objects. Its oscillatory component is contributed by ocean waves. The spectral peak component of Doppler velocity is close to the peak wave period measured by a nearby buoy and the significant wave height can be accurately calculated. With radar range coverage on the order of ten dominant wavelengths, reliable assessment of peak wave period and significant wave height is achievable with radar data as short as one second. Wave direction can also be determined with a scanning system. [C1891]

#### "Decomposition methods for the estimation of bare soil surface parameters using fully polarimetric SAR data 1"

This study wants to demonstrate that two different polarimetric target decomposition methods can improve SAR data accuracy for estimating the parameters of bare soil surface. To achieve this goal, two experiments are conducted: (1) both Freeman and Cloude decomposition methods are performed on JPL/AIRSAR L-band fully polarimetric data; and (2) Advanced Integral Equation Model (AIEM) is used to simulate backscattering coefficients. The root mean square errors (RMSEs) of  $\sigma_{0hh}$ ,  $\sigma_{0vv}$  between original data and AIEM simulated data are 1.96 and 1.25 dB. However, if Cloude method is used to decompose original data, the RMSEs will be reduced to 1.45 and 1.14dB, respectively; for Freeman method, the RMSEs are 1.64 and 1.35 dB. Therefore, polarimetric target decomposition compensation, especially Cloude method, can help to improve the accuracy of SAR data for estimating the parameters of bare soil surface. [C1892]

#### "Canopy height, crown cover, and aboveground biomass maps for the southwestern United States from MISR, 2000 and 2009"

Red band reflectance factor data from NASA's Multiangle Imaging SpectroRadiometer (MISR) were used to create maps of woody plant canopy cover, fractional height, and aboveground biomass for the southwestern United States, via inversion of a geometric-optical (GO) model provided with reflectance magnitude and anisotropy via a Li-Ross bidirectional reflectance distribution model. Crown cover, canopy height, and biomass distributions are compatible with those seen in other data sets, although there are anomalies associated with the use of the same set of background prediction coefficients over the 10-year period. [C1893]

#### "A two-pass random forests classification of airborne lidar and image data on urban scenes"

Random forests ensemble classifier showed to be suitable for classifying multisource data such as lidar and RGB image for urban scene mapping. However, two major problems remain: (1) the class boundaries are not well classified, a common issue in classification (2) the data are highly imbalanced raising another issue more specific to urban scenes. In this paper, we propose a new ensemble method based on the margin paradigm to improve the classification accuracy of minor classes. Random forests classifier is used in a two-pass methodology with an improved capability for classifying imbalanced data. [C1894]

#### "Radarsat Constellation, moving toward implementation"

The Canadian Space Agency initiated the development of a three-satellite SAR mission, known as the RADARSAT Constellation Mission (RCM), in 2005. The main objective of the mission is to assure C-band data continuity in the next decade, while allowing a greater use of data for operational applications by providing more

persistent observation over Canada and better system reliability. The Phase B contract was awarded in November 2008 for a period of 16 months. The Space and Ground Segment Requirements reviews were held at the end of February 2009. The spacecraft and Ground Segment concepts were adopted and design decisions have been taken to allow preliminary design to proceed. A Payload and Bus Preliminary Design reviews were held in Fall 2009. A Mission Preliminary Design review was held in February 2010. The CSA is currently in phase C and preparing for the Critical Design Review. Several challenges, such as the implementation of the ship detection mode or the final selection of the launcher must be resolved and important decisions must be taken to allow the progress of the program toward full implementation. The first spacecraft will be built and tested as a proto-flight and launched in 2014. The following two spacecrafts will then be built and tested in parallel and launched in 2015. [C1895]

#### "MIMO SAR processing with azimuth nonuniform sampling"

This paper analyses ambiguity suppression caused by multiple-input multiple-output (MIMO) SAR azimuth nonuniform samplings. Two methods are analyzed: azimuth spectrum reconstruction algorithm and minimum mean square error (MMSE) imaging algorithm. The azimuth spectrum reconstruction algorithm can reconstruct the scene fine resolution, while the nonideal orthogonality of multi-channel encoding waveforms causes azimuth ambiguous in SAR imaging. The MMSE imaging algorithm can perfectly reconstruct, while it requires high SNR. [C1896]

#### "Automation of object extraction from LiDAR in urban areas"

Light Detection and Ranging (LiDAR) has become a valuable data source for urban data acquisition. This paper gives an overview about current trends in the automation of object extraction from LiDAR data. These trends are caused by the technical development of LiDAR sensors that enable the acquisition of point clouds at higher resolution as well as the recording of the full waveform of the returned signal, and by the adoption of processing techniques from the Computer Vision and Pattern Recognition communities. Triggered by these developments, new applications are being found for LiDAR data. [C1897]

#### "What is the information content of TRMM precipitation radar for determining radiometer observations and vice versa?"

Both the space borne radar and the radiometer suite on the TRMM satellite observe the same column of precipitation and derive rain rates, however at different spatial resolutions. The observations from TRMM PR and TMI are fundamentally different measurements. While the radar provides a backscatter measurement resolved in the vertical direction, the radiometer is a passive instrument obtaining integrated observations over the full depth of the cloud. In addition, they respond to different physical mechanisms. Nevertheless, they observe the same precipitation medium and retrieve the same output products. Therefore, it begs the question, what type of information about radiometric observations can be directly retrieved from radar observations. This question can be further focused and stated as: To what extent can one predict the radiometric observations from radar observations? This question can be answered in several ways, and one of them is an informational theoretic approach using neural networks which is described in this paper. [C1898]

#### "Detection of land subsidence in Beijing, China, using Interferometric Point Target Analysis technique"

Land subsidence in Beijing is supposed to be caused by over-exploitation of ground water, which is leading to a rapid decline of water levels, drying out clay layers that finally result in land subsidence. The Interferometric Point Target Analysis (IPTA) is an advanced method to monitor vertical motion of the land surface over time. IPTA identifies backscattering objects, named as coherent points or points targets, at the ground surface that persistently reflect radar radiation emitted by the SAR antenna. The core component of the IPTA technique is the iterative estimation of phase differences for all measurement points over the sets of the SAR data using a linear model. In this paper, IPTA technique was used to retrieve the phase history, extract the linear deformation information from interferometry phase and weaken atmosphere phase delay in Beijing. 20 ENVISAT ASAR images acquired between June-18-2003 and March-14-2007 have been selected. The intention of this article is to demonstrate how IPTA technique could be used to extract valuable information in Beijing area. [C1899]

#### "Polarimetric and interferometric applications in a bistatic hybrid SAR mode using Terrasar-X"

A lot of bistatic experiments have recently been performed by different researchers to show the differences between monostatic and bistatic SAR. The acquired data was needed to verify the developed bistatic processing algorithms. To extend the conventional bistatic SAR experiments, we investigated whether bistatic systems can

be used in the field of bistatic interferometry and polarimetry, also shown by [3]. For this purpose we have used our stationary receiver system together with TerraSAR-X as transmitting satellite. This paper describes the experiments and shows some results we obtained using single and repeat pass SAR configurations. [C1900]

#### "A comparison on the new electronic attack techniques against pulse compression radars"

In this study, the mathematical models of Smeared and Chopping/Interleaving Spectrum techniques, which are recent electronic attack techniques against the pulse compression radars, are presented. Then, matched filter outputs are compared by means of a simulator. Moreover, the effect of the weighting filter in the radar receiver is also analyzed. [C1901]

#### "A new algorithm for wind speed at low incidence angles using TRMM Precipitation Radar data"

Large datasets from crossovers of Precipitation Radar (PR) and buoy observations clearly demonstrate that ocean PR backscatter correlates with both the near-surface wind speed and the sea surface wave slope. Multi-incidence angles PR data are used to retrieve surface wave slope parameter and normalized nadir backscatter. After that, an empirical wind speed model was developed based on those two parameters that attenuates the surface tilting effect. The inversion is defined using a multilayer perceptron neural network with radar-derived backscatter and surface wave slope parameter as inputs. Results show the root mean square errors between retrieved wind speeds and in situ buoy observations is 1.36m/s, bias is nearly zero, revealing good agreements in wind speed estimations. [C1902]

#### "Monitoring flooded area fraction in floodplains of Parana basin using passive and active microwave systems"

Over the past two decades, orbital passive microwave systems have proven to be sensitive to flood condition in large floodplains. This sensitivity is rooted in the well differentiated emission properties of calm water with respect to non-flooded land of any kind. In this paper, AMSR-E observations of an herbaceous wetland area on the Parana River sub-basin were analyzed during the 2009-10 timeframe when this region was affected by a strong and long lasting flooding. Evident effects on the difference between vertically and horizontally polarized brightness temperatures ( $\Delta T$ ) were observed at C-band. The fraction of vegetated flooded area was estimated by applying an improved algorithm which uses ENVISAT ASAR data at specific dates to calibrate AMSR-E temporal series. Also, using a theoretical emission model, the behavior of  $\Delta T$  flooded is discussed. [C1903]

#### "Iceberg size and orientation estimation using SeaWinds"

From 1999 to 2009, the SeaWinds scatterometer has been used to detect and track large Antarctic icebergs on a daily basis. Here, we develop an automated estimation algorithm to supplement iceberg position reports with estimates of the iceberg's major axis length, minor axis length, and angle of orientation. A maximum-likelihood objective function that relates measured backscatter to model-based simulated backscatter is developed. The utility of the estimation approach is analyzed in simulation and via a case study of iceberg A22a. Subsequent results agree with and supplement reports compiled by the United States National Ice Center. [C1904]

#### "The characteristics of post-seismic surface deformation of the Wenchuan MS 8.0 earthquake from InSAR"

The D-InSAR technology is used to acquire four strips of post-seismic surface deformation of Wenchuan M8 earthquake of 2008 from the ALOS/PALSAR satellite data of Japan. The result covers the Yingxiu town, Wenchuan, Shifang, Maoxian county, Beichuan, Pingwu and Qingchuan county in Sichuan Province. Some post-deformation characteristics is showed in the final result. Around Yingxiu town, the epicenter of main shock, a area of uplift is present with small amplitude 0-5cm at the northern wall of the causative fault, while relative subsidence took place with the amplitude 0-15cm on the other wall. Near Shifang county, there are slightly arranged concentric fringes, reflecting another subsidence area with amplitude 0-20cm. Around the Beichuan and Anxian county, there exists a relatively small uplift of an strip area with 0-5cm along the causative fault on its both side. A small area of dense concentric fringes(indicated by a rectangle box) appeared in 30km northeast of Qingchuan, which coincide with the locations of the aftershocks Ms6.1 of 5 Aug. 2008. On the lower wall, we can see another large uplift area of sparse concentric fringes located in more than 100km southeast of Qingchuan, because it is far from the causative fault, it's impossible so large deformation took place, and it should attribute to atmospheric component. the deformation characteristics of the whole area is complicated generally. [C1905]

#### "Characterization of volume scattering of dry sand at millimeter-wave frequencies"

Fully polarimetric measurements of volume scattering contribution from dry layer of fine sand with smooth air/sand interface were performed at millimeter-wave frequencies. The measured radar response was compared to predictions made by the numerical solution of the DMRT model. Sand particles were modeled as spherical particles. The simulated response was able to predict the angular dependence of the data but was not able to predict accurately the absolute level, especially for the cross-polarized return. Furthermore, a simpler model, which was developed earlier for asphalt surfaces and is based on 1st order solution of RT for semi-infinite medium, was tested against the measured data. The model was not able to predict the angular dependence demonstrated by the measured data. [C1906]

#### **"Validation of tie-point concepts by the DEM adjustment approach of TanDEM-X"**

The aimed accuracies for the final TanDEM-X DEM of 10m absolute and 2m relative height error will be ensured by calibration data. One crucial data set for the relative accuracy is tie-points that connect adjacent DEM acquisitions in the approximately 4km-overlap-area with each other. In this paper an improved concept for tie-point candidates is presented that is based on averaging a larger region instead of comparing single points. This concept should be more robust against noise. It is validated by applying the DEM calibration on a simulated test area, as real TanDEM-X data was not yet available. Also, the DEM calibration will be validated for the first time on a larger "real" test site by applying the TanDEM-X processing scenario. [C1907]

#### **"Forest parameter retrieval from SAR data using an estimation algorithm applied to regrowing forest stands in Queensland, Australia"**

The use of a non-linear estimation algorithm for retrieving the biomass and structure of vegetation from polarimetric Synthetic Aperture Radar (SAR) data is demonstrated for woody regrowth in Queensland, Australia dominated by *Acacia harpophylla* (Brigalow). By varying the size and density of trees and associated woody components (branches and trunks), multiple simulations of the backscattering coefficient ( $\sigma_0$ ) were performed based on the SAR simulation model of. Functions relating  $\sigma_0$  to these variables were subsequently used to generate spatial estimates from NASA JPL airborne SAR (AIRSAR) data. Above ground biomass was estimated from stem density and size measurements using available allometric relationships. The study demonstrates potential for retrieval of regrowth structure and biomass through nonlinear estimation. [C1908]

#### **"Forest biomass estimation in northeastern China using ALOS PALSAR data combined radiative transfer model"**

Forest above ground biomass (AGB) is an important variable for evaluating ecosystem function and structure across landscape, which is necessary for studying forest productivity, carbon balance and nutrient allocation in forest ecosystem. In this study, a forest biomass estimate technique based on forest backscattering database is developed, and is used to retrieve AGB of Changbai mountain area from ALOS PALSAR dual-polarization data. The forest growth model and the 3D forest radar backscattering model were combined to build a forest multi-polarization radar backscattering database. Then forest AGB was estimated based on this database using statistic regression method and look up table (LUT) method. Two types of LUT searching methods (nearest distance and distance threshold) were used to find the accurate results. The biomass retrieved from forest inventory data was taken as ground truth to evaluate the inversion methods and the precision of the AGB estimation. The inversion results derived from PALSAR FBD data shows that both the statistical regression method and nearest distance LUT method underestimate forest aboveground biomass. The distance threshold LUT method gives the better biomass estimation compared with forest inventory data, the mean absolute error (MAE) of the whole research area is less than 10 Ton/ha. [C1909]

#### **"An experiment for oil spill recognition using RADARSAT-2 image"**

In this paper, an experiment that is oriented to discriminate between different oil slicks using polarimetric SAR image was introduced. Dark patches which often appear in SAR images such as biogenic slicks, atmospheric front, and crude oil with different chemical composition were identified according to the result of Eigenvector-Eigenvalue based Incoherent Target Decomposition. The experiment demonstrated that polarimetric SAR can be of great help in classifying of oil spills. [C1910]

#### **"Characterization of forest opacity using multi-angular emission and backscatter data"**

This paper discusses the results from a series of field experiments using ground-based L-band microwave active/passive sensors. Three independent approaches are applied to the microwave data to determine vegetation opacity of coniferous trees. First, a zero-order radiative transfer model is fitted to multi-angular microwave emissivity data in a least-square sense to provide "effective" vegetation optical depth. Second, a ratio

between radar backscatter measurements with a corner reflector under trees and in an open area is calculated to obtain "measured" tree propagation characteristics. Finally, the "theoretical" propagation constant is determined by forward scattering theorem using detailed measurements of size/angle distributions and dielectric constants of the tree constituents (trunk, branches, and needles). The results indicate that "effective" values underestimate attenuation values compared to both "theoretical" and "measured" values. [C1911]

#### "A radar profiling algorithm designed for use with multiresolution radiometer measurements"

We have developed a radar profiling algorithm that can be incorporated into a larger radar+radiometer retrieval framework. The modular nature of the framework provides the opportunity to test the sensitivity of the retrieval to the inclusion of different measurements, retrieved parameters, and models for microwave scattering properties of hydrometeors. [C1912]

#### "Applicability of the iterative backward retrieval method for the GPM dual-frequency precipitation radar"

The dual-frequency precipitation radar (DPR) on the core satellite of the Global Precipitation Measurement (GPM) mission will measure the radar reflectivity factor in the Ku-band and Ka-band. A rain-rate retrieval algorithm that does not require surface reference was developed (called the MA04 method). However, MA04 cannot give the true solution in some cases of heavy rainfall. MA04 is a simplified version of the iterative backward retrieval method (IBRM) and the IBRM is equivalent to the forward retrieval method with a constraint. The purpose of this study is to clarify the essential conditions under which the IBRM and MA04 can give the true solution. [C1913]

#### "Airborne DInSAR time series at X-Band"

Differential SAR Interferometry (DInSAR) is a remote sensing technique which allows monitoring ground deformation with accuracy of the order of the transmitted wavelength by exploiting the phase difference (interferogram) of two temporally separated SAR images relevant to the same area. In addition, when more than two multi-pass acquisitions relevant to the same area are available, they can be properly combined by means of recent multitemporal DInSAR algorithms, in order to detect and follow the temporal evolution of ground deformation via the generation of spatially dense time series. Such a multitemporal DInSAR technique is nowadays developed and operative with space-borne SAR data, whereas specific problems may limit its application to airborne data. In this work, starting from the results already shown in previous works and relevant to an X-Band airborne DInSAR experiment carried out over the Perugia area (center of Italy) by using the OrbiSAR system, we carry out a DInSAR multitemporal analysis of data relevant to a 16 km (in azimuth) by 4 km (in range) region. [C1914]

#### "Potential and limitations of forward-looking bistatic SAR"

Bistatic synthetic aperture radar (SAR) operates with spatially separated transmit and receive antennas that are mounted on separated platforms. Provided that there is an overlap of both antenna footprints, the platforms can move with different velocities in arbitrary directions. A special configuration is given, when the receive antenna looks in forward direction, which is called bistatic forward-looking SAR. Besides the well known advantages of bistatic SAR like the increased information content of the data because of different RCS and scattering characteristics, such a configuration enables high resolution imaging in forward direction, which is not possible with conventional monostatic SAR systems. This paper analyzes a bistatic forward-looking configuration and demonstrates the capability and feasibility of imaging in forward or backward direction using the radar satellite TerraSAR-X as transmitter and the airborne SAR system PAMIR as receiver. [C1915]

#### "Tropical land cover change detection with polarimetric SAR data"

There is an increasing need for fast and accurate data on tropical land cover status, and a baseline for land cover monitoring. Remotely sensed SAR data are not sensitive to cloud cover and can be useful for such purpose. Polarimetric SAR data are available in orbital systems, such as RADARSAT-2, and still have to be tested for the classification of tropical land cover and the detection of land cover change, particularly forest conversion. This work presents a study of RADARSAT-2 polarimetric images, acquired in two different dates (September 2008 and October 2009), to assess their potential in classifying forest and non-forest classes in Brazilian Amazonia. SAR images were acquired following different orbit and incidence angles, which anticipated varied conditions for images interpretation and classes discrimination. The complex SAR data were classified based on the distance of Wishart, and information from field campaigns was used for the training and test samples. Classification results were compared to evaluate possibilities for change detection in the forest cover. Classification accuracy figures were around 80%. The use of RADARSAT-2 images allowed the mapping of land

cover and land cover change, considering forest and non-forest classes. [C1916]

#### **"Oil Spill statistics from SAR images in the North Eastern Baltic Sea ship route in 2007-2009"**

A large number of illegal oil pollutions impose considerable threat to marine environment especially in marginal seas like the Baltic Sea. Illegal spills are mainly detected on essential navigation routes. The monitoring of Oil Spills (OS) using remote sensing imagery (SAR data) was performed on the northeastern Baltic Sea ship route. The pre-analyzed satellite images for detecting marine pollution were provided to marine surveillance agency in Estonia. Out of 137 detected potential pollutions 76 were confirmed by aerial surveillance missions within two-year period. OS were mainly of low confidence, had small area, low contrast with surrounding water and smeared edges. The entrance to the Gulf of Finland was classified as the area where illegal spills of oil and bilge water take place, mainly. Between 30-50% of actual oil pollutions are not detected by SAR. [C1917]

#### **"High resolution optical and sar image fusion for road database updating"**

This paper addresses the issue of cartographic database creation or updating using high resolution SAR and optical images. It proposes a processing chain to create or update road databases in urban environment. The approach is composed of two steps. First, if a database is available, the presence of each database object is checked in the images. Then, we verify if road hypotheses extracted from images should be included in the database. These two steps are conducted by extracting relevant features from the images in the neighborhood of the considered object. The object removal/inclusion in the database is based on a score obtained by the fusion of features in the framework of Dempster-Shafer evidence theory. [C1918]

#### **"Extension of the Target Scattering Vector Model to the bistatic case"**

The polarimetric information has been widely used to interpret the Synthetic Aperture Radar (SAR) scene. Hence, many decompositions have been introduced to extract polarimetric parameters with a physical meaning. Nevertheless, for most of them, the reciprocity assumption is assumed. For a bistatic PolSAR sensor, the cross-polarization terms of the scattering matrix are not equal. This paper presents a generalization of the Target Scattering Vector Model (TSVM) to the bistatic case. [C1919]

#### **"Synergistic use of multi-temporal ALOS/PALSAR with SPOT multispectral satellite imagery for land cover mapping in the Ho Chi Minh city area, Vietnam"**

This paper discusses the synergistic use of multi-temporal ALOS/PALSAR and SPOT multi-spectral images for land cover classification in the Ho Chi Minh city area in Vietnam. Five PALSAR images and SPOT 2 multispectral image were used for classification. Integration of additional information such as interferometric coherence, textural data was also studied. Different combinations of multi-temporal SAR backscatter images, coherence data, SPOT multi-spectral bands, texture measures were generated and tested in order to determine the best combination, which gives the highest classification accuracy. Results indicate that the combination of SAR and optical images gives significantly higher classification accuracy than using a single type of data, and that the Support Vector Machine (SVM) classifier could outperform the Maximum Likelihood (ML) classifier in cases of classification of the combined datasets. [C1920]

#### **"The use of ALOS PALSAR imagery for Cerrado's land use and land cover mapping"**

In Brazil, land use and land cover (LULC) mappings are obtained mainly from optical images. Radar data are also promising since they are independent of solar illumination and the microwave radiation can penetrate clouds and depict differences in canopy structures. This study analyzed the potential of ALOS PALSAR data for LULC mapping of Federal District of Brazil (FD). L-band, HH-, HV- and VV-polarized amplitude images from the end of wet season were processed through the image segmentation technique by growing region. The segments were exported into a geographical information system software package as shapefile format and then visually interpreted in the computer screen. The following classes were discriminated: consolidate urban areas; urban areas in consolidation; natural grasslands; Cerrado shrubland; croplands; gallery forest; indiscriminated forests: pasturelands; reforestations; and water reservoirs. Cerrado shrubland was the most representative mapping class of the study area, followed by consolidated urban areas and natural grasslands. [C1921]

#### **"Real-time road traffic monitoring using a fast a priori knowledge based SAR-GMTI algorithm"**

Radar systems operating on high altitude platforms can provide traffic information over wide areas, independent of sunlight illumination and weather conditions. In the paper, a novel a priori knowledge based ground moving target indication (GMTI) and parameter estimation algorithm applicable on single- as well as on multi-channel synthetic aperture radar (SAR) data is presented. Only the intersection points of the moving vehicle signals with

the a priori known road axes, which are mapped into the range-compressed data domain, are evaluated. The algorithm needs low computational load and is hence well suited for real-time traffic monitoring applications.

[C1922]

### "Three-dimensional deformation field caused by the Gaize earthquake by Multi-LOS DInSAR measurement technology"

This paper firstly presents the Multi-LOS DInSAR measurement result of the coseismic deformation field caused by the Gaize Ms6.9 mainshock and Ms6.0 aftershock in Tibet, China, and then obtain the 3D deformation field based on the 3D resolving mode. The characteristic analysis of coseismic deformation field shows the rupture of mainshock is majority normal, left-lateral striking with a little rotation; and the aftershock is typical normal rupture nature. The mainshock and aftershock had induced the east and west rupture(maybe buried) successively, and produced the east and west two subsiding centers. [C1923]

### "A combined approach to detect urban features from multi-spectral and radardata"

With increase of urban population, the cities have an impact more and more important on environment. Because of artificial surface, building morphology, economical activities, traffic several natural ecosystem are modified. To analyze this impact, the land covers/land uses have to be identified exactly in an urban area. To reach this objective, remote sensing represents an important and complete source of information. Joint use of radar and optical data allows improving results of classical classification to identify the cover mode. Re-sampled to 1m resolution, the difference between the two classifications is analyzed to detect the confusion in each class corresponding to a land cover/land use. Finally, a vector process allowed to transform the geometry of the results: a polygon aggregates several pixels. Combination of results is also possible with GIS functionalities like contains, intersect, cut, and permits to propose a land cover/ land use description on the study area. [C1924]

### "Detecting depolarizing targets with satellite data: A new geometrical perturbation filter"

Target detectors using polarimetry are often focused on single (coherent) targets, since these are the ones that can be more simply characterized polarimetrically. The new proposed algorithm is aimed at the more difficult problem of partial target detection (i.e. targets with any degree of polarization). A new feature vector is defined starting from the coherency matrix, and then a perturbation method is performed. Starting from the partial target detection, a novel classification algorithm is proposed. The validation is carried out against fully polarimetric satellite data. In particular, X band TerraSAR-X and L band ALOS PALSAR are employed, providing significant agreement with the expected results and the supervised Wishart classifier. [C1925]

### "Autoregressive modeling of dechirped spotlight-mode sar rawdata in transform domain"

Raw data collected by synthetic aperture radar (SAR) is commonly assumed to be uncorrelated and with a zero-mean Gaussian distribution. In this paper, we show-both analytically and numerically-that the range-wise inverse Fourier transform of the dechirp-on-receive circular SAR data exhibits significant correlation in the azimuth direction. Moreover, we show that a block adaptive autoregressive model well represents the transformed SAR data. [C1926]

### "Investigation on moving target detection and velocity estimation with Triple-Channel MIMO-SAR"

Triple-Channel SAR system can detect moving target, and estimate its range velocity. However, the problems of blind velocity and velocity ambiguity still exit. To resolve these problems, Triple-Channel Multi-Input Multi-Output SAR (Triple-Channel MIMO-SAR) system, with a displaced phase center antenna (DPCA) and interferometry method based on matched Fourier Transform (MFT), is proposed in this paper, which could combine detection and estimation results of different working frequencies and obtain accurate Doppler frequency modulated rate estimation. Using this method, we can not only detect moving target and estimate its range velocity, but also resolve the problems of blind velocity and velocity ambiguity and get accurate azimuth velocity estimation. The effectiveness of this approach is validated by the computer simulation results. [C1927]

### "Change detection in a multitemporal series of radar images"

In the literature, several works are led around the radar images especially the detection of the cartographic objects, the 3D reconstruction and the change detection. Concerning this last application, several techniques compete to ensure the best possible result. In this paper, we aim first at developing an automatic detection procedure to compare between similarity measures. Then we propose a change detection technique based on the fusion of two similarity measures. The first one is the Contrast (C) measure [1] and the second one is the Rayleigh Distribution Ratio (RDR) measure [2]. The proposed method has been validated on simulated data and

then applied on three radar images. [C1928]

#### **"Numerical study on the statistics of the phase in backscattered signals from time-evolving sea surfaces"**

The linear and Creamer sea surface models are combined with the first-order small slope approximation (SSA1) technique and the method of ordered multiple interactions (MOMI) to study the statistics of the phase difference in backscattered signals from time-evolving sea surfaces. The impact of sea surface models and electromagnetic (EM) scattering computation methods on the backscattering signal phase is investigated. Numerical results are compared with theoretical distributions to validate the models and computational procedures proposed. Good agreements between simulated statistics and the theoretical counterparts demonstrate that the sea clutter returns are essentially joint Gaussian distributed on short time scales. [C1929]

#### **"Classification of polyphase and polytime LPI radar signals with eigenimage methods"**

LPI (Low Probability of Intercept) radars are based on an advanced architecture which makes use of coded pulses. As a synergetic byproduct, a low probability of intercept is also achieved due to the low power levels of LPI radars. In this study, some classification based methods for the uncooperative detection of LPI radar pulses are proposed. We specialized on polyphase and polytime type LPI signal pulses and developed methods for the automatic identification of these types of signals by eigenimage methods based on time-frequency transformations. [C1930]

#### **"A new bistatic doppler measurement system with reduced contamination by sidelobe echoes"**

A new bistatic Doppler measurement system with an array receiving antenna is proposed. In this system the spacing of receiving array elements is more than a wavelength (e.g. 10 wavelengths), and it leads to forming many sharp grating lobes. With these sharp lobes (beams) and some signal processing techniques like a digital beam forming, it can be expected that the effect of sidelobe contaminations, which is a serious problem of bistatic measurement, can be effectively reduced. [C1931]

#### **"Advances in the integration of ALOS PALSAR and Landsat sensor data for forest characterisation, mapping and monitoring"**

Based on case studies undertaken in tropical forests in Brazil and Indonesia and subtropical woodlands in Australia, the paper highlights how data acquired by the Advanced Land Observing Satellite (ALOS) Phased Arrayed L-band Synthetic Aperture Radar (SAR) and Landsat sensors can be integrated to better quantify the extent, biophysical characteristics and/or dynamics of undisturbed, degraded and regenerating forests. The benefits of using time-series of Landsat sensor data to support the interpretation of ALOS PALSAR data and to identify areas with greatest potential for ecosystem recovery are conveyed. [C1932]

#### **"Simulating and mitigating ionospheric effects in synthetic aperture radar"**

The ionosphere is magnetized plasma that forms above the neutral atmosphere due to solar ionization of upper atmosphere constituents. It presents an obstacle to space based synthetic aperture radar (SAR) systems since it affects the radar signals traveling through it. Its impact can be split into two groups: uniform effects (those caused by a spatially uniform non-turbulent ionosphere) and nonuniform effects (those caused by irregularities in the ionosphere). In this paper, we present a method for simulating the uniform non-turbulent effects such as dispersion, group delay, Faraday rotation, and phase shift. This method is then validated using PALSAR data of Washington, DC. We also show the coherence in this scene after ionospheric effects are added. Finally, the model is used to predict the level of ionospheric effects in future space based SAR systems such as ALOS-2. [C1933]

#### **"A specific methodology for atmospheric effect reduction on SAR interferograms"**

Interferometric Synthetic Aperture Radar (InSAR) measurements are often biased due to atmospheric effects. Especially, the tropospheric water vapor engenders a delay of SAR signal propagation. In this paper, we propose a specific methodology for atmospheric effects correction on SAR interferograms. It is based on ancillary data collected from NOAA-AVHRR sensor. The specificity of the approach consists in its applicability where no ground truth GPS measurements are available neither for calibration nor for result validation. An adaptive validation demarche is also proposed. [C1934]

#### **"Design considerations for a dual-frequency radar for sea spray measurement in hurricanes"**

Over the last few years, researchers have determined that sea spray from breaking waves can have a large effect on the magnitude and distribution of the air-sea energy flux at hurricane-force wind speeds. Characterizing the fluxes requires estimates of the height-dependent droplet size distribution (DSD). Currently, the few available measurements have been acquired with spectrometer probes, which can provide only flight-level measurements. As such, in-situ measurement of near-surface droplet fluxes in hurricanes with these instruments is, at best, extremely challenging, if at all possible. This paper describes an airborne dual-wavelength radar profiler concept to retrieve the DSD of sea spray. [C1935]

#### "Spaceborne P-band SAR for BIOMASS mission"

In the frame of the BIOMASS mission promoted by ESA for evaluating and monitoring Earth biomass, the expected performance of a P-band SAR instrument based on very large Direct Radiating Array antenna is addressed, as well as its architecture and the accommodation challenge on a platform. [C1936]

#### "Signal: SAR for ice, glacier and global dynamics"

SIGNAL is an innovative earth exploration mission proposal with the main objective to estimate accurately and repeatedly topography and topographic changes associated with mass change or other dynamic effects on glaciers, ice caps and polar ice sheets. Elevation measurements are complemented with glacier velocity measurements, providing valuable additional information for a better understanding of the hydrology of glacierized basins and of the Arctic and Antarctic water cycle. SIGNAL is capable of monitoring all critical regions with a high spatial resolution and an adequate revisit time. This paper gives an overview about the actual mission design status and provides a brief description of the topography (DEM-digital elevation map) self-calibration strategy and the estimated global interferometric performance. [C1937]

#### "Focusing general bistatic SAR data using frequency scaling"

This paper presents a method to focusing the general bistatic synthetic aperture radar (BiSAR) data. First, using the extended Taylor series, the general BiSAR data are transformed into the azimuth-invariant BiSAR one. Second, the monostatic frequency scaling algorithm is extended to the bistatic one. The numerical experiment indicates that our methodology is valid and the proposed algorithm can process the data of the general BiSAR. [C1938]

#### "Study on emitter signal recognition based on rough sets and grey association theory"

Recognition degree of unknown radar emitter signal can be describe by upper and lower approximation sets of Rough Sets. From the uncertain degree measure by multi-sensors, pessimistic and non-pessimistic distances of every object to sensors and grey association matrix can be calculated by grey association theory. According  $\alpha, \beta$  and grey association matrix, grey association degree and fusion result can gain. The simulation results show the method of combining Rough Sets and Grey Association theory is effective, and it can be applied on radar emitter signal recognition, especially in decreasing the uncertain degree introduced by multi-sensors. [C1939]

#### "Generalised decentralised fuzzy CA-CFAR detector in Pearson distributed clutter"

In this paper, we analyze the decentralized CA-CFAR detector using fuzzy fusion rules in heavy tailed clutter modeled by a Pearson distribution. We generalize our study by considering a distributed detection system with "L" detectors and using the "Maximum", "Minimum", "Algebraic sum" and "Algebraic product" fuzzy rules at the data fusion centre. We derive the membership function which maps the decision to the false alarm space and compute the threshold at the fusion centre. From the Monte-Carlo simulations conducted to assess the detection performance in homogeneous Pearson distributed clutter, we observe that the probability of detection increases with the number of detectors. However, there a maximum number of detectors ( $L = 11$ ) above which no improvement is obtained. [C1940]

#### "Feasibility of tunnel detection under rough ground surfaces using Underground Focusing Spotlight Synthetic Aperture Radar"

Detecting and imaging the presence of illicit tunnels in any given volume of soil is occasionally possible because the air that fills them is materially quite different from anything else underground. The Underground Focusing Spotlight Synthetic Aperture Radar (UF-SL-SAR) concept has been suggested for sub-surface tunnel detection due to its ability to scan large areas of terrain in a short amount of time. This paper explores the feasibility of tunnel detection under rough ground surfaces using an algorithmic implementation of the UF-SL-SAR concept. In particular, detectability is investigated as a function of tunnel depth, ground surface roughness and soil type. [C1941]

### "Currents in rivers, coastal areas, and the open ocean from TerraSAR-X along-track InSAR"

Since the first presentation of a TerraSAR-X along-track InSAR (ATI) derived current field in November 2008, considerable progress has been made with the implementation and testing of various ATI modes of the instrument, improvements of data processing techniques, and test dataset acquisitions over a variety of test sites. Furthermore, receiving and processing capabilities for TerraSAR-X data have been established at the University of Miami's Center for Southeastern Tropical Advanced Remote Sensing (CSTARS), which will permit a complete processing and analysis of TerraSAR-X ATI-derived current fields at CSTARS in the future. We give an overview of these developments and show a few results of recent experiments. [C1942]

### "The propagating speed of internal solitary waves investigated by X-band radar near Dongsha island"

Shipboard X-Band radar images acquired on June 24th, 2009 are used to study internal solitary waves (ISWs) characteristics at northeast of the South China Sea (SCS). The studied images show one ISW in a packet. A methodology based on the Radon Transform (RT) technique is introduced to calculate internal wave parameters such as direction of propagation, internal wave velocity from backscatter image. The result shows that the ISW amplitude is more than 100 meters and it approximately propagates northwestward continent shelf at a speed of 3.04 m/s. Compared with the other researches, especially only with satellite remote sensing images, the ISW propagation speed we got seems higher than other results. A new explanation is presented among different remote sensing images. The periods of most internal waves at northeast of SCS acquired from SAR images aren't regular M2 tidal period ( $T = 12.4h$ ), but less than 12.4h. This may be the reason that the ISW propagation speed we got from X-band radar images is higher than others from SAR images. [C1943]

### "Moving target refocusing algorithm for synthetic aperture radar images"

In the area of SAR imaging, it is of interest to be able to focus moving targets. In this paper, an algorithm for moving target focusing is presented. The algorithm is able to refocus a smeared moving target in a SAR image processed at one relative speed to the correct one%. The algorithm works in the frequency domain and is based on the Range Migration algorithm. The refocusing can be made on the whole SAR image or small sub images corresponding to physical areas of interest for the end user. By applying the algorithm to a small image, the computational cost is greatly reduced compared with using the full SAR image. The performance is illustrated by applying the algorithm to simulated SAR data according to the parameters for the LORA system. [C1944]

### "Automatic target recognition based on neural networks"

Several researches published about artificial neural networks are connected with military problems. This research put forward ideas connected with the processing of military information to search and identify targets-automatic target recognition (ATR). A main-purpose automatic target recognition system did not exist. The research put forward here was demonstrated on military data, however it could only be considered as a proof of principle until systems were fielded and proven "under-fire". A TR data could be in the form of non-imaging one-dimensional sensor returns, such as ultra-high range resolution radar returns for air-to-air automatic target recognition and vibration signatures from laser radar for recognition of ground targets. The ATR data could be two-dimensional images. The most common ATR images were infrared, but current systems might also deal with synthetic aperture radar images. Finally, the data could be three-dimensional, such as sequences of multiple exposures taken over time from a no stationary world. [C1945]

### "A distributed multi-agent tracking, awareness, and communication system architecture for synchronized real-time situational understanding, surveillance, decision-making, and control"

In this paper we deal with the design and analysis of an intelligent multi-agent-based architecture for synchronized real-time situational understanding, awareness, decision-making, and control in a geographically networked distributed computing environment. In particular, we focus here on the design and implementation of a middleware framework for agent intra and inter-node communication as well as computing nodes synchronization. While the proposed work finds applications in many areas including networked chemical sensors, large key infrastructures and resources such as highways and transportations, here as application of the proposed method we consider the challenging scenario case of a set of distributed collaborating radars (multi-agent) system geographically distributed over a large terrain environment with several moving targets. Here, each radar agent, taken separately, does not have the capabilities and resources to span the monitoring of the totality of a given large terrain. However, when collaborating with other radars distributed in the large terrain environment, each with similar limited capabilities, we show and illustrate the proposed distributed agents (radars) capability of not only monitoring their respective regions, but also tracking, communicating with

neighboring agents, and decision-making, to collaborating span the monitoring the totality of a given large terrain. We show how the neighboring agent radars do not necessarily have to be running on the same computing node. Similarly, as part of the scenario we also consider the case of existence of friendly and unknown forces/stressors targets that are capable of moving throughout the same distributed environment. We show how the proposed algorithms are scalable. They are implemented on the CMINDS High Performance Distributed Computing Engine (HDPC) test-bed taking full advantage of a distributed environment and multiple processing systems. [C1946]

#### **"A novel array calibration method based on spatial correlation matrix for HFSWR"**

This paper addresses a new method based on spatial correlation matrix to calibrate uniform linear array for HF Surface Wave Radar (HFSWR). Strong point echoes, such as target, clutter, transponder and so on, which are highly spatial correlated, can be used to structure spatial correlation matrix. And the matrix contains angles of echoes and phase errors information. In this paper, we use two-dimension FFT to estimate angle of strong point echo, and then obtain the corrections. Computer simulations and experimental results are conducted to show the validity of the new method. [C1947]

#### **"Space registration algorithm based on UKF using hybrid states"**

A new UKF based for radar and infrared sensor registration method is provided. A so-called "hybrid states" concept is introduced to describe target's state, which consists of the target's range, bearing and elevation and its velocity in the Cartesian coordinate system. The dynamic function and the measurement function are deduced in hybrid states. Simulation results show that the proposed method has higher accuracy and stronger robustness in the estimation of system biases. [C1948]

#### **"A comparison of experimental and modeled results of an active millimeter wave inverse synthetic aperture radar system used to perform standoff detection of person-borne improvised explosive devices"**

With the recent rise in casualties resulting from person-borne improvised explosive devices (PBIEDs) or "suicide bombers," there is an urgent need for standoff detection of such threats. An optimum system that fulfills the requirements of standoff detection must be portable, low cost, and have a high probability of detection with low probability of false alarm at a distance of at least 20 meters. Currently there are a variety of modalities being researched to perform standoff detection of PBIED's including: backscatter X-ray imaging, infrared imaging, optical detection, terahertz imaging, video analytics, and millimeter-wave (MMW) imaging. MMW imaging at 94 GHz is a very good modality for performing standoff detection of PBIEDs. MMWs can propagate through the atmosphere and clothing with very little attenuation, while at the same time do not cause damage to human skin tissue. A mono-static linear frequency modulated continuous wave (LFMCW) circular inverse synthetic aperture radar (ISAR) system has been developed and tested. A model of such a system using a two dimensional full wave analysis based on the finite difference method in the frequency domain has been developed and compared with results of the experimental system. Using a two dimensional matched filtering technique in the frequency domain, simulated images have been used as a means of performing target detection and classification. The imaging results of both simulated and experimentally obtained data is presented in this paper. Initial results using the 2D matched filtering target classification technique will also be presented. [C1949]

#### **"An improved algorithm for passive bistatic radar detection and parameters estimation"**

In passive bistatic radar system, both detection and joint estimation of time delay and Doppler shift of target are based on the cross-ambiguity function (CAF) between direct-path signals and target echoes. However, the drawback of this approach is the excessive processing load which is caused by the fast Fourier transforms (FFT) for long input samples. Since the interested frequencies of target often occupy a small portion of the whole frequency range, it only required to analyze the sub-band of the whole frequency. A decimation technique which can decrease the operation complexity was applied to solve this issue. The cascaded integrator-comb filter (CIC filter) theory was briefly introduced, followed by detailed signal processing procedures used to implement the target detection and parameters estimation. This improved algorithm needs several extra steps to decimate the signals, while greatly reduces the overall computation complexity with almost no loss of signal processing gain. Finally, the effectiveness of this proposed algorithm is verified by the real data analysis. [C1950]

