Wind turbines located near radar installations can significantly interfere with a radar's ability to detect its intended targets. In order to better understand and mitigate the adverse effects of wind turbines on radar, the government and wind farm community need tools that can be used to analyze the radar returns from wind turbines. Remcom's XGtd@software is a high frequency solver capable of calculating the radar cross section of electrically large objects. In this paper, interference from wind turbines is predicted using XGtd simulations and new post-processing algorithms that calculate Doppler shift quantities based on points of interaction with the rotating turbine blades. Results of the analysis are used to calculate the bistatic radar cross section and Doppler shift from two blade orientations. In addition, the time-varying monostatic radar cross section and Doppler shift for a single wind turbine are analyzed and shown to agree well with measured data from actual wind turbines. [C2351]

### "High availability and fault management in Objective Architecture systems"

At the heart of many real-time and near real-time distributed computing systems, such as radar, navigational, missile defense, and command and control, you find mission critical requirements. This designation demands continuous system availability even in the face of system faults. Lives are at stake and mission success is at risk. Standards-based high availability and computing resource management solutions with well defined functional boundaries and interfaces are gaining traction. This is seen in such Navy examples as Aegis Modernization, Littoral Combat Ship, Common Processing System, and more recently within the PEO-IWS Objective Architecture DoD Information Technology Standards Registry (DISR). As implemented, Objective Architectures hold the promise of providing a path to meet current and future demands placed on these system designs. Examples of these demands include: increased functional density and complexity, resource consolidation, mixed criticality systems and the ever present size, weight and power concerns. The architectural approach must be both flexible and scalable to fit the broadest set of cases, minimizing or eliminating special-case solutions. There are a set of standards published by the Service Availability (SA) Forum that address these issues. SA Forum standards are currently being used in the programs mentioned above. We will also consider how SA Forum specifications can be used to support operational availability in legacy systems while laying the groundwork for evolution of the objective architecture. This paper reviews the above issues and the specific benefits brought about by a SA Forum-based solution. [C2352]

### "Power allocation schemes for target localization in widely distributed MIMO radar systems"

Widely distributed multiple-input multiple-output (MIMO) radar systems offer parameter estimation improvement for target localization, proportional to the product of the number of transmitting and receiving radars and the total transmitted power. Thus far, power allocation has been uniformly distributed between the system transmitters. For a large number of radars, the achievable localization mean-square error (MSE), with full resource allocation, may extend beyond the system predetermined performance goals, such as target localization accuracy (i.e., minimum estimation MSE) and total power radiation. In this study, power allocation schemes are developed, taking into account system constraints. The first is concerned with minimizing the total transmitted power such that a predefined estimation MSE objective is met, while keeping the transmitted power at each station within an acceptable range. The second, optimally distributes a given power budget among all transmitting radars to maximize performance, i.e., minimize the attainable localization MSE. As the Cramer-Rao bound (CRB) is known to be asymptotically tight to the maximum likelihood estimator (MLE) MSE at high SNR, it is used as a metric for the estimation MSE. The CRB is derived for a signal model that incorporates the propagation path loss, the target radar cross section (RCS), and the transmitters' powers. It is shown that uniform or equal power allocation is not in general optimal and that the proposed allocation algorithms result in a local optimum that provided either better localization MSE for the same power budget or requires less power to establish the same performance in terms of estimation MSE. A physical interpretation of these conclusions is offered. [C2353]

### "Robust target estimation in compressive sensing based colocated MIMO radar"

A colocated multiple-input multiple-output (MIMO) radar system is considered, in which the transmitters and receivers are nodes of a small scale wireless network. The sparsity of targets in the illuminated space allows target detection based on compressive sensing (CS) techniques. A receive node compresses the received signal via a linear transformation,  $\Phi$ , referred to in CS theory a measurement matrix. The compressed samples are subsequently forwarded to a fusion center, where an  $\ell_1$ -optimization problem is formulated and solved for target information. CS-based MIMO radar achieves the same localization performance as do traditional methods but with many fewer measurements. Unlike previous work, we consider the case in which the targets might be located across several range bins, and the delay of the first reflected signal is unknown and, due to the small number of compressed samples, cannot be estimated accurately. A new measurement matrix is proposed that is constructed based on the transmit signal waveforms and also accounts for all possible discretized delays of target returns within a given time window. It is shown that reduced bandwidth transmit waveforms can lead to a measurement matrix that improves signal-to-interference ratio (SIR), but on the other hand, using waveforms that are too narrowband increases the coherence of the sensing matrix, thus invalidating the conditions for the application of the CS approach. Therefore, the transmit waveforms must be chosen carefully to guarantee the desired performance. [C2354]

### "Analog auto-correlation based receiver architecture for radar systems"

Analog signal processing based radar systems enable reduction in total system power consumption, over conventional digital signal processing based radar systems. In this paper, detection performance degradation of a previously proposed system, based on analog cross-correlation, due to time synchronization is addressed and analog auto-correlation based radar architecture is proposed. By adopting the digital radio frequency memory technique, accurate and tunable delays for autocorrelation process are realized. The probability of detection performance degradation of the previously proposed system, due to mismatch, is evaluated by simulations while varying signal to noise ratios and mismatches at the matched filter. The proposed system's probability of detection performance will also be simulated versus varying signal to noise ratios, compared to the results of the previously proposed system and analysis of conditions when the proposed system is more beneficial than the previously proposed system will be made. [C2355]

### "Visual data mining analysis for information operations in complicated information environment"

The method of visual data mining analysis is important in acquiring the intelligible knowledge in massive initial data. Based on the characteristics of information operations in complicated information environment, the basic flow of requirement design and analysis for the visual data mining analysis for information operations was presented; then, take the visual data mining analysis of radar systems as the key experimental example, the spectral distribution of complicated information environment, the electromagnetic energy distribution, the ability of detection and tracking of radars as well as the assessment of the barycenter of a radar chain, etc. were discussed and analyzed in detail according to the basic content, flow and objective of the designed visual data mining analysis for information operations; finally, the outlook of the study was depicted. [C2356]

### "Studying on state prediction for radar transmitter using GM(1,1)"

Through analyzing the importance of component modules of a kind of radar transmitter, both the cathode current of multiple-beam klystron and the ripple voltage of high-voltage power supply are selected as the prediction signals. By studying on their characteristics, a improved GM (1,1) is proposed to predict the state of transmitter, where the idea of metabolism is applied to make the parameters of GM (1,1) on-line change. Particle Swarm Optimization(PSO) is used to select the best prediction dimension. The performance of the proposed method is tested, and the experiment results show that the proposed method has better prediction capability than the popularly used ARMA model, and then it provides technical support for preventive maintenance. [C2357]