#### **"Performance analysis of multiple signal detection using the ESPRIT algorithm"**

An array antenna system with an innovative signal processing algorithm "Estimation of signal parameters via rotational invariant technique" (ESPRIT) is used in this paper to estimate the direction of arrival (DOA) for multiple targets. The DOA angles are derived indirectly from the generalized eigenvalues of the auto-correlation

and cross-correlation matrices. The estimated autocorrelation and cross correlation matrices in this study are based on a combination of temporal averaging and spatial smoothing method. Two different methods of estimating the multi-signal DOA are: (1) Choice of appropriate pairs of generalized eigenvalues from the two sub-arrays according to their relative distance from the unit circle, and (2) Choice of appropriate pairs of generalized eigenvalues from the two sub-arrays according to their Euclidean distances [1]. Since the performance of the second approach provides a better estimation, it is used in this simulation study. A 19-element array antenna is used in this simulation study. Extensive computer simulations are used to demonstrate the performance of the processing algorithms. The DOA performance as a function of signal to noise ratio (SNR) and varying numbers of snapshots is presented in this paper. [C1951]

#### **"Surface current retrieval from TerraSAR-X data using Doppler measurements"**

The purpose of this paper is to investigate the estimation of surface currents directly on stripmap TerraSAR-X data, as an alternative to Along Track Interferometry. The algorithm relies on efficient baseband magnitude-based Doppler estimation, preventing the estimate from possible biases like azimuth ambiguities and strong target reflections. The validation of the algorithm is made with acquisitions over the Elbe estuary river in Germany and the Eyjafjallajökull volcano in Iceland. [C1952]

#### **"Assimilation of D-InSAR and sub-pixel image correlation displacement measurements for coseismic fault parameter estimation"**

In this paper, 2 data fusion strategies from SAR images are investigated through application to measurement of displacement field due to the Kashmir earthquake (Mw=7.6, 2005). Firstly, the 3D displacement field at the Earth's surface is retrieved by a linear inversion, using the measurements from sub-pixel image correlation and differential interferometry. In addition to the generalized least square method, a fuzzy approach is applied to represent the measurement uncertainty. Secondly, the geometry of the fault is optimized by a non linear inversion, using the same measurements. The inter-comparisons between strategies and approaches are performed in order to highlight the advantages and disadvantages of each strategy and approach. [C1953]

#### **"An innovative spaceborne radar concept for global maritime surveillance: Description and performance demonstration"**

The paper describes an alternative concept to conventional SAR instruments for ship detection over all ocean surfaces. The concept is specifically oriented for ship detection, and not for land or sea imaging. It allows wide swath coverage (as high as 1000 km). It exhibits high detection performances of small ships even in adverse sea states conditions. Its power consumption is reduced allowing a permanent operation all along the orbit. At least, it uses already developed and low cost technologies. [C1954]

#### **"X-band backscatter map generation using TerraSAR-x data"**

The goal of this work is the generation of an X-Band backscatter map by assembling images acquired by the TerraSAR-X mission. Global backscatter data is required for accurate performance estimation and instrument commanding inside the TerraSAR-X and TanDEM-X missions. Moreover, many scientific applications can be based on the analysis of backscatter behavior and evolution. The complete ground coverage will be achievable with TanDEM-X mission data. An interpolator, that allows the estimation of the backscatter for any required polarization and incidence angle from the available data, has been implemented. In this paper, the backscatter map generation algorithm will be presented, together with the first obtained results, generated using TerraSAR-X data. Moreover, the validity of the interpolation models will also be discussed, presenting the preliminary results of a statistical analysis of backscatter from TerraSAR-X data. [C1955]

#### **"Clutter detection algorithms for airborne pulse-Doppler radar"**

Clutter detection is an important stage of target detection. Clutter may not always appear around zero Doppler frequency when realistic terrain models and moving platforms are considered. Two algorithms developed for clutter detection using range-Doppler matrix elements and their performance analysis are presented in this paper. The first algorithm has higher error rates but lower computational complexity whereas the second one has lower error rates but higher computational complexity. The algorithms detect clutter position by filtering range-Doppler matrix elements via non-linear filters. [C1956]

#### **"Shallow water bathymetry with an incoherent X-band radar using small (smaller) space-time image cubes"**

The approach most commonly used in bathymetry by "depth inversion" starts by transforming a space-time cube

of ocean surface images into a wavenumber-frequency spectrum. The depth is determined by fitting the shallow water gravity wave dispersion equation to the 3D spectrum. The depth error using this method is inversely proportional to the image cube size. Very large image cubes are required for accurate bathymetry. Typical cube dimensions are on the order of 250 m  $\times$  250 m  $\times$  100 s. A new algorithm, originally developed for satellite images, can achieve the same accuracy with much smaller cubes, on the order of 100 m  $\times$  100 m  $\times$  10 s. This paper describes a test of this algorithm on low grazing angle radar data. The algorithm offers the potential for rapid near shore bathymetry surveys using marine X-band radars flown on aircraft. [C1957]

### "Combining GIS and InSAR data for 3D building reconstruction"

Today space-borne high resolution SAR sensors (e.g., TerraSAR-X, TanDEM-X, SAR-Lupe or Cosmo-SkyMed) provide SAR images up to spatial resolutions of 1-3m and even better in spotlight modes. Hence, one major issue of these missions is the development of methods to automatically derive detailed cartographic information from their data. Especially, the analysis of rural and urban areas is on demand in case of disasters (e.g., earthquakes), where active remote sensing systems are highly attractive. Here, an important issue is the development of automatic methods for damage assessment or change detection, in general. For that it is advisable to combine existing GIS data with current SAR data. In this paper an approach for 3D building reconstruction is presented, based on information fusion by utilizing GIS and InSAR data. Thereby, the GIS data are providing the 2D building footprints and the acquired InSAR data the height information. An InSAR simulation step and the subsequent assessment between the real and simulated InSAR phase data enables the extraction of the current building shape. [C1958]

### "Change detection in urban areas with high resolution SAR images using second kind statistics based G0 distribution"

This paper presents a SAR image change detection algorithm for urban areas which mainly contains three steps: (i) modeling the Synthetic Aperture Radar (SAR) image by G0 distribution; (ii) generating a change map by computing the Kullback-Leibler divergence; (iii) masking the change map to obtain the final change areas. We propose to use the second kind statistics based parameter estimation method via Mellin transform to figure out the three parameters of G0 distribution. Experiment results indicate the second kind based G0 distribution model outperforms the moment based methods and can achieve a satisfactory result. [C1959]

### "Spaceborne fully polarimetric time-series datasets for land cover analysis"

The objective of this paper is to make a review of the current status of the project entitled Evaluation of RADARSAT-2 quad-pol data for functional assessment of wetlands (Id6842), developed in the frame of the CSA-ESA SOAR-EU (Science and operational applications research for Europe) program by a consortium comprising I.E.T.R at the University of Rennes 1 and COSTEL-LETG at the University of Haute-Bretagne. The main objective of this project concerns in evaluating fully polarimetric RADARSAT-2 time-series datasets to delineate precisely effective and potential wetlands, map detailed vegetation distribution, identify agricultural practices and determine water cycle and waterlevels. [C1960]

### "Propagation of subinertial variations in the Soya Warm Current revealed by HF ocean radars"

Propagation of subinertial variations in the Soya Warm Current (SWC), which flows through the Soya Strait located between Hokkaido, Japan and Sakhalin Island, Russia, is investigated using data from HF ocean radars together with in situ observations, such as bottom-mounted acoustic Doppler current profilers (ADCPs) and coastal tide gauges. The subinertial variations with periods from 5 to 20 days were captured by the HF radars. The subinertial variations were significantly correlated with the meridional wind stress component over the region, suggesting that the sea level difference through the strait caused by wind-generated coastally-trapped waves on the east coast of Sakhalin and west coast of Hokkaido are considered to be a possible mechanism causing the subinertial variations in the SWC. Propagation of the subinertial variations was also clearly captured by the HF radars. The estimated phase velocity suggests that the subinertial variations propagate downstream along the coast as the 3rd-mode barotropic continental shelf waves. [C1961]

### "Multi-source SVM fusion for environmental monitoring in Marquesas archipelago"

Mapping plant species in montane tropical ecosystems needs the use of complementary information sources to be optimally accurate. In this paper, we study SVM fusion as a tool to classify several sources as optical, synthetic aperture radar and topographical ones. Our fusion scheme consists first in applying a single SVM on each individual data. Their outputs are then used for a SVM-based decision fusion to predict the final class membership of each sample. SVM fusion outperforms all mono-source SVM, our fusion method showing

numerous successful traits. [C1962]

### "Bistatic Radar Cross Section of a complex target on sea surface"

This paper deals with modeling interaction between Electro-Magnetic (EM) wave and the complex target. The first objective is to estimate monostatic and bistatic Radar Cross Section (RSC) of a complex target. The second objective is to present a new approach to compute the RCS of complex target (typically a boat). The target is modeled in 3D using computer aided design (CAD) to generate triangular facet meshing, as does CATIA software. From the triangular mesh, we propose to implement a parallelepiped mesh technique. This new mesh approach allow to introduce more precesely target in its environment and can be used in remote sensing domain. [C1963]

### "Analyzing tomographic SAR data of a forest with respect to frequency, polarization, and focusing technique"

In this paper, two fully-polarimetric tomographic SAR data sets of a forested area, at L-band and P-band, are analyzed with respect to the localization of scattering sources and scattering mechanisms. In particular, the 3D SAR data is examined regarding the performance of three different tomographic focusing techniques multilook standard beamforming, robust Capon beamforming, and MUSIC, as well as for both, the two frequency bands and the different polarimetric channels. [C1964]

### "Radiometric performance of the Advanced Wind Scatterometer radar ASCAT"

The Advanced Wind Scatterometer (ASCAT) instrument [1 & 2] is one of the instruments carried by the ESA / EUMETSAT METOP satellites (METOP A, B & C). The ASCAT is a six-beam radar instrument designed to measure wind fields over the oceans; the instrument also provides useful data for ice and land applications. The radiometric performance of the ASCAT carried by METOP-A is estimated and discussed. [C1965]

### "Application of aperture extrapolation beamformer in multibeam bathymetric sonar"

Limited by the cost, the size of multibeam bathymetric sonar becomes smaller. It is a significant issue to increase the beamforming capability of small aperture array. As the most commonly used method at present, virtual aperture technique together with LPAE beamforming method is discussed in detail in the paper. Compared with conventional beamforming method through theoretical analysis and computer simulation, LPAE beamforming has better performance for higher SNR, narrower receiving beams, and better resolution ability on nearly spaced goals. This method is proved to be effective, practical and superior by the processed results recorded with multibeam sonar sea trial data. [C1966]

### "The joint estimation of source number and DOA non-based on the Eigen decomposition approach"

A new concept 'propagator' for array signal processing is recently introduced, the properties of which have been proven useful for DOA (Direction of Arrival) estimation. This attractive concept is the propagator which can easily be extracted from the cross spectral matrix of the received signals for DOA estimation without Eigen-decomposition. But supplying propagator for DOA estimation has to know the number of sources received by array, which limits the application of propagator in Radar, Sonar and passive detection system. Based on multivariate analysis method, a joint estimation of the number of sources and DOA by propagator method (PM) is presented. It shows that the performance of proposed method with less complexity, effectiveness and high resolution. [C1967]

### "UWB LFM echo signal detection and time-delay estimation based on compressive sensing"

UWB linear frequency modulated (LFM) signals are widely used in radar, sonar and communication systems. In some applications, the detection of LFM signals and estimation of time-delay are very important. It needs very high sampling rate to address the problems for UWB LFM signal under Nyquist sampling theory which exceeds the current ADC capacity. In this paper, we propose a Compressive Sensing (CS) based method to solve the problem with ultra low sampling rate. We adopt an FrFt based sparse dictionary for CS because of the energy concentration property of LFM signal in the fractional Fourier domain. The performance is much better than the already existed method which used signal-matched sparse dictionary in noise condition. Experiments based on simulated data are carried out to testify the results. [C1968]

### "Altitude measurement using three circular marks"

This paper describes a system for a new altitude measurement method, using three circular marks on the

landing location for a Vertical Take-Off/Landing (VTOL) aircraft without an altimeter. This system costs less than a radar altimeter, yet it is more accurate than a pressure altimeter at low altitude and simpler than the Carrier Phase Differential Global Positioning System (CDGPS). The proposed method requires only an onboard camera, three circular marks placed on the landing site, and a control computer. The onboard camera must be facing toward the front of the aircraft and configured to detect the shape of the circular mark in image data form. The flight control computer calculates the altitude based on the known distance between the circular marks and the landing point. The accuracy of the proposed method is described in the analysis results section. [C1969]

### "Detection performance and configuration of Network Radar: A study based upon symmetry cross entropy"

Network Radar realizes the integration of the radar and radar countermeasures; it is a new trend of radar and radar countermeasures system. At first, it introduces the concept and some research results of the configuration of Network Radar. In succession, the CE (cross entropy) theory is utilized to evaluate the detection performance of Network Radar. We investigate the CE and put forward the concept of SCE (symmetry cross entropy) to compensate its inability to meet symmetry, and then prove in theory that it is a distance measure; thus the new evaluation model comes into existence which adopts the SCE as an evaluation criterion. By means of the simulations of the detection performance and configuration of Network Radar, The results prove that the method we have proposed is effective and feasible. [C1970]

### "Urban area extraction from Polarimetric SAR imagery using only positive samples"

In this paper, we present a study of extracting urban areas from Polarimetric Synthetic Aperture Radar (PolSAR) images using only positive samples. We solve this problem by learning a standard binary classifier (urban/non-urban) given an incomplete set of positive samples (urban) and a set of unlabeled samples (some of which are urban and some of which are non-urban) based on the work of Elkan and Noto. Our experiments on RADARSAT-2 fully PolSAR data show that learning with only positive samples can significantly reduces the manual work to select completed positive and negative samples that required by a traditional binary classifier, while providing satisfactory results. Meanwhile, multiple diverse features can be effectively combined for better extraction accuracy. [C1971]

### "A micro-motion feature deception jamming method to ISAR"

One of the main features of IS AR target recognition is the micro-motion feature. In order to jamming target recognition of IS AR, a micro-motion feature deception jamming method to ISAR based on digital image synthesizer is presented in this paper. In this method, the constant Doppler frequency of the scatterer in the template of false-target is replaced by the time-varying micro-Doppler frequency that produced by micro-motion scatterer, and the intercepted radar signals are modulated by the modified template of false-target in the slow time. The research results shows that this method can add the micro-motion information to the echoes of rigid body targets, and realize the micro-motion feature deception jamming to ISAR, Furthermore, the validity of the jamming method is justified by simulation experiment. [C1972]

### "Orthogonal waveform set design for netted radar"

Orthogonal netted radar system requires the transmitted waveforms with a very low autocorrelation and cross-correlation sidelobe peak level. Pseudo-random Phase Coded Modulation (PCM) waveform is suitable for orthogonal design in this sense. In this paper, the correlation properties of Gold sequences as binary phase codes are discussed. Numerical examples are presented to demonstrate the desired orthogonal properties of the coded pulse signal. The effect of Doppler shift and computation cost are also discussed. [C1973]

### "Pilot response to off-nominal conditions in merging and spacing operation"

This paper examines pilots' responses during a human-in-the-loop simulation to off-nominal conditions. During the simulation pilots used advanced flight deck tools to achieve automated spacing and merging assignments while in cruise, and prior to performing a continuous descent approach (CDA) into Louisville International Airport. The off-nominal conditions were represented by sparse and dense weather-patterned perturbations. Simulation results showed that, for the baseline nominal condition, the pilot response and the operation worked as expected. However, during off nominal conditions, qualitative analysis of traffic scenarios and quantitative data showed that pilot behavior in deviating for weather was difficult to predict, and that pilots often took aircraft-centric strategies to make decisions. These strategies lacked a system-centric perspective that could have allowed them to explore the availability of less disruptive and safer options. These responses formed emergent behaviors that may not have been anticipated by the system, and, can be attributed to the mismatches between the pilot strategies, the intended system/operation functionality, and the procedures/environment. Collectively

these mismatches created dispersion in the temporal spacing at the merge point prior to the descent, flight path stretches that are likely larger than required, higher workload, and ultimately unfavorable initial conditions for the CDA operation subsequent to the weather encounter. To further develop the interval managed CDA concept, a number of recommendations were provided for aligning these mismatches by considering the nature of the decision processes within the operational concept and incorporating them into automation designs, by developing a battery of off-nominal scenarios and by conducting simulations to model and specify what the system should and should not do. [C1974]

#### "Human-In-The-Loop simulation of area navigation visual flight procedures at atlanta international airport"

The Federal Aviation Administration (FAA) has committed to implementing Area Navigation (RNAV) procedures at airports throughout the National Airspace System (NAS). Delta Airlines (DAL) and air traffic controllers from the Atlanta Terminal Radar Approach Control (TRACON) (A80) facility have collaborated to design RNAV Visual Flight Procedures (RVFPs) at Atlanta's Hartsfield-Jackson International Airport (ATL). These procedures are comprised of a modified RNAV Standard Terminal Arrival (STAR) runway transition, a Constant Radius to Fix (RF) turn from the downwind to the final approach course, and the existing RNAV Global Positioning System (GPS) approach procedure. The RVFPs are designed to increase efficiency of properly-equipped ATL arrivals in Visual Meteorological Conditions (VMC). Implementing new RNAV procedures requires consideration of current traffic patterns to ensure a more efficient operation while maintaining high levels of operational safety. A80 requested that The MITRE Corporation's Center for Advanced Aviation System Development (CAASD) conduct a Human-In-The-Loop (HITL) simulation to evaluate the operational acceptability of implementing the proposed procedures from the pilot and controller perspectives. The HITL simulation allowed participants to identify design and procedural issues that required change. These changes were implemented during the course of the HITL simulation, yielding a procedure acceptable to both pilots and controllers. [C1975]

#### "TCAS Operational Performance Assessment in the U.S. National Airspace"

Ongoing monitoring of safety critical systems is an important means of ensuring that system performance meets requirements and facilitating proactive identification and resolution of potential problems. The Federal Aviation Administration (FAA) recently implemented one such effort, the TCAS Operational Performance Assessment (TOPA) program. This program records automatic downlinks of all TCAS Resolution Advisory (RA) events within sensor coverage and correlates the RAs with surveillance data, calculates performance parameters and permanently stores the data for future analysis. Periodic and focused reports are prepared based on these data. This paper summarizes key analyses of over 15,000 TCAS RAs collected in the period April-September 2009 at 5 major terminal areas in the U.S. National Airspace (NAS). Most RAs occurred below 5,000' in Class E airspace and involved low performance General Aviation (GA) intruders. Although no significant issues were observed with the performance of TCAS logic, the analysis showed that pilot compliance with Climb and Descend RAs did not meet system design assumptions. These results indicate that pilot training and the design of future systems must explicitly consider these factors. [C1976]

#### "A method for Ground Moving Target Indication and Velocity Estimation based on InSAR system"

For InSAR system, the increasing clutter degree of freedom (DOF) with the terrain is caused by long cross-track baseline. It degrades the performance of Ground Moving Target Indication (GMTI) greatly. In this paper a new method based on InSAR system is proposed for GMTI and Velocity Estimation. In our approach, the joint pixel technique is adopted to improve the coherence of clutter. In this way the clutter can be well cancelled. For the velocity estimation, neighboring pixel pairs is used to compensate the terrain interferometric phase. Therefore, the accuracy of velocity estimation can be improved. Stimulation experiments illustrate the effectiveness of the proposed algorithm. [C1977]

#### "System integration issues in Apollo 11"

"Houston, Tranquility Base here. The Eagle has landed." Two obscure errors almost prevented these words from being spoken. The errors were not made by the crew of Apollo 11 or by the controllers in Houston, nor were they made during the mission. Rather, they were made by engineers and managers, years before the flight. How they happened, and how they went substantially undetected and effectively ignored, is a pair of lessons in system integration that avionics engineers must never forget. The Apollo Program is justly famed as a giant leap for the techniques of management of complex system design and implementation. Nonetheless, these tools were used by human beings and so, necessarily, imperfectly. One of the most challenging tasks in any complex system is controlling and testing the interfaces between major components that are developed by different organizations. Among the management tools deployed by NASA were ICDs (Interface Control Documents). The

author has not been able to determine whether this phrase was first coined for the Apollo program or the Mercury and Gemini programs that preceded it, but it was certainly a major tool in Apollo. One of the errors under discussion here was caused by a blatant failure to update an ICD in response to an engineering change, which can be classed as a management error of omission. The other is much subtler, involving a question of how previously unsuspected vulnerabilities (to crew procedures, in this case) should be communicated when they fall outside the scope of an ICD, yet turn out to have relevance to the way the interface is used. This becomes a problem because an ICD is a top-level document limited to specifying the design parameters of one subsystem insofar as they are of concern to one other subsystem. It's not surprising that the symptoms caused by the latter problem have been totally misunderstood by almost everyone from President Nixon on down, and only partially understood even by Buzz Aldrin,--who along with Neil Armstrong had to deal with them at the time. This misunderstanding is so widespread that almost everyone with any acquaintance with the Program Alarms during the Apollo 11 landing believes that the LM's Primary Guidance Navigation System (PGNS) "failed" in some way and had to be rescued by human intervention. That is the exact opposite of the truth, which is that performance margins built into this very robust system quarantined the effects of the errors so that the landing could proceed with the designed level of human involvement, specifically dodging the "field of boulders" that the PGNS could know nothing about. This paper is largely a retelling of the higherlevel parts of a paper, Tales from the Lunar Module Guidance Computer by the author's colleague Don Eyles [1], but with the orientation changed from a historical narrative to a cautionary tale with recommendations for modern avionics development management. Results of more recent research by the author and two colleagues are also incorporated. [C1978]

### "Weber-Haykin based Automatic Censoring and detection in Weibull background"

In this paper, we study the problem of automatic target detection in Weibull clutter and multiple target situations, without any prior knowledge of neither the non-stationary clutter statistics in which the radar operates nor the number of outliers that may be present in the reference window. In doing this, we develop the Forward/Backward Order Statistic Automatic Censoring and Detection Constant False Censoring and Alarm Rates Detectors based upon the Weber-Haykin adaptive threshold (WH-based F/B-OSACD-CFCAR). These detectors select repeatedly a suitable set of ranked cells among reference cells surrounding the cell under test to estimate the unknown background level and set the adaptive threshold, accordingly. The censoring and detection performances are evaluated by means of Monte Carlo simulations. [C1979]

### "Design based on MCU for the echo simulator of the range extended target"

It is important for the high resolution radar to design the simulator for generating the echoes of the range extended target. In this paper, a simulator design which is based on Micro Controller Unit (MCU) is proposed for generating the echoes of the range extended target. Because those echoes change rapidly and the corresponding period is longer, the high speed FIFO is selected as the data cache. In the idle time of system, waveform data is transferred from MCU to FIFO, whereas in the operating time of system it is transferred from FIFO to D/A converter at a high speed in order to output the waveform. The experimental results show the design can meet the purpose of the echo simulator of range extended target. [C1980]

### "Instantaneous Frequency estimation of multicomponent signal based on complex argument distribution"

Instantaneous Frequency estimation of multicomponent signal with nonlinear frequency modulation is a challenging problem in time frequency analysis community. A new time frequency distribution named complex argument distribution is introduced to resolve this problem due to its capabilities of high concentration and low cross-term artifacts. A instantaneous frequency estimation algorithm based on this new distribution and Viterbi estimator is proposed in the paper. Experiments result show the performance of estimation algorithm with simulated data and radar data. [C1981]

### "A CKF based spatial alignment of radar and infrared sensors"

Spatial alignment is the prerequisite for the successful data fusion of multiple sensors. A CKF based spatial alignment algorithm for the estimation of bias between radar and infrared sensors on a same platform is presented. The system dynamics of this problem is established in a hybrid coordinate, i.e., the target position in the spherical coordinate while the target speed in the Cartesian one. The system bias is then estimated by the cubature Kalman filter (CKF) in an augmented system state equation. Simulation results show that the proposed algorithm is effective and efficient. [C1982]

### "Evaluating information assurance performance and the impact of data characteristics"

Research and development of new information assurance techniques and technologies is ongoing and varied.

Each new proposal and technique arrives with great promise and anticipated success as research teams struggle to develop new and innovative responses to emerging threats. Unfortunately, these techniques frequently fall short of expectation when deployed due to difficulties with false alarms, trouble operating in a non-idealized or new domain, or flexibility limiting assumptions which are only valid with specific input sets. We believe these failures are due to fundamental problems with the experimental method for evaluating the effectiveness of new ideas and techniques. This work explores the effect of a poorly understood data synthesis process on the evaluation of IA devices. The point of an evaluation is to independently determine what a detector can and cannot detect, i.e. the metric of detection. This can only be done when the data contains carefully controlled ground truth. We broadly define the term "similarity class" to facilitate discussion about the different ways data (and more specifically test data) can be similar, and use these ideas to illustrate the pre-requisites for correct evaluation of anomaly detectors. We focus on how anomaly detectors function and should be evaluated in 2 specific domains with disparate system architectures and data: a sensor and data transport network for air frame tracking and display, and a deep space mission spacecraft command link. Finally, we present empirical evidence illustrating the effectiveness of our approach in these domains, and introduce the entropy of a time series sensor as a critical measure of data similarity for test data in these domains. [C1983]

### "Challenges of remote border monitoring"

Monitoring long lengths of remote borders with ground surveillance methods, presents many challenges. This paper will discuss three in particular that must be addressed in order to build an effective remote ground surveillance system. The three issues are: (1) providing reliable and efficient power, (2) providing adequate and timely maintenance to minimize downtime, and (3) networking systems for effective data transmission. A well planned remote ground surveillance system that overcomes each of these three challenges will provide a cost-effective solution requiring minimal support infrastructure solution to meet border monitoring and protection needs. [C1984]

### "Generalized likelihood ratio test for distributed targets in heterogeneous environments"

Adaptive detection for distributed target or targets in non-homogeneous environments is studied in this paper. It is assumed that the covariance matrix of the secondary data  $M_s$  is a random matrix following inverse Wishart distribution with its conditional expectation proportional to that of the primary data, i.e.  $E(M_s | M_p) = \gamma M_p$ . Firstly, the maximum likelihood estimator (MLE) of  $M_p$ ,  $\gamma$  and target amplitudes are given and the generalized likelihood ratio test (GLRT) are proposed subsequently, which turns out to be in the form of the summed adaptive coherence estimator (ACE). The detector is coincident with the generalized adaptive subspace detector (GASD) based on deterministic unknown covariance matrix and it has CFAR property. When the target exists only in one range bin, the detector is boiled down into the ACE based on the partial homogeneous environments. [C1985]

### "A commercial approach to successful persistent radar surveillance of sea, air and land along the northern border"

The benefits of a commercial approach to the deployment of radar surveillance along the Great Lakes St. Lawrence Seaway System (GLSLSS) is discussed. Surveillance solutions must be multi-mission suitable, scalable, flexible, maintainable, upgradeable, interoperable, shareable, and affordable. This flexibility is fundamental to successfully leveraging tomorrow, investments made today in order to keep up with changing threats and technology. Not only can homeland security surveillance solutions benefit by leveraging commercial technologies, but non-sensitive target information, can drive significant human and commercial benefits. The paper presents a radar surveillance framework whose network architecture, COTS components, specially designed components and open interfaces are discussed. The modular nature of the framework includes software definable algorithms for acquisition of sea, air or land targets of interest, built-in integration of target information that fully scales in support of wide-area surveillance, and open interfaces in support of new, multi-mission situational awareness applications. [C1986]

### "High order Doppler parameter estimation of bistatic forward-looking SAR based on CPF-Radon transform"

For high quality synthetic aperture radar (SAR) processing, Doppler parameter estimation is an essential procedure. In this paper, the azimuth data of bistatic forward-looking SAR are modeled as cubic polynomial phase signals, and the CPF-Radon transform is used to estimate the high order Doppler parameter. Simulation results validate the effectiveness of this method. [C1987]

### "A study of frequency diversity MIMO radar beamforming"

Compared to traditional phased-array radar, multiple-input multiple-output (MIMO) radar can transmit multiple probing signals that are correlated or uncorrelated with each other. An interesting current research topic in MIMO radar is the frequency diversity MIMO (f-MIMO) radar. The frequency between two adjacent transmitted signals of f-MIMO radar are not identical but stepped uniformly at the same time. In this paper, a f-MIMO radar array processing model is developed. It is shown that the f-MIMO radar array processing can form a range-dimension beam, so it has the ability to distinguish targets in different ranges. The range resolution of array processing is derived, and then, the virtual array aperture of f-MIMO radar is also investigated. [C1988]

#### **"Target decomposition for fully polarimetric wideband radar system"**

For fully polarimetric wideband radar system, a novel method of radar target recognition using polarimetric feature is proposed. First, polarimetric scattering matrix is obtained from fully polarimetric high resolution range profiles (HRRPs). Then, two different kinds of polarimetric features are extracted by polarimetric target decomposition theorem. At last, K-Nearest Neighbors (KNN) classifier is applied to verify the recognition performance of these two features. The simulation experiments indicate target recognition via polarimetric features can reach a higher recognition performance in different experimental scenarios. [C1989]

#### **"Cross-correlation detection and time difference estimation in non-cooperative bistatic radar systems"**

In this paper, the basic geometrical relationship and signal energy relationship of non-cooperative bistatic radar are introduced, and the method using the cross-correlation to obtain the time difference of direct signals and target scattering echoes in noisy environment is discussed. Some experiments have been done to simulate the process of cross-correlation detection and time difference estimation. What's more, on the basis of them, some parameters affecting the performance of the algorithm, such as the signal-noise ratio, pulse width and pulse number of cross-correlation, are analyzed by Monte Carlo simulation. [C1990]

#### **"An adaptive beamforming method based on properties of cyclostationary signals"**

Blind beamforming, which consists of recovering signals only from observed instantaneous linear mixtures without a priori information about array manifold, is an important problem in many practical applications including radar, sonar, wireless communication and so on. For blind separation of cyclostationary signals encountered usually in communication, recently, reference [1] proposed a novel approach (ATH3) under the assumption that the cyclic correlation functions of signals are all real number. In this paper, we relaxed this assumption to signals with complex cyclic correlation functions, which is usually this case in practice, and proposed a method to accomplish blind adaptive beamforming. Several numerical simulations also are provided to illustrate the effectiveness of the proposed method. [C1991]

#### **"An improved passive location algorithm for maneuvering target emitter"**

With the merits as hiding receiving, far responding distance and easy-deploying, the single observation passive location has a broad application in military domain. Especially, it plays an important part in passive radar, navigation and aerospace, etc. With the information of phase-difference, phase-difference rate of change and Doppler frequency rate of change, a new algorithm based on EKF (called PFRC) is proposed. Compared with two popular passive location methods which are bearing-only (BO) and phase-difference rate of change (PRC), the PFRC has good performance in that it has higher precision and higher speed. However, the PFRC, based on the EKF, can only give a biased state estimation, which has poor robustness and precision against model mismatching and is inapplicable for maneuvering target tracking. In order to overcome the above limitations, based on the PFRC and the strong tracking filter (STF), an improved passive location algorithm is proposed. Simulation results show that the proposed algorithm has better performance. [C1992]

#### **"Zero Correlation Zone Codes and Extended Zero Correlation Zone Codes for MIMO radar signal separation"**

Pseudo random codes are easily constructed and can be used in multiple-input multiple-output (MIMO) radar to provide for signal separation. However it has the drawbacks of high aperiodic cross-correlation and auto-correlation sidelobes. Fortunately, in some applications, codes with low correlations are needed only over a narrow window. In this paper, we introduce the Zero Correlation Zone Codes (ZCZC) which have zero correlations in a narrow zone. In other applications, the targets are stationary, which allows for using a long code sequence. In this case we propose an Extended Zero Correlation Zone Codes (EZCZC) where the zero correlation zone is extended to cover the whole sidelobes area. Design examples are given. [C1993]

### "Review of Observing System Simulation Experiments to evaluate the potential impact of lidar winds on weather prediction"

Observing System Simulation Experiments (OSSEs) are an important tool for evaluating the potential impact of proposed new observing systems, as well as for evaluating trade-offs in observing system design, and in developing and assessing improved methodology for assimilating new observations. Extensive OSSEs have been conducted at NASA/GSFC and NOAA/AOML in collaboration with Simpson Weather Associates and operational data assimilation centers over the last 25 years. These OSSEs determined correctly the quantitative potential for several proposed satellite observing systems to improve weather prediction prior to their launch, and evaluated trade-offs in orbits, coverage, and accuracy for space-based wind lidars. In this paper, we summarize OSSE methodology and present results from OSSEs to assess the potential impact of lidar winds. [C1994]

### "Integrating object-oriented image analysis and decision tree algorithm for land use and land cover classification using RADARSAT-2 polarimetric SAR imagery"

Traditional pixel-based classification methods yield poor results when applied to SAR imagery because of the presence of speckle and limited information in backscatter coefficients. A novel classification method, integrating polarimetric target decomposition, object-oriented image analysis, and decision tree algorithms, is proposed for the classification of polarimetric SAR data (PolSAR). The polarimetric target decomposition is aimed at extracting physical information related to the scattering mechanism of targets for the classification of scattering data. The main purposes of the object-oriented image analysis are delineating objects and extracting various spatial and textural features. The decision tree algorithm provides an efficient way to select features and create a decision tree for the classification. A comparison between the proposed method and the Wishart supervised classification was made. The overall accuracies of these two methods were 89.34% and 79.36%, respectively. The results show that the proposed method is an effective method for the classification of PolSAR data. [C1995]

### "Maximum Likelihood texture tracking in highly heterogeneous PolSAR clutter"

This paper introduces a generalisation of the conventional Maximum Likelihood (ML) texture tracking algorithm in the context of highly heterogeneous PolSAR clutter. The statistical criterion is defined in both uncorrelated and correlated texture cases. Some results on simulated data are computed and an application on temperate glaciers velocity estimation is processed. Finally, some additional improvements are performed: an adaptative sliding windows is set and a basic Bayes inference for flow model constraint is added. [C1996]

### "Estimating rice growth parameters using X-band scatterometer data"

In this study, we constructed an X-band automatic scatterometer system and analyzed scattering characteristics of paddy rice over the whole period of rice growth from transplanting to harvesting. The backscattering coefficients were calculated from the measured data at incidence angle  $45^\circ$  and full polarization (HH, VV, HV, VH) by applying the radar equation and compared with rice growth data such as plant height, stem number, fresh and dry weight and Leaf Area Index (LAI) that were collected at the same time of each scatterometer measurement. Based on the analysis of the relation between backscattering coefficients at X-band and rice growth parameters, we predicted the rice growth parameters using the radar backscattering data. Relationship between measured and estimated grain dry weight using the X-band backscattering coefficients (VV-polarization) is highly correlated ( $R^2=0.94^{***}$ ). Results from this study show that backscattering coefficients X-band appear effective to estimate rice growth parameters. [C1997]

### "Building extraction from VHR multi-spectral images using rule-based object-oriented method: A case study"

Object-oriented classification has been demonstrated a promising method for large-scale detailed urban structure mapping using very high-resolution space-borne or airborne remote sensing images. In the paper, the object-oriented classification method for building extraction using pan-sharpened IKONOS multi-spectral images was applied to roof mapping combined with Lidar data. The scheme to produce the vector polygon database of buildings includes the following steps: (1) image pre-processing and derivation of secondary inputs to image segmentation and classification procedures; (2) segmentation of processed data layers into image objects; (3) classification of image objects; (4) export classified map objects and average building height data; and (5) polygon generalization and/or geometrical regularization. The experimental result is visually satisfactory and may suit overall investigations of building development. [C1998]

### "Retrieval of Aerosol optical thickness and size distribution from PARASOL in Pearl River Delta area"

AOTs(Aerosol optical thicknesses) and aerosol size distribution functions in Pearl River Delta area are derived from PARASOL (Polarization and Anisotropy of Reflectances for Atmospheric Science coupled with Observations from a LIDAR)multi-directional, multi-spectral polarized signals. Based on analyzing the products of AERONET(Aerosol Robotic Network), aerosol size distribution function and complex refractive index over Pearl River Delta area are received. After that, the particular aerosol model is abstracted. The land surface polarized contribution is calculated using semi empirical model as a function of surface type and NDVI, and the pure atmospheric contribution is computed with a radiative transfer code. Compared with the products of the ground-based AERONET, the derived AOTs are underestimated against AERONET measurement. The retrieved size distribution for the radii bigger than 0.2 micron is also underestimated due to that polarization is insensitive to coarse model aerosol. [C1999]

#### **"Towards fully automatic generation of land cover maps from polarimetric and metric-resolution SAR data"**

Information mining from heavy SAR images is considered from the point of view of the procedure automatization. Two schemes based on Neural Networks are evaluated, one based on the Self Organizing Map method exploiting polarimetric information and oriented to land cover classification, the other based on the Pulse-Coupled Neural Networks aiming at characterizing the imaged buildings. [C2000]

#### **"Statistics of depolarization ratio from an airborne backscatter lidar"**

An important cloud optical property derived from elastic backscatter lidars is depolarization ratio because it is used to determine cloud phase. Statistics and trends of volume depolarization ratio were analyzed for four years, 2003-2007, of Cloud Physics Lidar data during five projects of varying geographic locations and meteorological seasons. The volume depolarization ratio was computed using the parallel and perpendicular polarized 1064 nm channels. The majority of the cloud layers yielded a volume depolarization ratio between 0.3 and 0.6 with the volume depolarization ratio frequency distribution centered at 0.45 for ice clouds and 0.05 for water clouds. On average for ice clouds, volume depolarization ratio increased significantly as temperatures decreased. No trend for water clouds was observed, since all water particles are in theory spherical. [C2001]

#### **"A comparative study of polarimetric and non-polarimetric lidar in deciduous-coniferous tree classification"**

As an important active remote sensing tool in forest remote sensing, lidar is able to provide information on tree height, canopy structure, aboveground biomass, among other parameters. It has become desirable to be able to classify tree species using lidar data during recent years. Research has been performed using commercial non-polarimetric lidar in tree species classification, at either dominant species level or individual tree level. The objective of this research is to classify deciduous and coniferous trees using the newly developed polarimetric lidar system. Lidar data from five different tree species were collected in the field. These included ponderosa pine, Austrian pine, blue spruce, green ash and maple. Data were preprocessed and artificial neural network method was developed for classification. Data analysis demonstrated that the classification performance using polarimetric lidar data was far better than that using the non-polarimetric lidar data. [C2002]

#### **"National ecological observatory network (NEON) airborne remote measurements of vegetation canopy biochemistry and structure"**

The National Ecological Observatory Network (NEON) is a continental-scale research platform for discovering, understanding and forecasting the impacts of climate change, land-use change, and invasive species on ecology. Site-based flux tower and field measurements will be coordinated with high resolution, regional airborne remote sensing observations. This data combined with satellite observations, national data sets and ecosystem models will extend site-based and regional coverage to the continental scale. The NEON Airborne Observation Platform (AOP) will carry remote sensing instrumentation designed to achieve sub-meter to meter scale ground resolution to bridge scales from organism and stand scales to the scale of satellite based remote sensing. The capability of the airborne system will be well beyond existing systems in its ability to produce quantitative information about ecosystem structure and functioning covering nearly 2 million hectares each year for 30 years or more. [C2003]

#### **"QEM-based simplification of building footprints from Airborne LiDAR data"**

This paper presents a QEM-based simplification approach for extracting and delineating building footprints from Airborne LiDAR data. Our approach consists of three steps: first of all, Digital Surface Model (DSM) is generated from the raw point cloud by using the interpolation method. Secondly, the potential points on building outlines

have to be aggregated to form connected building blobs. Those blobs that exceed a certain size and have certain characteristics (e.g. consisting of planes) are supposed to be building candidates. In a third step these outlines are simplified to building footprints. The focus lies on taking the characteristics of buildings into account to produce a meaningful 2D building shape and simplifying different possibilities to generalize the building footprints. [C2004]

### "Soil dielectric and sensitivity analysis for subsurface imaging applications based on distributed Sensor Networks"

The concept of a subsurface imaging technique based on Unattended Ground Sensor Networks operating in the VHF range using ultra-wideband waveforms was recently proposed in. In this approach a forward model for realistic subsurface environment based on the Dyadic Green's function for a stratified medium and an inversion technique using an ultra-wideband near-field focusing were presented. Simulation results showed that very good lateral and depth resolution could be achieved. Before carrying out an experiment to test the proposed technique, three vital aspects of the work which are imposed by practical limitations are investigated and presented in this paper. First, the sensitivity analysis to assess the signal penetration depth in realistic subsurface environments for various frequencies is performed. Analysis of the frequency requirements of the inversion as they relate to depth resolution is also analyzed. A semi-analytic soil dielectric model originally devised for microwave frequencies is extended to VHF and validated using measurement results available in literature. [C2005]

### "The Semi-Analytic Mode Matching algorithm for GPR wave scattering from multiple complex objects buried in a dielectric half space"

The Semi-Analytic Mode Matching (SAMM) algorithm is a quick and efficient computational method that can model wave scattering from multiple objects in half spaces. This algorithm relies heavily on the appropriate choice of coordinate scattering centers (CSCs) for its modal expansions. Here, the radius of curvature method of finding CSCs is extended to "tune" the CSC loci. Because the CSC locations are essentially frequency independent and independent of the dielectric contrast between scatterer and background, it is worthwhile to analyze carefully particular scattering object shapes and store the optimal CSC locations for future use. Scattering from multiple targets buried within half spaces can be constructed from simpler simulations of the individual targets taken independently in uniform media-combining these initial simulations correctly can greatly reduce overall computational time and increase robustness in full simulations. Excellent results are found comparing SAMM and Finite Difference Frequency Domain (FDFD) for multiple 2D scattering objects 0.1-15 wavelengths in size located beneath half spaces. [C2006]

### "Generation of DEM by radargrammetric techniques"

Thanks to the signal processing applied to radar signal, radar systems can provide images with a very high resolution. With regard to these properties, one can estimate that radar images are used to get elevation terrain considering the basic characteristics of a radar image. This paper examines one way to produce DEM (Digital Elevation Models) from a mountainous area (the French Alps). So, we organize the discussion in three parts. First, we present the basic operations that the radargrammetric processing requires to be performed. So we deal with the different steps to obtain a DEM. Secondly, we expose two classical image matching improvements: the epipolar geometry and the pyramidal scheme. At the end, we present the results of DEM generation from a SIRC shuttle mission image pair and the way to improve these results. [C2007]

### "Compressive sensing for high resolution differential SAR tomography-the SL1MMER algorithm"

Differential SAR tomography extends the synthetic aperture principle into the elevation and time directions for 4-D imaging. With modern meter-resolution space-borne SAR systems like TerraSAR-X (TS-X), systematic tomographic imaging of urban infrastructure and its deformations becomes feasible. We demonstrate the potential of TS-X data for this purpose and introduce several novel concepts. Since building deformation in general is nonlinear, e.g. due to thermal dilation, we start from a tomographic system formulation that is general enough to allow for the inclusion of motion models (linear, periodic, etc.). By appropriate warping of the time axis we map the motion model function to become linear and lead to a peak in the spectral domain. For the differential tomographic inversion itself we propose a 2-D compressive sensing (CS) based approach-"SL1MMER". We demonstrate the super-resolution power and the robustness of SL1MMER both with simulated and with real data. We also show that it provides an attractive compromise between parametric and non-parametric methods. A full reconstruction of a building complex and its seasonal deformation from a stack of TS-X spotlight data is finally presented. [C2008]

### **"Processing and segmentation of COSMO-SkyMed images for flood monitoring"**

In the framework of the application of remote sensing to civil protection from floods, the problem of the detection of flooded areas in high-resolution images is addressed in this paper. Specifically, the high-resolution multitemporal observation capability offered by the current COSMO-SkyMed synthetic aperture radar (SAR) constellation is exploited. This work is framed in the context of the "OPERA-Civil protection from floods" pilot project funded by the Italian Space Agency in cooperation with the Italian Department for Civil Protection. Several SAR image processing methods are presented in order to identify flooded areas after a flood event. Both fast-ready and detailed maps are obtained from a pair of multitemporal images of the monitored area. Experiments are presented with COSMO-SkyMed images related to a flood in the areas of Alessandria (Italy). [C2009]

### **"A portable 35 GHz cross-track interferometer for topographic and surface change measurements"**

In the following, we present first results obtained from the design, construction and deployment of a 35 GHz fixed-point radar interferometer, that uses the principles of FMCW for generating a range resolving signal. Using a single transmit antenna and two receive, separated by an interferometric baseline, it is possible to determine phase differences between the two receive channels, and given the viewing geometry, to solve for the target topography. To test the system described in this short paper, it was deployed on a local mountain top, some 270m above the local terrain. With knowledge of the nominal topography (measured by the Shuttle Radar Topography Mission; SRTM), and sufficiently large interferometric height ambiguity, it is possible to solve for the topography, as seen at 35 GHz, and to monitor differences in the observed topography which may be due to differences in volume scattering, surface motion, and surface dielectric change. [C2010]

### **"Mapping earthquake damage in VHR radar images of human settlements: Preliminary results on the 6th April 2009, Italy case"**

Automated earthquake damage assessment from post-event only remotely sensed data is highly desirable, especially when new generation, Very High Resolution (VHR) spaceborne data is concerned, lacking extensive pre-event archives. Though, most damage assessment method either rely on human interpretation or on pre-post-event comparison. In this paper we illustrate some possible tracks for investigating damage assessment on post-event only data, focusing on the 6th April 2009 Abruzzi, Italy earthquake and on related COSMO/SkyMed acquisitions. [C2011]

### **"Topographic correction for biomass retrieval from P-band SAR data in boreal forests"**

The influence of the ground slope on radar backscatter has been proven to be greater for lower radar frequencies due to deeper canopy penetration. In this study, multiple heading, P-band SAR data of boreal forest in Sweden was used to find a model for topographic correction for improved biomass retrieval. Eleven models were tested and the best model was selected. The selected model was then used for biomass retrieval. Even by means of the most simplified approach, forest biomass could be established with a root-mean-square error of approximately 50 t/ha for HV and 66 t/ha for HH. [C2012]

### **"Application of Fractional Fourier Transform to finite difference time domain method"**

With the improvement in the computer speed and memory, Numerical Methods are frequently used in the solution of electromagnetic problems. Numerical Methods can be classified as the frequency domain and the time domain based methods. While the time domain methods are suitable for modeling of the transient response and wideband problems, the frequency domain methods are suitable for modeling of the steady state response and narrow band problems. A numerical method that has the advantages of both time and frequency domain approaches can be developed. Applying Fractional Fourier Transform in space and/or time can reduce the computational complexity for some cases. The Fractional Fourier Transform is a generalization of the continuous Fourier Transform. In last decades, there are several studies and applications concerning this transform. Generally, it is used in signal processing and noise filtering. In this study, Fractional Fourier Transform is applied to the Maxwell's Equations for the first time in literature. Finite difference equations are obtained by the application of finite difference approximation to the differential equations. [C2013]

### **"A new approach to modeling ice crystal aggregates and its implications for radar remote sensing"**

Backscattering cross sections of model ice crystal aggregates are computed at 35.6 GHz using the generalized multiparticle Mie (GMM) method and compared against a commonly used equivalent dielectric model (also referred to as the "soft sphere" or the "bulk" model). It is shown that the bulk model underestimates the backscattering cross sections by 7 to 20 dB over aggregate sizes from 3 to 19 mm. This raises concerns about

using bulk models for the interpretation of millimeter wave radar measurements of ice clouds and snow. [C2014]

### "Implementing a reactive semantics using OpenRTM-aist"

The expression of reactive behaviour is a significant and important requirement in robotic software engineering, since robots must cope with a wide range of unpredictable events and environments. However it is important that the semantics for reactive expression can be used across different architectures and languages. The RADAR robot programming language provides architecture- and language-independent semantics for managing the reactive parts of robot software together with the deliberative parts, allowing greater interaction between the two. We evaluate the architecture-independence of RADAR, as an example, by implementing its reactive semantics using the OpenRTM-aist component-based, distributed architecture. Our goal is to evaluate what limitations the choice of implementation environment may place on the capabilities of such an architecture-independent semantics. In our implementation, we aimed to produce a standard OpenRTM-aist system using the RADAR semantics. We have found that the architecture-independent semantics concept works well in the case of RADAR, although some specific improvements are needed for full interaction between deliberative and reactive sections of robotic software. [C2015]

### "Contribution of Cosmo/SkyMed data into PRIMI: A pilot project on marine oil pollution. results after one year of operations"

In this paper we present the Pilot Project PRIMI, designed to provide information on marine oil spills, and its validation campaign, held in august 2009, conducted with the oceanography ship Urania. During the experiment CosmoSkyMed has provided an extraordinary contribution supplying almost any day images over the area inspected by the ship and in some cases also images requested with short notice. [C2016]

### "First experiments of sector interpolated SAR tomography"

SAR Tomography (Tomo-SAR) is an experimental advanced coherent data combination mode allowing full 3-D imaging of volumetric and layover scatterers from a multibaseline (MB) synthetic aperture radar (SAR) data stack. However, the linear Fourier-based Tomo-SAR is generally affected by unsatisfactory imaging quality due to a typically low number of baselines with irregular spatial distribution. Recently, to improve the elevation focusing technique, a sector interpolation approach has been proposed by the authors, in which a set of uniform baseline data is recovered from the available non-uniform one by exploiting the a priori information about the extension of a height sector which contains the scatterers. In this work, first experiments are presented of sector interpolated Tomo-SAR carried out with real spaceborne MB SAR data acquired over the Cinecitta area of the city of Rome. [C2017]

### "The COSMO SKYMED constellation turn on the l'aquila earthquake: Dinsar results of the morfeo project"

On April 6th2009 a Mw=6.3 earthquake struck the area around the city of L'Aquila in Italy. SAR systems have been proven to be valuable sensors for analyzing the effect of earthquakes and monitoring post-seismic displacements. Due to the low deformation rate, the study of post-seismic events requires the use of a multi-temporal InSAR approach. COSMO/SKYMED is a constellation of SAR sensors of 4 X-band sensors operative also for the civilian use. Thanks to the availability of a stack of ascending acquisitions, ad hoc programmed by ASI on the area stricken by the earthquake, it was possible to provide post-seismic deformation maps by using two different multi-temporal interferometric approaches: the SPINUA and SBAS techniques. The work is carried out in the framework of the MORFEO project dedicated to the monitoring of the landslides risk by means of Earth Observation data. The displacement maps related to the post-seismic activity are presented and commented. The results clearly show the potentiality of the COSMO/SKYMED constellation use for emergency monitoring. [C2018]

### "Cognitive diversity sensing"

Radar sensing is and will continue to have great importance in both the civil and military communities. This importance will increase in proportion to the tasks that radar is able to reliably carry out. New methodologies and new technical capabilities offer the potential for new functionality and improvements in existing ones. Radar is currently going through a quiet revolution in which new methodologies are starting to be explored that highlight exiting new possibilities whilst demonstrating some of the challenges yet to be overcome. In this paper we examine the emerging topic of cognitive diversity sensing. Put simply this is the dynamic adjustment of radar parameters on both transmit and receive to maximize the extraction of desired information from the scene being surveyed. Further this brings into play the key topic of cognition exploiting the natural relationship between the

sensor and the sensed. It is this combination that provides a powerful new paradigm based on diversity sensing for future radar systems. This has huge potential enabling autonomous capabilities right across the whole spectrum of radar applications. [C2019]

#### "The analysis of surface deformation based on two-pass and three-pass D-InSAR"

The Differential Synthetic Aperture Radar Interferometry (D-InSAR) is widely used in large-scale ground deformation monitoring such as crustal deformation, seismic changes, land subsidence, landslides, volcanic deformation, glacial movement. In this paper, The deformation analysis based on two-pass differential and three-pass differential InSAR is done. We have shown that the analytic results by the three-pass differential method is better. The quality of result may be effected in phase unwrapping in two different methods. The deformation fields obtained by two different differential methods have been compared with traditional methods. With the changes in topographic factor, climatic conditions and vegetation types, the coherence effect is different, results have been given. It is not easy that the strong coherence is satisfied in three SAR images in the same time. Therefore, the optimizing methods depend on the purpose of application and the characteristics of studied area. [C2020]

#### "COSMIC-2: The future of global navigation satellite system-remote observation (GNSS-RO) sensing"

COSMIC is a joint U.S.-Taiwan 6-microsatellite demonstration mission that was launched in April 2006. It is the world's first operational GPS radio occultation (RO) mission for global Earth weather forecast; climate monitoring; atmospheric, ionospheric, and geodetic research. The GPS-RO data has been demonstrated to be valuable to the climate, meteorology, and space weather communities. COSMIC has proven to increase the accuracy of the predictions of hurricane/typhoon behavior, significantly improve long-range weather forecasts, and monitor climate change with unprecedented accuracy. COSMIC will reach the end of its design life in 2011, and the critical capability it provides will begin to degrade as satellites become no longer operational. As a result, NOAA and NSPO intend to jointly develop and launch COSMIC-2, a high-reliability next generation follow-on system. COSMIC-2 is will provide the next generation of global navigation satellite system (GNSS)-RO data to users who critically rely on it. [C2021]

#### "Hidden Markov based target detection for track-before-detect"

A tracking filter using conventional methods perform target detectios by setting a threshold at the output of the sensor's signal processor. The result of using thresholding brings out that, targets with low signal-to-noise ratio (SNR) may not be detected if the signal power is below the required threshold. Track-before-detect (TBD) techniques avoid the usage of a detection threshold and provide detecting and tracking targets with lower signal-to-noise ratios. Although TBD techniques eliminate the need for detection threshold at sensor's signal processing stage, they often use tuning thresholds at the output of the filtering stage. This paper presents a Hidden Markov Model (HMM) based target detection method for employing with TBD techniques which does not use any of the thresholding method. [C2022]

#### "New trends in SAR tomography"

In this paper a comparison between two techniques developed to recover layover solution in SAR images is presented. SAR Statistical Tomography and Compressive Sensing techniques are described and analyzed in order to provide a set of instruments for 3D SAR imaging able to tackle different scattering mechanisms in layover areas and to recover height reconstruction of an observed scene. The performances of the two techniques are compared on simulated data and some conclusions are drawn. [C2023]

#### "Overview of SMOS Level 2 Ocean Salinity processing and first results"

SMOS (Soil Moisture and Ocean Salinity), launched in November 2, 2009 is the first satellite mission addressing the salinity measurement from space through the use of MIRAS (Microwave Imaging Radiometer with Aperture Synthesis), a new two-dimensional interferometer designed by the European Space Agency (ESA) and operating at L-band. This paper presents a summary of the sea surface salinity retrieval approach implemented in SMOS, as well as first results obtained after completing the mission commissioning phase in May 2010. A large number of papers have been published about salinity remote sensing and its implementation in the SMOS mission. An extensive list of references is provided here, many authored by the SMOS ocean salinity team, with emphasis on the different physical processes that have been considered in the SMOS salinity retrieval algorithm. [C2024]

#### "Characteristic analysis of vehicle target in Quad-Pol Radarsat-2 SAR images"

Radarsat-2 satellite offers general users the Quad-Pol SAR image service with a resolution of 8 meters, which provides valuable data source for the research of traffic vehicles monitoring on Quad-Pol SAR images. According to the vehicle target in such new SAR images, this paper put forward a target characteristic analysis method, which is a combination of target RCS measurement and polarization decomposition. Moreover, it choose the large trucks as an example, give out a conclusion of characteristic analysis of vehicle targets through the on-site synchronous experimental data obtained at different incident angle. Thus provides the research foundation for further exploration of realizing the traffic monitoring with space-born Quad-Pol SAR images. [C2025]

#### **"Topographic gray level multiscale analysis and its application to histogram modification"**

This paper describes a framework for multi-scale gray level analysis of images. It defines scales based on gray levels and organizes the basic "atoms" with a topographic map. The aim of this approach is to separate a large number of pixels concentrating in a narrow range of gray values. The main advantage of the methodology is that it allows manipulating pixels according to gray levels and spatial relations simultaneously. We apply it to histogram modification of Synthetic Aperture Radar (SAR) images. The experiments on displaying and classification prove the superiority of the approach. [C2026]

#### **"A review of ionospheric effects in low-frequency SAR-Signals, correction methods, and performance requirements"**

Ionospheric signal distortions are commonplace in low-frequency space-borne SAR observations and can lead to the degradation of SAR data quality and data consistency if no signal compensation is applied. In this paper we will give an overview of the problem of ionospheric influence in SAR, PolSAR, and InSAR data. We will characterize the spatiotemporal signal properties of ionospheric signals, introduce a selection of currently available correction methods, and present a list of performance requirements to be met by ionospheric correction. [C2027]

#### **"Impact of the wave number estimation in Underground Focusing SAR images"**

This work studies the impact estimating soil wave number in Underground Focusing SAR imaging for tunnel detection applications. It is demonstrated that poor underground imaging results when wave refraction at the ground surface is neglected, but that incorporating refraction with sufficiently high estimates of soil dielectric constant produce clear target images. Using a wrong wave number for the soil incorrectly predicts the tunnel's depth, but gives positive identification of its transverse and extent. [C2028]

#### **"Rotated dihedral and volume scattering behavior in cross-polarimetric SAR"**

In this study we analyze Radarsat-2 quadruple polarization (quad-pol) mode data acquired over the Everglades wetlands in south Florida. We analyzed the phase information of each polarization mode independently, and obtained similar fringe patterns representing water level changes in all four interferograms. It is surprising, because common scattering theories indicate that cross-polarization (cross-pol) observations reflect volume scattering due to the interaction of the radar signal with upper sections of the vegetation. However, our cross-pol interferometric observations suggest that the cross-pol signal reached the water surface and scattered back to the satellite by a rotated dihedral double bounce mechanism. Based on these new observations, we developed a new scattering formulation that accounts also for double bounce component in cross-pol. [C2029]

#### **"Characterization of the scattered field by an urban area in the X-frequency band for bistatic and monostatic radar configurations"**

The application of the ray-tracing technique in combination with the asymptotic method Uniform Theory of Diffraction (UTD) for an analysis of the electromagnetic (EM) wave propagation in urban areas is presented. The frequency of the study is in the X-frequency band from 8 to 12 GHz but can be applied for Ku-band and a three-dimensional model of the geometry is proposed. The transmitter and receiver can be separated to present both bistatic and monostatic configurations. At the end of the work, we evaluate the amplitude and the phase of the far field diffracted by urban scenarios. [C2030]

#### **"Burst mode to strip-map mode SAR interferometry of ALOS PALSAR"**

A complete processing flow is proposed to implement burst mode to strip-map mode interferometry for ALOS PALSAR data. The processing flow is applied to an interferometric pair comprised of FBD (High Resolution mode [Dual polarization], belonging to strip-map mode) and WB1 (Wide observation mode, belonging to burst mode) mode of PALSAR. Interferometric products including differential interferometric phase and DEM are generated. The evaluation of these products shows satisfactory precision. [C2031]

### "Study of snowmelt impact on SST and TSM fields in the coastal zone of Barents Sea"

Spatial and temporal variations of SST and biological fields were observed in the coastal area off Novaya Zemlja, Barents Sea. Focus is on the relation between SST and biological parameters. The variations of snowmelt runoff from land (glaciers and river runoff) were estimated using SAR imagery. A relation between snowmelt input from land and ocean Chl a as well as TSM concentration was observed based on a case study. The data showed that the TSM and Chl a concentration increased significantly ~30 days after the snowmelt over land started to increase. [C2032]

### "Monitoring tree farms and coastal environments using RADARSAT-2 PolSAR data"

This paper addresses the feasibility of using RADARSAT-2 fine Quad-Pol mode to monitor coastal environment and young tree growth. It will be shown that interferometric coherence may not be high enough for the height estimation of young trees at C-band, but polarimetric sensitivity could be used for tree and crop classification. For coastal environment, we found that polarimetric signature of oyster farm reveals the effect of double bounce scattering and the orientation angle effects. [C2033]

### "Ultra-wideband radar measurements of snow thickness over sea ice"

An ultra-wideband, frequency modulated, continuous wave radar working from 2.0 to 6.5 GHz was designed, built and tested at the Center for Remote Sensing of Ice Sheets (CReSIS) at the University of Kansas to measure snow thickness over sea ice. Improvements and modifications to the existing radar, compared to previous versions, allow for snow thickness measurements from fast-moving, long-range aircraft. Over the past year, the radar has recorded snow thickness measurements over sea ice in the Arctic and Antarctic oceans as part of NASA's Operation Ice Bridge. [C2034]

### "Effects of surface roughness on sea ice freeboard retrieval with an Airborne Ku-Band SAR radar altimeter"

Results from two years of the CryoSat Validation Experiment (CryoVEx) over sea ice in the western Arctic Ocean are presented. The estimation of freeboard, the height of sea ice floating above the water level, is one of the main goals of the CryoSat-2 mission of the European Space Agency (ESA) in order to investigate sea ice volume changes on an Arctic wide scale. Freeboard retrieval requires precise radar range measurements to the ice surface, therefore we investigate the penetration of the Ku-Band radar waves into the overlying snow cover as well as the effects of sub-footprint-scale surface roughness using airborne radar and laser altimeters. We find regional variable penetration of the radar signal at late spring conditions, where the difference of the radar and the reference laser range measurement never agrees with the expected snow thickness. In addition, a rough surface can lead to biases of the airborne validation dataset, since the radar overestimates the amount of open water and thin ice as well as the freeboard of heavy ice deformation zones. [C2035]

### "A generalized logical format for inter-calibrated brightness temperatures for the global precipitation measurement mission"

An important aspect of the GPM mission is the merging of precipitation data from multiple radiometers on different satellites. This requires that each radiometer be consistently calibrated and that each be intercalibrated with a mission reference standard. For GPM the reference standard is to be the core satellite carrying a dual frequency precipitation radar and a well calibrated conically scanning radiometer. This paper describes a common format for representing these intercalibrated brightness temperatures which will be used for all radiometer products from GPM partner satellites. The use of common formats ensures that users obtain all the required information and also facilitates the rain retrieval algorithm code preparation as it can always expect to have the data that it needs for the retrieval. [C2036]

### "Scatterometer image reconstruction from aperture-filtered samples"

This paper considers sampling and reconstruction theory with application to scatterometer image reconstruction. Backscatter imaging is approached as the inversion of a noisy aperture-filtered sampling operation. A reconstruction estimator based on maximum a posteriori probability (MAP) estimation is proposed to recover the conventional samples from noisy aperture-filtered samples. Examples from the SeaWinds scatterometer and the Advanced Wind Scatterometer (ASCAT) are presented. [C2037]

### "Radargrammetry of high resolution synthetic aperture radar onboard KOMPSAT-5"

This paper reports the preliminary results on the study of radargrammetry especially for a high-resolution satellite synthetic aperture radar system. Theoretical configurations for radargrammetry in terms of coverage, orbit selection, incidence angles, height sensitivity of parallax and height resolution of DEM were calculated according to the proposed orbit characteristics and the imaging modes of KOMPSAT-5 SAR. Possible imaging strategies and mission scenarios for coverage versus rapidity are suggested for a future mission dedicated to radargrammetry. [C2038]

#### "Fusion of LiDAR data and orthoimage for automatic building reconstruction"

Recent years LiDAR data is widely used for constructing 3D terrain models which provide realistic impressions of the urban environment. This paper presents an automatic method for extracting 3D building model by the fusion of LiDAR data, 2D building outlines and orthoimage. 2D building outlines is generated by classifying the LiDAR data to terrain and off-terrain points, then detecting building edges points through step-structure detector and generalization. 2D building boundaries are added on the DSM (Digital Surface Model) from LiDAR data to generate complex buildings by using CSG with the Boolean operations of union, intersection and differences. [C2039]

#### "Extraction of frequent grouped sequential patterns from Satellite Image Time Series"

This paper presents an original data mining approach for extracting pixel evolutions and sub-evolutions from Satellite Image Time Series. These patterns, called frequent grouped sequential patterns, represent the (sub-)evolutions of pixels over time, and have to satisfy two constraints: firstly to correspond to at least a given minimum surface and secondly to be shared by pixels that are sufficiently connected. These spatial constraints are actively used to face large data volumes and to select evolutions making sense for end-users. Successful experiments on an optical and a radar SITS are presented. [C2040]

#### "Soil moisture detection using KOMPSAT-5 SAR data"

The applicability of the KOMPSAT-5 (Korea Multi-Purpose Satellite-5) SAR on soil moisture detection is addressed in this paper. At first, the penetration into and reflection from bare soil surfaces at X-band are compared with those at L-band for homogeneous and inhomogeneous moisture profiles. The sensitivities of the X-band radar backscatter on soil moisture are examined for rough bare soil surfaces. Then the sensitivities of the X-band radar backscatter on the soil moisture of vegetated surfaces are also examined for various vegetation densities and incidence angles. The applicability of an X-band radar for soil moisture detection may be as good as L-band radar for bare soil surfaces. For vegetated surfaces, the soil moisture can be detected using an X-band radar at lower incidence angles, where the upper limit of the incidence angles depends on vegetation density. [C2041]

#### "The inversion of crop height based on small-footprint waveform airborne lidar"

Due to limited vertical resolution, the waveform of vegetation whose height is relatively low will superpose on soil waveform. Therefore, lidar full-waveform data were mainly used in forestry, but no research in the crop. In this paper, in order to derive crop height, a gaussian decomposition algorithm based on transmitting waveform is adopted to distinguish the crop waveform from soil waveform, and to extract peak location and pulse width from raw waveform data, proving it is a reliable and highly accurate decomposition algorithm. Moreover, the decomposition algorithm lays the proper foundation for obtaining other crop biophysical parameters. [C2042]

#### "Extraction of building's geometric axis line from LiDAR data for disaster management"

Fast and reliable building damage analysis is crucial for survivors rescue and disaster management when a destructive natural disaster occurs which helps to limit life losses. For this purpose, a method was developed in this paper to extract building's geometric axis line from aerial LiDAR data which helps to do further building damage analysis like to identify inclined buildings. To extract building's geometric axis line, several steps were carried out such as segmentation of buildings, extraction of roof facets, fitting of mean roof plane and getting main roof. The aerial LiDAR data was captured over the area of Port-au-Prince, Haiti which contains numerous of inclined buildings. The results demonstrate the feasibility and effectiveness of the proposed approach to identify inclined building for damage management. [C2043]

#### "Glaciermonitoring: Correlation versus texture tracking"

Synthetic aperture radar (SAR) images provide scattering information which can be used under any weather conditions for glacier monitoring. Our purpose is to estimate a displacement field characterizing at each position the local speeds and orientations of the glacier displacement. Recent proposed methods build a vector field by

tracking patches between two SAR images co-registered on static areas and sensed at different times. The tracking is performed either by evaluating the correlations or the similarities from one acquisition to the other. We propose to estimate locally the displacement vectors by using either the maximum correlation or a maximum likelihood estimator. This local estimation is then refined to provide a sub-pixelic result. The efficiency of both methods are compared. [C2044]

#### "A non-local approach for SAR and interferometric SAR denoising"

Recently, non-local approaches have proved very powerful for image denoising. Unlike local filters, the non-local (NL) means introduced in decrease the noise while preserving well the resolution. In the proposed paper, we suggest the use of a non-local approach to estimate single-look SAR reflectivity images or to construct SAR interferograms. SAR interferogram construction refers to the joint estimation of the reflectivity, phase difference and coherence image from a pair of two co-registered single-look complex SAR images. The weighted-maximum likelihood is introduced as a generalization of the weighted average performed in the NL means. We propose to set the weights according to the probability of similarity which provides an extension of the Euclidean distance used in the NL means. Experiments and results are presented to show the efficiency of the proposed approach. [C2045]

#### "Data visualization and analysis tools for the Global Precipitation Measurement (GPM) Validation Network"

The Validation Network (VN) prototype for the Global Precipitation Measurement (GPM) mission compares data from the its predecessor Tropical Rainfall Measuring Mission (TRMM) satellite's Precipitation Radar (PR) to ground radar (GR) measurements from U.S. and international operational weather radars. This prototype is a major component of the GPM Ground Validation System (GVS). The VN provides a means for the precipitation measurement community to identify and resolve significant discrepancies between the GR observations and similar satellite observations. The VN prototype is based on research results and computer code Liao et al. [1]. Morris and Schwaller [3] describe the VN prototype and initial results in detail. This paper describes software tools that have been developed for visualization and statistical analysis of the original and volume matched PR and GR data. [C2046]

#### "Mapping of wind-thrown forests using satellite SAR images"

The study focuses on investigation and evaluation of wind-thrown forest mapping using satellite remotely sensed data from three synthetic aperture radar (SAR) sensors. The study is carried out at Remningstorp, a test site in the south of Sweden dominated by coniferous forest, where trees were manual felled to simulate wind-thrown forest. The satellite data consisted of time series of HH polarized SAR images acquired by the Advanced Land Observing Satellite (ALOS) Phased Array type L-band Synthetic Aperture Radar (PALSAR), Radarsat-2 (C-band) and TerraSAR-X (X-band). The results from visual interpretation of SAR images acquired before and after the simulated wind-throw together with corresponding ratio images show that ALOS PALSAR HH polarized intensity images are not able to detect wind-thrown forest, probably due to too coarse spatial resolution. In contrast, the wind-thrown forest is clearly visible in the Radarsat-2 and TerraSAR-X HH polarized images, implying that it may be possible to develop a new application using these SAR data for mapping of wind-thrown forests. [C2047]

#### "Full exploitation of the SBAS-DInSAR algorithm in active seismogenetic scenarios"

We perform a full exploitation of the Differential SAR Interferometry (DInSAR) algorithm referred to as Small Baseline Subset (SBAS) technique to investigate long term surface deformation occurring in extended, seismogenetic areas. To this aim we benefit of the SBAS technique capability to work in multi-frame and multi-sensor scenarios in order to improve the spatial and temporal coverage, as well as to employ new generation SAR sensors to increase the temporal sampling of the retrieved time series. In this work we apply the SBAS algorithm to analyze the temporal evolution of the detected displacements affecting three different seismogenetic scenarios by means of deformation time series retrieved through data acquired by European (ERS-1/2, ENVISAT) and Italian (COSMO-SkyMed) satellites. In particular, we focus on the analysis of the deformation patterns associated with the activity of the San Andreas (SAF, California, USA), the North Anatolian (NAF, Turkey) and the Paganica (PF, Abruzzo, Central Italy) Faults. The achieved results provide a clear idea of the surface deformation retrieval capability of the SBAS procedure. [C2048]

#### "Optimal parameter estimation in heterogeneous clutter for high resolution polarimetric SAR data"

This paper presents a new estimation scheme for optimally deriving clutter parameters with high resolution POLSAR data. The heterogeneous clutter in POLSAR data was described by the Spherically Invariant Random

Vectors model. Three parameters were introduced for the high resolution POLSAR data clutter: the span, the normalized texture and the speckle normalized covariance matrix. The asymptotic distribution of the novel span estimator is also investigated. The proposed method is tested with airborne POLSAR images provided by the ONERA RAMSES system. [C2049]

#### "A method to estimate Snow Water Equivalent using multi-angle X-band radar observations"

Active microwave sensors, especially high-frequency radar systems, are highly sensitive to snow pack parameters, including Snow Water Equivalent (SWE). With the availability of several X-band space-borne SAR systems, the study attempts to make use of multiple-angle SAR observations and develop relevant SWE inversion algorithms. Analysis was carried out based on parameterized scattering models for both soil surface and snowpack. It is found that the backscattering signals at two incident angles are well correlated for both soil surface and snowpack; and snow optical thickness can be well defined and estimated through snow volume scattering at two different angles. The snow and soil parameters can be estimated through two pairs of adjacent observations. The technique was tested using theoretical simulated database. Initial analysis shows that current technique needs to be further improved and a better estimation of single scattering albedo is needed. [C2050]

#### "Monitoring time-dependent volcanic dynamics at Long Valley Caldera using InSAR and GPS measurements"

Continuous monitoring Long Valley Caldera since the late 1970s, including data from seismic and geodetic networks has shown renewed episodic unrest activities with accelerated uplift separated by reduced uplift, no activity or slow deflation. We examine the time-dependent behaviors at Long Valley Caldera in 1996-2009 by integrating InSAR and continuous GPS (CGPS) measurements. The ERS-1/2 radar data between 1992 and 2008 and reprocessed three-component continuous GPS (CGPS) data from Long Valley GPS network in 1996-2009 were combined to invert for source geometry and volume change in the following deformation episodes: 97-98 uplift, 02-03 uplift, 04-07 slow subsidence, and 07-09 slow uplift. Our results show that all post-2000 events locate in the shallow depth range of ~7-9 km and have nearly identical source location, suggesting that these events are caused by the same partial melt magma source at the mid-crustal level. All three events are characterized by the low volume change, in comparison with previous 1997-1998 inflation event that has much larger volume change and steeper source geometry. If we regard post-2000 events as proxy for future eruption hazard, the inferred source dynamics (e.g., mid-crustal location and low volume change) from these post-2000 events suggest that the probability for near-term eruption is low. Our study demonstrates that CGPS, along with InSAR, are important tools in monitoring time-dependent source process at the active volcano region. [C2051]

#### "Estimation of the degree of polarization in dual-polarized SAR imagery"

Analysis of dual-polarized SAR imagery has gained new importance with the recent launches of ALOS PALSAR, RADARSAT-2, and TerraSAR-X polarimetric SAR systems. Information contained in polarimetric images, collected by these SAR systems, can be characterized by a scalar parameter called the degree of polarization. This parameter has long been recognized as one of the most important parameters characterizing a partially polarized electromagnetic wave. In this paper, we provide maximum likelihood and moment-based estimators of the degree of polarization in dual-polarized SAR imagery. We evaluate and compare the performance of these estimators on RADARSAT-2 polarimetric data, over various terrain types such as urban, vegetation, and ocean. [C2052]

#### "Individual tree species classification using structure features from high density airborne lidar data"

The paper investigated the advantage of high density airborne LiDAR data for improving species classification of individual tree. The investigation is comprised of two stages, feature extraction and classification. Several feature metrics were derived from LiDAR data, most of which were to characterize the vertical structural properties of difference species. Some other metrics were calculated statistically from intensity and return number information. A supervised decision tree algorithm was applied on the extracted features to perform both feature selection and classification. Two classification themes were carried out: classification of coniferous and deciduous trees, and classification of five species. Experiment was conducted in Canadian boreal forests dominated by mature trees. The results demonstrated LiDAR derived vertical profile metrics are capable for species classification either to separate coniferous and deciduous or to separate multiple species. The best overall classification accuracy is 81.7% validated by using the test data from the same ecosystem as the training data. [C2053]

#### "On the use of transponder measurements for high precision assessment and calibration of polarimetric Radarsat-2"

An independent assessment and calibration of polarimetric RADARSAT-2 (RS2) are conducted using transponder measurements extracted from uncalibrated data collected at various incidence angles between 20° and 40°. It is shown that RS2 antenna is highly isolated (better than -32 dB), and only crosschannel relative phase correction is required to provide calibrated data that meet comfortably the CEOS Cal-Val requirements. To take full advantage of the excellent RS2 performance in terms of low noise floor (-38 dB), transponder measurements are used for high precision assessment of RS2 calibration parameters. It is shown that the antenna cross-talks are stable with incidence angle, and only one transmitter-receiver distortion matrix is required for accurate calibration of the 20 modes of RS2 (Right looking) from 20° to 40°. A new method based on high precision transponder measurements is introduced for polarimetric RS2 calibration. Data collected at various incidence angles are used to validate the calibration. Transponder measurements using calibrated data indicate a residual cross-talk lower than -43 dB. The residual cross-channel error is lower than 0.3 dB in radiometry, and 5° in phase. [C2054]

#### "Biomass retrieval based on UAVSAR polarimetric data"

Parameters of vegetation spatial structure have important effect on the carbon cycle and biodiversity of the ecosystems. How to estimate above-ground biomass is still a problem need to be worked out. In this paper we tried to use UAVSAR datasets to discuss the relation between backscattering coefficient and local incidence angle in different forest types. By the relation, a method based on scattering mechanism for correcting radiometric distortion caused by large range of incidence angle is developed. Biomass retrieval is based on incidence angle correction. The result shows good correlation between biomass and backscattering coefficient in 1 ha scale. [C2055]

#### "Spurious signal in measurement of the third Stokes parameter from space at L-band"

Spurious spikes in the third Stokes parameter have been observed in numerical simulations of the signal expected from the L-band radiometers to be flown as part of the Aquarius instrument. These signals are present over scenes with large contrast such as land water boundaries and are due to cross polarization coupling and the relatively large footprint of the antennas. [C2056]

#### "Space-time focusing of HF skywave radar signals with application to nonlinear scattering phenomenology"

Increasing the power density incident on a target without raising the radiated power may offer a number of benefits to HF skywave radar systems. Among these is the prospect of detecting nonlinear echoes, which could greatly enhance detection in sea clutter. Other prospects include improved detection of low RCS targets and more effective use of sub-apertures for multiple simultaneous task operations. In this paper we review the physics underlying these missions and assess the potential of various approaches to concentrating energy in localized regions within the illuminated zone. [C2057]

#### "CRInSAR for landslide deformation monitoring: A case in threegorge area"

Landslide in threegorge area is a severe geohazard threatening many people. Conventional differential SAR interferometry (DInSAR) and Persistent Scatterers for SAR interferometry (PSInSAR) technique are unsuitable for landslide deformation monitoring in this area due to temporal and lack of natural phase stable point targets. The method of DInSAR using corner reflectors (CRInSAR) is a powerful tool in the vegetation area. The procedure of DInSAR using corner reflectors (CRInSAR) used by this paper is briefly introduced. Using ENVISAT ASAR time series data, the deformation of 12 corner reflectors (CR) in Shuping landslide are analyzed. As to the CR with slow creep deformation, the CRInSAR results are reliable. But as to the CR with nonlinear accelerated deformation, our CRInSAR method still needs to be enhanced. [C2058]

#### "Target detection based on granularity computing of quotient space theory using SAR image"

Target detection is a hot topic and key technique of SAR image interpretation. There are many detection methods, such as CFAR detector and Extended Fractal (EF) feature detector. In order to overcome their shortcomings and combine their merits at the same time, the combination of some different detection methods need be implemented. Granularity computing is just an approach that solves the problem at different granularity space due to different principles. Therefore, SAR image target detection based on granularity synthetic algorithm of quotient space theory is proposed in this paper. Firstly, CFAR detector and EF feature detection method are performed to generate different detection results as coarse granularity spaces. Then combine the different quotient spaces and construct the fine granularity space by using granularity synthesis algorithm. Finally, obtain the final target detection result. The experimental result of RADARSAT-I C band SAR image proves that the proposed algorithm is effective. [C2059]

### "Landslide detection by indices of LiDAR point-cloud density"

The deliverables of an airborne LiDAR survey usually include all points, ground points, digital surface models (DSM) and digital elevation models (DEM). Indices of point clouds tested in this study include density of all points, density of ground points, density of only returns, and density of multiple returns. Shallow landslides are the most common landslides triggered by torrential rainfalls and explicit fresh scars after rainfall events. Multiple returns in forest area give the possibility of differentiating landslide scars from vegetated lands. Classification results from the indices derived from these four kinds of densities are verified by the result obtained by manual interpretation of the derived nDSM images. The experiment is carried out using the dataset obtained in I-Lan County after Typhoon Kalmaegi on 17 July 2008. The results show that a proper definition of the parameters for the indices is most critical for the detection of shallow landslides. [C2060]

### "Global trends in remote sensing of human settlements"

Advances in both airborne and spaceborne remote sensing systems have provided a range of tools for monitoring and managing human settlements. In particular the availability of very high spatial resolution satellite systems has dramatically increased access to high quality two-dimensional spatial information, while laser profilers and interferometric synthetic aperture radar have allowed acquisition of the third dimension. Over the past 100 years sensor systems have changed dramatically, from early airborne cameras that imaged only small parts of an urban area on a project return basis, to very high resolution spaceborne systems, covering a wide spectral range, with regular return periods down to a few weeks or days. This paper provides a brief history of urban remote sensing, followed by an examination of the properties of current systems and their acquired data, some processing methods and urban applications. It concludes with an overview of future developments. [C2061]

### "Direct-path mitigation for underground imaging in RF Tomography"

Belowground imaging using RF Tomography is challenged by strong direct-path coupling between sensors. In this work, a direct-path mitigation procedure is introduced, consisting of two steps. First, the Tx and Rx dipoles are rotated in along particular directions that maximizes the signal with respect to the direct-path contribution. Then, the remaining contribution is removed by using a hybrid analog/digital feedback loop at the receiver side. [C2062]

### "ISAR imaging of maneuvering targets via matching pursuit"

An algorithm based on matching pursuit (MP) technique is proposed for inverse synthetic aperture radar (ISAR) imaging of maneuvering targets. The received ISAR echo is decomposed into many basis sub-signals that are generated by discretizing the target spatial domain and synthesizing the ISAR data for every discretized spatial position, and then the ISAR imaging problem is converted into the sub-signal selection problem. The basis sub-signals that indeed contribute to the ISAR echo are selected by using the MP technique, and the projection coefficients of the ISAR echo on the selected basis sub-signals represent the ISAR image. In the case of unknown rotation rate of the target, the true rotation rate is obtained by combining the MP technique with the maximum contrast search. Numerical examples show that the proposed algorithm can produce high resolution and remove sidelobe artifacts. [C2063]

### "Coherent scatterer in forest environment: Detection, properties and its applications"

In this paper, the first detection result of coherent scatterers (CSs) in forest environment is addressed. As a scatterer associated with CS, the dihedral structure consists of the tree-trunk like a vertical cylinder and the ground surface is assumed. The potential of CSs as being the phase stable scatterers as permanent scatterers will be also demonstrated with P-&L-band Pol-InSAR datasets acquired in repeat-pass InSAR mode over boreal forest test site by German Aerospace Center's E-SAR airborne system. [C2064]

### "Modeling attenuation of melting hydrometeors with a method based on volume integral equations"

The attenuation of spheroidal melting hydrometeors is simulated in C-, Ku- and Ka-band utilizing a microphysical melting layer model. The scattering properties are obtained with Mie scattering solution. In C-band the polarimetric radar parameters are computed utilizing a method based on volume integral equation. Polarization difference is detectable, but reflectivity values are regularly smaller than those calculated with Mie solution. This is dependent on the process of formatting the particle structure according to the change in liquid water mass fraction. [C2065]