### "Synthetical Generalized Discriminant Analysis for radar HRRP target recognition"

The prevalent applications of traditional statistical discriminant methods for radar High Range Resolution Profile (HRRP) target recognition are designed to obtain Common Discriminant Information (C-DI) among all classes at the expense of Individual Discriminant Information (I-DI) between them, so they may lose slight I-DI between close-set classes and result in a dissatisfied recognition performance. To overcome this weakness, we design a Distributed Generalized Discriminant Analysis (D-GDA) for I-DI extracting, and accordingly, a new variation called Synthetical Generalized Discriminant Analysis (S-GDA) is presented to deal with C-DI and I-DI equally. Experimental results for simulated data show that GDA and D-GDA are complementary in many facets and can be considered as a feature extraction method couple. Furthermore, compared with GDA and D-GDA, the

proposed S-GDA not only achieves the best recognition performance, but also is more robust to many challenges, such as noise disturbance, aspect variation and Small Sample Size (SSS) problem. All these experimental facts confirm that C-DI and I-DI are different as two aspects of Discriminant Information (DI) but both are beneficial to target recognition. [C2358]

#### "A parameter estimation method for polyphase codes using time-frequency distribution"

Due to the desirable performance, polyphase codes have been widely used in low probability of intercept radar. By analyzing the characteristic of the time-frequency distribution of polyphase codes, a new parameter estimation method based on time-frequency distribution is proposed. Simulation results show that this method have good estimate precision even in low signal-to-noise ratios. [C2359]

#### "Removing multiplicative noise by improved regularization term"

This paper focuses on the problem of multiplicative noise removal. Multiplicative noise models are central to the study of coherent imaging systems, such as synthetic aperture radar and sonar, and ultrasound and laser imaging. Classical ways to solve such problems are filtering, statistical(Bayesian) methods, variational methods, and methods that convert the multiplicative noise into additive noise, apply a variational method on the log data or shrink their coefficients in a frame and recover the result using an exponential function. We draw our inspiration from the diffusion tensor. By using a edge-directed enhancing based anisotropic diffusion as regularizer, we can derive a functional whose minimizer corresponds to the denoised image we want to recover. Both theory analysis and numerical results show that the new model has better denoising results than the known SO model with high peak signal to noise ratio. [C2360]

#### "Fast algorithm for direction of arrival based on time-frequency distributions"

Time-frequency distribution (TFD) method has received a considerable amount of attention in Direction of Arrival (DOA) estimation of multi-senor and time space processing, which lead to improved spatial resolution and source separation performances. According to the characteristic of the different time-frequency distribution of each source, a novel approach of time-frequency DOA estimation is provided based on the propagator method (PM). Compared with the conventional approaches, the presented method has lower computational complexity with insignificant performance degradation for DOA estimation. Furthermore, in the proposed method of time-frequency DOA estimation, propagator can be obtained without a priori knowledge of the number of impinging sources on array if t-f points in time-frequency domain are chosen appropriately, which widens the application of propagator to Radar, Sonar and passive detection system. The effectiveness and high resolution of the algorithms is verified via computer simulations. [C2361]

#### "Research on robust unscented regularized particle filtering"

In nonlinear and non-Gaussian systems, particle filtering is effective but it is difficult to select the importance distribution function and diverges more greatly. Aiming at this problem, the paper represents robust unscented regularized particle filtering to improve the performance of filtering. This algorithm is more suitable for filtering calculation in nonlinear system, not only because overcomes the limitations of the general particle filter and uses the equivalent weight, but also takes advantage of the high efficiency of unscented particle filtering and regularized particle filtering. In importance sampling process, the UT transformation is applied and the equivalent weight makes good use of more reasonable information, it considers the latest measured values and slows down the particle degradation. In resampling process, particles are from the continuous kernel density distribution function owned the minimum mean square error. Simulation results show that the algorithm is efficient and outperforms in terms of accuracy based on SINS/SAR integrated navigation system. [C2362]

#### "Separating respiration artifact in microwave doppler radar heart monitoring by Independent Component Analysis"

With a microwave radar, chest wall movements originating from cardiac and respiratory activity can be recorded non-contactly. A major challenge is how to separate the desired low-amplitude cardiac signal from large-amplitude artifacts, such as respiration. Commonly, the separation is performed with a narrow band-pass filter. This causes the signal edges to be rounded, which complicates the accurate timing estimation in the heart rate variability (HRV) analysis. In addition, the harmonics of the respiration signal might fall into the same frequency spectrum as the cardiac signal. In this study, we recorded data with two radars and studied signal separation using a complex-valued Independent Component Analysis (ICA). After ICA, the respiratory signal is greatly attenuated, although still present, in two of the independent components (ICs). However, respiration harmonics are reduced as well, and thus, the residual respiratory signal can be removed by filtering. [C2363]

### "Performance Characterization Parameters on Voice and Data Transmission in Mobile Terminals to Cellular Networks"

This work presents the experimental results related to performance measurements in GSM and GPRS cellular data networks. Two Mobile Terminals were used, in order to take place the scenario. Power Level, Power vs. Time, Modulation Analysis, Modulation Spectrum, (BER) Bit Error Rate and Throughput were considered in this analysis. [C2364]

### "An Efficient Frequency-Domain Velocity-Filter Implementation for Dim Target Detection"

An efficient Fourier-domain implementation of the velocity filter is presented. The Sliding Discrete Fourier Transform (SDFT) is exploited to yield a Track-Before-Detect (TBD) algorithm with a complexity that is independent of the filter integration time. As a consequence, dim targets near the noise floor of acquisition or surveillance sensors may be detected, and their states estimated, at a relatively low computational cost. The performance of the method is demonstrated using real sensor data. When processing the acquired data, the SDFT implementation is approximately 3 times faster than the equivalent Fast Fourier Transform (FFT) implementation and 16 times faster than the corresponding spatiotemporal implementation. [C2365]

### "Automatic Building Detection Using LIDAR Data and Multispectral Imagery"

An automatic building detection technique using LIDAR data and multispectral imagery has been proposed. Two masks are obtained from the LIDAR data: a 'primary building mask' and a 'secondary building mask'. The primary building mask indicates the void areas where the laser does not reach below a certain height threshold. The secondary building mask indicates the filled areas, from where the laser reflects, above the same threshold. Line segments are extracted from around the void areas in the primary building mask. Line segments around trees are removed using the normalized difference vegetation index derived from the orthorectified multispectral images. The initial building positions are obtained based on the remaining line segments. The complete buildings are detected from their initial positions using the two masks and multispectral images in the YIQ colour system. It is experimentally shown that the proposed technique can successfully detect buildings, when assessed in terms of 15 indices including completeness, correctness and quality. [C2366]