### "Modification of slant range model and imaging processing in GEO SAR"

In this paper, considering the relative motion between satellite and earth during signal propagation time, the accurate analysis method for propagation slant range is presented in geosynchronous SAR. Furthermore, the difference between accurate analysis method and 'Stop-and-Go' assumption is analytically obtained. Meanwhile based on the derived accurate slant range model, it is found that the corresponding range migration correction and azimuth reference function must consider the high order term, and therefore the modified SPECAN algorithm is proposed. The simulation results verify the correctness of 'Stop-and-Go' assumption error derivation and SPECAN algorithm modification. [C2066]

### "Rotation and scale invariant template matching applied to buried object discrimination in GPR data"

In this study, a template matching approach to buried object discrimination problem is proposed over ground penetrating radar (GPR) B-scan images. The technique is scale invariant, which compensates for the change in the swinging speed of the detector. It is also rotation invariant to some extent, which reduces the number of templates to be used by compensating for the change in the scanning direction. The algorithm is tested on real GPR data and results are observed to be promising. [C2067]

### "Mapping urban subsidence with TerraSAR-X data by PSI analysis"

With a spatial resolution of up to 1 m, the German radar satellite TerraSAR-X has significantly improved the applicability of spaceborne SAR interferometry (InSAR) technique for fast ground motion monitoring due to its high spatial resolution and short time interval. In this work we present the first Permanent Scatterer Interferometry analysis with TerraSAR-X data for urban subsidence mapping in Tianjin city in China. Totally 17 scenes strip mode SAR images have been collected from Feb to Oct 2009 to perform the PSI analysis. The resulted average subsidence velocity demonstrates the ability of high resolution data for detailed monitoring of urban subsidence. Comparison between PSI result of TerraSAR-X and ENVISAT show the potential of TerraSAR-X data for urban motion as well as large scale manmade linear infrastructure monitoring. [C2068]

### "A phase screen simulator for predicting the impact of small-scale ionospheric structure on SAR image formation and interferometry"

We describe the SAR Scintillation Simulator (SAR-SS), a new phase screen model for simulating the impact of small-scale ionospheric structure on SAR image formation and interferometry. We compare simulated and observed PALSAR imagery over Brazil, and our preliminary findings show that SAR-SS can reproduce the essential features of azimuthal streaking and contrast degradation caused by small-scale structure in the ionosphere. [C2069]

### "Operational evaluation of damages in flooded areas combining Cosmo-SkyMed and multispectral optical images"

The management of a flood event requires singling out the affected area, quantifying the damages and programming an effective rescue plan. This requires rapid and easy access to all the geographical and observational information available for the target area. Optical imagery allow the identification of land uses, critical infrastructures and the extraction of important information to quantify the actual vulnerability of the area. In this case, the main advantage of satellite imagery is the much higher refresh rate with respect to classical in-situ surveys. When floods occur, the detection of flooded areas allowed by SAR observations such as those provided by Cosmo-SkyMed, helps in rapid and effective evaluation of the damage and organization of the management of the crisis. Here we present an integrated system developed by the team of the Italian Space Agency pilot project "Opera". The system allows the end user to integrate multispectral high resolution imagery and Cosmo-SkyMed products, in a 3-D environment, providing all the tools to virtually survey the observed area and extract quantitative information for many features relevant to the emergency management. The system has been tested in real time on a prolonged flooding event occurred in Januray 2010 in the Shkoder plain in Albania. [C2070]

### "Metacognition in radar"

An airborne ground looking radar sensor's performance may be enhanced by selecting algorithms adaptively as the environment changes. A short description of an airborne intelligent radar system (AIRS) is presented with a description of the knowledge based filter and detection portions. A second level of artificial intelligence (AI) processing is presented that monitors, tests, and learns how to improve and control the first level. This approach is based upon metacognition. [C2071]

### "Progressive spatial clustering of content-based satellite imagery retrieval results"

The ProgressiveDBSCAN algorithm allows for the progressive clustering of results from a geospatial information retrieval system. Results can be clustered by a combination of both their spatial and non-spatial attributes. The benefit of this clustering is that users are able to sort through the results returned from a geospatial information retrieval system in a spatial context. No longer are results from disparate locations presented to the user, but instead compact spatial clusters are displayed. There is a 98% reduction in the spatial distance between consecutive CBIR results and the spatial distance between the compact clusters; this leads to more efficient analysis of results by reducing the amount of time users spend context switching while on average only adding a few seconds to the query time. [C2072]

### "Sparsity enhanced fast subsurface imaging for stepped frequency GPRs"

A sparsity enhanced and fast data acquisition and imaging method is presented for stepped-frequency continuous-wave ground penetrating radars (SFCW GPRs). In previous work it is shown that if the target space is sparse like the point like targets, an image of the target space can be constructed with making measurements at only a small number of random frequencies by solving an  $\ell_1$  minimization problem. This greatly reduces the data acquisition time but the computational complexity for the imaging method is high. In this work, subsurface imaging is done with a suboptimal but fast method, orthogonal matching pursuit. Similar results to  $\ell_1$  minimization images are obtained within much shorter times. Also the results are sparse and less cluttered compared to standard backprojection images. [C2073]

### "A target tracking method with a single antenna using time-reversal UWB radar imaging in a multi-path environment"

UWB (Ultra Wide-Band) radar systems are promising imaging tools covering a variety of application fields including surveillance systems. UWB radar technology can provide advanced capabilities for current surveillance systems. An imaging algorithm for UWB radars, the TR (Time-Reversal) method enables high-resolution imaging in a multipath environment. Conventional TR methods have been applied to antenna array systems while our previous work proposed a TR method with a low-cost single antenna-based system. In this study, we propose a radar system with a single antenna on a vehicle in a multipath environment. This vehicle is assumed to get close to a moving target by adaptively tracking the target location. Some numerical simulation results show that the proposed low-cost system works well in a multi-path environment. [C2074]

### "Calibration system stability plans for a long-term Ecological Airborne remote sensing project"

The National Ecological Observatory Network (NEON) Airborne Observation Platform (AOP) will fly an imaging spectrometer, small footprint waveform LiDAR and high-resolution digital camera to observe both the human drivers of climate change and the biological consequences of environmental change at a continental scale. The project is planned for a 30-year period. To be meaningful as an ecological climate data record, the AOP data set must have a continuous and consistent calibration effort. This paper briefly describes plans for the development of a robust calibration and validation plan to ensure data continuity from instrument-to-instrument, flight-to-flight, and year-to-year over the lifetime of the NEON project. [C2075]

### "3D velocity model and ray tracing of antenna array GPR"

Migration is an important signal processing method that can improve signal-clutter ratio and reconstruct subsurface image. Diffraction stacking migration and Kirchhoff migration sum amplitudes along the migration trajectory, which generally is hyperbolic. But when the ground surface varies acutely, the migration trajectory is not hyperbolic. To computer the migration trajectory need the technique of ray tracing. We introduce a method of ray tracing based on 3D velocity model. Firstly, we build the 3D velocity model depending on the estimation of both ground surface topography and velocities. Then we compute the travel time between transmitter, receiver and each subsurface scattering point, and search the propagation ray depending on the Fermat's principle. The method is tested by an experiment data acquired by the stepped-frequency (SF) CMP antenna GPR system. The target is a metal ball that is buried under a sand mound. A nice result of ray tracing is shown in the case. [C2076]

### "Support vector machines regression for estimation of forest parameters from airborne laser scanning data"

Estimation of forest stand parameters from airborne laser scanning data relies on the selection of laser metrics sets and numerous field plots for model calibration. In mountainous areas, forest is highly heterogeneous and

field data collection labour-intensive hence the need for robust prediction methods. The aim of this paper is to compare stand parameters prediction accuracies of support vector machines regression and multiple regression models. Sensitivity of these techniques to the number and type of laser metrics, and use of dimension reduction techniques such as principal component and independent component analyses are also tested. Results show that support vector regression was less accurate but more stable than multiple regression for the prediction of forest parameters. [C2077]

#### "Time reversal adaptive waveform in MIMO radar"

EM multipath propagation is common in radar and wireless communications. Most radar systems are designed assuming line-of-sight (LOS), not multipath. In this paper, we extend our prior work on Multi-Input Multi-Output (MIMO) radar in the absence of interference [1], to consider MIMO radar detection in high clutter. We develop a subspace MIMO target model and a statistical model for MIMO radar clutter that accounts for the spatial and spectral properties of radar returns. We show that, using orthogonal waveform signaling, the time reversal MIMO radar yields higher detection performance than conventional statistical MIMO radar in high clutter. [C2078]

#### "Using lidar to estimate the capacity for storm water recycling and solar energy collection"

In this paper two lidar applications are addressed so that the data from large-scale airborne laser scanning of three New South Wales towns and the University of New South Wales can be used to estimate the capacity for storm water recycling and solar energy collection. The building outlines in each of these surveyed areas are extracted using the lidar point cloud to provide an accurate measurement of the total area of roofing within each region. The accurate area measurements are used with simple modelling equations to calculate the amount of rainfall runoff that could be collected and solar energy that could be produced, during an average year. The final results show the potential savings that could be produced each year if these towns and the university campus became more water and energy conscious. [C2079]

#### "Towards an improved wind and rain backscatter model for ASCAT"

The ASCAT scatterometer measures the backscatter from the ocean surface with which it infers the near-surface wind vector. When rain is present in the observation area the wind-induced backscatter is modified by the rain. This paper uses co-located observations from TRMM PR to model the effects of rain on the ASCAT observed backscatter. Two model types are considered, a phenomenological rain model and a lumped effect rain model which are comparable for most rain rates. For low rain events the ASCAT observed backscatter due to rain is not substantial, however for moderate to high rains the rain-induced backscatter from the ocean surface can be significant, and for extreme rain rates the atmospheric scattering and attenuation are dominant. [C2080]

#### "3D subsurface visualization by suppressing ground reflection and direct wave with bistatic GPR"

A ground reflection and a direct wave which propagates directly from a transmitting antenna to a receiving antenna are often arisen as issues especially for a ground penetrating radar (GPR) to monitor a near-surface region. In this paper, a 3D subsurface radar image by suppressing those components with a bistatic GPR system is presented. A relative permittivity of a ground surface is measured at the beginning, and a Brewster angle is estimated from that value. Then, the transmitting antenna is located to match an incident angle with the Brewster angle. In this case, the ground reflection does not occur, and all the energy penetrates into the ground. The direct wave is suppressed with an f-k filter which works automatically from position information of the antennas. An experimental result gives the 3D subsurface image without the ground reflection and the direct wave under a condition that a landmine model is buried at a depth of 10cm in a dry sand. [C2081]

#### "Studies of radio frequency interference at L-band using an airborne 2-D interferometric radiometer"

Potential radio frequency interference (RFI) sources at L-band include L-band radars; mobile, navigation and other satellite services; and various land services. We have collected data using our airborne L-band interferometric HUT-2D radiometer in order to support the ESA SMOS mission. We participated in April-May 2008 in ESA's rehearsal campaign for SMOS satellite validation activities in Germany and Spain. Additional data have been collected in Finland. Two basic categories of RFI have been observed: (1) Point-wise weak sources that do not saturate the HUT-2D instrument, and (2) strong sources that totally saturate the sensor over a large area. [C2082]

#### "Tidal current measurement with TerraSAR-X Along-Track Interferometry"

In this paper we describe new achievements of surface current measurements obtained by space-borne Along-

Track Interferometry (ATI). We show how tidal currents can be mapped using the TerraSAR-X satellite and adequate dual-channel SAR data processing techniques. We present results from tidal currents at the Orkney Islands that clearly demonstrate the potential and suitability of the method. [C2083]

#### "Gulf stream thermal fronts detected by synthetic aperture radar"

Our objective is to detect ocean surface features, specifically oceanic thermal fronts, through analysis of SAR (synthetic aperture radar)-derived wind stress fields. Fine-resolution measurements of near-surface wind speeds over the Gulf Stream region of the Northwest Atlantic were made using SAR images collected by RADARSAT-2. Linear statistical relationships between the wind stress curl and divergence to the crosswind and downwind components of the sea surface temperature (SST) gradient field were used to derive a new method for detecting Gulf Stream thermal fronts from Synthetic Aperture Radar (SAR) imagery. In particular, sea surface temperature front features, as suggested by corresponding AVHRR and MODIS images, are evident in both of the wind stress curl and divergence fields. [C2084]

#### "Microwave remote sensing for marine monitoring: An example of *Enteromorpha prolifera* bloom monitoring"

The bloom of algae called *Enteromorpha prolifera* posed a potential threat to the Olympic sailing competition in June 2008. Synthetic Aperture Radar (SAR) technology plays an irreplaceable role in algal blooming monitoring. Based on the analysis of various influence factors, a procedure for E.P. detection is proposed. In this paper, multi-temporal SAR images especially with short time interval, currents datum from buoys and wind products retrieved from SeaWinds scatterometer have been employed for E.P. dynamic monitoring and drift trend analysis. The result of analysis shows SAR, currents and wind datum are available for forecasting the trend of the E.P. drift. [C2085]

#### "Monostatic calibration of both TanDEM-X satellites"

The primary object of the TanDEM-X mission is to generate a highly accurate digital elevation model (DEM) with never achieved accuracy on global scale. But in addition to this bistatic TanDEM-X mission the monostatic TerraSAR-X mission have to be operated in parallel with both satellites. Consequently the second satellite TDX, successfully launched in June 2010, has to achieve the same accuracy and performance as those of the first satellite TSX, already in-flight since 2007. Thus, the monostatic calibration of the second satellite TDX is performed according to the same strategy based on effective and exact calibration techniques successfully demonstrated by the first satellite TSX. The paper discusses the calibration results of the first satellite TSX derived two years after launch by an extended re-calibration campaign executed in summer 2009, and presents first results of the second satellite TDX. But it has to be mentioned, the main calibration activities of TDX will start three weeks after launch, i.e. after uploading of this paper. [C2086]

#### "An improvement for the unsupervised Wishart Freeman classification with fully polarimetric SAR data"

In this paper, we proposed an improvement for the Wishart Freeman classification, which is based on the Wishart distance measurement and the estimation algorithm of the number of clusters for fully polarimetric SAR data. Our experimental results show the effectiveness of the proposed method. [C2087]

#### "Image partitioning with kernel mapping and graph cuts"

A novel multiregion graph cut image partitioning method combined with kernel mapping is presented. A kernel function transforms implicitly the image data into data of a higher dimension so that the piecewise constant model of the graph cut formulation becomes applicable. The method yields an effective alternative to complex modeling of the original image data while taking advantage of the rapidity of graph cuts. A variety of noise models are, thus, considered by a single model. Using a common kernel function, we minimize the objective functional by iterating (1) regions parameters update and (2) image partitioning by graph cut iterations. A comparative performance evaluation is carried out over a large set of experiments using synthetic grey level data. Besides, a set of tests with real images such as SAR and medical images is shown to demonstrate the validity of the method. [C2088]

#### "Ultra-rapid optronic processor for instantaneous ENVISAT/ASAR scene observation"

This paper introduces a real-time compact optronic SAR processor that has the capability to generate ENVISAT/ASAR image swaths of 100 km  $\times$  100 km in 10 seconds exhibiting slant plane sampling distances of 4 meters in azimuth and 1 meter in range. It may be instantaneously reconfigured to process data from any of the

7 ASAR image swath modes. In this respect, numerous SAR image sets may be produced immediately on-demand without bottleneck. A rapid SAR processor that also provides fine ground sampling distances in both azimuth and range directions could provide benefits for such applications as ship detection, landslide and flood monitoring, snow and ice coverage and glacier monitoring. [C2089]

### "Advances in the generation of deformation time series from SAR data sequences in areas affected by large dynamics"

We propose advances on the generation of deformation time series in areas affected by large deformation dynamics, where the exploitation of the differential SAR phase can be strongly limited by severe misregistration errors or by very high fringe rates. First, to overcome the former issue, we present an extension of the amplitude-based Pixel-Offset (PO) analyses by applying the Small Baseline Subset (SBAS) strategy, in order to move from the investigation of single (large) deformation events to that of dynamic phenomena. Secondly, to handle the high fringe rate interferograms, we subtract from them properly generated synthetic deformation models allowing us to reduce the fringe rate, thus helping the phase unwrapping step. The proposed approaches have been tested on ASAR-ENVISAT data acquired on Galapagos Islands and validated via continuous GPS measurements. [C2090]

### "Integration of InSAR and GIS for an estimation of ground subsidence susceptibility"

Ground subsidence susceptibility at a coal mine by integration of L-band SAR measurements and a subsidence hazard model incorporated in GIS was estimated. A subsidence hazard map was constructed using JERS-1 SAR data from the early 1990s and the subsidence hazard model. A certainty factor analysis was employed for estimating the relative weights of four control factors influencing coal mine subsidence. The relative weight of each factor was then integrated to generate a subsidence hazard index (SHI) by a fuzzy combination operator. The hazard map was validated by comparison with subsidence observed by ALOS PALSAR interferometry in 2007-2008. The results showed a good agreement between the predicted locations vulnerable to subsidence and the actual subsidence occurrences with an accuracy of about 72.5%. These results showed that the map produced by integration of InSAR and GIS can be used to predict and monitor coal mine subsidence hazards, especially in remote regions. [C2091]

### "Rain effect on polarimetric SAR observation"

The purpose of this paper is to consider the radio wave propagation of Polarimetric SAR in rain and to verify the influence of rain quantitatively. We assume the Polarimetric SAR observation model in non-spherical rain drop environments and evaluate the influence of rain at 5.405, 9.65 and 13.9GHz by calculating the rain distortion matrix with parameters of rainfall rate and the rain drop canting angle. The results show that the rain attenuation, the attenuation difference between horizontal and vertical polarization, and the cross-polarization factor increase as the frequency and rainfall rate increase, and they depend on the rain drop canting angle and the incident angle. [C2092]

### "The Soil Moisture Active Passive (SMAP) mission L-Band radar/radiometer instrument"

The Soil Moisture Active/Passive (SMAP) mission is a NASA mission identified by the NRC "decadal survey" to measure both soil moisture and freeze/thaw state from space. The mission will use both active radar and passive radiometer instruments at L-Band. In order to achieve a wide swath at sufficiently high resolution for both active and passive channels, an instrument architecture that uses a large rotating reflector is employed. The active radar will further utilize SAR processing in order to obtain the sub-footprint resolution necessary for the geophysical retrievals. The SMAP radiometer uses a more conventional real-aperture resolution, albeit with a significantly larger antenna than flown before. Both the SMAP radar and radiometer must address the effects of radiofrequency interference (RFI). [C2093]

### "Deformation in Hawaii's volcanoes obtained from a ScanSAR-to-stripmap Small Baseline Subset technique"

We investigate the displacement phenomena affecting Mauna Loa and Kilauea volcanoes at Big Island (Hawaii, USA), by applying an advanced ScanSAR-to-stripmap differential Synthetic Aperture Radar Interferometry (InSAR) approach. The implemented method, based on the application of the well-known Small Baseline Subset (SBAS) technique, allows the generation of LOS mean deformation velocity maps and corresponding time series, leading us to characterize the complex deformation of Mauna Loa and Kilauea volcanoes. The presented analysis relies on the use of a SAR dataset composed by 49 ASAR ENVISAT satellite images, relevant to both stripmap and ScanSAR operational modes, acquired on descending orbits (track 200) from January 2003 to

September 2008. Moreover, in order to assess the quality of the proposed combined ScanSAR-to-stripmap approach, we perform a comparison between the achieved DInSAR results and the LOS-projected GPS displacement measurements. [C2094]

#### **"Automated Polar ice thickness estimation from radar imagery"**

This work focuses on automating the task of estimating Polar ice thickness from airborne radar data acquired over Greenland and Antarctica. This process involves the identification and accurate selection of the ice sheet's surface location and interface between the ice sheet and the underlying bedrock for each measurement. Identifying the surface and bedrock locations in the radar imagery enables the computation of ice sheet thickness, which is important for the study of ice sheets, their volume, and how they may contribute to global climate change. The time-consuming manual approach requires sparse hand-selection of surface and bedrock interfaces by several human experts, and interpolating between the selections to save time. [C2095]

#### **"Spread E, F layer ionospheric clutter identification in range-Doppler map for HFSWR"**

Wide range covering, strong intensity, time-variant, fluctuation and irregular distribution of the spread E, F layer ionospheric clutter badly affects the system performance of High Frequency Surface Wave Radar (HFSWR). A spread E, F layer ionospheric clutter identification method is proposed based on the region segmentation results and region characteristics of the clutter. First of all, convolution template is used for locating the edge of the clutter, then the ratio of the number of the samples belonging to some segmented region and the total number of the samples in the region of interest (ROI) is used for setting the determinative threshold of the clutter region. Experiments with real data manifest that the proposed method can describe the effect of the spread ionospheric clutter to HFSWR. The quantitative analysis is consistent with the real data observation. The result can be used as a worthwhile reference for clutter mitigation, carrier frequency selection or radar system evaluation. [C2096]

#### **"Building height extraction via a deterministic approach using a TerraSAR-X data stack"**

A method for building height determination via a deterministic approach is tested using three TerraSAR-X images from Barcelona, Spain. Using this method, the height of a building wall can be determined based on the strength of the double-bounce backscattering. The approach requires knowledge of the material properties of the measured building wall and the area in near range of the building wall. For certain test buildings the approach provides good results, while for other buildings the results are erroneous. [C2097]

#### **"Analysis of the effect of radio frequency interference on interferometric phase"**

The P-band ultra wideband synthetic aperture radar shares the band with other services, as for example TV broadcast and telecommunications transmitter stations, means distortion by radio frequency interference (RFI) to the SAR. It's well known the performance of UWB-SAR is degraded due to the existence of radio frequency interference. This paper describes the problems of RFI in InSAR, and analyses the effect of RFI to interferometric phase based on simulation. [C2098]

#### **"Quantification of the topographic slope from radar satellite imagery"**

A specificity of Synthetic Aperture Radar (SAR) scenes is to display geometric distortions depending on both the system of acquisition and its relation with the topography. Establishing the geometric relationship between the radar sensor parameters and the related surface deformation should therefore provide quantitative information on the topographic surface. Here, we propose a new technique for the computation of the terrain slope, which is based on the quantification of the geometric deformation generated during the acquisition of a SAR scene. The method uses a pair of radar scenes consisting of an orthorectified image and another in slant-range geometry to compute the local topographic slope of a reference ground segment identified on both images. Computed slope values using ENVISAT-ASAR and TerraSAR-X images and compared with measurements taken in the field in the Djebel En Negueb anticline located in south-central Tunisia reach 3° with both data. [C2099]

#### **"Environmental monitoring with the imaging MIMO radars MIRA-CLE and MIRA-CLE X"**

Several applications need imaging sensors for environmental monitoring which can continuously observe an area in a 24/7 mode independently from the weather and other atmospheric obscuration like dust and smoke. Imaging MIMO radar fulfills these requirements and enables the opportunity of low-cost and robust imaging systems by synthesizing many virtual antennas out of just a few real ones. MIRA-CLE is a fully configurable and expandable experimental MIMO radar in Ka-band while MIRA-CLE X works in X-band and is intended to be a low-cost experimental system for long range applications. This paper presents both MIMO radar systems and shows and discusses first imaging results of MIRA-CLE X. [C2100]

### "Modular Radar Core for airborne and space applications"

The development of Radar Core electronics for any air and spaceborne radar units has a long space heritage at EADS in Friedrichshafen. It encompasses the spaceborne radars SIR-C/ X-SAR, SRTM, TerraSAR-X, TanDEM-X, and the oncoming PAZ mission and many airborne missions. These missions demonstrated successfully the high end radar electronics performances. EADS initiated a product development program called SmartRadar (Scalable modular aerospace radar technology) for the next generation airborne and space radars. The Radar Core development is one step in the SmartRadar development road map at EADS. To summarise the status of the development: the new hardware and related software have been flown in a demonstration flight campaign in summer 2009. For this campaign the frequency band was chosen to be at X-Band to use an available Reflector Antenna and Travelling Wave Tube Amplifier (TWTA) and Front end equipment. Synthetic Aperture Radar (SAR) image results are of very good quality and performance parameters analysed from the recorded raw data match or exceed the chosen design parameters. [C2101]

### "Shadow region imaging algorithm using array antenna based on aperture synthesis of multiple scattered waves for UWB radars"

Ultra-wide band (UWB) pulse radar has a definite advantage over optical ranging techniques, as to applicability to the harsh optical environment, such as the dark smog, or strong back-light. We have already proposed the extended Synthetic Aperture Radar (SAR) algorithm employing the multiple scattered waves, which aims at enhancing the reconstructible region of the target boundary including the shadow. However, it still suffers from the shadow region in the case of the target with a sharp inclination or deep concave boundary, because it assumes the antenna scanning whose real aperture size is too small. To resolve this difficulty, this paper proposes an extension algorithm using the array antenna model. While this extension is quite simple, the effectiveness of the proposed method is nontrivial regarding to the expansion of the imaging range. The results from numerical simulations verify that our method remarkably enhances the visible range of target surfaces without a priori knowledge of target shapes or a preliminary observation of its surroundings. [C2102]

### "Extraction of area-averaged orientation angle from POLSAR measurement"

We have shown that area-averaged structure orientation angles relative to incident angle of POLSAR in urban area can be estimated from argument of correlation coefficient of circularly-polarized observation bases. It is quite interesting that by this approach we can estimate area-averaged urban parameters even if we can not distinguish them from conventional received signal component intensity map due to lack of spatial resolution. [C2103]

### "STAP based ground moving target detectability in the airborne/spaceborne array radar"

A space-time adaptive processing (STAP) can be effective in detecting the ground moving targets from the airborne/spaceborne moving platform in the severe ground clutter and jammer environments. In this paper, the characteristics of target, ground clutter and jammer signals are analyzed and designed the adaptively weighted clutter notch filter in two dimensional spatial and temporal azimuth angle-Doppler domains. The simulation is performed for ground moving target detection by rejecting both clutter and jammer simultaneously through the STAP processing. The probability of target detection is investigated depending on the SNR and the minimum detectable velocity (MDV) in the given false alarm rate. The simulation results show that the MDV can be ideally achieved up to 2 m/s ~ 3 m/s at the 90 % of detection probability in the given false alarm rate of 10<sup>-3</sup> and 10<sup>-6</sup>. This technique may be applied for the surveillance and traffic monitoring of moving vehicle on the road. [C2104]

### "Accurate focusing of single-pass airborne InSAR data at L-band"

Long wavelength airborne single-pass InSAR systems call for very accurate SAR focusing and motion compensation algorithms. We have analyzed 3 different techniques and evaluated their performance using real data acquired with an L-band single-pass interferometer in Canada. Time domain backprojection with terrain-dependent motion compensation shows the best performance with results close to the theoretically expected values. [C2105]

### "Characterization of affected areas of the 2008 Iwate-Miyagi, Japan, earthquake using SAR intensity images"

SAR images obtained before and after a natural disaster are considered to be useful for emergency response due to its all-weather and sunlight-independent characteristics. Recently, the spatial resolutions of SAR systems have been improved significantly. In this paper, SAR intensity images acquired before and after the 2008 Iwate-

Miyagi, Japan, earthquake from ALOS/PALSAR (L-band) and TerraSAR-X (X-band) are employed to investigate the radar backscattering characteristics for various acquisition and surface conditions. The spatial resolution, radar frequency, flight path, and incidence angle were shown to affect SAR backscattering echo, depending on surface materials and roughness. It is also observed that the difference of the backscattering coefficients at the pre- and post-event times gets large and their correlation coefficient becomes small at the locations of landslides and slope failures. [C2106]

### "Contextual remote-sensing image classification by support vector machines and Markov random fields"

In the framework of remote-sensing image classification support vector machines (SVMs) have recently been receiving a very strong attention, thanks to their accurate results in many applications and good analytical properties. However, SVM classifiers are intrinsically noncontextual, which represents a severe limitation in image classification. In this paper, a novel method is proposed to integrate support vector classification with Markov random field models for the spatial context, and is validated with multichannel SAR and multispectral high-resolution images. The integration relies on an analytical reformulation of the Markovian minimum-energy rule in terms of a suitable SVM-like kernel expansion. Parameter-optimization and hierarchical clustering algorithms are also integrated in the method to automatically tune its input parameters and to minimize the execution time with large images and training sets, respectively. [C2107]

### "Pose estimation for ISAR image classification"

This paper presents aircraft target recognition (ATR) system using Inverse Synthetic Aperture Radar (ISAR) images. Knowing the pose of the target can improve the ATR performance (recognition rate and computational complexity). So, we propose in this paper a new pose estimator from ISAR images, based on the axis of symmetry and the similarity measure. The method proposed is compared with several approaches proposed recently in the literature, such as 2-D Continuous wavelet Transform and Hough transform. Once the pose of target is estimated, the classification is finally performed by K-Nearest Angle (KNA) classifier which insert the pose information into image retrieval task. [C2108]

### "RADAR and AIS sensors constellation for global maritime surveillance"

In the frame of SAMSON study (a Feasibility study of a space-based maritime surveillance system), funded by CNES, several concepts for a dual sensor RADAR + AIS (Automatic Identification System) constellation have been addressed. One of them supported by Thales Alenia Space is described in this paper. Its interest for global maritime surveillance is discussed. The constellation performance is presented in terms of revisit time and detection probability for each sensor before data fusion processing. Instruments are described as well as the proposed satellite concept. [C2109]

### "Predictive quantization of dechirped spotlight-mode SAR raw data in transform domain"

Synthetic aperture radar (SAR) systems collect large volumes of data that must be transmitted to a ground station for storage and processing. However, given the limited bandwidth of the downlink channel it is imperative that SAR data be compressed before transmission. While it is commonly believed that raw SAR data is uncorrelated, it is shown in that the inverse Fourier transform of spotlight-mode SAR exhibits non-negligible correlation that can be exploited in a predictive quantization scheme. In this paper, we propose two predictive quantization algorithms-transform-domain block predictive quantization (TD-BPQ), and transform-domain block predictive vector quantization (TD-BPVQ)-to encode dechirp-on-receive spotlight-mode SAR raw data. Experimental results indicate that, on average, TD-BPQ and TD-BPVQ outperform the well known block adaptive quantization (BAQ) by 5 and 6 dB, respectively. [C2110]

### "Z-R relation for snowfall using two small doppler radars and snow particle images"

Snowfall data was simultaneously recorded by two small Doppler radars, two high sensitive snow gages and an image processing system with high accuracy at short time interval. The snowfall rate  $R$  was measured with two gauges and radar reflectivity factor  $Z$  was measured using small bistatic X-band radar and monostatic K-band radar. The images of falling snow particles were used to obtain size distribution. Since all the measurements were located in a small area, it can be said that the obtained data corresponds well to others, and it is possible to analyze Z-R relation in detail. The relationships between two radar reflectivity factors and snowfall rate were investigated and compared to the characteristics of snow particles. [C2111]

### "Analysis of geosar dual-band InSAR data for peruvian forest"

At present there is no consensus as to which remote sensing technologies are appropriate for tropical forest biomass estimation. Cloud cover in the tropics and biomass saturation suggest that a combination of low-frequency SAR and interferometry (either PolInSAR or dual-band interferometric SAR DBInSAR) could provide a solution. Tropical forest biomass recovery using X-P DBInSAR has been demonstrated from an airborne platform using the X-P DEM height difference. This height is known to be considerably lower than the tree height as a result of penetration of microwaves into the canopy that can be significant even at X-band. We model the penetration using the RVOG model and show that in the strong attenuation approximation the interferometric coherence magnitude can be used to estimate penetration depth. We compare the model with GeoSAR DBInSAR observations of Peruvian forest, and, by comparison with LiDAR data, show that the GeoSAR Xband interferometric height can be corrected towards the upper canopy using knowledge of the coherence magnitude combined with the high-frequency "X-RVOG" model. We employ the corrected height with a biomass inversion equation derived from plot samples covered in the Peru campaign and generate a map of above ground forest biomass. [C2112]

#### "Application of KOMPSAT-5 data for emergent oil spill monitoring"

In this paper, we discussed the functionalities of KOMPSAT-5 from the emergency response perspective to oil spill detection, describing its technical abilities in terms of maneuverability, system response time, image quality, and damping ratio. The damping ratio at the X-band was higher than that at other available frequencies, which increased the probability of oil spill detection from SAR data. However, the detection of oil spills depends significantly on the wind condition and the presence of look-alikes. Oil spill detection algorithm for KOMPSAT-5 estimates wind information directly from SAR data, and is expected to enhance the detection capability. [C2113]

#### "Snow wetness retrieval inversion modeling for C-band and X-band multi-polarization SAR data"

This paper is concerning the estimation of snow wetness from multi-polarization SAR data. In this paper, microwave interaction with snow covered terrain and different scattering mechanism from snowpack and their backscattering model for developing inversion algorithm with wet snow conditions are described in order to estimate snow wetness. SAR data processing and field measurement of snow parameters are also discussed. In this study, snow wetness has been measured with a dielectric moisture meter with synchronous satellite passes over the part of snow covered Indian Himalayan region (e.g. Dhundi observatory in Himachal Pradesh, India). [C2114]

#### "Random noise SAR based on compressed sensing"

Recent theory of compressed sensing (CS) suggested that exact recovery of an unknown sparse signal can be achieved from few measurements with overwhelming probability. In this paper, we combine CS technology with a random noise SAR and proposed the concept of random noise SAR based on CS. The block diagram of the radar system and the collected data processing procedure was presented. Theoretic analysis show that the sensing matrix of the random noise SAR exhibits good restricted isometry property (RIP). When the target scene is sparse or sparse in any basis, the random noise radar based on CS can get high accuracy image by collecting far less amount of echo data than traditional noise radar does. The conclusions are all demonstrated by simulation experiments. [C2115]

#### "A real-time grid map generation and object classification for ground-based 3D LIDAR data using image analysis techniques"

A grid map generated from ground-based 3D LIDAR point clouds is a critical component for facilitating autonomous system navigation without crashing into obstacles and also to generate a road map for a large local area. This paper proposes a novel approach to generate an occupancy grid map along with object classification in real-time for autonomous ground robot applications. Based on geometric analysis of the raster-scanned LIDAR data, we formulate criteria to distinguish 3D points directly from coordinate values and generate three grid maps; occupancy, ground, and scatter maps which directly correspond to hypotheses on object type. Then 2D and 3D shape analysis are carried out to verify the object hypotheses. Our experimental results show that the new method performs well providing an autonomous system with surrounding 3D information and object classification. [C2116]

#### "Local multi-modal image matching based on self-similarity"

A fundamental problem in computer vision is the precise determination of correspondences between pairs of images. Many methods have been proposed which work very well for image data from one modality. However, with the wide availability of sensor systems with different spectral sensitivities there is growing demand to automatically fuse the information from multiple sensor types. We focus on the problem of finding point and local

region correspondences in an inter-modality imaging setup. We use a Generalized Hough Transform to determine small regions with a similar geometric relationship of local image features to robustly identify correct matches. We additionally optimize region correspondences by a fast non-linear optimization of a self-similarity distance measure. This measure outperforms standard multi-modal registration approaches like mutual information or correlation ratio in case of local image regions. The method is evaluated on Visible/Infrared (IR) and Visible/Light Detection and Ranging (LiDAR) intensity image data pairs and shows very promising results. Potential applications are numerous and include for instance multi-spectral camera calibration, multi-spectral texturing of 3D-models, multi-spectral segmentation or multi-spectral super-resolution. [C2117]

#### "SAR data collection over rain forests at VHF- and UHF-band"

Radar imaging of tropical vegetation at VHF- and UHF-band has been performed using the airborne SAR sensors CARABAS-II and LORA, respectively. The acquired data set is limited to HH-polarized registrations only. The area mapped exhibits a rough terrain with dramatic topographic variations, mostly covered by dense tropical rain forests. Multiple illumination directions spanning 360° were adopted in the data collection for both sensors to overcome the shadowing due to the high relief topography. For each heading, the SAR images generated, adjacent in azimuth and from all imaging passes, were calibrated and geocoded separately and then merged into a mosaic representing the full ground coverage. A first output from the forest backscatter analysis indicates a 12 dB lower level at VHF-band at an incidence angle of about 70°. However, this preliminary result is based on one sample point only, where the investigated forested area was located on a fairly flat ground surface. [C2118]

#### "Multi-frequency and polarimetric measurements of snow microwave reflection and emission by C- and Ku-band, combined scatterometer-radiometer systems"

In this paper the results of simultaneous and spatially coincident, dual-frequency (at C- and Ku-band), multi-polarization measurements will be represented, of bare soil and snow microwave reflective (radar backscattering coefficient) and emissive (brightness temperature) characteristics angular dependences at 5.6GHz and 15GHz. [C2119]

#### "Electromagnetic scattering from arbitrary random rough surfaces using stabilized extended boundary condition method (SEBCM) for remote sensing of soil moisture"

In this paper, the stabilized extended boundary condition method (SEBCM) is developed based on the classical EBCM to solve both 2D and 3D electromagnetic scattering from arbitrary random rough surfaces. The SEBCM gives accurate full wave solutions over large range of surface roughnesses and medium losses, which are far beyond the validity range of analytical methods, and perform with much higher efficiency than numerical methods. These properties make SEBCM a competitive forward model in the inverse problem for soil moisture retrieval from radar measurements. [C2120]

#### "Code sequence selection for SAR radiometric calibration"

It is an important significance for SAR radiometric calibration accuracy to select a proper code sequence about active coded transponder (ACT), in the process of active coding radiometric calibration using synthetic aperture radar (SAR). According to the principle of active coding radiometric calibration, a signal processing model of active coded reflected signals is proposed in this paper. And m sequences, Gold sequences and random sequences are studied. Simulation experiments with the compression of SAR azimuth signals are carried out. [C2121]

#### "2D uesprit superresolution SAR imaging algorithm"

One of the driving forces of the development of SAR image formation has been to obtain better and better image resolution. Conventional radar imaging methods based on Fourier transform provide good resolution as long as the backscattered data is available over a large bandwidth and a sufficient aspect region. The paper proposes a 2D Unitary ESPRIT superresolution SAR imaging method exploiting that the SAR image in phase history domain is a band-pass function with a main frequency support domain. Thus, the problem of superresolution SAR imaging is transformed to solve sinusoid harmonic estimation, which can be solved by 2D Unitary ESPRIT. From the experiments using simulation and measured data, we can see better resolution obtained by the method of the paper than the FFT method. [C2122]

#### "SAR focusing of P-band ice sounding data using back-projection"

SAR processing can be applied to ice sounder data to improve along-track resolution and clutter suppression.