### "Chipless RFID tag with integrated sensor"

A chipless tag based on multiresonators with integrated temperature sensor is presented. The tag consists of a UWB monopole antenna loaded with multiple cascaded spiral EBGs which have a 1:1 correspondence with data bits. The data bits are encoded into the spectrum hence the tag has a unique spectral signature. The chipless tag is less sensitive to tag orientation and has smaller size than earlier generations of the tag. The temperature sensor is a NTC thermistor which changes the radar cross-section of the tag antenna. The change in radar cross-section is used to determine the temperature while the spectral signature is used to identify the tag's unique ID. A proof-of-concept tag is developed and tested which has 6-bits and operates between 2-2.6 GHz. The chipless RFID tag is designed for ultra-low cost sensing applications. [C2367]

### "Feasibility of wireless gas detection with an FMCW RADAR interrogation of passive RF gas sensor"

The feasibility of the remote measurement of gas detection from an RF gas sensor has been experimentally investigated. It consists of a Frequency-Modulated Continuous-Wave (FMCW) RADAR interrogation of an antenna loaded by the passive sensor. The frequency band of the RADAR [28.8-31GHz] allows the detection of the resonant frequencies of Whispering Gallery Modes that are sensitive to gas concentration. Reported experimental results provide the proof-of-concept of remote measurement of gas concentration fluctuation from RADAR interrogation of this new generation of passive gas sensors. [C2368]

### "Indoor location estimation system based on evolutionary matching"

The indoor Real Time Location Systems (RTLS) is attracting more and more attention while a series of challenging problem still exists such as the real-time performance, location precision, and the large amount of disturbance signal brought by complex indoor circumstances. However, existing location estimation technology cannot satisfy the requirements of indoor RTLS. In this paper, a high-precision indoor location estimation technology based on Ultra Wideband and evolutionary matching mechanism is proposed, based on which an indoor location service platform is built with intelligent alerting strategy based on Newton collision graphic engine. Experimental results show that the proposed method improves not only the location estimation accuracy but also the ability to eliminate the multipath signals with low computational cost. [C2369]

### "On the application of ethernet in a distributed radar system"

This paper firstly introduces the structure of VHF radar system and then studies the data transmission rate between the digital of VHF radar and the host computer. Through analyzing the calculating rate, the size of the data packet and the influence of UDP and TCP on the transmission rate, the author intends to find out the optimum method to meet the engineering requirements. [C2370]

### "A Multi-Objective Antenna Placement Genetic Algorithm for matched array synthesis on complex platforms"

A Multi-Objective Antenna Placement Genetic Algorithm (MO-APGA) has been proposed for the synthesis of matched antenna arrays on complex platforms. The total number of antennas required, their position on the platform, location of loads, loading circuit parameters, decoupling and matching network topology, matching network parameters and feed network parameters are optimized simultaneously. The optimization goal was to provide a given minimum gain, specific gain discrimination between the main and back lobes and broadband performance. This algorithm is developed based on the non-dominated sorting genetic algorithm (NSGA-II) and Minimum Spanning Tree (MST) technique for producing diverse solutions when the number of objectives is increased beyond two. The proposed method is validated through the design of a wideband airborne SAR. [C2371]

### "Multi-object tracking using feed-forward neural networks"

In this article we present an approach for robust multi-object tracking. Typically the task of object tracking can be divided into two subtasks: object detection and object labeling. The main focus of the work presented here is on an approach for consistently labeling objects across a series of video frames using neural networks. Due to the specialization of object detection algorithms it is necessary to divide detection and labeling to enhance their individual skills. In the evaluation we show that the developed labeling is robust against occlusions and can handle low object detection rates. [C2372]

### "Inverse filtering operation for reconstruction of distorted GPR response"

This study proposes inverse filtering operation for reconstruction of ground penetrating radar (GPR) responses in order to remove waveform distortion caused by transmitting and receiving antenna characteristics. As an example, we apply it to measured pulse response from a metallic sphere and show the effectiveness of the method. [C2373]

### "Robust adaptive coregistration of InSAR images using multisource information and joint data fusion"

This paper addresses an adaptive coregistration method of synthetic aperture radar interferometry (InSAR) phase images. The method for adaptive coregistration of InSAR images is characterized by using multisource information and joint data fusion. We propose a strategy and criteria incorporating the weighted joint data information to evaluate the accuracy of the registered method by the using the mean-squared differences. Numerical results on the simulated data demonstrate the efficiency and precision of the proposed method. [C2374]

### "Research on the 3D visualization of information operations based on STK"

Information Operation is the main style of Modern War. The visualization of Information Operations could reflect the whole operation procedure directly. At the Same time, the visualization could help the research on information Operations. This Paper analyzes the needs of the visualization of Information Operations. According to the characteristics of Information Operations, this paper focuses on to achieve the visualization of Information Operations through STK methods and techniques. [C2375]

### "Two Insar procedures for wide and noise interferograms"

In unwrapping interferograms with large size and dense residues, the path-following algorithm as a fundamental unwrapping method may produce retrieval error caused by long branch-cuts and repetitive connection of residues. In this paper, two unwrapping algorithms, i.e. the multiple patches method connecting opposite residues and the center expansion method searching opposite residues, are alternatively presented. Some examples of ENVISAT-ASAR datasets demonstrate our improvement better than conventional methods in InSAR data processing. [C2376]

### "Development of phased array systems in Japan"

This paper reviews the research and development on the phased array antennas (PAAs) for several applications in Japan. First, the author shows the historical overview of the PAA for radar, satellite and mobile communication uses. Then, the author introduces a millimeter-wave PAA as a modern application to communication systems. [C2377]

### "Multi-layer and multi-dimensional information based cooperative vehicle localization in highway scenarios"

In this paper, we propose a cooperative approach based on unscented Kalman filter (UKF) for vehicle positioning in Vehicular Ad hoc Networks (VANET). In our system, various kinematic parameters (e.g., position, speed, heading, and acceleration) of a vehicle are considered as a multi-dimensional data. Accordingly, the kinematic parameters of all the vehicles in the cluster can form a multi-layer and multi-dimensional information (MLMDI) database. Due to the motion characters, most kinematic parameters vary nonlinearly. We specially introduce the UKF to fuse the MLMDI data from different information sources, since UKF has an advantage to reckon the statistics of a random variable undergoing a non-linear transformation compared with extended Kalman filter (EKF). Simulation results show our approach can get more accurate, reliable and computationally efficient than GPS/DR system and the Extended Kalman Filter (EKF) based solution. [C2378]

### "1-D superresolution ISAR imaging algorithm"

A novel 1-D scattering centers extraction algorithm of radar target based on conjugate unitary Root-MUSIC was introduced in this paper. To improve the resolution of 1-D scattering centers, the information of conjugated data was used available by combining the observation data matrix with its conjugated data matrix. Centro-Hermitian data matrices with hermitian property was constructed by forward-backward(FB) averaging, Unitary transform was applied which convert the FB covariance matrix to a real matrix, and the computational efficiency is improved by real-valued eigendecomposition. Theory analysis and simulation result show that the new approach can improve the resolution and reduce significantly computational complexity. [C2379]

### "K-band micro-strip antenna array applied in anti-collision radar"

A K-band micro-strip array double-antenna applied in 24GHz automotive collision warning radar is presented in this paper. The double-antenna consists of two individual 14x6 elements arrays which both are placed on ROGERS RT5880 substrate with 0.254 mm thickness, one for the transmitter (TX) and one for the receiver (RX). The results of simulation show that the double-antenna has gain of 26.5dB and efficiency of 60%, the -10dB bandwidth is 1GHz from 23.6GHz to 24.6GHz, three-decibel beamwidth in azimuth is 6° and in elevation is 18°, the sub lobe suppression in azimuth is better than -20dB and in elevation is better than -15dB. The isolation between two antennas array is better than -32dB. [C2380]

### "Speckle noise reduction in SAR images using adaptive morphological filter"

Speckle noise is one of the most critical disturbances that alter the quality of Synthetic Aperture Radar (SAR) coherent images. Before using SAR images in automatic target detection and recognition, the first step is to reduce the effect of speckle noise. Several adaptive and non-adaptive filters are widely used for despeckling in SAR images. In this paper, an adaptive mathematical morphological filter is proposed to reduce the speckle noise in SAR images. The new filter performance is compared with a number of despeckling filters with different parameters. For performance measurements, several parameters were evaluated to test the filter ability to attenuate the speckle noise and keep target information. From experimental results, the new proposed morphological filter gives promising results for significantly suppressing speckle noise and preserving the potential targets. [C2381]

### "The study of Range Doppler Algorithm in focusing Bistatic SAR"

Comparing to monostatic SAR, Bistatic SAR has specific advantages, such as the reduced vulnerability in military systems, additional information about the target and characteristics of signal. Nevertheless, it brings the complication of processing algorithms because of the range history of a Bistatic target is the sum of two hyperbolic range equations, which give a double square-root term in the range equation, and the traditional RD algorithms using in monostatic SAR can not apply for processing Bistatic SAR. This paper obtained the point target signal by establishing the echo signal model, then derived the approximate two-dimensional spectrum of echo signal by using POSP, and a Range Doppler Algorithm suitable for Bistatic SAR is presented. The algorithm is validated by the simulation experiments of point targets. [C2382]

### "A method for Doppler Weather Radar raw data compression based on wavelet transform modulus maxima denoising"

A lossy data compression algorithm based on wavelet transform modulus maxima denoising (WTMM-D) has been proposed. Firstly, analysis for radar raw data is presented to identify data characteristics and correlation. Then, we transform the data format and compare the experimental results using different lossless compression algorithms to compress the transformed raw data. Finally, a method based on WTMM-D is presented, which is using a high-performance lossless compression algorithm to compress the reconstructed coefficients of WTMM-D. Experimental results show that the proposed algorithm can compress raw data efficiently under the premise of a certain distortion. [C2383]

### "Predicted radar/optical feature fusion gains for target identification"

Airborne tracking and identification (ID) of high value ground targets is a difficult task impacted by sensor, target, and environmental conditions. Layered sensing, using a combination of standoff and short-range sensors, maintains target track and identification in cluttered environments such as cities or densely vegetated areas through sensor diversity. Data, feature, decision, or information fusion is necessary for high confidence target classification to be achieved using multiple sensors and sensor modalities. Target identification performance is improved by exploiting the extra information gained from independent sensing modalities through information fusion for automatic target recognition (ATR). Increased target ID has been demonstrated using spatial-temporal multi-look sensor fusion and decision level fusion. To further enhance target ID performance and increase decision confidence, feature level fusion techniques are being investigated. A fusion performance model for feature level fusion was applied to a combination of sensor types and features to provide estimates of a fusion gain. This paper presents a fusion performance gain for Synthetic Aperture Radar (SAR), electro-optical (EO), and infrared (IR) video stationary target identification. [C2384]

### "Study of efficient broadband beamforming based on extended towed array measurement"

In this paper, extended towed array measurement and broadband beamforming in frequency domain are combined together to form a new efficient broadband beamforming based on extended towed array measurement (ETAM-FCBF). The angular resolution of this method is higher than the conventional beamforming, and the detection ability of the weak target is more excellent. Moreover, this method is fast enough for real-time processing. [C2385]

### "Analysis of an improved fixed-point loop for satellite navigation receiver"

Aim to avoid the deficiency of huge computation load and resource use in conventional fixed-point loop control method, base on the study of signal tracking method and accuracy of navigation receiver, an improved one is proposed, along with theoretical analysis and actual verification of the accuracy loss of signal tracking compared to the floating-point loop control method from the following two aspects respectively: quantization error of phase discriminator, approximation of filter coefficients, as well as the discipline when choosing appropriate filter coefficients. The results demonstrate that the accuracy loss of signal tracking in the improved method is very small with appropriate filter coefficients, which can be accepted. [C2386]

### "Radar target discrimination using neural networks"

Time domain response based neural network and frequency domain response based neural network have been proposed for radar target recognition. In this paper, we propose a natural frequency based neural network for radar target recognition. Our scheme makes advantage of an aspect angle independence of a natural frequency. In the results, we show that, for the multiple aspect angles, natural frequency based neural network is superior to time domain response based neural network. [C2387]

### "A GMTI method via comparing two consecutive phase difference maps of the same target area for small UAVs"

In this paper, we present a Ground moving target indication (GMTI) method based on the analysis of the two phase difference maps (PDM) of the same target scene obtained by one antenna phase center on a slow moving platform. For small unmanned aerial vehicles (UAVs) only one antenna is available to detect moving targets. Using a single antenna and the two PDMs method, odd numbered spatial samples are used to construct the first synthetic aperture radar (SAR) image, and the even numbered spatial samples are used to construct the second SAR image of the same target scene. The along track neighboring pixels phase difference is calculated for each image; and, thus two PDMs are generated. The phase difference values of the corresponding pixels in

the two PDMs are almost the same if there are only static objects in the target scene; while if there is a moving target with a reasonable speed in one pixel, it will generate extra phase change based on the phase change generated by the platform motion. The extra phase change generated by the moving target would be detected in comparing the two PDMs, and thus the moving target is detected. Simulations conducted confirm that the proposed method can detect ground moving targets with very low speeds. [C2388]

#### "Hyper-fuzzy modeling and control for bio-inspired radar processing"

Modern RF Radar signal processing has been receiving much attention for wide range of domains that include industrial, environmental, and military applications. Inherently, the received raw spatial-temporal signals can be 1-D, 2-D, or 3-D and are usually of uncertain nature, because of changing conditions and optical background variations. In this paper, we apply novel concepts for hyper-neural theory that allow for incorporation of variables attribute definitions and uncertainties for the purpose of effective evidential learning and subsequent key output features determination in the radar processing. Application to wide-band angle of arrival data sets at several carrier frequencies has been carried out in order to illustrate the strengths as well weakness of the approach. Using interval set-based operations together with segmentation of the data is proved useful and gave good sensitivity of detection. [C2389]