This paper presents a time-domain back-projection technique for SAR focusing of ice sounder data. With this technique, variations in flight track and ice surface slope can be accurately accommodated at the expense of computation time. The back-projection algorithm can be easily parallelized however, and can advantageously be implemented on a graphics processing unit (GPU). Results from using the back-projection algorithm on POLARIS ice sounder data from North Greenland shows that the quality of data is improved by the processing, and the performance of the GPU implementation allows for very fast focusing. [C2123]

#### "A test statistic for high resolution polarimetric SAR data classification"

Modern SAR systems have high resolution which leads the backscattering clutter to be non-Gaussian. In order to properly classify images from these systems, a non-Gaussian noise model is considered: the SIRV model. A statistical test of equality of covariance matrices is used to classify pixels, taking into account the critical region of the test which rejects the likeliness of a covariance matrix to any of the class centers. This test is applied on experimental data obtained with the ONERA RAMSES system in X-band. The results show a good separation between natural and man-made areas of the image. [C2124]

#### "Investigating co-seismic deformation of the 2008 Wenchuan earthquake with ALOS SCANSAR interferometric observations"

On May 12th, 2008, a destructive earthquake of magnitude 8.0 struck Wenchuan. The seismic region is located at the transition zone between Qinghai-Tibet Plateau and the Sichuan Basin, which has a complex geological tectonic background. In this paper, we intend to investigate the Wenchuan earthquake using the Differential Interferometric SAR (D-InSAR) technique. Due to the large scale of the crustal deformation affected by the disastrous earthquake, SCANSAR images show more advantages than conventional strip-map mode images. And taking account the vegetation conditions, the L band images are suitable than the C band images for our study. Therefore, we choose to use ALOS SCANSAR interferometric observations to obtain a preliminary co-seismic displacement field of the Wenchuan earthquake. [C2125]

#### "Evaluation of the influence of the polarimetric calibration process on the H/A/ $\alpha$ decomposition"

The objective of this article is to evaluate the influence of the cross-talk and channel imbalance calibration on the estimation of the entropy and the alpha images. Few studies can be found in SAR literature concerning the influence of the polarimetric image calibration process on the target decomposition methods and their consequences on the characterization and discrimination of different ground targets. This influence is illustrated here by using a methodology based on an L-band fully polarimetric SAR data acquired by the SIPAM (Amazon Protection System) airborne R99-SAR over two areas of study, located in the Brazilian Amazon Forest and urban area regions. [C2126]

#### "A novel range migration algorithm of GEO SAR echo data"

The key problem of the imaging processing in geosynchronous earth orbit (GEO) SAR system is the space-variance of the Doppler parameters, which will result in the defocus of the SAR image with classical imaging algorithm. In this paper, a Modified Range Migration Algorithm (RMA) is proposed to overcome the space-variance of Doppler parameters by compensating the velocity change along the location of the target. Furthermore the simulation results fully verify the effectiveness of derived algorithm after velocity compensation. [C2127]

#### "Analysis and compensation for motion errors in FMCW SAR data"

In this paper, we present a motion error model for a Frequency-Modulated Continuous-Wave (FMCW) SAR system, and analyze the characteristics of the intrapulse motion error. Furthermore, we develop an effective compensation approach to handle motion errors based on our previous result. Finally, we validate the formulated signal model and compensation method by using simulated FMCW SAR data. [C2128]

#### "The extended SBAS technique for generating full resolution ERS/ENVISAT deformation time-series"

In this work we extend the Small Baseline Subset (SBAS) Differential SAR Interferometry approach to allow the generation of deformation time-series by processing long sequences of ERS-1, ERS-2 and ENVISAT SAR data at the full spatial resolution scale. Our idea is to avoid the generation of ERS/ENVISAT cross-interferograms, severely affected by noise phenomena, and to consider single-platform interferograms only (i.e. ERS/ERS and ENVISAT/ENVISAT interferograms), that are properly combined by applying the SVD-based SBAS approach. The presented results, achieved on two dataset relevant to the Napoli Bay area and to the Murge region (Italy),

confirm the effectiveness of the presented technique and demonstrate the relevance of deformation analysis carried out at the scale of single buildings with more than 15 years of ERS and ENVISAT acquisitions. [C2129]

### "Target localization methods for frequency-only MIMO radar"

In Multi Input-Multi Output (MIMO) radar, the target localization is possible by using only the frequencies of received signals instead of using whole data on the received signals for moving targets. As target is moving, received frequency will be shifted as doppler frequency. Received frequencies which are scattered from non-manouvering and constant speed target, can be written in two dimensional (2D) space with respect to the target coordinates. A cost function can be defined by the help of these frequencies, and than by using grid search, local minimum of this cost function can be found in (x, y) coordinates. In this work, a new target localization method is poroposed for frequency-only MIMO radar. [C2130]

### "Progressive SAR imaging technique"

A progressive SAR imaging technique is proposed as a novel SAR raw data processing scheme in this paper. Different from the classic SAR imaging algorithms which focus the SAR raw data as a whole regardless of the backscattering signal, the novel scheme discriminate the backscattering signal and choose the proper ones to be focused progressively according to some application context while the others will be discarded. The new scheme makes the SAR imaging algorithm not only focus the energy back to the scattering points but also form an image more suitable for some special applications. In this paper, a realization of the scheme present via Atomic Decomposition (AD)[1]-[3]. AD helps estimate the parameters of backscattered signal of a scattering point and detach it from the raw data. With the parameters, the backscattering-signal can be reconstructed and focused. Targets or scatter-points in the scene will be imaged progressively in a sequence of their energy due to the greedy natural of matching pursuit employed during AD. Therefore, the contents in the final SAR image can be controlled by an energy threshold. Besides the interested targets can be extracted easily from the background clutter and this may be helpful for the SAR image understanding. [C2131]

### "Evaluation of the self-consistency principle for calibration of the CASA radar network using properties of the observed medium"

The Center for Collaborative and Adaptive Sensing of the Atmosphere (CASA) has deployed a Distributive, Adaptive and Collaborative Sensing (DCAS) network of four radars in central Oklahoma. The radars operate at the X-band frequency and are capable of polarimetric and Doppler measurements. The radar network is being evaluated for Quantitative Precipitation Estimation (QPE). QPE algorithms based on radar power measurements (e.g. ZHand ZDR) require bias correction. The polarimetric self-consistency principle is applied to the CASA radar data to estimate any bias in ZH. Results show a ZHcalibration accuracy of 0.6 dBZ or less for two the analyzed events. ZHbias estimates from the self-consistency principle in rainfall are compared and validated with ZHbias estimated from the comparison of the X-band and the S-band radars' data. Comparison of the two approaches shows a difference in the ZHbias estimation of 0.61 dBZ or less and validates the use of the self-consistency principle in rainfall for the absolute radar calibration of the CASA radars. [C2132]

### "Application of the moving target detection by focusing technique in civil traffic monitoring"

This paper presents an application of the moving target detection by focusing technique (MTDF) in civil traffic monitoring. The experimental results based on simulations show that the basic civil traffic monitoring can be solved using MTDF using a single-channel airborne SAR system. With an assumption of known moving directions of vehicles, MTDF allows detecting, estimation of speed, and finally reconstructing a SAR image of the vehicles of interest. In this study, the focusing approach of MTDF is based on ultrawideband chirp scaling (UCS) algorithm. [C2133]

### "A high accuracy method for interference fringes suppression in SAR distributed targets' raw data simulation"

Interference fringes will be generated in SAR image when distributed targets' echo signal is simulated because of the uniform model of targets. The fringes can be suppressed by adding random height in space or random phase on backscatter coefficient of the distributed targets. However, the former method will introduce location error and the latter method will increase speckle noise twice in simulated image. In this paper, we develop a high accuracy method for fringes suppression based on targets' position randomizing and RCS re-sampling via bilinear interpolation. The validation of method is successfully proved by simulation results and the performance of the method is discussed on accuracy and computational complexity at the end of this paper. [C2134]

### "Calibration of a rotating multi-beam lidar"

This paper presents a technique for the calibration of multi-beam laser scanners. The technique is based on an optimization process, which gives precise estimation of calibration parameters starting from an initial estimate. The optimization process is based on the comparison of scan data with the ground truth environment. Detailed account of the optimization process and suitability analysis of optimization objective function is described, and results are provided to show the efficacy of calibration technique. [C2135]

### "Analysis of the correlation properties of digital satellite signals and their applicability in bistatic remote sensing"

This paper presents a study of relevant correlation properties of signal transmitted from commercial communication satellites in order to evaluate their potential use as "signal of opportunity" for bistatic remote sensing. The ambiguity function for the XM radio satellites was computed analytically from published information on the modulation schemes and bandwidth, under the assumption that the data modulation is random. The model was then experimentally tested by recording the received signals from these satellites. Next, a cross-correlation waveform for digital signal reflected from random rough surface was simulated. Scattering model that were originally developed for Global Navigation Satellite System (GNSS-R) signals was applied to the modified simulator to incorporate the derived ambiguity function. The simulator was then used to generate synthetic waveform with a realistic signal to noise ratio (SNR). Retrieval algorithms for ocean surface roughness and reflectivity that were derived originally for GNSS-R, were applied to these simulated signals. Non-linear least square methods were applied to invert a scattering model and estimate the slope variances of the probability density function (PDF), which best fits the measurements of the reflected XM signal waveform. The SNR for the experimental data was found to be within 0.5dB of the theoretically calculated SNR. [C2136]

### "Ship detection with RadarSat-2 Quad-Pol sar data using a notch filter based on perturbation analysis"

Target detection of marine feature is a major topic for the security and monitoring of coastlines. Synthetic Aperture Radar (SAR) has been shown to be particularly useful for this application because of its all-weather and night capability. In this paper a new ship and iceberg detection methodology is described. The algorithm proposed is based on a perturbation analysis in the target space recently developed and published by the authors, which was focused on land based target detection. The algorithm can be considered to be a negative filter focused on sea. Consequently, all the features which have a polarimetric behaviour different from the sea are detected. To demonstrate and validate the technique two RadarSat Fine Quad-Pol mode scenes were acquired off the south coast of the UK at Portsmouth harbour. An extensive ground truth campaign was also conducted that was coincident with these acquisitions. Portsmouth is one of the busiest harbours in the UK and this afforded the opportunity to capture a wide range of vessel sizes and types for analysis. [C2137]

### "A biomass estimate over the harvard forest using field measurements with radar and lidar data"

The National Research Council's decadal survey recommended DESDynI as one of the high priority missions for NASA. The mission envisions an InSAR/Lidar instrument for observing ecosystem structures on global scales with high spatial resolutions. Consistent and highly resolved global maps of biomass and carbon stocks require highly accurate observations of vegetation, in fact it is expected that such accuracies would require a combination of the high vertical precision of Lidar observations and the large spatial extent of SAR/InSAR measurements. Here we analyze radar backscatter data along with biomass estimates from a field campaign conducted in the Harvard forest in Massachusetts, USA. [C2138]

### "Earth documentation: Overpass detection using mobile Lidar"

This paper presents an application of using geo-data from Lidar and GPS/IMU to detect overpasses. Three characteristics make it a good example of processing large point sets in real-time: a stream paradigm that exploits system parallelism and memory-access coherence, a multi-level detection strategy that distributes computational burden across different operations, and a multi-resolution data structure that suits the need of detecting urban objects. Experimental results proved the excellent performance in terms of speed and accuracy. [C2139]

### "PSI analyses of land subsidence due to economic development near the city of Hangzhou, China"

In this work we mapped the spatial and temporal patterns of the land subsidence near the city of Hangzhou, China by PSI analysis with 49 scenes of ERS-1/2 SAR images acquired from 1992 to 2006 to detect and retrieve the subsidence due to economic development. The main reason of land subsidence in Hangzhou is groundwater

exploitation, which is necessary for the rapid economic development, especially in China. Xiaoshan Economic and Technological Development Zone was approved as a state-level development zone by the State Council in May, 1993. Since then the zone has been suffering land subsidence. There have been more than 300 overseas-funded enterprises with investors from 26 countries and regions by the year 2006. The development of this area can be divided into three periods according to its pace: construction period (1993-1996), stable increase period (1996-2001) and high-speed period (2001-2006). [C2140]

#### **"A nonlocal approach for SAR image denoising"**

Speckle reduction is a key step in several SAR image processing procedures. In this paper, a new despeckling technique based on the "nonlocal" denoising filter BM3D [1] is presented. The filter has been modified in order to take into account SAR image characteristics. The experimental results, conducted on both synthetic and real SAR images, confirm the potential of the proposed approach. [C2141]

#### **"Global laser pulse reflectance at 1064 nm of snow and land surfaces from the Glas satellite Lidar"**

During the development of the Geoscience Laser Altimeter System (GLAS), launched in 2003, it was understood that the values of surface pulse reflectance was an important design parameter for satellite laser altimeters and that the magnitude of observed pulse reflectance would have valuable applications. Thus a significant effort was made to obtain calibrated surface pulse reflectance from GLAS measurements. In this paper we describe the calibration and atmospheric correction procedures and present global measurement results for earth surface laser pulse reflectance. [C2142]

#### **"Investigation of forest height retrieval using SRTM-DEM and ASTER-GDEM"**

Interferometric SAR (InSAR) data have been used to measure canopy height. Polarimetric interferometric SAR (PolInSAR) data can be used to derive canopy height without using ground surface elevation data. But in most cases, only single polarization InSAR data are available and the elevation of ground surface in the forested areas is needed to get the height of the scattering phase center. On contrary, the elevation of canopy surface is relatively easy to obtain by Stereo imagery. In this study the feasibility of the estimation of forest height using SRTM-DEM and ASTER-GDEM was investigated. The ASTER-GDEM was firstly resampled to the pixel size of SRTM-DEM (3 arc-second) and then was registered to SRTM-DEM using the points selected from their aspect maps. The results showed that the registration is necessary because the geolocation error at east-west direction is about half of the pixel size. The relationship between the forest height and the elevation difference was analyzed. The results showed that the elevation difference between registered ASTER-GDEM and SRTM-DEM is positively correlated with the forest height. Although there are some problems when the terrain is rough, it provides us a way to estimate the height of mature forest in flat terrain. [C2143]

#### **"C- and Ku-band (at 5.6GHz and 13.6GHz), dual-frequency, multi-polarization, short pulse, combined scatterometer-radiometer system for low altitude platform, vessel and aircraft applications"**

In this paper C-, and Ku-band, dual frequency, multi-polarization, combined, short-pulse scatterometer-radiometer system is described, for short (from low altitude platform), middle (from vessel) and long (from aircraft) distance remote sensing applications for water surface, soil and land snow cover's microwave reflective and emissive characteristics simultaneous and spatially coincident measurements. [C2144]

#### **"Change detection for earthquake damage assessment in built-up areas using very high resolution optical and SAR imagery"**

Information on the impact of catastrophic events (e.g. earthquakes) can be derived from suitable satellite imagery by comparing data from a chosen reference before the event (pre-event) to imagery acquired shortly after the event (post-event). In this paper, we propose a novel method that detects buildings destroyed in an earthquake using pre-event very high resolution (VHR) multispectral and post-event detected VHR synthetic aperture radar (SAR) imagery. The core concept of the proposed method is the evaluation of the presence of the predicted undamaged building SAR signature in the post-event SAR scene. The decision if a building belongs to the damaged or undamaged building class is performed with a Bayesian classifier, trained either in a supervised or unsupervised manner. We show the results of the proposed method using VHR TerraSAR-X and COSMO-SkyMed, as well as VHR optical data for a subset of the town of Yingxiu, China, which was heavily damaged in the 2008 Sichuan earthquake. [C2145]

#### **"The Cloudsat Education Network: Scientifically significant collaborative research between students"**

## and scientists"

The CloudSat Education Network (CEN) is the primary education and public outreach component of the CloudSat mission. Approximately 116 schools in 16 countries around the world participate in the CEN, and are recruited from schools in the GLOBE program. Students and teachers in the CEN make atmospheric observations of temperature, precipitation, and crucially, of cloud type and cloud cover amount (including photographs of cloud observations), using a modified GLOBE Atmosphere protocol as a guide for observations. CEN observations are taken coincident with CloudSat overpasses, providing coincident spaceborne- and student surface observations. A preliminary comparison study using CEN-collected observations of cloud type during the period from 2007-2008 compared the observed cloud types to those retrieved using the CloudSat 2B-CLDCLASS product. In this preliminary study, there were 227 coincidental measurements between CEN schools and CloudSat overpasses, with an agreement rate of approximately 66% between the surface observers and satellite observations. [C2146]

## "Mapping tropical forest using ALOS PALSAR 50m resolution data with multiscale GLCM analysis"

PALSAR orthorectified HH and HV produced at 50m resolution is used for analysis. Since only two bands (HH and HV) have been limited in land cover discrimination, textures have been used as additional information for classification. This research derives second-order textures at different spatial resolutions and compares second-order textures at multiple scales to demonstrate their contributions in land cover classification. The discriminating capability of texture features is derived by the transformed divergence on several selected regions of interest. Optimum combination of backscattering and textures are used as input data into a supervised multi-resolution maximum likelihood classification. It is found that by including the texture information, the overall classification accuracy is improved by 10%. [C2147]

## "Multi-frequency and polarimetric measurements of bare and vegetated soils microwave reflection and emission by C- and Ku-band, combined scatterometer-radiometer systems"

In this paper the results of simultaneous and spatially coincident, multi-frequency, polarimetric, spatio-temporally collocated measurements of bare, dry vegetated and ash covered soils microwave reflective (radar backscattering coefficient) and emissive (brightness temperature) characteristics angular dependences at ~5.6GHz and ~15GHz are presented. During these experiments the observed area was set ablaze and multi-frequency, multi-polarization, microwave active and passive measurements at 300 incidence angle were continued for smock, fire and ash situations. For these measurements C-, and Ku-band, polarimetric, combined scatterometric-radiometric systems were used, set jointly on a mobile buggy moving along the measuring platform. Structures, operational features and the main technical characteristics of the utilized systems are presented too. The paper has an aim as well to attract attention of interested researchers and to invite them to perform their own or joint researches using available devices and facilities. [C2148]

## "Polarimetric and structural properties of forest scenarios as imaged by longer wavelength SARs"

SAR data gathered from forested areas collect contributions coming from the vegetation layer, from the ground below and from other scattering mechanisms (SMs). Multi-baseline data allow a tomographic analysis thus retrieving information about the vertical structure of the target. Multi-polarimetric acquisitions enrich the data, providing ways to identify the targets basing on their electromagnetic properties. The joint exploitation of multi-polarimetric and multi-baseline data suggests the possibility of linking the estimation of the vertical structure of different SMs with their polarimetric signature. A formal framework in which this task can be accomplished is provided by the Algebraic Synthesis (AS) technique, which extends the concepts within PolInSAR through the assumption of the Sum of Kronecker Products (SKP) structure. By assuming the presence of two SMs (for example ground and volume scattering), the SKP assumption leads to a cross dependence between the polarimetric and interferometric coherences, in that ground structure is shown to be related to volume polarimetry, and dually volume structure is shown to be related to ground polarimetry. The aim of this paper is to investigate the implications of this cross relation. Experimental results will be shown basing on a data-set of multi-polarimetric and multi-baseline SAR images at P-band acquired by DLR's E-SAR over the Krycklan catchment, in northern Sweden, in the framework of the ESA campaign BioSAR 2008. [C2149]

## "Received signal strength based localization in sensor network"

In this paper, we present the accuracy of location engine of CC2431 ZDK development kit which is widely used in sensor network localization problems. Initially, distance vs received signal strength indicator graph has been established, then accuracy of location engine and Cayley-Menger based localization algorithm have been compared. 11411 meter area test result shows that location engine is more accurate than Cayley-Menger based algorithm. [C2150]

### "Esprit-based scattering power decomposition by using modified volume scattering model"

The scattering power decomposition for POLSAR data is one of the powerful tools in the radar polarimetry. There are several model-based decomposition techniques. However, since the number of independent observables in POLSAR images is limited, these techniques require several assumptions to obtain unique solution. The authors have proposed an alternative technique with POL-InSAR dataset. By using the POL-InSAR dataset, we can increase the number of observables. However, selection of volume scattering component was still a problem. Recently, Dr. Arii et. al., proposed a generalized volume scattering model, and applied it to the POLSAR dataset with the adaptive non-negative eigenvalue decomposition technique. In this report, we apply the model to the ESPRIT-based POL-InSAR decomposition technique and verify the estimation performance experimentally. [C2151]

### "Analysis of observed information in multistatic radar network"

In this study, observed information matrix has been calculated in a multistatic radar network where an Unscented Kalman filter, that utilized bistatic range and range rate measurements, was employed as a 3D tracker. Variation of the observed information with respect to target's location in the network has been analyzed through simulations and the results are presented in contrast to tracking error. [C2152]

### "Multi-Channel RADAR Depth Sounder (MCRDS) signal processing: A distributed computing approach"

In response to problems surrounding measuring ice sheet thickness in high attenuation areas of Greenland and the Antarctic, the Center for the Remote Sensing of Ice Sheets (CReSIS) created a Multi-Channel RADAR Depth Sounder (MCRDS). The MCRDS system was used to measure ice thicknesses of up to five kilometers in depth. This system produced large datasets, which required greater processing capabilities in the field. The purpose of this project was to test processing performance on a 32-core cluster through distributed computing resources. Testing involved a six-node cluster with an attached storage array and use of the CReSIS Synthetic Aperture RADAR Processor (CSARP) through the MATLAB Distributed Server Job Manager. Performance testing was derived from average run times collected once CSARP jobs completed. The run times were then compared using an ANOVA test with a five percent significance level. [C2153]

### "Processing for airborne interferometric SAR data with high squint"

A novel approach for the highly squinted airborne InSAR data processing is presented. Using the IMU data to resolve the PRF ambiguity and moving azimuth windows according to the Doppler centroid varying in the different range, as well as combining the auto-registration imaging algorithm, such approach not only can compensate the squint effect and motion error directly at the imaging processing stage, but also can improve the coherence and restrain the interferometric phase error of the image-pair. The simulative and practical results indicate that the proposed approach is very suitable for the processing of the data with a high squint for a dual-antenna airborne InSAR system with its efficiency in improving the image quality and enhancing the interferogram and coherence. [C2154]

### "A dual-frequency SAR mosaic of the Amazon"

The development and availability of accurate landcover information is critical to the ecological science questions [Cerri, et al., 1995; Hall, et al., 1995], such as defining the rate and extent of deforestation within the Amazon. This need can only be met by techniques that are sensitive to phenomena at the scale of the landscape patch and can be efficiently applied in a consistent fashion over very large regions. For example, estimation of Amazonia's carbon budget will require a large-scale mosaic of the location and spatial extent of landcover types, forest regrowth biomass, and selective logging. Vegetation type and surface condition exert control over carbon and trace gas fluxes. Estimates of the biotic carbon pool are also important since carbon accumulation rates vary not only with vegetation types but with successional stage and management practices as well. Both the extent and carbon accumulation rates of regenerating tropical forest are poorly known. If the ages of forest disturbance can be established (i.e., from the Landsat time series), then the SAR-derived estimates of aboveground biomass can be used to estimate annual sequestering of carbon. Though these data were acquired at higher resolution, it is possible to use this data to map landcover, biomass and selective logging at a spatial scale of 100m for the Amazon basin. [C2155]

### "Comparison of crop classification capabilities of spaceborne multi-parameter SAR data"

With the arisen spaceborne multi-parameter Synthetic Aperture Radar (SAR) systems, such as Envisat ASAR,

TerraSAR-X, ALOS PALSAR, and RADARSAT-2, the interest of crop mapping has been increasing. The present study compares the capabilities of the multi-parameter SAR in discriminating the main crop types by object-based classification in Haian county of Jiangsu province, South China. Two kinds of information, SAR intensity based and SAR statistical properties based are used for Maximum Likelihood Classification (MLC) and Minimum Distance Classification (MDC) respectively. The results show that, the L-band SAR can uniquely identify mulberry from dry-land crops, such as maize and vegetable and C-band SAR has some advantages in mapping rice. Specifically, the polarimetric RADARSAT-2 data can identify the rice with accuracy about 75% ~ 80% which is similar as the result from X-band TerraSAR-X Spotlight data but higher than that from C-band dual-polarization Envisat ASAR data. Nevertheless, both of X- and C-band can hardly separate the mulberry from the other dry-land crops. [C2156]

#### "A fully polarimetric borehole radar based numerical modelling: Fully polarimetric response to synthetic fractures and "fluid substitution""

A fully polarimetric borehole radar system with four combinations of dipole and cylindrical slot antennas was developed to acquire fully polarimetric data sets in drilled boreholes. To better understand the fully polarimetric response to subsurface fractures with different roughness, in this study, synthetic fractures with different roughness are generated on a computer via fractal theory based simulation techniques. Quantitative assessment for the roughness of synthetic fractures is possible by use of three main parameters: the fractal dimension, the rms roughness at a reference length, and a length scale describing the degree of mismatch between the two fracture surfaces, allowing future detailed study of mechanical and transport properties of fractures and fully polarimetric radar response on them. Next, a 3D sub-grid FDTD numerical simulation is used to synthesize fully polarimetric data sets with synthetic fractures as primary reflectors. Based on the synthetic data sets, it is possible to evaluate the applicability of different radar polarimetry analysis approaches to physical characterization of subsurface fractures in future. [C2157]

#### "Morphological-based source extraction method for HFSW radar ship detection"

In this contribution, High Frequency Surface Wave (HFSW) radars are considered for target detection. These systems, commonly used for oceanographic purposes, are of interest in maritime surveillance because of their long range detection capabilities. Unfortunately, the received signals are strongly polluted by different noises. To improve target detection a method based on Morphological Component Analysis (MCA) is investigated. Shortly, this paper introduces HFSW radars and gives an overview of the MCA. Then, numerical results from simulated data illustrate the MCA-based target detection method. Comparisons with classical detection methods based on CFAR techniques (GOCA-CFAR and GOOS-CFAR) are proposed through Receiver Operating Characteristics (ROC) curves. [C2158]

#### "Polinsar forestry applications improved by modeling height-dependent temporal decorrelation"

We model the temporal decorrelation in volumetric media imaged by a repeat-pass SAR interferometer by using a temporal correlation function that varies with depth. An expression of this function is proposed and based on the Brownian motion of the canopy and soil elements. The spatial and temporal correlation terms are merged in a single coherence model that includes a large class of decorrelation effects, such as those induced by changes in the structure of the medium. We discuss the effects of the temporal correlation function and its implications on the parameters estimation using the POLINSAR random volume over ground model. [C2159]

#### "Contrast in speckled imagery with stochastic distances"

Synthetic aperture radar (SAR), ultrasound-B, laser, and sonar imagery are contaminated with speckle noise. The statistical modelling of such contamination is well described by the multiplicative model, which yields the G0 distribution. In particular, reliable image contrast measures are sought in order to discriminate targets. To that end, we present statistical methods based on stochastic divergences and on the Kolmogorov-Smirnov distance for G0 data. Their performance is quantified according to their test sizes and powers. A robustness analysis is also presented for several degrees of contamination. We show that the proposed tests based on triangular and arithmetic-geometric measures outperform the Kolmogorov-Smirnov distance. [C2160]

#### "Exploiting spatial domain and wavelet domain cumulants for fusion of SAR and optical images"

The aim of this paper is to introduce a novel statistical model-based image fusion method for Synthetic Aperture Radar (SAR) and optical images. The current fusion algorithms are effective only in specific areas of the scene. Hence, the fused image may not contain enough information for subsequent processing like classification and feature extraction. Our proposed method aims to keep the maximum contextual and spatial information from the source data by exploiting the relationship between spatial domain cumulants and wavelet domain cumulants. Our

contributions are in integrating the relationship between spatial and wavelet domain cumulants of source images into an image fusion process as well as in employing these wavelet cumulants for optimization of weights in a Cauchy convolution based image fusion scheme. The superior performance of the proposed algorithm is demonstrated in comparison to existing fusion algorithms using real SAR and optical images. [C2161]

#### "Comparison of alternative image representations in the context of SAR change detection"

This article compares four different alternative image representations in the context of a structure-based change detection. The framework is taken from the already published Curvelet-based change detection approach. Only the transform step is modified by inserting three additional transforms: the Laplacian pyramid, the Wavelet and the Surfacelet transform. The results of the change detection are compared to the single pixel difference image in order to find the representation that best illustrates the underlying structures. The Curvelet transform again turns out to be very powerful in describing man-made objects and landscapes. [C2162]

#### "Microphysical retrieval from dual frequency precipitation radar board GPM"

Global Precipitation Measurement (GPM) is poised to be the next generation observations from space after Tropical Rainfall Measuring Mission (TRMM). The GPM mission concept is centered on the deployment of a core observatory satellite with an active dual-frequency radar (DPR), operating at Ku and Ka bands. The DPR is expected to improve our knowledge of precipitation processes relative to single-frequency radar on microphysics retrievals. Hydrometeor classification method is a key part of any microphysical retrieval algorithm. This paper is focused on the hydrometeor classification method which might be applied to GPM DPR and maps the results to Zdr- DFR plane to cross verify with the pixel based hydrometer identification method. In addition a comparison is made between the DSD retrieval algorithm proposed by the author and other existing algorithm. [C2163]

#### "Estimation of sea ice concentration in the Sea of Okhotsk using PALSAR polarimetric data"

The objective of this research is mainly in estimating sea ice concentration from Phased-Array L-band SAR (PALSAR) polarimetric data. This paper shows the results of estimating sea ice concentration from PALSAR data acquired from 2008 to 2010. The AMSR-E sea ice concentration data are also used to verify the result of sea ice concentration derived from PALSAR data. The difference in two sea ice concentrations was found especially in AMSR-E low concentration area. The high resolution backscattering and scattering entropy images give us an idea that there is some difficulty in AMSR-E to detect thin sea ice in the Sea of Okhotsk. [C2164]

#### "Application of aspect angle normalized polsar images for urban building detection"

Variation in the building aspect angle, defined as the angle between the flight direction of a satellite (azimuth direction) and the vertical wall of a building, is a significant cause of accuracy reduction in building detection and terrain classification from Polarimetric Synthetic Aperture POLSAR (POLSAR) images. However, the existing building detection methods usually are effective for the buildings with a limited aspect angle range. Considering the relationship between the aspect angle of the building and the orientation angle shift, an aspect angle normalization method is introduced to remove the disadvantageous influences caused by the aspect angle. From a comparison between the double-bounce building detection results of the original and aspect angle normalized RadarSat-2 data acquired in Beijing, China, buildings with any aspect angle can be detected effectively from aspect angle normalized data. [C2165]

#### "Progressive change detection in time series of SAR images"

The aim of this paper is to present a general framework for change detection in a time series of radar images, for an operational purpose and in the context of environmental monitoring. The change detection procedure is turned into the framework of detecting a random signal into the noise; the detection of this signal leads to the detection of a change in the time series. This framework is based on a non-parametric detection method that assume a sparse representation of the data. When using radar images, the speckle noise invalidates the hypothesis of sparsity. Then a pre-processing technique is required to provide an appropriate sparse representation of data, whatever the initial noise characteristics. The paper focuses on the change indicator, based on recursive median filtering, yielding a piecewise regular representation of a scene obtained by spreading the statistically most reliable pixel values over the image. The recursive median filtering leads to simple change indicators that are more efficient than the Kullback-Leibler change indicator when using small analyzing sliding window. Furthermore, it induces an simple extension to perform progressive change characterization through a multi-temporal filtering approach. Results are shown with a two-date change detection from RADARSAT images and from a time series of ERS and ENVISAT images. [C2166]

### **"Investigations on the full polarimetric PALSAR data to discriminate macrophytes species in the Amazon floodplain wetland"**

The purpose of this work is to evaluate the capacity of full polarimetric L band data to discriminate macrophyte species in Amazon wetland. Fieldwork was carried out almost simultaneously to the acquisition of the full polarimetric PALSAR data. Coherent and incoherent attributes were extracted from the image, and macrophyte morphological variables were measured on the ground. The image attributes and the macrophyte variables were compared in order to evaluate their application for discriminating macrophytes species. The findings suggest that polarimetric information could be adopted to discriminate plant species based on morphology, and that estimation of plant biomass and productivity could be improved by using the polarimetric information. [C2167]

### **"On the feasibility of tsunami detection using satellite-based sea surface roughness measurements"**

Observations of tsunamis away from shore are critical for improving early warning systems and understanding of tsunami generation and propagation. Using analysis already applied to the 2004 Sumatra-Andaman tsunami, we positively identify the 2010 Chilean tsunami in satellite altimeter measurements of sea surface roughness. Use of radar backscattering strength measurements from satellite altimeters would be impractical for tsunami detection and early warning purposes due to the limited temporal and spatial resolution. On the other hand, it is likely that tsunami-induced changes in sea surface roughness are observable with other types of space- and airborne sensors that sense sea surface roughness over much wider swaths. With this in mind, we explore the feasibility of using existing instruments and technology as the basis for a tsunami detection and early warning system. [C2168]

### **"Log-polar and polar image for recognition targets"**

We describe in this paper, data processing algorithms applied on radar image in order to extract feature descriptors and then to perform recognition task. Several kinds of descriptors can be used to acquire information about target characteristics from radar images such as ISAR (Inverse Synthetic Aperture Radar) images. This paper presents two types of vector descriptors extracted via two kinds of transformed images so-called polar and log-polar images obtained respectively from the polar and log-polar mapping. In order to guarantee the invariance of some geometrical transformation, additional processing are proposed. In this paper, we present the polar and log-polar transformations and then the classification scheme adapted on correspondent polar and log-polar templates. In the classification step, log-polar and polar mapping results are compared using adapted classification scheme. [C2169]

### **"Random Forests for building detection in polarimetric SAR data"**

Building detection from Synthetic Aperture Radar (SAR) images states a particular important as well as difficult problem. The high-resolution which is necessary to distinguish single buildings as well as the geometric and dielectric properties of dense urban areas cause most assumptions to fail, that are commonly made in SAR data analysis. This paper proposes the usage of Random Forests for building detection from high-resolution Polarimetric Synthetic Aperture Radar (PolSAR) imagery. Random Forests can handle high-dimensional input and therefore a large set of different features, they are known to lead to good classification performance in terms of robustness and accuracy, and are nevertheless seldomly applied to analysis of PolSAR images in general and building detection in particular. This paper presents first results of Random Forests when applied to a building detection task and shows their successful applicability. [C2170]

### **"Deployment of the ASCAT calibration transponders"**

The METOP-A Advanced Scatterometer Radar has stringent radiometric requirements requiring regular, accurate, calibration. The specified stability of 0.2 dB or better is too demanding for targets such as rain forest or simple corner reflectors, so three highly stable return signal sources have been precisely sited to give accurate measures of the beam patterns over the satellite repeat cycle. The Scatterometer is required to provide full coverage over all the oceans, so the three calibration transponders have been installed in Turkey, as the Black Sea and Eastern Mediterranean are not used in the ASCAT programme. [C2171]

### **"Effect of the polarization on SISAR imaging and feature recognition in forward scattering radar"**

In this paper, the effect of the polarization and the multipath on shadow inverse synthetic aperture radar (SISAR) imaging is analyzed respectively in forward scattering radar (FSR). The multi-polarization and the multipath imaging results of targets, based on SISAR, are discussed respectively. In addition, the target forward scattering (FS) RCS under multi-polarization conditions are also obtained using CST simulation software to research the effect of multi-polarization on moving target feature recognition in FSR. [C2172]

### "Automatic image classification of landslides improved with terrain roughness indices in various kernel sizes"

Using spectral-only information for landslides classification is usually confusing with houses, roads, and other bare lands because these ground features have similar spectral patterns on images. The terrain roughness can be measured by significant wavelengths; some studies have linked the relationships between terrain roughness and the landslide by using numerical analyses of topography data. In this study, airborne LiDAR data of 1m grid are used to explore the possibility of improvement of landslide classification, the LiDAR-derived data include DEM slope and terrain roughness indices including diversity, dominance and relative richness with different grid size data are used to improvement classification accuracy. The improvement of accuracy when including DEM slope is 22% in producer's accuracy and 27% in user's accuracy. The accuracy of diversity, dominance and relative richness indices all are improved when kernel sizes enlarge in Maximum Likelihood and Mahalanobis Distance algorithms. [C2173]

### "Orthogonal polarimetric SAR processor based on signal and interference subspace models"

We develop a new SAR processor based on several orthogonal projections. We take into account the scattering properties of the target and the interferences by using subspace models. To detect the target without detecting the interferences, we process images from the orthogonal projection of the received signal into the target subspace and from the orthogonal projection of the received signal into a part of the interference subspace. We can combine these two images to firstly detect the target and to secondly reduce interference. This new SAR processor is applied to realistic simulated data for FoPen (Foliage Penetration) application. [C2174]

### "Electromagnetic characteristics of simple targets embedded in chiral multilayer structures"

The scattering properties of a chiral stratified multilayer structure having an printed planar electric dipole are addressed in this paper. In order to obtain the scattered fields the method of moments in spectral domain is applied. The dipole scattering is characterized by the radar cross section (RCS), the polarimetric response, the  $\alpha$ -angle from Cloude-Pottier's target decomposition theorem and the directivity function. The results point out that all parameters are sensible to variations on the chiral layer admittance. The chiral layer impinges a rotation on the polarization plane of linearly incident wave for all frequency analyzed. [C2175]

### "Recent advances in the development of the open source Toolbox for Polarimetric and Interferometric Polarimetric SAR Data Processing: The PolSARpro v4.1.5 Software"

The objective of this paper is to make a review of the current status of the PolSARpro v4.0 Software (Polarimetric SAR Data Processing and Educational Toolbox), developed under contract to ESA. The objective of this current project is to provide Educational Software that offers a tool for self-education in the field of Polarimetric SAR data analysis at University level and a comprehensive suite of functions for the scientific exploitation of fully and partially polarimetric multi-data sets and the development of applications for such data. The PolSARpro v4.0 Software establishes a foundation for the exploitation of Polarimetric techniques for scientific developments and stimulates research and applications developments using PolSAR and PolInSAR data. [C2176]

### "Characterization of ENVISAT multipolarization SAR data with bidimensional statistics"

This paper is about evaluating the interest between studying directly dual images statistical indices and the use of statistical indices build from two SAR multipolarization images. We show an original way of using this kind of images by using two dimensionned statistical calculation in a Markov random field classification. We present results of our segmentation on urban, forest and mangrove areas. Those results are computed from ENVISAT ASAR data in HH and VV polarizations in a tropical context, near Libreville. [C2177]

### "Semantic segmentation of Polarimetric SAR imagery using Conditional Random Fields"

The paper proposes a fast and accurate semantic segmentation approach for a large Polarimetric SAR (PolSAR) image using Conditional Random Fields (CRFs). It efficiently incorporates the polarimetric signatures, texture and intensity features into a unite CRFs model, and employs a fast max-margin training method for parameters learning. Experiments on RadarSat-2 PolSAR data in Flevoland test site demonstrate that our approach achieves precise segmentation results with a few well-selected training samples. [C2178]

### "Forest structure from longer wavelength SRS"

In this paper we address three topics related to SAR Tomography of forest scenarios at P-Band. In first place we discuss the role of pulse bandwidth, which is shown to play a critical role as for the capability of the Tomographic system to separate ground and canopy contributions. Accordingly, vertical resolution depends not only on baseline aperture, but also on pulse bandwidth. Another factor to be accounted for is phase calibration, as the quality of the vertical focusing carried out by SAR Tomography is strictly related to the condition that phase contributions due to platform motion or atmospheric propagation are properly compensated for. Finally, multiple scattering phenomena are likely to occur at longer wavelengths, resulting in Tomographic techniques not being suffice for the aim of discriminating ground and volume scattering. The three points above are here discussed in light of the results achieved in the framework of the ESA campaign BioSAR 2008. The analysis has been carried out by exploiting the Algebraic Synthesis technique, which provides a theoretical framework to decompose the SAR signal into ground-only and volume-only contributions. Ground-only contributions provide an easy and viable way to phase calibrate the data stack. Volume-only contributions, if correctly identified, allow a direct Tomographic imaging of the vegetation layer. The impact of pulse bandwidth is tackled by assuming a Common Band Filtering approach, which results in a vertical resolution improvement by a factor 2. [C2179]

### "Improved hurricane active/passive simulated wind vector retrievals"

Microwave scatterometers are the standard for satellite ocean vector winds (OVW) measurements, and they provide the major source of global ocean surface winds observations for scientific and operational applications. A major challenge for Ku-band scatterometry missions is to provide reliable retrievals in the presence of precipitation, particularly in extreme ocean wind events that are usually associated with intense rain. This paper explores the advantages of combining dual frequency (C- and Ku-band) scatterometer measurements and passive microwave observations to improve high wind speed retrievals. For this study, a conceptual design proposed by the Jet Propulsion Laboratory for a Dual Frequency Scatterometer (DFS) to fly onboard the future Japan Aerospace Exploration Agency (JAXA) GCOM-W2 mission with the Advanced Microwave Scanning Radiometer (AMSR) was adopted. A computer simulation that combines the DFS and AMSR measurements was used to develop an artificial neural network OVW retrieval algorithm. The Weather Research and Forecasting (WRF) numerical weather model of Hurricane Katrina (2005) was used as the nature run (surface truth), and simulated OVW retrievals demonstrate that this new technique offers a robust option to extend the useful wind speed measurements range beyond the current operating scatterometers for future satellite missions. [C2180]

### "Interferometric processing algorithms of TanDEM-X data"

The purpose of this paper is to provide an algorithmic overview of the interferometric processing embedded in the Integrated TanDEM-X Processor (ITP), settled to the generation of the raw digital elevation model (DEM). The main processing blocks are described, with a focus on the spectral matching of the azimuth spectra, the high-precision coregistration, the dual-baseline phase unwrapping and the geocoding of the products. The robustness of the algorithms is demonstrated through a dual-pass TerraSAR-X scenario. [C2181]

### "Extrapolation of LiDAR for forest structure estimation using SAR, InSAR, and optical data"

One of the most fundamental new technical challenges of a DESDynI spaceborne mission is the fusion of the several sensor modalities-LiDAR, SAR, InSAR, and Optical-in order to accurately estimate desired 3D Vegetation structures and biomass parameters at their point of intersection and to extrapolate them over continuous areas. The objective of this paper is to use both our simulation models and measured dataset to develop and validate fusion and extrapolation methods while simulating DESDynI-type missions. We use existing datasets to develop and validate our fusion and extrapolation approach, which involves using our four sensor simulators, including our fractal-based tree geometry generator, in tandem with our in-house parameter estimation software which performs fusion and retrieval functions. We then use existing field and radarlidar-VNIR data for the Boreas southern study area to validate our simulators in this region and construct a large set of boreal trees for use in our fusion and extrapolation processes. [C2182]

### "Merging multi-track PSI result for land subsidence mapping over very extended area"

The Permanent Scatterer Interferometry (PSI) technique is usually applied for surface deformation mapping at local area from 1 up to a maximum of 100 km<sup>2</sup>. Although the ability to provide deformation map of regional area exceeding 10,000 km<sup>2</sup>, the processed area of interest is mostly limited to SAR acquisitions in a single satellite track and frame. In this work we present the study of merging multi-track PSI results for land subsidence monitoring over very extended area. Apart from the description of the PSI method used for long strip SAR data processing, datum connection of multiple adjacent tracks, including conversion of a common coordinate system and the connection of the PSI derived velocity maps are demonstrated. The application of the proposed method to monitor large coverage land subsidence in the central North China Plain (NCP) is described. The presented

results obtained by merging 3 adjacent tracks of ENVISAT ASAR data acquired between Jan, 2007 and Dec, 2009, with a coverage of 2004260km<sup>2</sup> are very significant and indicate the effectiveness and potential of this technique for land subsidence mapping over very extended area. [C2183]

### "Unsupervised change detection with very high-resolution SAR images by multiscale analysis and Markov random fields"

Change detection represents an important tool in environmental monitoring and disaster management. Here, a novel unsupervised change-detection method is proposed for very high-resolution SAR images, by integrating wavelet multiscale feature extraction, Markov random fields for contextual modeling, and generalized Gaussian models. Experiments with COSMO-SkyMed data remark the effectiveness of the method as compared with previous methods. [C2184]

### "Composite scattering from electric-large target over randomly rough surface in numerical approaches"

Numerical study of radar echoes from the targets in environmental clutters has been of great interest in many applications. In this paper, the bidirectional analytic ray tracing (BART) method for composite scattering from three-dimensional (3D) electrically large complex target above a randomly rough surface is reported. Analytic tracing of polygon ray tubes in bidirectional tracing is developed to precisely calculate the illumination and shadowing of facets, which exempt large patches of the target from any finer meshing. It significantly reduces the complexity relevant to the target electric-size. Numerical examples of angularly composite scattering from a three-dimensional electrically large, e.g., a ship-like target over a randomly rough surface are presented and discussed. [C2185]

### "Towards an operational daily soil moisture index derived from combination of MODIS, ASAR and AMSR-E data"

This work aims at deriving a methodology for calculation of a soil moisture index based on the apparent thermal inertia (ATI) approach. For the processing, MODIS images have been exploited which have a higher resolution (1 km) if compared with METEOSAT images and are suitable for the ATI calculation. Furthermore, the approach considers the soil moisture estimates derived from SAR sensors and use them to calibrate the information coming from the optical data. The main advantage of this approach is to transform a soil moisture index derived from optical images in soil moisture values by using a comparison between spatial distributed data. In order to make the calibration more robust and consider the variability from different areas, three main test sites have been chosen located in Italian regions with different meteorological and landscape characteristics. In case of anomalous values due to the not appropriate acquisition time, AMSR-E soil moisture data are used as prior information in order to improve the estimates. [C2186]

### "Deriving soil moisture with the combined L-band radar and radiometer measurements"

In this study, we develop a combined active/passive technique to estimate surface soil moisture with the focus on the short vegetated surfaces. We first simulated a database for both active and passive signals under SMAP's sensor configurations using the radiative transfer model with a wide range of conditions for surface soil moisture, roughness and vegetation properties that we considered as the random orientated disks and cylinders. Using this database, we developed 1) the techniques to estimate surface backscattering and emission components and 2) the technique to estimate soil moisture with the estimated surface backscattering and emission components. We will demonstrate these techniques with the model simulated data and its validation with the airborne PALS image data from the soil moisture SGP'99 and SMEX'02 experiments. [C2187]

### "Effects of forest disturbances on forest structural parameters retrieval from lidar waveform data"

The effect of forest disturbance on the lidar waveform and the forest biomass estimation was demonstrated by model simulation. The results show that the correlation between stand biomass and the lidar waveform indices changes when the stand spatial structure changes due to disturbances rather than the natural succession. This has to be considered in developing algorithms for regional or global mapping of biomass from lidar waveform data. [C2188]

### "Development of a signal processing subsystem for a spaceborne rotating, fan-beam scatterometer"

This paper introduces an on-board signal processing subsystem of a spaceborne rotating fan-beam

scatterometer in China. The subsystem processes returned signal after downconversion to intermediate frequency. To reduce the data stream downlinked from the satellite, the final data bins are summed into 34 energy slices, each with a range resolution of 10 km. Then a simulation process is adopted to analyze the Doppler effects due to the motion of the spacecraft, and to generate the Doppler compensation table and the bin summation table. This method is also used to analyze the measurement variance  $K_{pc}$  of each detected slice. Finally, the coefficients of the expression of  $K_{pc}$  are presented. [C2189]

#### "Investigation of cirrus clouds using the calipso lidar data"

Cirrus clouds normally exist in the upper troposphere and sometimes extend into the stratosphere. Unlike low altitude clouds that have a cooling effect on solar radiation through scattering, cirrus clouds scatter only a small amount of solar radiation and prevent a large quantity of long-wave radiation from leaving the earth-atmosphere system. Cirrus clouds are globally distributed and are composed almost exclusively of non-spherical ice crystals. Tropopause cirrus tends to occur over regions of intense convective activity like equatorial Africa and South America, which are sites for vigorous continental convection, and the western Pacific, which is a site of significant oceanic convection. Few instruments can deduce the global presence of cirrus clouds. The Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observations (CALIPSO) satellite mission provides comprehensive observations of cloud vertical structure on a near-global scale. [C2190]

#### "Monitoring environmental conditions in Muuga harbor using Envisat MERIS and ASAR data"

Environmental conditions were monitored using in situ measured inherent optical properties and water sampling together with remote sensing imagery (MERIS and ASAR) in Muuga Bay, Baltic Sea. Simultaneous monitoring using different methodologies gave detailed overview of suspended matter (SPM) load into the water column during the dredging operations. MERIS FRS data enabled to receive the distribution of SPM on water surface. The measurements of inherent optical properties revealed the particle concentration on vertical scale. Backscattering from the ASAR data was in correlation with oil products determined from water samples when ballast water discharge was detected during field sampling. [C2191]

#### "Field test of KOMPSAT-5 Calibration Equipment"

Korea Aerospace Research Institute (KARI) is developing the KOMPSAT-5 (K-5, the fifth of KOREA MultiPurpose SATellite) system of which primary payload is X-band Synthetic Aperture Radar (SAR). K-5 CALVAL (Calibration & Validation) activities must be important tasks for successful operation. The field test of K-5 Calibration Equipments can support a direction of CALVAL activities during not only IOT (In-Orbit Test) phase but also normal operation phase. [C2192]

#### "High resolution D-INSAR measurement for land subsidence"

In this paper, a study area of subsidence in the city of Taiyuan has been investigated using TerraSAR-X high resolution data and D-INSAR technique. In order to determine the accurate location and shape of each subsidence center, a time series of differential interferograms has been first generated and applied to preliminary location determination and rough subsidence rate estimation for each subsidence center, then the time series analysis of persistent scatterers including single point objects and highly coherent surface pieces for each subsidence center has been used for accurate positioning of subsidence center and precise subsidence rate estimation. [C2193]

#### "Preliminary results of a low-frequency 3D-sar approach for glacier volume mapping"

First experimental results with a low-frequency, ultra wideband (UWB) radar for estimating the height of glacier beds are illustrated. We use a 3-dimensional Time-Domain Back-Projection (TDBP) algorithm which incorporates the influence of the refractivity of ice to reconstruct the glacier bed of the Aletsch Glacier in the Swiss Alps using several CARABAS data sets. As the results indicate, the proposed method underlines the ability of low-frequency Synthetic Aperture Radar (SAR) to penetrate into glacier ice and thus, to map glacier volumes on a large scale even with only few, suboptimal data acquisitions. [C2194]

#### "Radar-based human detection and characterization with non-linear phase modeling"

Many current radar-based human detection systems employ some type of Doppler or Fourier-based processing, followed by spectrogram and gait analysis to classify detected targets. However, in Fourier-based techniques the maximum output signal-to-noise ratio (SNR) is given by targets whose target phase is linear. On the contrary, the phase variation of the human target response is nonlinear. This difference causes a significant loss in SNR, and therefore detection performance. In this paper, two novel, nonlinear phase detector designs based on human

modeling are presented. In the first method, only the human torso reflections are modeled and unknown model parameters computed using Maximum Likelihood Estimation. In the second method, the entire human body is modeled as a different parametric model. The expected radar response for each combination of parameter values is stored in a database. An optimal sparse approximation to the data is found using Orthogonal Matching Pursuit. The performance of the proposed techniques and optimal space-time adaptive processing algorithm is compared and target characterization applications examined. [C2195]

#### "Monitoring of thawing process using envisat asar global mode data"

Due to the high temporal sampling rate of ASAR Global Monitoring mode, it has an application potential for analyzing seasonal changes in permafrost environment. The objective of the study is to develop a robust method for monitoring freeze/thaw cycles beyond threshold approaches. In order to use ASAR GM time-series for analyzing freeze/thaw states, a least square fitting of piecewise step function is introduced in this paper. An experiment result for Siberian permafrost area near Yakutsk illustrates that it can be a promising approach in monitoring permafrost ecosystems. [C2196]

#### "KOMPSAT-5 spotlight SAR processor using FSA with calculation of effective velocity"

In KOMPSAT-5 program, Korea Aerospace Research Institute has made SAR imaging chain analysis tool to evaluate imaging system of KOMPSAT-5. The tool consists of a simulator and a processor. The simulator simulates observation of a scene by the operational mode of KOMPSAT-5 and generates SAR raw data. The processor generates an image of the scene. This paper is about the second part of processing the simulated raw data that is acquired by the step steering sliding spotlight mode of KOMPSAT-5. For this observation mode, dechirp on receive is operated in receiving the echoes. So, extended frequency scaling algorithm is used to process the raw data in order to directly handle the dechirped data. This paper mainly contributes for the accuracy of effective velocity. The effective velocity criterions for range and azimuth processing allows that the processor uses only one scene center effective velocity in range processing and several ones in azimuth processing. In this paper, a method to increase the accuracy of calculation of effective velocity is also proposed. Simulation result shows that the proposed method is valid. [C2197]

#### "Fusion: A fully ultraportable system for imaging objects in nature"

To improve satellite-derived estimates of terrestrial plant production and exchange of CO<sub>2</sub>, water, and energy with the atmosphere, scientists need to consider ecosystem composition, structure, function, and health. This can be accomplished through the fusion of Light Detection And Ranging (LiDAR) data, which can provide 3D information about the vertical and horizontal distribution of vegetation and hyperspectral remote sensing, which can inform us about variations in biophysical variables (e.g., photosynthetic pigments) and responses to environmental stressors (e.g., heat, moisture loss). Satellite observations from upcoming Decadal Survey missions will provide NASA with the unique opportunity to fuse LiDAR data from ICESat-II, DESDynI, and LIST with hyperspectral and thermal imagery from HypSIRI and GEO-CAPE. This synergy will augment and enhance the individual science objectives of decadal survey missions, and will allow scientists the opportunity to develop 3D models of plant canopies that better describe global cycling of carbon, water and energy. Multiple NASA's Earth Science Focus Areas are served by this science, including carbon cycle and ecosystems; water and energy cycle; and climate variability and change (i.e., ecosystem responses and feedbacks to climate change). One of the major obstacles to the development of data fusion algorithms is the availability of accurately co-registered data of similar grain size. This is often the case when instruments are flown on different platforms and at different times during a field campaign. We believe that "instrument fusion" is a prerequisite to "data fusion", and we have developed a system that integrates a full-waveform LiDAR, narrow band hyperspectral imager, and broad band thermal imager in a single, compact and portable instrument package that could be readily deployed on a number of observation platforms. FUSION will provide accurate co aligned datasets that are needed for: (i) calibration and validation of satellite-derived land products; (ii) development of data fusion algorithms; and (iii) combine observations from multiple sensors to characterize ecosystem composition, structure, function, and health. [C2198]

#### "Overview of KOMPSAT-5 program, mission, and system"

Korea Aerospace Research Institute (KARI) are developing the KOMPSAT-5 system of which primary payload is X band Synthetic Aperture Radar (SAR). The program overview, mission and system characteristics of KOMPSAT-5 are described in this paper. [C2199]

#### "UWB electromagnetic borehole logging tool"

Based on a theoretical model of the geosteering borehole logging tool, which operates the broadband pulse, we

demonstrate the possibility of detecting an interface between oil- and water-saturated layers in the oil-gas formation. [C2200]

### "Temporal analysis of the magma supply system beneath the Okmok caldera by Interferometric Synthetic Aperture Radar and statistical seismology"

The temporal characteristics of the magma supply system beneath the Okmok caldera is examined using Interferometric Synthetic Aperture Radar (InSAR) and statistical seismology. Surface deformation produced by a shallow magma chamber is studied through time series analysis of InSAR imagery acquired between 1995 and 2008 by the ERS-1/2 satellites. A spherical source model (Mogi Source) is utilized to simulate the deformation pattern produced by the shallow magma chamber's fluctuating geometry. Statistical seismology provides an independent estimate of the magma chamber's depth to reduce the non-uniqueness of the Mogi source model solutions. Seismic results show that a shallow magma chamber is located approximately 4.0 km below the caldera floor. InSAR imagery indicates the chamber has expanded continuously between 1997 and 2008. Modeling results suggest that magma replenishment has occurred at an average rate of approximately  $7.0 \pm 10\text{-}3\text{km}^3/\text{year}$  and that the volume within the chamber returned to its pre-1997 eruption state by June 2008. [C2201]

### "Directional-adaptive despeckling for high-resolution SAR"

In this study, an iterative maximum a posteriori (MAP) approach using a Bayesian model of Markov random field (MRF) was proposed for despeckling images that contains speckle. Image process is assumed to combine the random fields associated with the observed intensity process and the image texture process respectively. The objective measure for determining the optimal restoration of this "double compound stochastic" image process is based on Bayes' theorem, and the MAP estimation employs the Point-Jacobian iteration to obtain the optimal solution. In the proposed algorithm, MRF is used to quantify the spatial interaction probabilistically, that is, to provide a type of prior information on the image texture and the neighbor window of any size is defined for contextual information on a local region. However, the window of a certain size would result in using wrong information for the estimation from adjacent regions with different characteristics at the pixels close to or on boundary. To overcome this problem, the new method is designed to use less information from the neighbors located in the direction to an adjacent different region and more information from the neighbors located in the inner region of same characteristics. It can reduce the possibility to involve the pixel values of adjacent region with different characteristics. [C2202]

### "Target detection above rough surfaces in microwave imaging using Compressive Sampling"

A subspace extraction approach for detection of targets embedded in the clutter is presented in this work. Subspace extraction approach that makes use of both Compressive Sampling and Principal Component Analysis (PCA) is presented in this paper. Inverse Synthetic Aperture Radar (ISAR) Imaging measurement data is used to validate the proposed approach. Experimental results of targets above rough surface with intermediate roughness are presented. Results showed the dimensionality of an intermediate scale rough surface is generally larger than the dimensionality of the finite size targets. Results showed that by compressing the dimensionality through compressive sampling and extracting the principal components, significant improvement in target subspace extraction can be achieved. [C2203]

### "Research on interferometric deformation detection for geosynchronous SAR"

The nadir track of geosynchronous satellite can be "figure-8", circular or ellipse track which could be produced with appropriate orbit parameters. In this paper, the characteristics of the interferometric deformation detection for geosynchronous SAR with circular aperture are analyzed. The connection between the interferometric phase and the deformation of repeat pass geosynchronous SAR is derived, and its potential to get three-dimensional 3D deformation measurement is interpreted. [C2204]

### "MVM based SAR image processing for ship pose estimation"

As an essential approach of SAR image interpretation, a good pose estimation calls for two conditions: an accurate extraction of the scattering centers and a thorough exploration of the structural information among them. The article focuses on these two topics successively. Firstly, the power spectrum estimation methods are recommended to improve the scattering center resolution and the Minimum Variance Method (MVM) is chosen for its sidelobe suppressing ability and signal model independence. With the segmented MVM image, the axis extraction problem is then solved by a new strategy, namely the Angle Entropy of Radon transform (AER) strategy. Data from computational electromagnetics are used for experiments. It is shown that the MVM image shows better morphologic feature than the Fourier ones (both original and Hanning-windowed), and the AER strategy achieves more accurate and robust estimation compared with the edge-based Hough transform (HT)

technique. [C2205]

### "Generic object recognition in high resolution SAR images"

This paper presents a non-parametric modeling scheme for high resolution SAR data, based on Short Time Fourier Transform which is able to integrate the radiometrical and morphological properties of the data, for object recognition, scene and target indexing, addressing the problem of large data base queries and information retrieval.. The method is assessed by using a Bayesian Support Vector Machine image search engine based on a hierarchical learning model. The method allowed for the recognition of over 30 different classes, both homogeneous and heterogeneous urban objects with high levels of details. Qualitative and quantitative measures for evaluation are presented and discussed. [C2206]

### "A ground-based Arc-scanning synthetic aperture radar (ArcSAR) system and focusing algorithms"

KIGAM and KNU are developing a ground-based Arc-scanning SAR system (ArcSAR) mounted on a truck. The system achieves the coherent integration of radar returns from ground targets by the circular motion of the antennae attached to the end of an extendable arm. Precise control of antenna position and the extended coherent-integration-length enable the formation of high-resolution, high-precision and phase-preserving SAR images. Based on the Polar Format Algorithm, two SAR-focusing algorithms were developed for the data acquired from two different scanning modes of this unique system: the scan mode and the spot mode. [C2207]

### "A filtering approach to improve deformation accuracy using large baseline, low coherence DInSAR phase images"

Phase noise in an interferogram hinders the accuracy and reliability of interferometric synthetic aperture radar (InSAR) measurements, including deformation estimation and topographic mapping. The Goldstein filter is one of the most commonly used interferogram filters to reduce the effects of phase noise. In this paper, we present a modification to the Goldstein interferogram filter such that the maximum value for the filtering parameter alpha is set to greater than 1 over less coherent areas so that aggressive filtering is implemented on incoherent areas. We also discuss the combined use of estimated coherences from linear and non-linear filters to deal with the coherence saturation due to the strong filtering, which is crucial in generating InSAR deformation products. [C2208]

### "Lidar integrated airborne imaging spectroscopy for root disease detection and measurement of foliar chemistry"

Root disease is a serious concern for the softwood timber industry. This paper reports on the development of a root disease detection procedure that applies lidar integrated with imaging spectrometer data. Chlorophyll-a was found to be significantly affected by the disease in a needle level study[I]. Chlorophyll-a was estimated from canopy reflectance through partial least squares regression and achieved an R2value of 0.82. Continuum removal metrics, which proved to be good estimators at the needle level where found to be insufficient at the canopy level. Through the union of decreased stand density and decreased foliar chlorophyll, potential disease sites were identified in the Greater Victoria Watershed District test site. [C2209]

### "Submerged dunes and breakwater embayments mapped using wave inversions of shore-mounted marine X-band radar data"

Surveying very shallow coastal areas, particularly around coastal defences, can be a logistically difficult and time consuming process. A marine-radar based bathymetry mapping technique has been used to remotely map the embayments around a series of shore-parallel breakwaters at Sea Palling on the south east coast of England during the LEACOAST2 project. The duration of the deployment spanned over 2 years, with the aim of observing any evolution of bathymetric features over that timescale while providing a clear indication of the spatial variability of wave and current patterns contributing to such evolution. The embayments generated by the shore parallel breakwaters at that site are resolved and a field of subtidal dunes with a wavelength of the order of 200m and amplitude around 1m located in approximately 6-10m of water were within the radar field of view and are evident in the remotely sensed bathymetry. Comparisons between bathymetric data obtained using conventional survey techniques and the radar based technique are presented together with measurements of tidal currents mapped using the same remote sensing method and compared with ADCP data during a storm event. [C2210]

### "Application of conventional marine radars for measuring ocean wave fields in shallow water conditions"

This work presents the estimation of wave field properties derived from X-band marine radar measurements taken close to coastal locations, where the wave fields are affected by the finite water depth conditions. The work is focused on the detection of individual waves and their related characteristics, such as the estimation of the local and instantaneous wave envelope derived from the wave elevation fields estimated from X-band marine radar time series. [C2211]

#### "Multispectral classification of remote sensing imagery for archaeological land use analysis: Prospective study"

Much of human history can be traced through the impacts of human actions upon the environment. The use of remote sensing technology offers the archeologist the opportunity to detect these impacts which are often invisible to the naked eye. The extraction of remote sensing signatures from a particular geographical region allows the generation of geophysical signature maps; this can be achieved using an accurate and recently developed multispectral image classification approach based on pixel statistics for the class description, which is referred to as the Weighted Pixel Statistics method. This paper presents the prospective study of the effectiveness that this approach provides for supervised segmentation and classification of sensed archaeological signatures for land use analysis. The results obtained with this study uses real multispectral scenes obtained with remote sensing techniques (high-resolution synthetic aperture radar) to probe the efficiency of the classification technique. [C2212]

#### "Approach for volcanic surveillance using satellite-borne microwave radiometer data"

Volcanic surveillance is one of the practical fields for remotesensing technology. Monitoring of thermal anomalies on volcanoes by infrared radiometer and detection of slight landsurface deformations around volcanoes by interferometry of synthetic aperture radar (SAR) are good examples. However, an infrared radiometer is a little nervous for clouds which cover volcanoes, and interferometry of SAR also has a weakness that the time resolution becomes low in exchange for high spatial resolution. Meanwhile, focusing on microwave radiometer, we know it is less affected by clouds than infrared radiometer. Its time resolution is also higher than interferometry of SAR. Therefore, microwave radiometer can become a promising tool for volcanic surveillance. But, a new methodology to compensate its coarse spatial resolution is essential. It was a serious problem. [C2213]

#### "A study on anomalous signal detection using HMM for ELF electromagnetic wave"

A seismic radiation emitted from the earth's crust is useful for predicting earthquakes. The electromagnetic (EM) wave in the Extremely Low Frequency (ELF) band have been observed at many places in Japan. In this paper, we propose the anomalous signal detection method based on HMM whose input vector is the amplitude density distribution of an EM wave. The amplitude density distribution is calculated from the image of an EM wave data. The optimal scale of an image to calculate an amplitude density distribution and the optimal number of states of HMM are investigated to achieve an accurate detection. [C2214]

#### "Application of TerraSAR-X data to the monitoring of urban subsidence in the city of Murcia"

This paper presents an analysis of the performance of TerraSAR-X for subsidence monitoring in urban areas. The city of Murcia has been selected as a test-site due to its high deformation rate and the set of extensometers deployed along the city that provide validation data. The obtained results have been compared with those obtained from ERS/ENVISAT data belonging to the same period and validated with the in-situ measurements. [C2215]

#### "Closed-loop pallet manipulation in unstructured environments"

This paper addresses the problem of autonomous manipulation of a priori unknown palletized cargo with a robotic lift truck (forklift). Specifically, we describe coupled perception and control algorithms that enable the vehicle to engage and place loaded pallets relative to locations on the ground or truck beds. Having little prior knowledge of the objects with which the vehicle is to interact, we present an estimation framework that utilizes a series of classifiers to infer the objects' structure and pose from individual LIDAR scans. The classifiers share a low-level shape estimation algorithm that uses linear programming to robustly segment input data into sets of weak candidate features. We present and analyze the performance of the segmentation method, and subsequently describe its role in our estimation algorithm. We then evaluate the performance of a motion controller that, given an estimate of a pallet's pose, is employed to safely engage each pallet. We conclude with a validation of our algorithms for a set of real-world pallet and truck interactions. [C2216]

### "Signal analysis and modeling of wind turbine clutter in weather radars"

Lately, the continuing expansion of wind energy industry has led to the installation of several wind farms which are often in the vicinity of the weather radars. This is a source of growing concern for the weather radar community since wind turbines interfere with the normal operation of the weather radars. The wind turbine tower can drive the receivers into saturation and the Doppler shift from the moving blades can introduce errors in the estimation of wind speed, reflectivity and rainfall rates. The radar cross-section of the wind turbines has a large temporal and spatial variation which poses additional difficulties for traditional clutter filtering algorithms. This paper presents a first-order theoretical model of the radar signature of a wind turbine that can be helpful in deducing its unique features to be incorporated in filtering out the wind turbine clutter. A comparison with the observations from an S-band radar is made later in the paper. [C2217]

### "Passive imaging exploiting multiple scattering using distributed apertures"

We develop a new passive image formation method capable of exploiting information about multiple scattering in the environment using measurements from a sparse array of receivers that rely on illumination sources of opportunity. We use a physics-based approach to model wave propagation and develop a statistical model that relates measurements at a given receiver to measurements at other receivers. We formulate the imaging problem as a spatially resolved binary hypothesis testing problem using the model between the measurements at different receivers, statistics of the objects to be imaged and statistics of the additive noise and clutter. We address the spatially resolved hypothesis testing problem by constraining the associated discriminant functional to be linear and by maximizing the signal-to-noise-ratio of the test-statistic, and use the resulting spatially resolved test-statistics to form the image. We present numerical simulations to demonstrate the performance of the passive imaging algorithm. [C2218]

### "A real time Breast Microwave Radar imaging reconstruction technique using simt based interpolation"

Breast Microwave Radar(BMR) is a novel imaging modality that is capable of producing high contrast images and can detect tumors of at least 4mm. To properly visualize the responses from the breast structures, BMR data sets must be reconstructed. In this paper, a real time BMR image formation technique is proposed. This approach is based on the use of a Single Instruction Multiple Thread(SIMT) interpolation method. By using this programming model, the proposed approach can be implemented on General Purpose Graphic Processing Unit (GPGPU) platform to speed up the reconstruction process. The proposed method yielded promising results when applied to simulated data sets obtained using anatomically accurate numeric phantoms. In average, the proposed approach yielded speed increases of one order of magnitude compared to its CPU counterpart, and two orders of magnitude with respect to current BMR reconstruction techniques. [C2219]

### "GPM Microwave Imager design, predicted performance and status"

The Global Precipitation Measurement (GPM) Microwave Imager (GMI) Instrument is being developed by Ball Aerospace and Technologies Corporation (Ball) for the GPM program at NASA Goddard. The Global Precipitation Measurement (GPM) mission is an international effort managed by the National Aeronautics and Space Administration (NASA) to improve climate, weather, and hydro-meteorological predictions through more accurate and more frequent precipitation measurements. The GPM Microwave Imager (GMI) will be used to make calibrated, radiometric measurements from space at multiple microwave frequencies and polarizations. GMI will be placed on the GPM Core Spacecraft together with the Dual-frequency Precipitation Radar (DPR). The DPR is two-frequency precipitation measurement radar, which will operate in the Ku-band and Ka-band of the microwave spectrum. The Core Spacecraft will make radiometric and radar measurements of clouds and precipitation and will be the central element of GPM's space segment. The data products from GPM will provide information concerning global precipitation on a frequent, near-global basis to meteorologists and scientists making weather forecasts and performing research on the global energy and water cycle, precipitation, hydrology, and related disciplines. In addition, radiometric measurements from GMI and radar measurements from the DPR will be used together to develop a retrieval transfer standard for the purpose of calibrating precipitation retrieval algorithms. This calibration standard will establish a reference against which other retrieval algorithms using only microwave radiometers (and without the benefit of the DPR) on other satellites in the GPM constellation will be compared. The instrument has completed the Critical Design Review phase of the program. The design of the instrument is complete. We describe the instrument and predict the performance of the GMI instrument. The instrument interfaces have been finalized and the design completed. The final mechanical and electrical interfaces are described. The mechanical interface was specifically designed to provide isolation from the spacecraft and allow accommodation on future low inclination spacecraft. An electrical interface was added coming from the spacecraft that allows the GMI integration to be blanked during Dual Precipitation Radar pulses.

The implementation of this blanking is described. The instrument is currently in the flight production phase. Status and initial test results on the flight hardware are presented. [C2220]

### "Multiresolution despeckling of VHR SAR images based on MRF segmentation"

In this work, maximum a posteriori (MAP) despeckling, implemented in the multiresolution domain defined by the undecimated discrete wavelet transform (UDWT), will be carried out on very high resolution (VHR) SAR images and compared with earlier multiresolution approaches developed by the authors. The MAP solution in UDWT domain has been specialized to SAR imagery. Every UDWT subband is segmented into statistically homogeneous segments and one generalized Gaussian (GG) PDF (variance and shape factor) is estimated for each segment. This solution allows to effectively handle scene heterogeneity as imaged by the VHR SAR system. Segmentation exploits a Tree Structured Markov Random Field (TSMRF), which is a low complexity MRF segmentation that allows the estimation of the number of segments and the segmentation itself to be carried out at the same time. Experiments performed on a single-look VHR X-band SAR images demonstrate that the segmented approach is effective whenever the classical circular Gaussian model of complex reflectivity may no longer hold. [C2221]

### "Potential of mapping soil moisture by combining radar backscatter modeling and PolSAR decomposition"

The purpose of this study is to evaluate the capability of the Oh backscattering model in combination with the Freeman Durden decomposition to estimate soil moisture over agricultural fields from fully polarimetric RADARSAT-2 C-band SAR responses. Initially, soil moisture multi-polarization retrieval was accomplished by using a look-up table (LUT) approach applied to the Oh model. Two methods were considered: the multi-polarization method and the one-unknown configuration. Of the two methods, results showed that the HH-HV inversion provided the best estimates. In the second phase, the Freeman Durden decomposition was applied to the polarimetric data. The conceptual approach for retrieving soil moisture using the surface scattering component of the total power was implemented in a LUT inversion. The algorithm attempts to minimize the difference between measured single scattering power obtained by applying the Freeman Durden decomposition and simulated total power using Oh model. When compared with the multi-polarization approach, this polarimetry-based method improves the accuracy of soil moisture estimates. [C2222]

### "Triple collocation-A new tool to determine the error structure of global soil moisture products"

Recently Triple Collocation (TC) was adopted for soil moisture application. Results from a first application indicated that the method could be useful to estimate global error patterns. Here we test the method with new data sets. The results show that the method is robust and that it allows to derive objective error estimates. [C2223]

### "Characteristics of rough surface parameters estimated from measured surface profile of finite length"

Estimation of roughness parameters of soil surface is one of the important problems in the field of radar remote sensing. In order to estimate these parameters from measured surface height-profile, data samples with sufficiently long record length are required for accurate estimation. In an actual measurement situation, however, it is difficult to get the surface height-profile in pure form because a bias and inclination of the data are unknown. In this study, we present a method for estimation of the bias and inclination from measured surface height-profile and reveal the effect of the accuracy on the parameter estimates. [C2224]

### "Target detection performance analysis for airborne passive bistatic radar"

For a ground-based/airborne passive bistatic radar, its performance is dependent on the geometrical configuration and the passive transmit signal attributes. Theoretical power budget and ambiguity function analysis using a ground-based non-cooperative transmitter of opportunity with a passive bistatic radar being airborne but stationary (airship, etc.) had shown that target detection performance is limited by the strong direct path coupling signal. In comparison, the bistatic ground clutter power is significantly lower and even more so for noise power. For the passive radar to perform satisfactorily, sufficient attenuation must be provided for the direct path and strong ground clutter signals, corresponding to increasing the height of the target peak on the ambiguity function pedestal. In addition, performance could also be improved by increasing the time-bandwidth product (assuming no target migration issues), which lowers the pedestal of the ambiguity function of the strong direct path interfering signal. [C2225]

### "Imaging algorithm and experimental demonstration of rotating scanning interferometric radiometer"

Recently, a new concept of rotation scanning synthetic aperture interferometric radiometer (RS-SAIR) has been receiving more and more attentions for its advantage of much simpler configuration with looser requirements of antenna elements. In this article, we investigate the imaging theory of RS-SAIR, and introduce the pseudo-polar FFT algorithm to deal with the polar u-v samples. It only involves 1D interpolation and 1D FFT routine that guarantee a high accuracy and computation efficiency. The sampling strategy and aliasing effect of RS-SAIR are studied with this imaging algorithm. Numerical simulations are provided to validate the associate theory. Finally we develop a 5-elements RS-SAIR instrument and carry out rotating scanning imaging experiment successfully. The first imaging results consist with the expectation. [C2226]

#### "Automatic exclusion of surface deformation in InSAR DEM generation using differential radar interferometry"

The Digital Elevation Models (DEMs) are an important source of topographical data for many scientific and engineering applications. Where topographical data are unavailable, global coverage elevation data sets, typically DEMs from remotely sensed data, are the main sources of such information. Interferometric SAR (InSAR), is a useful method for low-cost, relatively precise and wide-coverage surface DEM generation. However, ground deformation should somehow be excluded from InSAR-based DEM generation. To identify surface deformation areas, the so-called Differential InSAR (DInSAR) is a commonly used method. In this paper, the authors propose a two-step DEM generation method: the ground deformation area detection using DInSAR technique and deformation area exclusion in InSAR DEM generation by detected mask. [C2227]

#### "Evaluation of system polarization quality for polarimetric SAR imagery and target decomposition"

The quality of polarimetric synthetic aperture radar (PolSAR) imagery and its polarimetric decompositions depends on the accuracy of polarimetric observations of the SAR system and its calibration. Polarization distortions on the polarimetric measurement can be incurred due to nonideal system polarization quality and propagation factors, such as channel imbalance, cross-talk, and Faraday rotation at lower frequencies. All these distortions have varying impacts on different target types as well as different decomposition methods. In this paper, we assess the polarization quality of the PolSAR system in the context of polarimetric imagery analysis and quantify the various effects of polarization distortions on polarization target decompositions. A generic metric is defined to measure the polarization purity of the system. Considering the fact that target decomposition plays an important role in imagery analysis, we apply several widely used decomposition methods to showcase the polarimetric system requirement based on the defined metric. [C2228]

#### "Contribution of small-scale correlated fluctuations of the microstructural properties of a spatially extended geophysical target under the assessment of radar backscatter"

The study of the collective effects of radar scattering from an aggregation of discrete scatterers randomly distributed in a space is important for a better understanding of the origin of the backscatter from spatially extended geophysical targets (SEGT). We consider the microstructural irregularities of SEGТ as the essential factor that affects radar backscatter. To evaluate their contribution, this study uses the "slice" approach: particles close to the front of an incident radar wave are considered to reflect incident electromagnetic waves coherently. The radar equation for a SEGТ is derived. The equation includes contributions to the total backscatter from correlated small-scale fluctuations in the slice's reflectivity. The correlation contribution changes in accordance with an idea proposed earlier by Smith (1964) based on physical consideration. The slice approach applied allows parameterizing the features of the SEGТ's inhomogeneities. [C2229]

#### "Building detection and radar footprint reconstruction from single VHR SAR images"

The development of methods for the automatic detection and reconstruction of building radar footprints from single very high resolution (VHR) synthetic aperture radar (SAR) images is a difficult task for two main reasons: i) the very high complexity of VHR SAR images; and ii) the need to develop efficient algorithms that can be applied to large images in order to be used in real applications. In this paper we present a novel method for automatic building detection, which also reconstructs the 2D radar footprint of the detected buildings. The method is based on the extraction of a set of low-level features from the images and on their combination in more structured primitives. Then the semantic meaning of primitives is used for the definition of building candidates and for the radar footprint reconstruction. In order to process large VHR SAR images, the method has been implemented on a computer cluster. We demonstrate the effectiveness of the method using a large TerraSAR-X spotlight scene. [C2230]

#### "Unsupervised nonparametric classification of polarimetric SAR data using the K-nearest neighbor graph"

Polarimetric SAR classifications are often based on assumptions about the shape of clusters in the data space. Such a scheme will fail for nonlinear structures in the feature space, unless the classification algorithm has the capacity to describe cluster shapes in sufficient generality. Existing polarimetric SAR classification methods are faced by this exact problem: typically they initialize clusters in the Cloude-Pottier parameter space [1], further optimizing them in the coherency matrix space [2, 3]. Methods using K-means [2] or agglomeration [3] require clusters that are spherical, or compact and well separated, respectively. In the Cloude-Pottier space, these requirements are not met, so initialization in the Cloude-Pottier space cannot be consistent with optimization by K-means or agglomeration. This paper sets out to address this problem, by implementing a new data-driven clustering approach, for arbitrarily shaped clusters. It is applied to quad-polarisation data, demonstrating the new methodology's potential for forest land-cover type discrimination. [C2231]

### "Development of a three-element interferometer at 50 56 GHz for Geostationary Interferometric Microwave Sounder (GIMS)"

The Geostationary Interferometric Microwave Sounder (GIMS) is a new concept imaging radiometer proposed by CSSAR, aiming for China's next generation geostationary meteorological satellite (FY-4M). The concept of GIMS is based on aperture synthesis with a rotating circular thinned array. A three-element interferometer has been developed and tested to investigate the feasibility of the GIMS system design. A full-scale ground-based demonstrator with 27 elements is also under development, which is defined as a minimum system intended to fulfill the threshold application requirements. In this paper, the preliminary results of these activities will be reported. [C2232]

### "High-resolution mapping of fluvial landform change in arid environments using terrasars-X images"

The high resolution acquisition mode of TerraSAR-X provides a new dimension in fluvial landform change detection. Here we analyzed high resolution (5 m) coherence images with temporal baselines of up to a year from the Palpa Valley in the hyper-arid coastal desert of southern Peru. The results provide evidence that this sensor is suitable for mapping the land surface changes caused by erosion and sedimentation following rainfall and runoff events in bare desert landscape units. [C2233]

### "Implementation of a low cost, lightweight X-band antenna with integrated SiGe RF electronics"

This paper presents an organic, lightweight X-band antenna array with integrated silicon germanium (SiGe) low noise amplifiers (LNA) and 3-bit phase shifters (PS). The SiGe LNAs and PSs were successfully integrated onto an 841 lightweight antenna stack-up utilizing a multilayer liquid crystal polymer (LCP) substrate. Successful comparisons of the measured and simulated results verify a working antenna array with a return loss of around 10 dB across the frequency band of 9.25 GHz-9.75 GHz. A comparison of radiation patterns for the 841 antenna with integrated SiGe LNA and the 841 antenna with integrated SiGe LNA and PS show a 16 dB and 25 dB increase in gain, respectively. The ultimate goal is to develop an airborne X-band radar capable of a beam steering of at least  $\pm 40^\circ$  through utilization of low power highly integrated SiGe electronics on a low cost multi-layer organic platform. This paper represents the first successful demonstration of a building block prototype (i.e., a fully integrated, high gain X-band antenna with SiGe LNAs and SiGe phase shifters) that can be expanded to a complete active phased array for remote sensing applications in X-band. [C2234]

### "Improvement of ship detection accuracy by sar multi-look cross-correlation technique using adaptive CFAR"

This paper describes a novel technique to improve the accuracy of ship detection by synthetic aperture radar (SAR). The methodology is to apply the algorithm of constant false alarm rate (CFAR) to the coherence images produced by multi-look cross-correlation (MLCC) of sub-images. The experiment was carried out in the Tosa bay, Kochi, Japan using three known fishing boats and the simultaneous data acquired by the Phased Array L-band SAR (PALSAR) on board of the Japanese Land Observing Satellite (ALOS) at four different modes. The inter-look coherence images were found to fit best to Gamma distribution, and using this distribution function, CFAR was applied to the coherence image. The results showed substantial improvement in signal to noise ratio and false alarm rate as compared with the coherence image alone. In the followings, the principle of MLCC-CFAR and experimental procedure are summarized, and the results are discussed. [C2235]

### "Japanese hyper-multi spectral mission"

The hyperspectral and the multispectral (hyper-multi spectral) mission is the Japanese next generation space-borne radiometer development project. This project is a heritage from ASTER launched in December 1999. The performance of the hyperspectral radiometer is 30m ground sampling distance, 30km swath width, 10nm and

12.5nm wavelength distance for VNIR and SWIR respectively, over 450@620nm and 300@2,100nm of the signal to noise (S/N) ratio. The performance of the multispectral radiometer is 5m ground sampling distance, 90km swath width, over 200 for all bands of S/N ratio. This project will be launched on ALOS-3 of JAXA in FY2014. The panchromatic sensor with stereo viewing will also be installed on ALOS-3. [C2236]

#### **"Automatic ship detection in sar images using aegir"**

Aegir is an automatic ship detection tool developed at FFI. Now it analyses the different polarisation channels independently. The goal is to fuse the channels before the analysis starts, and to detect the ships in the fused channels. When dual-polarised data is available it is possible to look at the channels individually and combined. When fully polarised data is available, it is also possible to use the scattering matrix and decompose it in different ways. [C2237]

#### **"Bistatic SAR along track interferometry with multiple fixed receivers"**

This paper presents an along-track interferometry (ATI) study for a bistatic or multistatic SAR configuration with fixed ground receivers. This technique can be useful for sea current estimation or for any problem of Ground Motion Target Indicator (GMTI). The proximity of the ground receivers to the scene allows to be very sensitive to velocities with small baselines. This paper also proposes a multibaseline approach for ATI able to differentiate among different velocity contributions in the same resolution cell. At the end of this paper, some results over real acquired bistatic data will be presented and discussed. The data have been acquired using the C-band SAR Bistatic Receiver for Interferometric Applications (SABRINA) and ESA's ENVISAT satellite, as a transmitter of opportunity. [C2238]

#### **"Radar retrieval of subsurface parameters for layered media with nonsmooth interfaces"**

The solution to the inverse problem for a three-layer medium representing a large class of natural subsurface structures is developed in this paper using radar data. The retrieval of the layered medium parameters is accomplished as a sequential nonlinear optimization starting from the top layer and progressively characterizing the layers below. The optimization process is accomplished by an efficient iterative technique built around the solution of the forward scattering problem. The forward scattering process is formulated by using the Extended Boundary Condition Method (EBCM) and constructing reflection and transmission matrices for each interface. These matrices are then combined into the generalized scattering matrix for the entire system, from which radar scattering coefficients are then computed. To be efficiently utilized in the inverse problem, the forward scattering model is simulated over a wide range of unknowns to obtain a complete set of subspace-based equivalent closed form models that relate radar cross section coefficients to the sought-for parameters including dielectric constants of each layer and separation of the layers. The inversion algorithm is implemented as a modified conjugate-gradient-based nonlinear optimization. It is assumed that multifrequency radar measurements are available from tower-mounted or airborne platforms, for example at typical radar frequencies of L-band and P-band (UHF). It is shown that this technique results in accurate retrieval of surface and subsurface parameters, even in the presence of noise. [C2239]

#### **"Combined active and passive measurements of snow, bare and vegetated soils microwave reflective and emissive characteristics by Ka-band, combined scatterometer-radiometer system"**

In this paper the results spatio-temporally collocated measurements of bare, dry vegetated and ash covered soils microwave reflective (radar backscattering coefficient) and emissive (brightness temperature) characteristics angular dependences at ~37GHz are presented. During the experiment with dry vegetated soil the observed area was set ablaze and microwave active and passive measurements at 300 incidence angle were continued for smock, fire and ash situations. For these measurements Ka-band, polarimetric, combined scatterometric-radiometric system was used, set on a mobile buggy moving along the measuring platform. Structures, operational features and the main technical characteristics of the used system are presented too. The paper has an aim as well to attract attention of interested researchers and to invite them to perform their own or joint researches using available devices and facilities. [C2240]

#### **"A new scalloping filter algorithm for scansar images"**

Due to its specific way of scanning over multiple sub-swaths of a radar image, a ScanSAR (scanning synthetic aperture radar) cannot sample Doppler histories continuously like a regular SAR in stripmap mode. This can cause an artifact known as azimuthal scalloping, a wave-like modulation of the image intensity in azimuth direction. Although the problem is theoretically understood, many ScanSAR images of ocean scenes continue to exhibit scalloping. This hampers their use for applications such as wave and wind retrievals. We have developed an efficient descloping algorithm that can be applied to such images as a post-processing tool. We describe

how it works and show examples. [C2241]