#### "Analytical studies of laser parameters for ranging and illuminating satellites from H-SLR station"

In this paper, the laser system used at the Helwan Satellite Laser Ranging Station (H-SLR) will be used in satellite's illumination as well as for satellite ranging. The estimated model which describes the energy and number of photons as well as the number of photoelectrons are investigated from the received signals of laser beam. For the ranging purposes, the equipment used at the H-SLR is described and also the method used for its calibration. The Range corrections due to the effect of the atmosphere on the laser beam is also discussed and applied for some satellites observed from Helwan. The ranging and illuminating space satellites are modeled and computed from the H-SLR parameters. The numbers of photons, of photoelectrons are then computed from the ranging data. [C2390]

#### "Comparison of pulse and FMCW based radiolocation for indoor tracking systems"

In this paper, pulse and FMCW based radiolocation techniques are compared with respect to their usability for an indoor person tracking system. The basic principles and parameters for pulse and FMCW based distance measurements are derived. To allow the calculation of the signal budget, channel models, noise limits and regulatory aspects in terms of transmit power are considered. The accuracy and the coverage range for the two approaches are estimated for ISM and UWB frequency bands. The shown advantages of FMCW with respect to coverage range, range accuracy and system requirements favour this approach for the target application, where a high path loss due to wave propagation through walls and various obstacles must be expected. [C2391]

#### "Short term DC breakdown and complex permittivity of Al<sub>2</sub>O<sub>3</sub>-and MgO-epoxy nanocomposites"

Electrical insulation based on epoxy resin is commonly used in high voltage applications. Examples are transformers, terminations, plugs or connectors. But, it is also used in high voltage applications where energy transportation or distribution is not the main purpose, e.g. in medical and industrial X-ray systems, or radar. This paper addresses the changes in the structure due to the introduction of surface functionalized nanoscale particles, namely magnesium oxide and aluminum oxide. Short term DC breakdown tests were performed alongside dielectric spectroscopy. The BD strength was measured for negative DC ramp voltages. Dielectric properties have been acquired by broadband dielectric spectroscopy. The base polymer is a commercially available bisphenol A epoxy with anhydride hardener. As filler material magnesium oxide powder was used with an average particle size of 22 nm and alumina filler with 50 nm average diameter. Both particle types were modified with a silane coupling agent, in order to achieve a uniform dispersion of particles in the host material. Neat epoxy samples were used as a reference. Both composites showed remarkable DC breakdown strength for low fillgrades. A possible explanation for this unique behavior is given and the differences between samples filled with aluminum oxide and magnesium oxide are discussed. [C2392]

#### "Antenna compensation for UWB GPR systems applied in Non-Destructive testing"

Non-Destructive testing is an enhanced technique based on applying the inverse scattering algorithms upon the received scattered Electromagnetic EM waves for computing some important parameters of the material characteristics as permittivity and reflection coefficients. Unfortunately, the Ultra Wideband (UWB) antennas can dramatically affect the received signal and result in considerable degradation of the overall performance of the UWB GPR system. The isotropic, fully matched, unity gain and frequency independent antenna assumption could never be accepted for the typical UWB antennas, where the radiation characteristics and matching

properties vary considerably with the frequency, introducing directionally asymmetric bandwidth reduction and waveform dispersion. Therefore an efficient antenna compensation technique would be introduced in this paper with the corresponding successive EM simulation results. [C2393]

#### "Measurement of pyramidal microwave absorbers using RCS methods"

In this work, a commonly used measurement techniques were used to define the reflection loss performance of pyramidal microwave absorbers mounted on a wall. The technique is namely, Radar Cross Section (RCS) measurement method. Six set of pyramidal microwave absorbers and flat square absorbers were installed at one side wall, in an RF shielded room in order to investigate the performance. Two types of cable losses measurement techniques were applied to compare its performance under different loss conditions. The reflection loss values resulting from this investigation were then analyzed and discussed. [C2394]

#### "Air traffic complexity based on dynamical systems"

This paper presents a new air traffic complexity metric based on dynamical systems. Based on a set of radar observations (position and speed) a vector field interpolating these data is constructed. Once the field has been obtained, the Lyapunov spectrum of the associated dynamical system is computed on points evenly spaced on a spatial grid. The results of the computations are summarized on complexity maps, with high values indicating areas to avoid or to carefully monitor. A first approach based on linear dynamical system enable to compute an aggregate complexity metric. In order to produce complexity maps, two extensions of the previous approach have been developed (one in space and another in space and time). Finally, an approximation is proposed in order to localize the computation of the vector field by the mean of Local Linear Models. [C2395]

#### "Continuous ant algorithm based on cooperation in radar network optimization"

From the perspective of deployment features and defense area partition, we establish the static radar network and optimal deployment model, and based on this model, we put forward the issue of high-dimensionally continuous spatial deployment. From the standpoint of ant colony optimization, and aimed at improving Continuous Multi Ant-Colony Optimization (CMACO) in which pheromone is normally distributed, we raise a Algorithm based on cooperation which faces high-dimensionally intelligent optimization. In this method, introduces queue interaction in search of ant colony, connects the mechanism of head ant guide and mass recruitment, and finally realizes cooperated search under high-dimension form. The practice of optimal design shows that this algorithm can be applied into high-dimensional, complex, and much restrained optimal problem, moreover, the optimal time takes less than that of traditional intelligent method, satisfying the warning demand of reentry stage. [C2396]

#### "Application of Newton method to natural frequency estimation"

In this paper, we propose a method for improving the accuracy of the previously extracted natural frequencies. After using the existing natural frequency extraction method, we use the extracted natural frequencies as an initial guess for the nonlinear sets of equations. The objective is to improve the accuracy of the previously extracted natural frequencies using the Newton method. The final residues and natural frequencies are obtained from the successive update of the initial residues and natural frequencies. The validity of the scheme is illustrated using the numerical results. [C2397]

#### "Atmospheric turbulence effects on radar systems"

The paper discussed the atmospheric turbulence effect such as angle-of-arrival, signal-to-clutter and noise ratio for lognormal clutter and Weibull clutter and detection probability of ultrawideband pulse in radar system. The detection probability is degraded for short pulse and for more turbulence. [C2398]

#### "NAECON 2011 Preview: "Intelligent Aerospace Sensor Integration""

The 2011 National Aerospace Electronics Conference (NAECON) will be held on July 20-22 at the Holiday Inn Conference Center in Fairborn, Ohio. The 2011 theme will be "Intelligent Aerospace Sensor Integration". This conference is a major forum for researchers, practitioners, and students interested in aerospace systems; and their impact on advanced control systems, reconfigurable computing, information processing, tomography, optics, imaging, RF devices and advanced design, radar, antennas and next-generation millimeter wave and THz applications. [C2399]