### "Geometric refinement of road networks using network snakes and SAR images"

In this paper, a new approach for the geometric refinement of road networks using network snakes and SAR images is presented. Network snakes are based on the well-known active contour models, but in addition to the image energy and internal energy the topology is introduced into the optimization process. This graph-based active contour method enables a complete topological and shape control during the object delineation. The method is applied to the geometric refinement of road networks to improve and correct GIS-databases as a basis for traffic navigation or infrastructure planning purposes. The proposed approach is either able to deal with roads from a database as initialization in an automatic system or, alternatively, within an interactive framework to derive a geometrically optimized road network. The derived results using SAR images are evaluated with reference data to demonstrate the benefit and transferability of network snakes. [C2242]

### "Characterization of full surface roughness in agricultural soils using groundbased LiDAR"

Microwave emission and scattering models require the parametrization of surface roughness. Traditionally this has been achieved by sampling the surface in transects. In this work, roughness is characterized from 3D surface models derived from ground-based LiDAR. The dataset consist 18 surfaces with varying roughness characteristics. 2D profiles extracted from the surface model constitute the baseline to compare to traditional profiling methods. It was found that sampling using profiles produces an underestimation of the RMS<sub>h</sub> by 25-63% and an even more severe underestimation in the correlation length that can reach up to an order of magnitude difference. From the 17,178 2D extracted profiles it was determined a significant sensitivity of the roughness parameters to the detrending methods, as well as a poor fit between the experimental ACF and the exponential and Gaussian models. Finally, methodologies to detrend quasi-periodic surfaces and the decomposition of surface at different scales are proposed and illustrate the advantage of having a 3D representation. [C2243]

### "Comparing data of two airborne L-band radiometers with different spatial resolution over a heterogeneous land surface"

This paper describes a first attempt of comparing data of the two airborne L-band radiometers EMIRAD and HUT-2D over land surface. While HUT-2D is an imaging system with a high spatial resolution, EMIRAD delivers data averaged over a relatively large footprint but can be considered to be more stable. The Upper Danube catchment, located mostly in Southern Germany, is one of two major test sites in Europe for the calibration and validation activities for the Soil Moisture and Ocean Salinity (SMOS) mission launched by the European Space Agency (ESA). For the study presented in this paper, the radiometric measurements collected during the SMOS Validation Rehearsal Campaign 2008 in the Upper Danube catchment are used. The results suggest that differences between the measurements are mainly controlled by temperature effects and can be limited by implementing a temperature correction in the processing of HUT-2D data. [C2244]

### "The NASA Soil Moisture Active Passive (SMAP) mission: Overview"

The Soil Moisture Active Passive (SMAP) mission is one of the first Earth observation satellites being developed by NASA in response to the National Research Council's Decadal Survey. Its mission design consists of L-band radiometer and radar instruments sharing a rotating 6-m mesh reflector antenna to provide high-resolution and high-accuracy global maps of soil moisture and freeze/thaw state every 2-3 days. The combined active/passive microwave soil moisture product will have a spatial resolution of 10 km and a mean latency of 24 hours. In addition, the SMAP surface observations will be combined with advanced modeling and data assimilation to provide deeper root zone soil moisture and net ecosystem exchange of carbon. SMAP is expected to launch in the late 2014-early 2015 time frame. [C2245]

### "Context-dependent landmine detection with ground-penetrating radar using a Hidden Markov Context Model"

Context-dependent approaches to landmine detection have been developed in recent years to exploit the sensitivity of ground-penetrating radar (GPR) to changes in environmental conditions. Previous approaches to context-dependent fusion have only considered the special case of statistically independent observations. This work proposes the use of Hidden Markov Models, trained on the GPR background, for modeling the context of observation sequences. The performances of context-dependent fusion using two statistical context models were compared in an experiment with field data. One approach utilized a Hidden Markov Context Model (HMCM), and the other utilized a Gaussian mixture. Experimental results illustrated that the HMCM improved performance of

context-dependent fusion. These results suggest that spatial dependencies are an important source of contextual information for landmine detection that warrants further investigation. [C2246]

### "Ka-band SAR interferometry studies for the SWOT mission"

The primary objective of the National Research Council (NRC) Decadal Survey recommended SWOT (Surface Water and Ocean Topography) Mission is to measure the water elevation of the global oceans, as well as terrestrial water bodies (such as rivers, lakes, reservoirs, and wetlands), to answer key scientific questions on the kinetic energy of ocean circulation, the spatial and temporal variability of the world's surface freshwater storage and discharge, and to provide societal benefits on predicting climate change, coastal zone management, flood prediction, and water resources management. In this paper, we present the overall concept of the SWOT mission, as well as the scientific rationale, objectives and development status of the technology items currently under development. [C2247]

### "Performance analysis of atmospheric correction in InSAR data based on the Weather Research and Forecasting Model (WRF)"

The influence of the turbulent atmosphere is seen as the main performance limitation for high-quality Interferometric Synthetic Aperture Radar (InSAR) techniques in ground deformation monitoring applications. Atmospheric correction using numerical weather prediction (NWP) models is widely seen as a promising emerging technology for mitigation of atmospheric signals. First results showed promising capabilities for correction of stratified delay yet have revealed limited performance for modeling and mitigating turbulent atmospheric water vapor signals from SAR [1, 2]. This paper presents an integration of InSAR observations with predictions from the high-resolution Weather Research and Forecasting Model (WRF). Special focus is put on investigating improvements in the weather model parameterization to achieve enhanced performance in atmospheric correction. First, a statistical analysis of the quality of absolute delay predictions is presented based on a comparison of vertically integrated WRF delays with radiosonde measurements. Second, the performance of WRF for atmospheric correction of InSAR data is analyzed by comparing WRF phase delay maps to SAR interferograms and analyzing structure functions and variances of the residual atmospheric delay signal. Here, significant improvements could be achieved through modifications of the WRF model parameterization, which are highlighted in Section 3.2. From our study, we conclude that the performance of latest generation high-resolution NWP models can be significantly improved if the setup and parameterization of the model domain is optimized. [C2248]

### "Multi-baseline along track SAR interferometric systems for ground moving target indication"

In this paper we analyze the performance of ground moving target detection by means of single-baseline and dual-baseline along track interferometric synthetic aperture radar (SAR) systems, obtained using a generalized likelihood ratio test (GLRT). Detection performance are evaluated in terms of probability of detection and probability of false alarm using data simulated with TerraSAR-X parameters. [C2249]

### "Improved Variable Index constant false alarm rate radar processors"

In the cases when the statistical distribution of range return samples are not known, constant false alarm rate (CFAR) processors can be used. Cell Averaging (CA) CFAR radar processors which have the best performance in Gaussian homogeneous environments, exhibits performance degradation in the presence of an interfering target or in regions of abrupt change in the background clutter power. The Greatest of (GO) CFAR radar processors are designed to control the false alarm rate, during the clutter power transition in the reference window (non-homogeneous clutter environment). The Smallest of (SO) CFAR radar processors improve detection performance when interfering targets exist in the environment but are unable to prevent excessive false alarm in non-homogeneous environments. Variable Index (VI) CFAR processors employ a composite approach based on CA-CFAR, SO-CFAR, GO-CFAR. Enhanced VI-CFAR (EVI-CFAR) radar processors proposed in this paper, shows performance improvement in different non-homogeneous environments when compared with VI-CFAR. [C2250]

### "Advanced techniques and new high resolution SAR sensors for monitoring urban areas"

In the last years MultiDimensional (3D and 4D) Synthetic Aperture Radar (SAR) techniques, also known as SAR tomography and differential SAR tomography, are emerging in the field of coherent combination of multibaseline/multitemporal SAR data. With respect to the classical differential interferometric processing, these techniques improve the capability of detection and monitoring of the ground targets. Moreover they were proven to be effective in resolving the signal interference due to the layover effect, that may occur in areas with high density of scatterers located on vertical structures, such as urban areas. Beside the development of these advanced techniques the new generation of sensor, such as TerraSAR-X and COSMO-SKYMED with very high

spatial resolution offer new perspectives in the imaging and monitoring of urban areas. In this paper we address the application of the SAR tomography to real spaceborne data. Particularly, we show and discuss the first results of the application of this technique to high resolution TerraSAR-X data. [C2251]

#### "Monitoring grasslands with radarsat 2 quad-pol imagery"

Radarsat 2 quad polarization imagery has been used to study the effectiveness of polarimetric radar to monitor the extent and health of prairie grasslands in southern Alberta, Canada. In this report of preliminary findings, the imagery is shown to be effective in the separation of cropped lands from rangelands, and in the separation of native grasslands and improved pastures. Classification was more accurate using Freeman-Durden decomposition parameters than using Cloude-Pottier parameters. Incidence angle differences were noted and use of multiple angles in classification improved accuracy. In a second part of the study, it was shown that polarimetric imagery was capable of identifying weeds and brush growing in native rangeland, and in separating different kinds of brush and weeds. Validated sample sets were too small to allow proper accuracy assessment, but a 'performance metric' showed that accuracy would be improved by use of multiple incidence angles, and by the use of Freeman-Durden or coherency matrix parameters. [C2252]

#### "DESDynI lidar for solid earth applications"

As part of the NASA's DESDynI mission, global elevation profiles from contiguous 25 m footprint Lidar measurements will be made. Here we present results of a performance simulation of a single pass of the multi-beam Lidar instrument over uplifted marine terraces in southern Alaska. The significance of the Lidar simulations is that surface topography would be captured at sufficient resolution for mapping uplifted terraces features but it will be hard to discern 1-2m topographic change over features less than tens of meters in width. Since Lidar would penetrate most vegetation, the accurate bare Earth elevation profiles will give new elevation information beyond the standard 30-m DEM. [C2253]

#### "Studies of the influence of rainfall upon scatterometer estimates for sea surface stress: Applications to boundary layer parameterization and drag coefficient models within tropical cyclone environments"

The use of satellite scatterometers to probe the winds in and near strong tropical cyclones (TCs) is a valuable tool for both numerical weather prediction (NWP) and weather forecasters. The presence of widespread rain in these storms complicates the estimation of surface winds from the satellite. Improvements in the techniques to infer surface winds from the satellite observations, which remove the effects of rain contamination at the ocean surface, will improve the modeling efforts as they pertain to the prediction of TC intensity. This study will demonstrate the use of collated and simultaneous high-resolution rain measurements obtained from nearby Next-Generation Radar (NEXRAD) and NASA Quick Scatterometer (QuikSCAT) measurements, respectively. Through the application of the National Oceanic and Atmospheric Administration (NOAA)/Atlantic Oceanographic and Meteorological Laboratories (AOML)/Hurricane Research Division (HRD) TC wind analysis (H\*WIND; Powell and Houston [1996]), we will study the dependence of a surface normalized radar cross-section (NRCS) on the TC wind-speed and rain-rate. The objective is to better observe and understand the dependence of the drag coefficient upon the surface stress across a wide range of conditions and spatial scales within these storms. [C2254]

#### "Multi beam joined estimation for persistent scatterer interferometry"

The persistent scatterer interferometry (PSI) is a powerful technique to monitor the line of sight (LOS) deformation with millimeter accuracy in urban areas. Nowadays, this technique is well established for the sensors ERS and Envisat/ASAR. Nevertheless, the availability of high resolution SAR sensors enables new applications which require new estimation principles. Application test cases for the sensor TerraSAR-X were demonstrated already. However, the high resolution data are not really fully exploited at the moment. This paper describes a newly developed PSI estimation principle which improves the spatial resolution by the support of distributed scatterers and increases the temporal sampling by the joined estimation of different beams. The prototyped technique needs to cope with the different projections of the horizontal and vertical deformation components onto the line of sight (LOS). Basically, this allows the inversion of the beam's observation equation and finally retrieves the vertical and horizontal deformation components. [C2255]

#### "Iterative calibration of relative platform position: A new method for SAR baseline estimation"

Baseline calibration is needed in most of SAR interferometry processing. An iterative optimization of baseline with constrain of relative platform position is presented in this paper. The SAR passes which gives inaccurate

platform position is successfully detected and calibrated using this algorithm. After processing, new estimated baseline improves the quality of interferogram. Existence of reference Digital Elevation Model (DEM) error and atmospheric phase screen (APS) can also be detected from the convergence value. This method is based on a reversed concept of platform position estimation from interferometric result. Validation of method performed on multiple SAR images over Singapore. [C2256]

#### "Multibaseline gradient ambiguity resolution to support Minimum Cost Flow Phase Unwrapping"

The TanDEM-X Mission has as primary objective to generate a high resolution global Digital Elevation Model. This paper proposes a new method for multibaseline Phase Unwrapping which is the critical point of this generation. We propose to combine both Minimum Cost Flow (MCF) and Maximum a Posteriori (MAP) estimation. The latter is used to solve phase gradient ambiguities. The problem is posed as an energy minimization one and solved using Belief Propagation (BP) which is an iterative process. Nevertheless, although very good results are obtained on loopy graphs, it is not guaranteed to converge. Thus, phase unwrapping of the most accurate interferogram is finally performed with the MCF algorithm and takes as input the unwrapped gradients. [C2257]

#### "Range-Doppler ambiguity mitigation via closed-loop, adaptive PRF selection"

In this paper, we present a method of calculating and updating target probabilities in ambiguous range-Doppler cells along with an adaptive pulse repetition frequency (PRF) selection technique based on mutual information (MI). We approach the problem of updating the probability in multiple ambiguous cells by using a multiple hypothesis test for the target state. The probability ensemble is then used to determine which PRF will maximize MI on the next update. Since MI is a measure of the reduction in entropy of the ensemble, it indicates the amount of information the radar stands to learn about the channel due to the selected PRF. We compare the results of MI-based PRF selection to two other PRF selection methods and demonstrate how blind zones and clutter aliasing can be seamlessly integrated into our PRF-selection procedure. [C2258]

#### "Performance of cell averaging constant false alarm rate (CA-CFAR) processors for M-correlated sweeps in multiple target environments"

In this paper, the detection performance of CA-CFAR processor is analysed for M-correlated sweeps in Gaussian clutter environment which contains interfering targets. The performance analyses are done for different number of sweeps, M, and sweep-to-sweep correlation coefficient, R, with Swerling-I target model in homogeneous and non-homogeneous environments. [C2259]

#### "Phase retrieval in SAR interferograms using diffusion and inpainting"

A high-contrast inpainting scheme based on the Complex Ginzburg-Landau equation recently applied successfully to image restoration is applied to SAR interferograms to improve their quality and therefore final quality of Digital Elevation Models (DEMs). The new technique attempts to recover the phase values in low coherence regions through diffusion and inpainting. After phase unwrapping low coherence regions are masked and discarded and a Complex Ginzburg-Landau (CGL) inpainting scheme is applied to regions where phase values are missing. We demonstrate that the residues reduce and the proposed algorithm leads to a higher Signal-to-Noise Ratio (SNR) if compared with MCF algorithm. The restoration technique has been applied to ERS-1 and ERS-2 data sets acquired on July 1995. Results appear to be very promising: the proposed algorithm provides good performances especially in presence of strong noise level and low coherence areas with relatively small dimensions. [C2260]

#### "Successive cancellation approach for Doppler frequency estimation in pulse Doppler radar systems"

In this paper, a successive cancellation approach is proposed to estimate Doppler frequencies of targets in pulse Doppler radar systems. This technique utilizes the Doppler domain waveform structure of the received signal coming from a point target after matched filtering and pulse Doppler processing steps. The proposed technique is an iterative algorithm. In each iteration, a target that minimizes a cost function is found, and the signal coming from that target is subtracted from the total received signal. These steps are repeated until there are no more targets. The global minimum value of the cost function in each iteration is found via particle swarm optimization (PSO). Performance of this technique is compared with the optimal maximum likelihood solution for various signal-to-noise ratio (SNR) values based on Monte Carlo simulations. [C2261]

#### "The bistatic electromagnetic signature of heterogeneous sea surface: Study of the hydrodynamic

### phenomena"

In this article, we carried out a preliminary study on the hydrodynamic effect (non-linear) produced by the breaking of a coastal wave on the scattering coefficient (in horizontal and vertical polarization) in the bi-static configuration (forward propagation). We calculated in X-band (10 GHz)  $\sigma_{HH}$  and  $\sigma_{VV}$  of a series of oceanic surfaces (different phases of construction of a breaking wave ( $\theta_i = -20^\circ$ )) then we studied the different characteristics for each scattering coefficients. In this first study we considered that the maritime surface is the perfect conductor. [C2262]

### "Disaster mapping from medium spatial resolution alos palsar images"

All-day and all-weather Synthetic Aperture Radar (SAR) can measure both intensity and phase of the reflected signal. The backscattering coefficients measured by SAR reflect the backscatter characteristics of surface targets. Changes happened to a target's surface roughness, geometric and structural characteristics will result in the change of its backscattering intensity recorded in SAR image. The 2008 Wenchuan earthquake, China have caused widely distributed geological disasters, such as landslides, mudfloods and barrier lakes, which resulted in the difference between pre- and post-earthquake SAR images. Comparison between the pre- and post-earthquake SAR intensity images will reveal the damage information. In this study, PALSAR Level 1.0 data acquired for the Wenchuan earthquake were used to analyze the geological disasters. Results show that medium spatial resolution SAR data, such as 10 m resolution ALOS PALSAR data, especially when both pre- and post-earthquake images are available, are useful in revealing the distribution of landslides and barrier lakes. [C2263]

### "A modified wind vector retrieval algorithm for polarimetric scatterometer"

Experiments and theoretical analysis demonstrate that the polarimetric scatterometer has the potential in enhancing the accuracy of the wind vector retrieval. However, currently, there is no special wind vector retrieval algorithm for the polarimetric scatterometer. Based on the distribution characteristic of the objective function, a modified wind vector retrieval algorithm was designed for the conically scanning polarimetric scatterometer in this paper. Simulation experiments indicated that this algorithm could further improve the retrieval precision of the polarimetric scatterometer in comparison with the traditional algorithm, especially in the nadir- and outer-swath. By extending the wind direction range for the first and second ambiguity in the nadir- and outer-swath, the algorithm can effectively reduce the uncertainty of the wind direction solutions with error magnitude of  $0^\circ$  to  $15^\circ$ . Up to  $2^\circ$  improvement in wind direction retrieval can be achieved in the nadir track. [C2264]

### "Status, results, potentiality and evolution of COSMO-SkyMed, the Italian Earth Observation constellation for risk management and security"

COSMO-SkyMed is a Dual-Use program, devoted to produce both civilian and military applications, and as such it is required to have a fast response time, to manage conflicts and to optimize resources. In order to provide operational continuity to COSMO-SkyMed mission, the Italian Space Agency (ASI) and Italian Ministry of Defense (It-MoD) are conceiving the next generation of the system. The new system, called "COSMO-SkyMed Seconda Generazione" (CSG), starting from the well established design of the first generation, will provide the end user with outstanding characteristics consolidating its position in the frame of SAR Systems. After a description of the current COSMO-SkyMed unique in-orbit performances, functionalities and Dual-Use operations, with examples of data already acquired in the last few years, the paper will introduce the CSG mission describing the main features and capabilities that will drive the design of the new system. [C2265]

### "One-day interferometry results with the COSMO-SkyMed constellation"

COSMO-SkyMed is a Dual-Use (Civilian and Defence) End-to-End Earth Observation System aimed at establishing a global service supplying provision of data, products and services relevant to a wide range of applications, such as Risk Management, Scientific and Commercial Applications and Defence Applications. The system consists of a constellation of four LEO mid-sized satellites, each equipped with a multi-mode high-resolution SAR operating at X-band. Three out of four COSMO-SkyMed satellites have been successfully launched, while the remaining satellite will be deployed within 2010. The first two satellites have been launched in 2007 while COSMO-SkyMed-3 has been launched on October 25th 2008. Since its launch COSMO-SkyMed-3 has been put in an orbital position at  $67,5^\circ$  from COSMO-SkyMed-2, in the so-called "one-day interferometry configuration". Since then COSMO-SkyMed-2 and COSMO-SkyMed-3 are providing a interferometric pairs for a wide range of applications. [C2266]

### "Comparison of Beijing-Tianjin Intercity Railway deformation monitoring results between ASAR and

### **PALSAR data"**

First comparison experiments by different datasets were done to estimate the subsidence pattern of China Beijing-Tianjin Intercity Railway roadbed in Tianjin area in this paper. The multi-baseline differential synthetic aperture radar interferometry technique was used to give the subsidence monitoring. During the period of middle 2008 to middle 2009, the experiment results show that the roadbed is relative stable during the first year running of the Intercity Railway. And the comparison analyses show that both experiment results give the same subsidence rate pattern along the roadbed corridor, meanwhile the PALSAR results give better railway imaged but larger subsidence velocity standard deviation. [C2267]

### **"The mathematic model of multipath error in airborne interferometric SAR system"**

In airborne two-antenna interferometric SAR system, the returned pulse may be reflected by parts of the aircraft platform into the antennas, and this is called multipath effect which will cause oscillating phase errors and hence height errors. This paper presents a theoretical model to compute the multipath error. In this model the multipath phase error is a function of look angle or ideal phase, and the unknown parameters of the model can be estimated from distributed targets with known elevation. On the basis of the model, a method and processing procedure can be used to correct multipath error effectively, and this paper illustrates its successful application to interferometric SAR data collected by Institute of Electronics, Chinese Academy of Sciences. [C2268]

### **"Detection of rapid land subsidence of civil constructions with TerraSAR-X interferometry"**

The TerraSAR-X SAR system provides high spatial resolution and geometric accuracy imagery which supports well the mapping of the 3-D structure of large-scale civil infrastructure and its motions (4-D). In this work, we investigated the potential of TerraSAR-X observations for monitoring rapid land subsidence induced by reclamation activities. A case study was conducted in Hong Kong Disneyland Theme Park (DTP) at the Penny's Bay, one of the largest land reclamation projects worldwide. A total of 16 TerraSAR-X scenes were used in a small-baseline PSI method for retrieving residual reclamation settlement in the study area. The preliminary results indicate that a remarkably high density of high coherent point targets ( $>2,500$  PS point/km<sup>2</sup>) was identified in the reclamation area and a large land subsidence rate on the order of 35 cm/yr could be detected in the center of reclaimed land. The high detail level of deformation field as well as the high sensitivity regarding rapid residual settlement makes TerraSAR-X interferometry a remarkable potential Earth Observation technique to enable the detection of ground deformation related to the large-scale infrastructure development in reclaimed land. [C2269]

### **"CFAR detection based on decision fusion of order statistic CFAR and order statistic clutter map CFAR processors"**

In automatic target detection radars, adaptive constant false alarm rate (CFAR) processors, which determine the threshold, are examined. Two techniques are used for achieving the required CFAR. The first technique determines the adaptive threshold using range neighbouring cells which are located in sliding window. The second one is based on clutter map. In this technique, adaptive threshold is determined using the samples of test cell from previous scans which are assumed to contain no target. In this study, new techniques based on combining the two techniques in the data fusion system (DFS), are proposed. Analytical equations for homogeneous and nonhomogeneous environment are derived and performance analysis are carried out. [C2270]

### **"Estimation and compensation of ionospheric delay for SAR interferometry"**

For spaceborne SAR (Synthetic Aperture Radar) systems, the dispersive effects of the ionosphere on the propagation of the SAR signal can be a significant source of phase error. While at X-band frequencies the effects are small, current and future L-band systems would benefit from ionospheric compensation. We consider two ways to estimate the ionospheric delay in SAR signals and evaluate them on L-band ALOS-PALSAR acquisitions. [C2271]

### **"Two-Thresholds CFAR detection of the range-spread target based on scattering centers accumulation"**

This paper concerns the detection algorithms based on the HRR component of detecting range spread target in white Gaussian noise and designs a detector. By setting a higher false alarm probability, we can obtain the first threshold and the information of the target scattering centers. Then we accumulate the energy of the cell with a scattering center and make use of the energy accumulation as the test statistic. The proposed detector shows a better performance compared with that of the integration detector and two-threshold GLRT detector for all the matched filter input SNR for a small value of the  $N_c$  and almost equals that of the Integration detector for a large

value of the  $N_c$ . Both of the proposed detector and the Integration detector lose a little dB of the SNR comparing the BS\_CLRT detector while the SNR below -30dB for a small  $N_c$ . The proposed detector could be applicable to the target with few scattering centers and propitious to the practical radar systems because of the general targets only with several scattering centers. [C2272]

#### "ISAR imaging analysis of Bistatic FMCW radar"

This paper studies the basic issue of Bistatic ISAR imaging using FMCW radar under the model of Bistatic radar systems. Firstly, the echo signal of FMCW radar which in Bistatic system is analyzed, the coupling terms of range fast time and azimuth slow time which including uniquely in FMCW signal are extracted from the phase of echo signal; then its forms in range Doppler domain and influences to range profile are analyzed; Simultaneously the corresponding compensation algorithm is applied to compensate the coupling terms. The last simulations show that the proposed compensation algorithm in this paper improves the defocus phenomenon which caused by using FMJCW signal and can achieve good imaging of targets. [C2273]

#### "Simulation modelling the GPS signal propagation in the tropospheric ducts"

This paper presents a thorough research on the GPS (Global Positioning System) signal propagation in the tropospheric ducts with ray tracing approach and the split-step parabolic equation (SSPE) method. In recent years, radio wave propagation in the troposphere has been attended extensively by many researchers, especially for the radio wave propagation in the ducting environment and its effect on radar system and electronic system. Generally, strong gradients of humidity and temperature can be observed closely to the air-water interface leading to anomalous propagation effects such as atmospheric ducting. Radio system and radar of maritime operation are greatly influenced by the existence of atmospheric ducts, it can give a rise to over-the-horizon detection and form the radar detection shadow zone. This paper introduced the GPS signal as the initial field by the PE method to study the electromagnetic wave propagation characteristics in the tropospheric ducts, and given the results by the ray tracing approach as comparison at the same time. [C2274]

#### "A fast and robust method for target and background estimation in RCS measurements based on 'hyperaccurate' algebraic circle fit"

The sample data points, which are obtained in radar cross section (RCS) measurement, will distribute theoretically on a circle when the target moving along the direction of the illuminating plane wave. The radius of the circle represents the target signal and the center of the circle represents the background signal. Based on theoretical analysis and numerical simulation, we have implemented the fast 'hyperaccurate' algebra circle fitting algorithms to fit circles to measurement data points. At the same time, a robust least-median-of-squares method has been implemented to eliminate the outliers. According to the fitting accuracy requirement of the target and background, the sampling number and the sampling range are determined. Two different spheres are measured with this algorithm in Compact Antenna Test Range (CATR) and their target signals and background signals are well separated, which improves the measurement accuracy. [C2275]

#### "An improved PGA algorithm for ionosphere phase perturbation correction"

Ionosphere phase perturbation destroys the coherence of echo signal for sky-wave Over-The-Horizon Radar (OTHR) and broadens the spectrum of signal and clutter, which will exacerbate the property of low-speed object detection. PGA (Phase Gradient Autofocus) is an excellent perturbation correction algorithm with properties of logical, concise, robust etc for various perturbations. In particular, it will reduce computation work enormously. However, the estimate accuracy of PGA is degraded when the Bragg peak filter bandwidth is selected improperly, or the zero frequency components are not acquired exactly, then the iteration times should be increased. An improved PGA is proposed for ionosphere phase perturbation correction, which can realize adaptive selection of the first order clutter filter bandwidth. At the same time, a method of zero frequency abstraction based on Bragg frequencies symmetry is presented, which can decrease iteration times with same perturbation function estimate accuracy and higher computation efficiency. [C2276]

#### "Comparison of TEC measurements from DORIS with the NeQuick model"

Doppler Orbitography and Radio positioning Integrated by Satellite (DORIS) is a high precision satellite orbit determination and ranging system based on Doppler shift measurements from dual frequency signals propagated between ground stations and a satellite. The Doppler shift measured on the 2.036GHz signal and an additional 401.25MHz is a very potential means for scientific researches on ionosphere. In this paper, global Total Electron Content (TEC) measuring principle of the DORIS system is analyzed, and an algorithm is presented to derive the space variations of TEC from the DORIS ionospheric correction data. Finally comparison of TEC latitudinal profiles are done to with the NeQuick model. And some advices on the improvement of the DORIS system are

put forward for advantaging ionospheric sounding and tropospheric sounding. [C2277]

### "Influence of rain Doppler frequency on MMW Doppler fuze"

Guided weapon systems require a proximity fuze device to trigger the explosive warhead. Various proximity fuze types are currently employed. The millimeter wave (MMW) radio Doppler fuze is a potential advantage system, and it is required for a wide range of military application. In this paper, the MMW fuze Doppler Effect is discussed in the encounter course of fuze and target. The target Doppler frequencies (DF) caused by the target moving relative to fuze are calculated at 35 and 95GHz. The relationship of the target DF with the distance between fuze and target is obtained. The rain Doppler frequencies induced by the volumetric rain medium for the interested rain area around target moving relative to fuze are calculated at 35 and 95GHz. The relation of the rain DF with the distance between fuze and the interested rain area are given. The influences of rain DF on target DF are analyzed. It is shown that when the distance between fuze and target is less than about 30m, the difference between the rain DF and the target DF decrease gradually with the distance decreasing. The influences of rain DF clutter on target DF information become gradually bigger with the distance approach, especially, for heavier rainfall, a smaller target and a wider fuze radar beam. Therefore, when the encounter distance between fuze and target is less than about 30m, the influence of the rain Doppler clutter on the target Doppler signal is severe, and need be considered for the MMW Doppler fuze application. [C2278]

### "A novel polarimetric FM-CW radar system for laboratory remote sensing experiments"

With the advantage of compact, low cost and high resolution, the frequency-modulated continuous wave (FM-CW) radar equipped in airborne or unmanned aerial vehicles (UAVs) has been well applied to small-scale remote sensing measurements. To make laboratory experiment, our Key Laboratory of Wave Scattering and Remote Sensing Information (KLWSRSI) has developed a fully polarimetric FM-CW synthetic aperture radar (SAR) system. This system can be applied to analysis and demonstration of targets scattering mechanism and polarimetric radar imaging. [C2279]

### "Application of AWE to scattering analysis of the double-negative medium"

The PMCHWT equation of the double negative media (DNG) is obtained based on its constitutive relationship. And the surface currents and radar cross section (RCS) at a single frequency point is computed by Method of moments (MOM). The asymptotic waveform evaluation (AWE) technique for dispersive dielectric medium is deduced and applied to electromagnetic scattering analysis of double-negative medium within a given frequency band. [C2280]

### "Doppler profile estimation in VHF radar signals using wavelets"

The wind profile estimations are the fundamental objective of the Indian MST radar with the received signal ranging from nearly 3.5-25 Km height. A widely accepted narrow band model is considered, for the analysis of the signal received. Though the received signal SNR is stronger at lower altitudes, as the height progresses the strength becomes feeble and the noise dominates the received signal. The classical Time-Frequency analysis is made on the received signal from different altitudes and observed that the zero Doppler influence is significant at higher altitudes along with the noise. A Hilbert transform based DC bias removal is proposed in contrast with the existing 3 point MA technique. To handle the noise, in particular at higher altitudes a wavelet based adaptive denoising is proposed and found satisfactorily for the spectral cleaning of the Doppler spectrum. The validation of the proposed algorithm is made with the GPS data. [C2281]

### "Influence of the CNT length on complex permittivity of composite laminates and on radar absorber design in X-band"

Due to the high aspect ratio, CNT dispersed in polymer matrix composites makes large electric dipoles bringing about high dielectric constant, as well as dense percolation networks for electric conductivity. The length scale of the CNT has the definite influence on the internal structures of percolation networks, affecting the characteristics complex permittivity of the composites. In a Dajllenbach type radar absorber made of a dielectric composite, the optimal thickness of lossy layer is dependent on the characteristics of complex permittivity. In this work, radar absorbers composed of E-glass composite laminates with CNTs of different length scales were developed in X-band. The design result demonstrates the influence of the CNT length on complex permittivity of composite laminates and on microwave absorber characteristics. [C2282]

### "High resolution radar imaging based on compressed sensing using sparse stepped-frequency signal"

In the face of sparse aperture data imaging, a method for high resolution radar imaging based on compressed sensing using sparse stepped-frequency signal is proposed in this letter. In the signal stretching process, high resolution target echo can be acquired through second sample for the coarse-resolution range profile. Based on the sparsity of the signal in the spectrogram, we can construct a reasonable partial fourier sparse basis matrix to realize the sparsity of radar data. Then, the high-resolution range profile information is recovered by using the Orthogonal Matching Pursuit (OMP) algorithm, and the high resolution target imaging can be gained whose target sidelobe is suppressed efficiently. Finally, the results with simulation data validate the feasibility and superiority of the approach. [C2283]

#### **"Algorithm optimization of piecewise polynomial modeling for ionospheric perturbation correction"**

Ionosphere phase perturbation made the clutter spectrum spread and influenced the precision of parameter inverse analysis for sky wave sea state radar. Recently, an algorithm based on piecewise polynomial signal (PPS) phase model and high-order ambiguity function has been applied to resolve this problem. The determination of the order for the polynomial phase is critical in the applications of the algorithm. Two order-selecting methods based on self-adaptive polynomial model are proposed and verified by simulation. The results indicated that the new methods (frequency-domain and time-domain) based on the characteristics of high-order ambiguity function (HAF) transformation improved greatly in accuracy and that the amount of calculation is reduced. The polynomial order can be judged exactly, especially at low signal-to-noise ratio (SNR) when employing the frequency-domain method. [C2284]

#### **"Numerical simulation of GPR based on 3-D high-order FDTD"**

The high-order finite-difference time-domain (HO-FDTD) technique is used in the simulation of ground-penetrating radar modeling in three dimensions (3-D), which can improve accuracy and reduce the error caused by numerical dispersion effectively. To absorb waves reflected from edges we implement convolutional perfectly matched layer (CPML) absorbing boundaries. It can efficiently absorb the reflections and greatly increase the computation efficiency. The surface-based reflection and cross-hole GPR modeling are simulated, and numerical results show the efficiency of the method. [C2285]

#### **"Impacts of velocity deviation on spaceborne high-resolution DPCA SAR"**

Synthetic aperture radar (SAR) based on displaced phase center azimuth multi-beam (DPCA) allows for high-resolution wide-swath imaging, which can overcome the inherent limitation of conventional single-aperture SAR. However, to obtain a uniform sampling distribution in the azimuth direction, the system parameters must fulfill a stringent requirement. Velocity or pulse repetition frequency (PRF) deviation will result in a nonuniform sampling in the azimuth direction. To resolve this problem, multichannel reconstruction algorithms are often employed. In this paper, the periodic nonuniform sampling in the azimuth direction caused by velocity deviation is investigated and the impacts on imaging performance of spaceborne DPCA SAR are analyzed. Simulation examples and simulation results are also provided. [C2286]

#### **"A New Method of Bridge Target Detection on ASAR Imagery"**

The result of linear target detection is advantageous to the content analysis and interpretation of ASAR imagery and can be regarded as the imagery matching reference as well as the GIS platform input to realize the map automatic update. On the foundation of the previous studies, the method of bridge target detection based on Combined wavelet transformation and mathematical morphology analysis is proposed according to the good local characteristic, multi-resolution and effectiveness of wavelet transformation in this article, and the result is revised by combining the fine characteristics of different methods, which is applied to ASAR data of Zhaoqing and Zhuhai of China for carrying on the bridge detection as well as the comparative experiment with classical methods, such as Sobel and Canny etc detection operators. Results indicate that the combined methods can detect the target bridge perfectly on the direction and size, at the same time can restrain the target missing and false warning. [C2287]

#### **"MATLAB COM Component in Radar Signal Processing Application Development"**

There are amount of calculations come down to arithmetic when we develop programs of radar signal processing. These programs are developed under higher languages. These languages are inefficient on calculations and their arithmetic are not enough well-rounded. MATLAB is used for calculations and arithmetic, and the arithmetic in it is well-rounded and steady, so the development is efficient. But it must be under the MATLAB environment. The "All-purpose Function" method is introduced according to the existing COM-based MATLAB and Delphi mixed programming. This method not only increases programming efficiency but also enhances readability of code. [C2288]

### "An efficient approach for near-field three-dimensional imaging radar"

Linear array antennas (LAA) synthetic aperture radar (SAR) three-dimensional (3D) imaging has received a vibrant identification in recent years. This paper proposes a digital-beam forming (DBF)-based three-dimensional imaging algorithm for linear array antennas downward-looking synthetic aperture radar with single-transmitting and multiple-receiving (STMR) configuration. To establish the radar echo signal and to simplify the signal processing performance of imaging algorithm, equivalent phase centers are applied to simplify the range-history into monostatic configuration; then, parabola approximation is applied to decouple the three orthogonal variables which coupled to each other. Unlike traditional RMA 3D imaging algorithm imaging the scenario point to point, algorithm proposed by this paper processes the image in batch regardless the location of targets as 2D range-Doppler Algorithm does. Finally, we carried out the simulation and analysis on phase error to validate the feasibility of this algorithm. [C2289]

### "Texture-Based Estimation of Physical Characteristics of Sand Grains"

The common occurrence and transportability of quartz sand grains make them useful for forensic analysis, providing that grains can be accurately and consistently designated into prespecified types. Recent advances in the analysis of surface texture features found in scanning electron microscopy images of such grains have advanced this process. However, this requires expert knowledge that is not only time intensive, but also rare, meaning that automation is a highly attractive prospect if it were possible to achieve good levels of performance. Basic Image Feature Columns (BIF Columns), which use local symmetry type to produce a highly invariant yet distinctive encoding, have shown leading performance in standard texture recognition tasks used in computer vision. However, the system has not previously been tested on a real world problem. Here we demonstrate that the BIF Column system offers a simple yet effective solution to grain classification using surface texture. In a two class problem, where human level performance is expected to be perfect, the system classifies all but one grain from a sample of 88 correctly. In a harder task, where expert human performance is expected to be significantly less than perfect, our system achieves a correct classification rate of over 80%, with clear indications that performance can be improved if a larger dataset were available. Furthermore, very little tuning or adaptation has been necessary to achieve these results giving cause for optimism in the general applicability of this system to other texture classification problems in forensic analysis. [C2290]

### "Pulse Repetition Interval Modulation Recognition Using Symbolization"

Information on the pulse repetition interval (PRI) modulation of a radar signal plays an important role in detecting and identifying each radar signal in an electronic warfare support (ES) system. In this paper, we present a new method for recognizing the PRI modulation type of a radar signal using symbolization. The proposed method uses three key feature parameters extracted from symbol sequences in order to discriminate each PRI modulation type. The recognition capability of the method presented is verified through extensive simulations. [C2291]

### "Mining Heterogeneous ADS-B Data Sets for Probabilistic Models of Pilot Behavior"

The University of North Dakota is developing airspace within the state where Unmanned Aircraft Systems (UASs) can be flown without an onboard sense and avoid system or Temporary Flight Restrictions (TFRs). With funding from the U.S. Air Force, a mobile ground-based radar system capable of detecting aircraft operating in Class E airspace and the software to display such information to UAS operators is being developed. The current system uses an Automatic Dependent Surveillance-Broadcast (ADS-B) transceiver to detect any ADS-B-equipped aircraft within the vicinity, and a Ground Control Station (GCS) to detect and control the UAS. Once one or more ground-based radars are integrated into the system, it will also be capable of detecting non-cooperative aircraft (i.e. aircraft that aren't equipped with ADS-B transceivers) operating within the vicinity. The current system uses a portable, high-availability architecture. Since the system is intended to detect potential airspace conflicts from the ground, greater computational power is available to it than to onboard sense and avoid systems. The probability of a midair collision is dependent on the proximity of aircraft to each other, the performance characteristics of the aircraft, and the probabilities of pilots performing basic maneuvers with the aircraft. In this paper the authors present the results of data mining an ADS-B data set from 11 days in early 2010. Probabilistic models of pilot behavior were automatically extracted from the data using a genetic algorithm for cluster analysis. [C2292]

### "Evolutionary approach for trajectory generation of unmanned aerial vehicles (UAVs) over hostile terrain"

This research focuses on point-to-point path generation algorithms that take into account the stealthiness of

autonomous UAVs; generating stealthy paths through a region laden with enemy radars. The proposed approach assumes that the UAV has detailed information of the environment and the enemy radars in its vicinity. The evolutionary approach involves generating a preliminary cost-effective path consisting of a series of straight-line segments. The actual trajectory of the UAV is then refined using a series of cubic splines in lieu of the straight line segments, resulting in a cost-effective path traceable by the UAVs. The shape of the trajectory is approximated using cubic B-splines. Simulated results are presented, illustrating the potential benefits of such algorithms. [C2293]

#### **"Research on remote wireless monitoring system based on GPRS and MCU"**

In the remote, hazardous, distributed and external environment, such as radiation source, pollutant source and pipeline of petrol, water and gas, it is difficult to collect and send the necessary message in real-time by traditional monitoring ways. In response to this demand, this paper presents the design of wireless remote monitoring system solution that is based on the GPRS(General Packet Radio Service)and the MCU(Micro-programmed Control Unit). The reliability and real-time performance of the system have been proved through practical application in the engineering project. [C2294]

#### **"A study on optical reflectivity of laser treated aircraft surfaces"**

For UAVs on mission that involve flights into region or environment with radar detection systems, the risk of detection of the UAVs is inevitable. The situation is detrimental particularly if the flight space of the UAV is in hostile region. Various computational methods have been proposed to show positive results in mitigating the risk of radar detection. Another potential avenue to improve on the risk of radar exposure is through modification of the vehicle's surface texture to reduce the optical reflectivity. In this paper, we consider the use of laser texturing as a means to enhance the stealth of a UAV carrying mission in a hostile territory. Although the results are preliminary, they gave a clear indication of the potential of laser texturing in stealth mission planning. In general, the results show that the roughness measured in terms of depth of the grooves patterned onto the surface has a direct correlation to the surface reflectivity. [C2295]

#### **"Research and implementation of dechirp pulse compression processing algorithm"**

In the processing of digital pulse compression for wideband LFM (Linear Frequency Modulation) signal, the dechirp algorithm can effectively reduce the sampling frequency and then reduce the pressure upon following signal processing and storage. By means of theoretical simulations, this paper analyses how to choose the sampling frequency for dechirp pulse compression system, and demonstrates the factors affecting dechirp performance-sampling frequency, time delay and imbalanced SNR. Besides, we implement a dechirp algorithm on FPGA platform and provide a reference of how to choose signal bandwidth, sampling frequency and the appropriate digital pulse processing method in the design of radar system. [C2296]

#### **"An evolutionary algorithm for multiple waypoints planning with B-spline trajectory generation for Unmanned Aerial Vehicles (UAVs)"**

In this work, we focus on multiple waypoints planning that take into account the stealthiness of autonomous UAVs; generating stealthy waypoints through a region laden with enemy radars. The important goal of waypoint planning for Unmanned Aerial Vehicles (UAVs) is to generate an optimal path for UAVs to visit all of the specified waypoints. We use the Traveling Salesman Problems (TSP) optimization to solve the visitation sequence planning problem for UAVs. The aim is to find the optimal solution that minimizes the distance travelled by the UAVs with low radar risk; under the strict constraints that each waypoint is visited exactly once by the UAVs, and the flying altitude does not exceed the specified threshold so as to minimize the radar exposure. The generated solution is then refined using a series of cubic splines in lieu of the straight line segments, resulting in a cost-effective path traceable by the UAVs. The shape of the trajectory is approximated using cubic B-splines. Simulated results are presented, illustrating the potential benefits of such approach. [C2297]

#### **"Multi-objective design of monopulse antenna with Two-lbests based multi-objective particle swarm optimizer"**

Monopulse antennas form an important methodology of realizing tracking radar and they are based on the simultaneous comparison of sum and difference signals to compute the angle-error and to steer the antenna patterns in the direction of the target (i.e., the boresight direction). In this study, we consider the synthesis problem of difference patterns in monopulse antennas from the perspective of Multi-objective Optimization (MO). The synthesis problem is recast as an MO problem, where the Maximum Side-Lobe Level (MSLL) and Beam

Width (BW) of principal lobe are taken as the two objectives to be minimized simultaneously. The approached Pareto Fronts are obtained for different number of elements and subarrays using the Two-lbests based multi-objective particle swarm optimizer (2LB-MOPSO). The quality of solutions obtained is compared with the help of Pareto Fronts on the basis of the two objectives to investigate the dependence of the number of elements and the number of sub-arrays on the final solution. Then we find the best compromise solutions for 20 element array and compare the results with standard single objective Particle Swarm Optimization (PSO) that has been reported in literature so far for the synthesis problem. Our experimental results indicate the 2LB-MOPSO yields much better final results as compared to the standard single-objective approach over all considered test cases.