#### "Automated image segmentation for synthetic aperture radar feature extraction"

Automated segmentation routines may be used to extract scattering features in synthetic aperture radar (SAR) images. The watershed transform segments real-valued images into regions associated with a local minima. Watershed algorithms suffer from over-segmentation which, for SAR image segmentation, results in many more regions than scatterers. We consider an algorithm called Peak Region Segmentation (PRS). PRS is an inverted version of the watershed transform that seeks to group pixel regions associated with a local maxima. We implement the algorithm to segment one, two, and three-dimensional images. We extend PRS to include region merging to avoid over-segmentation. Threshold settings allow the user to strike a balance between region merging and separation of closely-spaced scatterers. Image segmentation examples are shown for 1D, 2D, and 3D SAR images. [C2400]

#### "Dantzig selector based compressive sensing for radar image enhancement"

Compressive sensing (CS) is the technique for acquiring and reconstructing a signal utilizing the apriori knowledge that it is sparse in a certain domain. This paper investigates the application of this technique to radar imaging. Present radar systems operate on high bandwidths and demands high sample rates following the Nyquist-Shannon theorem. Compressive Sensing can prove to be a good alternative to reduce data handling, complexity, weight, power demands and costs of the existing radar systems. There are two major novelties in this work. First of all we have used Dantzig selector based CS which gives better result when applied on radar images than that using the conventional  $\ell_1$ -norm based CS. Secondly, we also show that Dantzig selector based CS suppresses speckle noise in radar images. We demonstrate the results on both simulated and real radar images. [C2401]

#### "Significance of dielectrics in space technology"

The main objective of this paper is to provide a brief and necessary background of dielectrics in the field of space technology. The mobile telephone, TV, Radio, Satellite or any type of modern communication is not possible without one type of antenna or the other and no radar works without an antenna. Antenna is a sensor of electromagnetic waves. Electric and magnetic fields exist in a dielectric material and also penetrate the dielectric material freely. When an electromagnetic wave is incident normally on the surface of a dielectric, reflection and transmission takes place. In this investigation, dielectric polarization studies were made in the liquid dielectric mixtures Epichlorohydrin, p-cresol in benzene using standard methods at 308K. The values of dielectric constant, refractive index and density were measured at different concentrations. The dipolar increment value has been calculated using Huyskens method based on Onsager's theory. [C2402]

#### "Chairman's introduction for NAECON 2010"

The 2010 IEEE National Aerospace Electronics Conference (NAECON) was held July 14-16, 2010 in Fairborn, Ohio. Approximately 100 papers, tutorials and keynotes were given in various areas of aerospace electronics including: cognitive systems, UAVs, bio-sensing, novel devices, smart textiles, smart antennas, flexible displays, RF reconfigurable microelectronics, radar, photonics, wireless communications, and wearable health-monitoring systems. New this year to NAECON was the Dr. Daniel William Repperger Outstanding Paper Award, to be given in memory of the late Dr. Repperger. A few of the highlights of the conference was a very significant and historical banquet speech entitled "The Dayton NCR WWII Codebreakers", given by Deborah Anderson, daughter of Joseph Desch, who was the focus of the 2006 PBS documentary film The Dayton Codebreakers and our NAECON Grand Challenge-The Smart Vest, which had two teams competing. [C2403]

#### "Effects of polarization on wide-angle SAR classification performance"

Including polarization to circular synthetic aperture radar imagery increases the diversity of information as compared to non-polarized collections. The additional information improves classification performance in a civilian vehicle identification application. Effects of azimuth extent are also investigated. Radar imagery is represented as sets of attributed scattering centers, and vehicles are identified by a pyramid match hashing based, point pattern classifier. The experiments contrast classification performance in a variety of experiments with and without polarization. [C2404]

#### "Design of mismatched filters for oversampled signals"

Most of the prior work in the field of sidelobe suppression filtering for radar pulse compression focused on the design of mismatched filters for binary codes. However, in practice these binary codes are spectrally shaped to obtain analytic signals. The spectrally shaped binary code can be sampled at as low as the Nyquist rate, but in practice it is oversampled to avoid aliasing. The spectral shaping determines the necessary bandwidth and hence the sampling rate for the waveform. One of the spectrally efficient modulation techniques is based on quadriphase coding. As this spectrally shaped waveform is analytic, design of the mismatched filters in complex

domain is needed. In this paper, application of minimax constrained complex LMS algorithm is proposed for the design of mismatched filters for oversampled signals. [C2405]

### "Atmospheric turbulence effects on radar systems"

Atmospheric turbulence has been shown to have measurable effects on several aspects of radar performance. In this paper we discuss the perturbation of the angle-of-arrival (AOA) of radar beams caused by the atmosphere, the effects of lognormal- and Weibull-distributed clutter on detection performance, and the detection probability of ultrawideband pulses propagated through the atmosphere in the presence of turbulence and Gaussian noise. We find that AOA effects are on the order of a few microradians, which is a negligible level for most applications, but that clutter and noise, when combined with turbulent fluctuations, give some surprising results when the ratio of signal to clutter and noise is calculated. The detection of ultrawideband pulses is analogous to the "needle in a haystack" problem. In this paper, we present theories describing each of these phenomena, together with calculated results. For AOA, we have made measurements for one-way propagation that agree well with this theory, but the other phenomena have yet to be measured. [C2406]

### "Wavelet-modulated pulse for compressive sensing in SAR"

A new wavelet modulated pulse is proposed for synthetic aperture radar (SAR). Conventionally SAR image is constructed using chirp, i.e., FM in the range direction, and the Doppler effect in the azimuth direction. The proposed scheme is to physically modulate the amplitude of the radar pulse (AM) using wavelets. Such a radar pulse results in the shift of the wavelets in the temporal domain due to the range, while the Doppler effect causes variation of the scaling coefficient. In both directions, pulse compression can be achieved by taking advantage of the autocorrelation function of the compactly supported orthogonal wavelets and processing the echo signal in the two directions accordingly. Furthermore, by using wavelet modulated pulses, the echo signal is equivalent to the wavelet transform (WT) to the target area. Since WT has been proved more effective in image compression than conventional discrete cosine transform (DCT), wavelet-modulated pulse is equivalent to compression to the SAR image thus to achieve compressive sensing. Experiments have been performed using the latest embedded software defined radio (SDR) technology. Equipped with the most recent FPGA and digital signal processors along with high speed analog-to-digital and digital-to-analog converters, the SDR allows signal processing tasks commonly done by analog circuits to be performed digitally with high flexibility in algorithm design. Based on the developmental need of the user, the small form factor software defined radio (SFF SDR) can serve as a simple data collection device for waveform testing or it can be programmed into a real-time embedded radar system. [C2407]

### "WiMAX ambiguity function for PCL systems"

Passive coherent location (PCL) radar systems use signals of opportunity as the off-board source of electromagnetic illumination. The analysis of the structure, spectral, and spatial properties of emerging commercial waveforms becomes a critical component of future PCL radar systems design. This paper presents an ambiguity function analysis of the emerging IEEE 802.16 OFDM signal known as "WiMAX" for passive radar applications. The simulated WiMAX wave structure shows desirable range and Doppler resolution properties for passive radar applications. [C2408]