[C2298]

### "The design of granary environmental monitoring system based on ARM9 and ZigBee"

Grain is an important strategic resource. Due to seasonal production, there are many problems in the stored procedure. This article designs an environment monitoring system of the granary combining Embedded and ZigBee wireless sensor network technology. In the actual situation of the design, using ZigBee wireless sensor network to complete Multi-point acquisition and transmission of environment parameters, using ARM9 to achieve precise control of the barn environment as system data controller; and using GPRS to achieve the system's remote control, it greatly improves the flexibility and scalability of the warehouse management. [C2299]

### "Convex parabolic reflector antenna design with cosecant-squared radiation pattern for microwave radar systems"

In this paper, symmetric and cosecant-squared radiation patterns are obtained by using parabolic reflector antennas which have different geometrical structures. The analytical regularization method (ARM) is used to solve the problem of E-polarized wave diffraction by parabolic shaped perfectly electrical conductive (PEC) cylindrical reflector with finite thickness. The initial boundary value problem is reduced to the infinite algebraic system of the second kind, which is an equation that can in principle be solved with any predetermined accuracy by means of the truncation number. The parabolic reflector is fed by a horn antenna which is designed to illuminate the reflector aperture efficiently. In contrast to traditional parabolic reflector structure that is used to obtain pencil beam, the upper side of the reflector geometry is designed as convex to obtain cosecant-squared radiation pattern and the obtained far-field radiation patterns are investigated. [C2300]

### "A novel application for sum-difference pattern detection of signal direction using time-modulated linear arrays"

A novel application using the time-modulated linear arrays (TMLAs) in determining the direction of unknown signal with sum pattern and difference pattern for tracking radar is presented in this paper. An optimized time sequence from the differential evolution (DE) algorithm is presented to produce multiple beams simultaneously. Based on the multiple beams of the sum patterns and their corresponding difference patterns at different sidebands, the directions of incoming signals can be detected. The comparison of the performance between TMLA and conventional antenna arrays under the same parameter demonstrates that the accuracy of the direction of target in TMLA is relatively high, and the range of angle detection is several times larger than those of the conventional antenna arrays. [C2301]

### "Design of an ocean atmospheric duct signal processor"

The atmospheric refractive section plane retrieved from radar sea clutter is of importance for the enhancement of military naval radar. In this paper, an atmospheric duct signal processor with hardware of an intermediate-frequency board and a high-speed DSP board, besides the arithmetic of clutter suppression and sea clutter extraction, have been designed and implemented to get radar sea clutter power, which works synchronously together with a Doppler weather radar in the science experiment of atmospheric duct sounding. Results show that this signal processor can perfectly implement the requirement of radar sea clutter and its real-time arithmetic processing. [C2302]

### "Adaptive pulse compression via maximum signal minus interference level in clutter environments"

Standard matched filter for pulse compression causes high range sidelobes, which may mask neighboring small targets. The adaptive pulse compression (APC) based on reiterative minimum mean square error (RMMSE) can mitigate the range sidelobes in white noise. However, its performance degrades in clutter environments. In this paper, an APC algorithm based on maximum signal minus interference level criterion (MaxSMIL) is proposed, in which the result of signal power minus interference power is maximized so that interferences including range sidelobes, clutter and noise are suppressed adaptively. Simulation results show that the proposed algorithm

outperforms the APC based on RMMSE in Weibull clutter environment. [C2303]

#### "A low-complexity C-band radar for non-invasive respiration measurement"

An interferometric radar operating between 6 and 9 GHz for non-invasive measurement of the respiration rate, is presented. An adaptive RF front-end tracks slow body movements by changing the operating frequency such that the sensing system always operates in its optimum point. Experimental results have been obtained from human beings and the good correlation between the radar signals and a reference signal obtained from a conventional respiratory sensor show the validity of this approach. [C2304]

#### "Evaluation to the performance of MTI radar anti-passive jamming"

The signal processing elements and working course of MTI radar are analyzed in this paper, and theory research is also done to the element and performance of double canceller. Aiming at the Gaussian power-spectral clutter with differ velocity value and variance, this paper calculates the performance of MTI system quantitatively and the corresponding improvement factor of anti-passive jamming is achieved, the performance of MTI radar is estimated synthesized. [C2305]

#### "Subspace in signal processing and communications"

Among the most powerful and applied mathematical tools, subspace has had a wide impact in signal processing and communications, and it continuously has a magic power for solving future problems. In this talk, I will present some of the triumphant examples of subspace that I have encountered in the past 25 years. These examples range from high-resolution processing of radar signals to blind system identification for communications and to smart relays for next generation of wireless networks. [C2306]

#### "Design of SAR tomography experimental system"

In this paper, a ground-based experimental system of SAR tomography is proposed in detail. Based on the analysis for the properties of signal in the height direction of SAR tomography 3-D imaging system, the effect and relationship of parameters related to resolution in the height direction are discussed, and proper experimental system parameters are proposed. By using the general SAR tomography imaging algorithm in the experiment, the experimental system is proved feasible. [C2307]

#### "Binary orthogonal code design for MIMO radar systems"

Multiple Input Multiple Output (MIMO) radar can effectively improve radar performance by transmitting specially designed orthogonal signals. A novel algorithm is presented to design binary orthogonal code for MIMO radar system. The proposed algorithm employs the Walsh function to maintain the orthogonal property of signals. The binary orthogonal code set is obtained by executing synchronal random exchange in column and random selection from rows to coding template, with using Genetic Algorithm (GA) for optimization. The simulation results show that the algorithm is feasible. [C2308]

#### "Parameter selection of MIMO radar under the long time integration"

Long time integration is a common work mode for multiple-input multiple-output (MIMO) radar. In this mode, the accumulation effect is seriously affected by range migration. To solve this problem, we derive an expression, which describes how the accumulation output changes with the target velocity, bandwidth, and other factors, based on the MIMO radar moving target echo model. This expression quantifies the relation between the range migration and the influence factors. It can be used to determine the range of the target velocity in which the motion compensation is needed. Further, through appropriate parameter selection, such as choosing a proper transmission bandwidth etc., the influence of the range migration on accumulation output is minimized. The correctness of the theoretical results is verified by simulations. [C2309]

#### "A model of non-coherent airborne MIMO space-time adaptive processing radar"

Compared to single-input multiple-output (SIMO) radar, airborne multiple-input multiple-output (MIMO) space-time adaptive processing (STAP) radar transmits mutually orthogonal or non-coherent waveforms. The waveform diversity increases degrees of freedom (DOFs) of MIMO STAP radar and results in the variation of clutter characteristics. To make things worse, there exists many non-ideal factors in practical project that affect performance of MIMO STAP. Considering all such situations, we derive the covariance matrix of echo signals by utilizing waveform covariance matrix (WCM) and error covariance matrix tapering (CMT) to simplify the MIMO STAP in this paper. Signal to interference plus noise ratio (SINR) performance simulation results verify that

MIMO STAP radar has a better spatial resolution than SIMO radar generally and improving in orthogonality of transmitting waveforms can obtain a better SINR performance. [C2310]

#### "A novel airport surface surveillance based on multi-video fusion"

Airport surface surveillance is an important issue guaranteeing the safety. Traditionally, this depends on the SMR (Surface Movement Radar) or ASDE (Aerodrome Surface Detection Equipment). However, these equipments are very complex and expensive, which is not suitable for the simple airports. On the other hand, video is a type of common and cheaper equipment and can be mounted largely in the airports. If the video also provides the ability of motion detection while guaranteeing the precision, it can be yet regarded as a substitute for non-cooperative radar like SMR and ASDE. This paper proposed such a solution based on optical flow field detection, dynamic fuzzy clustering and multi-sensor fusion. Experiments show that the solution is not only feasible but also with high detection precision. [C2311]

#### "Analysis of anti-interception performance of MIMO radar"

As a new radar system, MIMO radar has become the hotspot in radar research. Because the key point of radar's viability in battlefield is its RF stealth ability. Though the analysis of radar transmit power and the LFM signal detect technique based on time-frequency analysis, this paper makes a discussion on the discrepancy of the anti-interception performance between MIMO radar and conventional phased array radar, and therefore draws some meaningful conclusions. [C2312]

#### "Enhanced supervised neighborhood preserving embedding for radar target recognition"

Recently, the computer vision and pattern recognition community has witnessed the rapid growth of a new kind of dimensionality reduction method, namely manifold learning. Among them, neighborhood preserving embedding (NPE) is one of the most promising techniques, which can be performed in either unsupervised or supervised mode. In this paper, a new dimensionality reduction algorithm, called enhanced supervised neighborhood preserving embedding (ESNPE), is proposed. ESNPE can enhance the local within-class relations by taking into account class label information. Moreover, neighbors are found according to a new distance metric instead of Euclidean distance, aiming for better generalization. Experimental results on radar target recognition with range profiles indicate the superior performance of the proposed method, compared with PCA, NPE and supervised NPE (SNPE). [C2313]

#### "On the edge based artifact mitigation in wavelet packet transform for enhancement of spectral estimation"

Wavelet packet transform is a recent addition to the rich arsenal of the signal processing tool box. In this article, we investigate the application of wavelet packet transform as a novel spectral analysis tool. The estimator is realized by a tree structure obtained by cascading a pair of half-band high and low pass filters. The main attraction for wavelet packets (WP) is the tradeoffs they offer in terms of satisfying various performance metrics such as frequency resolution, side lobe suppression and variance of the estimated power spectral density (PSD). Furthermore, the state of art in the application of wavelet transform for spectrum estimation is carried forward by bringing in a few optimizations which correct undesirable edge based artifacts that occur in the standard implementations. The systems are evaluated through simulation studies the results of which show that the proposed wavelet based approach offers great flexibility and adaptability apart from its performances which are significantly better than Fourier based estimates. [C2314]

#### "Evolutionary Computational Tools Aided Extended Kalman Filter for Ballistic Target Tracking"

Tracking a ballistic target in its reentry mode by considering the radar measurements is a highly complex problem in nonlinear filtering. Kalman Filter (KF) is used to estimate the position of target when the measurements are corrupted with noise. If the measurements are nonlinear (radar measurements) then Extended kalman filter (EKF) is used. For obtaining reliable estimate of the target state, filter has to be tuned before the operation which is offline. Tuning an EKF is the process of estimating the process noise covariance matrix (Q) and measurement noise covariance matrix (R). This paper presents a new method of tuning the EKF using different evolutionary algorithms. [C2315]

#### "Frequency based oscilloscope triggering scheme"

This paper presents a novel frequency based oscilloscope triggering technique for measurements involving complex waveforms that are challenging even today. Proposed technique is capable of providing stable triggering even in the case of complex periodic waveforms category where commonly used level triggering scheme fail to

perform adequately and may be used in problem of estimating many typical signal processing situations, such as Doppler estimation of radar and sonar returns, vibration measurements, geophysical data processing, and surveillance observations of the electromagnetic spectrum. For stable display of a signal in an oscilloscope, it must be triggered at its base frequency. In this technique, frequency of all harmonics present in test signal is retrieved using FFT and the base repetition rate of the signal is found by selecting the frequency of lowest harmonics present in the test signal. Numerous complex test waveforms are generated and their harmonic contents are analyzed in the virtual environment of LabVIEW™ software. To verify the efficacy of the proposed technique, it is implemented using LabVIEW™ software and PCI DAQ card. It is found that the proposed technique is equally effective in detecting the base repetition rate of complex as well as simple waveforms. Technique proposed in this paper would be of interest to instrumentation design engineers. [C2316]

#### "Quantum dash mode-locked lasers for millimeter wave signal generation and transmission"

In this paper we present the remarkable characteristics of quantum dash mode-locked lasers and how they could be used for low phase noise signal generation, for high data rate wireless transmission and radar in the millimeter wave frequency range. [C2317]

#### "Radar cross section analysis of various objects and RCS optimisation"

This work is based on the analysis and optimization of the radar cross section that is indispensable for today's defense industry. In this study, radar cross section analysis of many objects from simple geometric structures to military vehicles are made. Nowadays, when the electronic war technology is growing rapidly in, the stealth technology in radar systems became one of the indispensable factors of the defence industry and is used widely in air, land, sea and undersea platforms. Usage of these techniques that reduces the detection probability of vehicles that are very important for a country such as ship, plane, helicopter, submarine, etc. is a very important technology in defence industry. On this scope by working on stealth technology the methods for reducing radar cross section was investigated detailed. [C2318]

#### "Parallelized Physical Optics computations for Scattering Center Models in radio channel simulations"

Scattering Center Models (SCMs) are an approach to efficiently characterize electromagnetic scattering of complex shaped objects in terms of a distribution of equivalent sources. SCMs have been widely used in the area of radar target modeling, particularly for object characterization and classification. Recently, the SCM approach has been adapted to model the electromagnetic properties of vehicles embedded in a comprehensive environment for the simulation of automotive radar channels. In this paper the application of SCMs for deterministic simulations of communication channels in automotive environments is presented. The main advantage of this concept is a drastic reduction of complexity for the ray tracing simulations. Instead of using a full geometrical description of the scene, the most complex objects are replaced by an equivalent SCM and a strongly simplified surface model. The SCM of an object is determined in advance, independent from the surrounding environment. In order to achieve a precise parameterization of individual Scattering Centers (SC), the Physical Optics (PO) approximation can be applied. Unfortunately, in contrast to a parameterization based on the Geometrical Optics (GO) contribution only, this approach requires field computations for a large number of observation directions. To handle this computational challenge, a parallelization concept is presented, which is based on multi-core architectures and on the utilization of Graphics Processing Units. [C2319]

#### "Emerging Trends of Computational Grid Based Near Real Time/Real Time Flood Assessment and Forecasting Models"

From recent past, the computational Grid based flood assessment and forecasting models is getting emerged as an interdisciplinary integrated 'near real time/real time model'. Many such, Grid based flood assessment and forecasting model supports in logically integrating various components of flood related scientific simulations such as Metrological, Hydrological, Hydraulic, RADAR, LIDAR Remote Sensing, GIS, Satellite Communication and other technologies and derives the end result which can be straight away used by the disaster mitigation team member/end user. This paper mainly brings out the emerging technological trends observed in the fields of computational Grid based flood assessment and forecasting models by surveying the flood forecasting model of 'Cross Grid' as well as the operational flood model of ESA Grid. Details reflecting the technology trends and simulation methods adopted by the 'GARUDA Grid' flood assessment experimental model have been given. [C2320]

#### "Advantage of non-etching adhesion promoter on high frequency signal loss"

In the age where demands for mobile electronic devices are ever increasing, the propensity for an exponential growth of wireless data transfer is inevitable. The massive data exchange is driven by rise in the signal frequency and the trend having high frequency applications is imminent. The prolific examples of high frequency applications include the next generation 4G mobile phones, satellite communications, Wi-Fi LAN, millimeter wave radars on automobiles, CPUs and GPUs. As the frequency signals carried by electronic devices continue to elevate, there is a greater risk of compromising the signal integrity. The main contributors of high frequency signal loss are the dielectric material and conductor which signals travel on. In order to minimize signal loss, material suppliers have been developing reliable high speed dielectrics with low dissipation factors and dielectric constants. On the other hand, the conductor loss of high frequency signals is largely dependent on the surface profile and roughness of the tracks. Uneven conductor surface profile and track roughness is a product of using conventional etch-based adhesion promoter. While the conventional etch-based adhesion promoters cause no major functionality issues to the manufacturing of commodity PCBs, the impact on the signal integrity for high frequency applications can be an issue. As signal frequency escalates, a phenomenon known as the "skin effect" propagates the signals on the track surface. The coupled impact of the "skin effect" and conductor roughness is an upsurge in resistance that results in signal loss. Contrary to the etch-based adhesion promoter, non-etching adhesion promoter (NEAP) can offer a flat conductor surface and a controlled track width. This can in turn reduce the high frequency signal loss significantly. The paper makes use of a commercially available non-etching adhesion promoters and copper foils in order to investigate the influence of surface roughness on high frequency signal loss. The characterization is carried out through the use of computer simulation as well as actual sample measurement in order to determine those factors which dominate the overall loss performance. [C2321]

### "The Application of MPI-TigerSHARC in SAR Processing System"

The demand of processing speed in SAR signal processing is huge and requires more computational power than what a single processor can provide. To address these demands, an implementation of MPI (Message Passing Interface) based on link DMA for TigerSHARC DSPs is introduced in this paper. Porting MPI to the embedded system will enhance application portability and make parallel programming much easier. This paper presents a real application of range-Doppler algorithm in SAR processing system. The result shows that MPI is suitable for parallel programming, especially suitable for processing large volume of data. [C2322]

### "A Novel Application of Support Vector Machines to Detect Targets"

In this paper we develop a novel pulse radar detection scheme using Support Vector Machines (SVMs). SVMs are a powerful tool for pattern classification. Exploiting this, we design a SVM for pulse radar detection of targets embedded in noise. An adaptive pre-processing stage is included when the echoes are very weak. It is observed that the signal-to-side lobe ratio obtained is much higher compared to neural network based pulse radar detection schemes. We further examine the noise tolerance, range resolution ability and Doppler tolerance of the new algorithm for pulse compression, and compare it with the ones available in literature. [C2323]

### "FFT Simulation and Implementation in TMS 320C6713"

This paper deals with simulation and implementation of the FFT algorithm in TMS 320C6713 as a radar signal processor unit. Furthermore it has provided a new method for real-time implementation of the Fast Fourier Transform algorithm that is a very time consuming calculation, in most DSP processors. There also has been indicated a method for conducting several simultaneous operation in a guideline cycle including several accessing to the memory, producing several address using pointers and hardware multiplication. Using Ping Pong technique also didn't result in loss of any sample and so system is working as Real Time. By combining Ping Pong technique and rotating buffers this paper will reduce the speed of calculation which is very important for radar processors. Results of our innovation indicates a very good performance of the method provided in designing and making a signal processing unit of a radar system which has been tested in a real environment. [C2324]

### "Coin insertion technology for PCB thermal solution"

The thermal management of electronic products is always a headache to the high power electronics design engineer. Since all electronic components are assembled on the PCB, it's important to develop a good solution to dissipate the heat from PCB to the chassis with conduction method. There are many material and process used for PCB thermal dissipation in the industry now. Some of them like IMS (Insulated Metal Substrate), can be used only for simple circuits like LED substrate. Some like metal bonded PCB that is heavy and expensive. The standard thermal pad/via is not capable for high thermal density components like QFN. It is necessary to develop a simple PCB construction to solve the thermal problem. This paper introduces new design which embeds a small piece of metal coin inside PCB under the high power components. The attached component, like

power transistor, sits on the exposed coin surface of the new developed PCB. During operation, the heat created from the components can be effectively dissipated through the coin to another side of the PCB. The heat can then be dissipated to the chassis of equipment or another heat sink. The system thermal problem can be solved for the low thermal resistance of the heat path. Since the coin is small and light weight, it has great advantage of lower cost and very good performance. Even component with dimension as small as 3 mm long can be applied. Besides, the coin can be electrically connected to the PCB ground layer with different methods. Its electrical performance runs very well in power amplifier PCB for telecommunication industry. This paper will also simulate the thermal performance of different PCB thermal design, include four different coin insertion constructions and its comparison with thermal via PCB and IMS laminate. This technology has been used in the PCB of cell phone base station, point-to-point radio and military radar system. It is also under testing for IC substrate application now. [C2325]

#### "UWB microwave imaging via modified beamforming for early detection of breast cancer"

Ultra-wideband (UWB) microwave imaging is a promising technique for detecting early stage breast cancer, which exploits the significant contrast in dielectric properties between normal and malignant breast tissues. In this paper, we have proposed a new modified compensation method and beamforming technique for microwave imaging. We used a three dimensional (3-D) Finite Integration Technique (FIT) based breast model, with normal breast tissue, supported on a layer of chest muscle and covered by a thin layer of skin. A small sized (1 mm diameter) tumor is placed within the breast tissue layer. A pair of rounded-edge bow-tie antennas at crossed position is used for transmitting and receiving microwave signals. This antenna pair is then placed at different positions over the breast surface and the incident and backscattered signal at each position are stored. Backscatters are then processed to eliminate artifacts. Finally they are passed through the beamformer and an image is formed. The beamformer is designed with adaptive weighting to compensate both propagation attenuation and lossy medium effect. Despite using the traditional delay-and-sum approach, new delay-and-product technique is used in beamforming. This modified beamforming approach is shown to outperform its previous counterparts in terms of resolution and sensitivity. [C2326]

#### "Dynamical Weather Radar Beam Blockage Correction"

Error of quantitative rainfall estimations due to partial or total weather radar beam blockage is important in complex orographic areas. A simple method named dynamical weather radar beam blockage correction different from the operational "look-up" table method is presented. The dynamical correction method is implemented with the multiplicative factor between two antenna elevation angles. Case study of quantitative rainfall estimation shows that the dynamical beam blockage correction is effective if the beam blockage azimuths are less than 10 degrees. [C2327]

#### "Fuzzy Logic-Based Image Fusion for Multi-view Through-the-Wall Radar"

In this paper, we propose a new technique for image fusion in multi-view through-the-wall radar imaging system. As most existing image fusion methods for through-the-wall radar imaging only consider a global fusion operator, it is desirable to consider the differences between each pixel using a local operator. Here, we present a fuzzy logic-based method for pixel-wise image fusion. The performance of the proposed method is evaluated on both simulated and real data from through-the-wall radar imaging system. Experimental results show that the proposed method yields improved performance, compared to existing methods. [C2328]

#### "Low Altitude Target Tracking Algorithm with Acoustic Wireless Sensor Network"

For the problem of low altitude target tracking with acoustic wireless network, the signal propagation time delay effect must be considered. The target has been far away from its emitting position when the signal is received by sensors. This effect leads to synchronous sensors in the measurement space sample asynchronously in the state space and the sample frequency becomes unknown and time varying. In this paper, a batch type distribution fusion algorithm is proposed which consists of two steps. First, a linear search method is used for estimating the time-varying state transition time which is the parameter of least square solution for the initial state. This initial state is used again to optimize the state transition time until the iteration termination condition is satisfied. Second, a time register procedure and a distribution fusion technique are presented to obtain the global track. Simulation results verify the efficiency of the proposed method. [C2329]

#### "Compressive Sensing for Radar Sensor Networks"

Motivated by recent advances on Compressive Sensing (CS) and high data redundancy among radars in radar sensor networks, we study CS for radar sensor networks. We demonstrate that the sense-through- foliage UWB radar signals are very sparse, which means CS could be applied to radar sensor networks to tremendously

reduce the sampling rate. We propose to apply SVD-QR and maximum likelihood algorithms to CS for radar sensor networks. SVD-QR could vastly reduce the number of radar sensors, and CS is applied to the selected radar sensors for data compression. Simulations are performed and our compression ratio could be 192:1 overall. [C2330]

### "Performance Analysis of Communications & Radar Coexistence in a Covert UWB OSA System"

Far-field target detection, multi-sensor communications, and security are essential requirements of first-emergency networks. A radar-communications system is a potential opportunistic spectrum access (OSA) solution, harnessing the coexisting advantages of radio detection and ranging (RADAR), and wireless communications. A multi-functional waveform has been designed, by embedding an Orthogonal Frequency Division Multiplexing (OFDM) signal within a spectrally notched ultra-wideband (UWB) random noise waveform. Extending that development, this paper analyzes the waveform's Bit-Error-Rate (BER) and Ambiguity Function (AF) formulations to demonstrate its OSA ability, that offers reliable multi-user communications, and high range and Doppler resolution in target detection. We further conclude that up to 30% of the available UWB bandwidth can be simultaneously utilized for concealed data communications without adversely affecting radar performance or its physical layer covertness. [C2331]

### "Advances in DSP design tool flows for FPGAs"

This paper highlights recent advances in digital signal processing (DSP) design tools for Field-Programmable Gate Arrays (FPGAs), concentrating on model-based design high-level synthesis. Next generation FPGA model-based design tools provide a mechanism for abstracted design definition at the algorithmic rather than implementation level. The tools make use of FPGA structural and timing knowledge, and of mathematical and graph theory techniques to optimize and technology map the algorithm to a pipelined FPGA implementation, controlled by high level parameters and threshold settings. Such tools allow simple design space exploration and retargeting of algorithms to different device families. This design-once and retarget as required method improves productivity over manual hardware description language (HDL) coding, especially for projects which are subject to change. The simple design style, optimized generated hardware and productivity in design change and implementation exploration are highlighted with two examples; a direct radio-frequency (RF) radar design and a simple 8 by 8 beamforming design. [C2332]

### "Innovative ad-hoc wireless sensor networks to significantly reduce leakages in underground water infrastructures"

This paper presents an ICT solution to overcome the problem of water dispersion in water distribution networks. Leakage prevention and breaks identification in water distribution networks are fundamental for an adequate use of natural resources. Nowadays, all over the world, water wasting along the distribution path reaches untenable percentages (up to 80 % in some regions). Since the pipes are buried within the terrain, typically only relevant breaks are considered for restorations: excavations are very expensive and consequently the costs to identify the position of the leakage or just the position of the pipe itself are too high. To address this problem, and simplify the leakage identification process, the authors have designed a wireless network system making use of mobile wireless sensors able to detect breaks and reveal unknown tracks and monitor the pressure spectrum of the fluid flowing in the pipe. The sensors transmit the acquired data from the terrain to the surface by use of a wireless connection. On the surface ground there are stations that receive the signal, process it, and communicate with a central unit where necessary intelligent signal processing techniques are used to detect leakage sources. Compared to other leakage detection solutions already available in the market (such as: Ground penetrating radar (GPR), pure acoustic techniques and tracer gases), the proposed technique appears very efficient and much more inexpensive. [C2333]

### "Waveform Design and Optimization in Radar Sensor Network"

We investigate the use of information theory to design waveforms for the measurement of extended radar targets in radar sensor networks (RSN). The different channel gains for transmitting signals from different radar sensors are introduced to model the radar system channel. Given the transmitting signals, we optimized the estimation waveforms that maximize the mutual information between a target ensemble and the received signal within additive Gaussian noise given the transmitting signals so that characteristics of the target could be well recognized. We also study the maximum mutual information with the constraints of the number of radar sensors, waveform energy and duration, which could be taken into consideration when waveforms are designed for RSN. [C2334]

### "Extraction method of large-scale linear objects from SAR images"

Public safety concerns have been raised by potential safety problems due to deformation of infrastructures such as railways, highways and bridges. Monitoring the deformation of large-scale man-made linear objects (LMLO) by permanent scatters (PS) interferometry would be critical to prevent this kind of disasters. However, the estimation of LMLO deformation is sensitive to the influence of those random PS from nearby natural objects. Thus, extraction of LMLO from PS images is the necessary condition for an accurate monitoring of LMLO deformation. In this paper, a new procedure of extraction LMLO from SAR images is proposed based on classification, morphological operations and line recognition methods. A preliminary step, merging optical image, would be identification of man-made objects regions from background. Image of permanent scatters (PS) points from PALSAR data will then be masked to remove unrelated PS points. Then a set of morphological operations and line feature extraction methods are performed to connect PS points continuously distributed along the linear target. This method is successfully applied to a PALSAR image to extract the Lantau Link highway (LLH), Hong Kong and the experiment result demonstrates its validity on comparison with the ground truth in optical image.

#### "An improved BP algorithm for high-resolution MIMO imaging radar"

The back-projection (BP) algorithm is a popular imaging method. Nevertheless, there exists a difficulty that the cross-range resolution acquired by the standard BP algorithm is dependent on the bandwidth of transmitted signal when the BP algorithm is directly used to the multiple-input multiple-output (MIMO) radar for imaging a target in the cross-range direction without any variation. In this paper, an improved BP algorithm is presented for high-resolution MIMO imaging radar to avoid the difficulty associated with the standard BP algorithm.

Furthermore, the theoretical expression of the cross-range resolution associated with the improved BP algorithm is given. Different from the standard BP algorithm, the cross-range resolution acquired by the presented BP algorithm can be independent on the bandwidth of transmitted signal since the presented algorithm can straight an integration curve and make the received echoes on the integration curve be focused by phase aligning to avoid the truncation error produced by the range resolution value. Simulations based on synthetic data are provided for testing the presented method. [C2336]

#### "Design of World Expo tour sites guide system based on RFID technology"

Facing growing groups of tourists, it's obviously that the traditional manual guides can't meet the needs of each visitor. Through scientific and technological means, an electronic smart guide system based on RFID technology is establishment, Expo visitors can get more information include audio and video about comprehensive equipment, exhibits, galleries by the system. It is an important means to improve the quality of services and the degree of satisfaction for tourist. In this paper, we propose a RFID application in smart guide system that voice explanation is played automatically with no need for manual operation; describe the components of guide system, software process and a feasible plan for its upgrade. An electronic smart guide system based on RFID is designed for Shanghai World Expo. [C2337]

#### "Implementation of battlefield electromagnetic environment ontology visualization system"

The battlefield electromagnetic environment generated by the electronic equipment or system in the battlefield, has a positive or negative effect on electronic equipment. The battlefield electromagnetic environment has an important influence on modern warfare. Considering the difficulty of comprehension and operation on battlefield electromagnetic environment ontology, a visualization system of battlefield electromagnetic environment ontology is designed and implemented which can perform importing and exporting the ontology files, ontology management, ontology operation as well as ontology visualization. [C2338]

#### "Extraction of wetland combining with Radarsat and HJ data of Yellow River Delta"

Wetland types of Yellow River Delta are various and serious phenomena of 'same object with different spectrum' and 'different object with same spectrum' is one of the reasons caused low classification accuracy. Combination with multi source images is an efficient method to mitigate this influence. In the paper, principal component transform was carried out to Radarsat four polarization data and the first principal component were fused with HJ images based on HIS, Brovey, PC and Wavelet transform. A maximum likelihood classifier was applied to extract wetland information of Yellow River Delta. The experiment results demonstrated that HIS transform performed well than the others and outstood the wetland information. The results also showed that the classification accuracies of HIS merged images and the stacked images were highest, through combining two different source data to make good use of information. [C2339]

#### "A visualization method of measuring the effectiveness of early warning and detection network based on simulation"

Computer simulations are often employed by operational research analysts to evaluate the relative effectiveness of various combinations of military equipment and tactics (i.e., options) for specific tasks within a conflict scenario. In order to value the effectiveness of Early Warning and Detection (EW&D) network, this article proposing a visualization method of Measuring the Effectiveness based on simulation. This method switches the problem into the task with clear military meaning, appraises the degree of completion of these missions respectively, and represents it visually. In this paper, the process of the evaluation based on simulation is discussed, in addition evaluation indicators and representative missions are presented. At last, we verify the method by analyzing an example briefly that proves the practicality of the method. [C2340]

### "Research on imaging simulation of airborne fire control radar for simulated training"

A uniform simulation method was presented to realize ground imaging of RBM, DBS and Spotlight SAR for simulated training. The three imaging modes are widely used by modern airborne fire control radars. Considering the requirement of training real-time and the simulated images used for pilots observation, this method computed RCS images of ground based on the facet model and fused the radar image features, such as shadows, layovers and speckles, to get simulated images directly. The problem of dynamic image display in GL Studio was solved at the same time. Specially, the reality and real-time of this simulation method was evaluated qualitatively and quantitatively. Experimental and probational results show that the radar simulated images obtained by the proposed method are competent for the simulated training in army. [C2341]

### "High performance element computing architecture"

This paper will describe High Performance Element Processing Architecture as a basis for large array RADAR/Communication systems, enabling system designers to increase levels of digitization by using open standards based hardware. [C2342]

### "Subspace compressive GLRT detector for airborne MIMO Radar"

In this paper, the design of a subspace compressive GLRT (SSC-GLRT) detector has been pursued for MIMO airborne radar system when the secondary sets of data are available in addition to the primary one. It is observed that with very reduced amount of measurement data at sub-Nyquist rate that is equal to the number of virtual bi-static radar in the presence of a single target, SSC-GLRT provides the same performance as the conventional GLRT with much larger length of the data, i.e., an order of magnitude higher given by the product of the number of elements in the received antenna array and coherent pulse interval (CPI). Therefore, SSC-GLRT is much energy efficient and useful in the scenario where the computational complexity becomes a burden. Also, this paper illustrates an elegant way of mapping the angular and Doppler domain to an one dimensional discrete vector for the formulation of compressive sampling (CS) based  $\ell_1$  reconstruction of the signal subspace when it is unknown so that it can successively be used in SSC-GLRT. The simulation example further corroborates the effectiveness of the proposed SSC-GLRT detector. [C2343]

### "Using a P2P architecture for voice and radar transportation in critical command and control systems"

The Brazilian air traffic service is constituted by a civil and a military organization, which provide tracking (radar), voice and data communication (VHF, UHF and HF) services, through an integrated network. To optimize the management of its air traffic system, Brazil divides the airspace into four independent Regional Centers. In each of these regions, the existing sensors (radars and radios) send information and products to only one of the Regional Centers, forming a star topology. In case of impediment in one Regional Center (eg, electrical failure or terrorist attack), even if the service node is able to send its information, the Regional Center will collapse, since there is no means to process the information generated locally. The solution presented in this article, develops the redundancy of the system through the digitization of audio and radar signals and its subsequent transport using an peer-to-peer network. To validate this proposal, experimental flights were developed. In these flights, aircraft flying over the city of Manaus (in the center of Amazonia) were coordinated by a center installed in Brasilia, which is located about 1000 km away. After these experiments, it was concluded that using this new architecture, we can provide a performance similar to those currently in operation, enabling air traffic systems, as well as those of similar function (eg coordination of civil defense and police ) to be operated with a high degree of reliability, even when they meet a hostile environment. [C2344]

### "CELP-like compression of spotlight-mode SAR raw data in transform domain"

Transmission of synthetic aperture radar (SAR) data requires large bandwidth due to its inherently high data rate. Consequently, compression of the data is often required. In this paper, we propose a raw SAR data compression

algorithm that employs a predictive coding scheme, based on the analysis-by-synthesis encoding method. The proposed algorithm is inspired by code excited linear prediction (CELP) algorithm used in speech compression and exploits the signal correlation across azimuth of the range-wise inverse Fourier transform of the raw SAR data. Our results show that the proposed CELP-like compression algorithm is 6 dB superior to block adaptive quantization (BAQ) in signal-to-noise ratio. Also, we show that the formed SAR image after compression preserves the main features of the captured scene at low data rate contrary to that of BAQ-compressed data.

[C2345]

### "A software demonstrator for IEEE 802.21 Media Independent Handover in heterogenous networks"

In this paper we present a software demonstrator, for a system built following the directions described in the IEEE 802.21 (Media Independent Handover) standard, capable of completing an independent vertical handover. We first bring in front the field's related work, and also propose methods of implementing the components described in the standard. The architecture and the functionalities of the demonstrator application are detailed, and we also mention aspects about surpassing the difficulties that rise during the implementation process.

[C2346]

### "Design of mine detection robot for Korean mine field"

This paper presents the critical design constraints of mine detection robots for Korean minefield. As a part of a demining robot development project, the environment of Korean minefield was investigated, and the requirements for suitable robot design were determined. Most of landmines in Korean minefield were buried close to the demilitarized zone (DMZ) more than half of a century ago. The areas have not been urbanized at all since the Korea War, and the potential locations of the explosives by military tactics have been covered by vegetation. Therefore, at the initial stage of the demining robot system development, the target areas were investigated and the suitable design for Korean minefield terrain was determined. The design includes a track type main platform with a simple moving arm and a mine detection sensor (consists of a metal detector and a GPR at this stage). In addition, in order to maintain the effective distance between the landmine sensors and ground surface, a distance sensing technique for terrain adaptability was developed and briefly introduced in this paper. The overall design of this robot was determined by considering the speed of the whole mine detection process and a point of economic view to replace human in minefield. Thus, the detail of the conceptual design and the mine detection scenario is presented in this paper. [C2347]

### "Intelligent surveillance and security robot systems"

This paper presents a new security solution that integrates vision, intelligent algorithm and robot technology. The solution can be applied to guarding large facilities, critical infrastructures and national borders. While conventional security solutions rely on human operator's vigilance on the images provided by cameras, the proposed solution uses machine intelligence to compensate for human factors and robots to provide immediate counter response. The system is currently deployed at Korea National Oil Corporation's Seosan oil reserve facility. Overall structure of the system and description of each component are presented. [C2348]

### "Multipath reflectivity estimation in urban environments for Synthetic Aperture Radar images"

Synthetic Aperture Radar (SAR) images a target region reflectivity function in the multi-dimensional spatial domain of range and cross-range. SAR synthesizes a large aperture radar in order to achieve a finer azimuth resolution than the one provided by any on-board real antenna. Conventional SAR techniques assume a single reflection of transmitted waveforms from targets. Nevertheless, today's new scenes force SAR systems to work in urban environments. Consequently, multiple-bounce returns are added to direct-scatter echoes. We refer to these as ghost images, since they obscure true target image and lead to poor resolution. By analyzing the quadratic phase error (QPE), this paper demonstrates that Earth's curvature influences the defocusing degree of multipath returns. In addition to the QPE, other parameters such as integrated sidelobe ratio (ISLR), peak sidelobe ratio (PSLR), contrast (C) and entropy (E) provide us with the tools to identify direct-scatter echoes in images containing undesired returns coming from multipath. [C2349]

### "Multi-target tracking using proximity sensors"

We consider the problem of tracking multiple moving targets in a continuous field using proximity sensors, which are binary sensors that can sense target presence by performing local energy detection subject to noise. Compared with more sophisticated sensors, proximity sensors have the advantage of having lower costs and lower energy consumption, but also the disadvantage of being less accurate. In this paper, we propose a hybrid tracking scheme where a coarse-scale tracking is first performed by proximity sensors to narrow down the areas

of interest, and then a fine-scale tracking is performed by high-end sensors to estimate the exact target locations, with our focus on the former. In contrast to classic multi-target tracking which assumes 1-1 association between measurements and targets, we show that proximity measurements do not have such association and thus require a different objective. Formulating the coarse-scale tracking as a problem of tracking the histograms of targets in a cell-partitioned field, we develop both an optimal and two approximate solutions via Bayesian Filtering (BF). In particular, one of our approximate solutions decouples the tracking of different targets and thus reduces the dimensionality of BF by relaxing the likelihood function, and the other further reduces the problem into discrete space by quantizing the target mobility model and the relaxed likelihood function. Together with the optimal solution, they provide flexible tradeoffs between accuracy and complexity. Simulations show that the proposed solutions can effectively track targets to the accuracy of a cell and thus reduce uncertainty for the fine-scale tracking. [C2350]

### "Modeling the effects of wind turbines on radar returns"