### "Ground-UAV platform geometries for radar imaging"

This paper provides a summary of comparative analysis pertaining to a systems trade study with platform geometries that encompass either one, two, or three distributed RF sensing platforms. The discussion is focused on analysis of a basic set of UAV trajectory parameters associated with performing sky-looking radar imaging. The baseline one-platform case corresponds to one ground-based radar transmitter/receiver. The two-platform case involves one ground-based radar transmitter/receiver and one UAV with a passive receiver and the three-platform case involves one ground-based radar transmitter and two UAV's each equipped with a passive receiver. This notional analysis is conducted with a narrow-bandwidth waveform within the L-Band region of the radar spectrum and notional parameters of the moon are adopted for the object-of-interest for radar imaging. Results indicate that the trajectories of the UAV's can be pre-selected to improve comparative radar imaging performance. [C2409]

### "Collision-avoidance radar for bicyclist and runners"

This paper provides a summary of the analysis and design process with respect to the development and prototyping of a Bicycle Radar for a Senior Capstone Project at Wright State University in collaboration with the Air Force Research Laboratory Sensors Directorate. The basic radar technology adopted for this project is a commercial integrated (miniaturized) K-band FMCW Monopulse Module that is recently designed for future

Intelligent Automotive Cruise Control Applications. The design documentation, preliminary test outputs, and discussions within the sections of this paper describe a number of novel features of this Bicycle Radar Design including the methodology for overlaying the K-band range-angle data onto streaming video on the iPhone. Additional discussions pertain to radar waveform generation, control, and processing. A section on potential follow-on activities as well as a discussion on technology options and applications of the resulting system concept is also provided. [C2410]

#### "A 2.9-30.3GHz fourth-harmonic voltage-controlled oscillator in 130nm SiGe BiCMOS technology"

Wide tuning range voltage-controlled oscillators (VCO) are envisioned for applications in radars, broadband communications, phase-locked loops and clock generation/distribution. In this paper, post-layout simulation results of a combined VCO with a ring quadrature VCO (QVCO), an exclusive-OR (XOR) and a fourth-harmonic summation block in 130nm SiGe BiCMOS technology are presented. The combined VCO can be tuned from 2.9 to 30.3GHz. At 2.9GHz, the VCO consumes 32.89mW of power and generates -56.5 dBm (2.24nW) of output power into a 50 Ohm load. At 30.3GHz, it consumes 34.2mW of power and generates -33.5 dBm (398nW) of output power. In both cases, the XOR consumes ~25mW of power and the fourth-harmonic block consumes ~5mW of power. The VCO phase noise at 10MHz offset frequency is -102.2dBc/Hz and -86.04dBc/Hz at 2.9GHz and 30.3GHz, respectively. The VCO figure of merit (FOM) is in the range of -136 to -141. The microchip area is 750µm<sup>2</sup>4500µm<sup>2</sup>. This VCO provides the widest tuning range in the 130nm ring VCOs reported till now. [C2411]

#### "A Port waterside security systemic analysis"

Most of current Port Security analyses provide a clear view of the land-side security measures (fencing, access control, area monitoring...) but the seaside security issues are not always that clearly defined (exact extent, Authority in charge, assessment of realistic threats etc.). In one hand, there is no doubt that proper seaside security measures are even more site-specific than terrestrial ones. In the other hand, providing some sort of systemic analysis can help for "setting the scene" and easing the alignment of all stakeholders for specifying the strictly compliant but most cost-effective solution lay-out. Water-side port security includes a range of activities, of preventive character, ultimately aiming at controlling who and what enters the port area from the water side. It includes crews, passengers and cargo entering on-board of large announced vessels, on-board of small un-announced surface crafts, swimmers, divers or even small submersibles. It also includes vessel under-keel appendices commonly used for smuggling and, potentially, for terrorism... Response measures are very diverse. They can range from intelligence and information management, satellite imagery, radar and VTS down to sophisticated underwater and/or above-water sensors, manned or unmanned patrolling and inspection assets etc. A number of these measures are local, but others require wide area surveillance activities and some might require controls as far as the port of departure or the last ports of call. This paper aims in providing a taxonomy of the waterside port threats and the respective means of protection / response, identifying possible gaps and technology requirements. [C2412]

#### "Evaluation of an HF-radar ship detection and tracking algorithm by comparison to AIS and SAR data"

Since several years, High Frequency (HF) Over-The-Horizon (OTH) radar is used to measure oceanographic parameters, such as currents, waves, and wind direction over large areas up to 200 km off the coast. Cost effective low power systems transmitting less than 50 Watts have been developed, e.g. the WERA (WEUen Radar), and are now commercially available. Besides their applications in oceanography within coastal monitoring systems, these systems can also be used to detect and track ships, if they are modified for this functionality. A ship detection and tracking algorithm for HF-radar has been developed at the University of Hamburg (UHH) in cooperation with the Technical University of Hamburg-Harburg (TUHH). A first evaluation of this algorithm has been done using a data set acquired at Figueira, Portugal, using an 8 MHz WERA system. In May 2009, the NATO Undersea Research Centre (NURC) initiated a measurement campaign in the Ligurian Sea off La Spezia, Italy, which involved two WERA HF-radar systems operated at 12.5 MHz, one directional waverider and a meteorological buoy. In addition AIS data were recorded and satellite borne synthetic aperture radar (SAR) images were acquired. This paper presents preliminary results which show the effectiveness of the HF-radar as a long range ( 130 km) continuous-time coverage surveillance system, despite of its low spatial resolution of 1.5 km. The performance of the HF-radar ship detection and tracking algorithms are evaluated by comparison to AIS and SAR. The detection error found for this data set is less than 1 km for 68% of the comparisons between HF-radar and (AIS) reported locations, which is comparable to previous results from the Figueira data set. [C2413]

#### "Ship detection using high resolution satellite imagery and space-based AIS"

This paper presents a trial carried out in the Malangen area close to Troms city in the north of Norway in September 2010. High resolution Synthetic Aperture Radar (SAR) images from RADARSAT-2 were used to analyse how SAR images and cooperative reporting can be combined. Data from the Automatic Identification System, both land-based and space-based, have been used to identify detected vessels in the SAR images. The paper presents results of ship detection in high resolution RADARSAT-2 Standard Quad-Pol images, and how these results together with land-based and space-based AIS can be used. [C2414]

### "Concurrent use of satellite imaging and passive acoustics for maritime domain awareness"

The research being conducted in the Center for Secure and Resilient Maritime Commerce (CSR), a DHS National Center of Excellence for Port Security examines some basic science issues and emerging technologies to improve the security of ports and inland waterways, as well as coastal and offshore operations. This research follows a layered approach utilizing above water and underwater surveillance techniques. The investigated layers include satellite-based wide area surveillance; HF Radar systems providing over-the-horizon monitoring; and nearshore and harbor passive acoustic surveillance. Integration of these systems is aimed at achieving vessel detection, classification, identification, and tracking. In this paper, we present the results of sea tests where satellite imagery was combined with concurrent passive acoustic surveillance. The wide area sensing was provided by the University of Miami CSTARS facility's electro-optical (EO) and synthetic aperture radar (SAR) satellite imaging capabilities. Satellites detected the ships using a panchromatic EO sensor FormoSat-2 and SAR from the COSMO-SkyMed constellation. The Stevens Passive Acoustic System was used for detecting sound produced by the same ships that were detected by satellites. Concurrent Satellite-Acoustic measurements provide the following advantages: 1. Increasing the probability of small vessel detection and decreasing false alarms. 2. The joint systems can provide redundant detection and classification in conditions where one of the systems fails. For example, EO satellite imaging does not work at night and in fog and cloudy conditions while acoustic detection has limits during stormy weather due to ambient noise. SAR imaging can detect vessels in all weather, but provides less detail about a specific vessel. 3. Acoustics can provide target classification and bearing and satellites can give target localization and heading. SAR data can be used to estimate vessel speed in some cases. 4. Satellite-imaging is helpful for the acoustic detection of an underwater target in cases when satellite information allows separation of surface and underwater targets. 5. Joint measurements provide more data (information) for target classification. Several tests were conducted in New York Harbor, where the satellite images and acoustic signatures of the same boats were recorded. The satellite registered a number of small boats. The small boats were acoustically detected at distances up to 4 km and the signal generated by a passenger ferry was observed at a distance up to 7 km. [C2415]

### "Maritime surveillance with integrated systems"

Securing harbors and coastlines includes the task of monitoring and detecting people or vehicles attempting to enter a confined/protected area, other than at the legitimate access points. Modern systems should provide a total solution-including sensors, software, hardware, and a "control unit" to ensure complete security. Today a standard border security system may include several platforms, providing short-range, medium-range and long-range surveillance like perimeter protection, cameras and radars on observation towers, mobile surface and subsurface observation platforms-including land vehicles as well as maritime vessels or observation aerostats and aerial vehicles carrying all kinds of sensors to give a broader view of an area of interest. The ability to integrate those different types of surveillance means is essential to get a full picture and situation awareness. The paper introduces the concept of a universal ground station as a dynamic integrator for heterogeneous sensor platforms and sensor types depending on the surveillance needs of a specific maritime area of interest. A standardized interface to outside information systems is described taking into account the future need for combined civil and military operations for maritime safety and security. [C2416]

### "Archimede: Integrated Network-Centric Harbour Protection System"

Confined/inshore waters may represent the best type of environment for the conduct of clandestine operations, especially from the sea: the features of such an environment weaken the detection and identification processes carried out by the defenders, while allowing the covert execution of illegal activities, as well as a better exploitation of surprise. The most significant illegal activities conducted in such an environment include infiltration, drugs/weapons smuggling, sabotage/disruption of infrastructures, up to terrorist acts; these activities are accomplished through the use of a variety of means of transportation, which include cigarette boats and power boats, rigid hull inflatable boats (RHIBs), Ashing vessels, sailing/leisure boats, midgets, swimmers/divers (with open/closed breathing systems), and swimmer delivery vehicles (SDV). Requirements as flexibility, rapid reaction, resilience, fast deployment, high level automation, modularity, plug & play have a key role in modern surveillance architecture definition. The paper will describe the guidelines adopted to develop a CIP (Critical Infrastructure Protection) tactical architecture in accordance with the previous requirements. The CIP system

integrates different types of sensors (e.g. radar, IR, TV, SONAR, underwater acoustic network) and classes of vehicles (Surface, Underwater, Air Unmanned Vehicles) which cooperate in a multi environmental scenario (above water, under water, sea surface, ground and air). The focus is to develop the following functionalities: fuse, classify, identify and present all the data provided by the sensors and consequently generate warnings on the Command and Control (C2) and interact automatically with the console. The integration is performed to guarantee flexibility and modularity by means of tactical gateways developed in order to decouple the C2 system from sensor systems and vehicles. In particular, these gateways are designed to translate the subsystem proprietary data in a unique format. This allows integrating every kind and numbers of systems tailoring each time the specific gateway without modifying sensors, vehicles or C2. The system shows Network-Centric features and a wide set of growth above capabilities, even vehicles/sensors swarms, due to the gateway implementing a flexible middleware oriented to publisher/subscriber philosophy. [C2417]

### "Vital Electronics, the key to the developing dynamic GIS for the Baltic or other maritime environments"

Dynamic GIS can provide geospatial information in real-time in support of first responses to natural disasters (e.g. flooding on the Baltic ecosystem), man-made disasters (e.g. oil spill in the Gulf of Mexico), and for Search and Rescue (SAR) missions. All these scenarios require the integration between the real time data acquisition and dynamic GIS. The proposed Vital Electronic System for Maritime Applications (SYSTEM) integrates: a land or sea-based Data Center; a "Mother Ship" (used for sensor deployment and local data collection); and a large number of easily deployed, disposable, intercommunicating, and intelligent "Floaters" (equipped with task-specific sensors). An embedded Vital Electronics Computer composed of a hierarchical network of a large number of wireless PSoC-based GNODEs (configurable at deployment), forms the core of SYSTEM. The Floaters include both task-specific Sensing-only GNODEs and Aggregation GNODEs dedicated to local data aggregation and global communications tasks. Sensing GNODE may be equipped with submerged sensors (e.g. water temperature, pressure, salinity, acidity, passive acoustic, SONAR), and/or above water sensors (e.g. air temperature, proximity, sound, light, thermal IR, passive RF, RADAR). Aggregation GNODEs provide absolute location (e.g. GPS or other means) and also long-range communications with the "Mother Ship", a satellite or airborne platform, and/or a land-based data center. Ultimately, the data collected by the system can be integrated with reference GIS data (such as existing terrain and sea-bottom maps, as well as other live information). The composite data should be web-accessible with the appropriate level of security to relevant agencies and other authorized users. Currently, breadboard proto-prototype Floater electronics is under development. [C2418]

### "An above-water testing's result of experimental surveillance radar with 64-channels digital antenna array"

In this article are analyzed a results of experimental radar with digital antenna array full-scale test against above-water targets, small-boat detection and tracking. [C2419]

### "Integrated visualization and analysis of threats for marine and coastal regions via a Web-based GIS"

The paper presents a Web-Based Geographic Information System for integration, visualization and analysis of data on terrorist, ecological and natural threats. The system uses Open Source solutions like the GeoServer internet map server and the OpenLayers Javascript GIS client library to provide easily accessible and up-to date information related to a region of interest. The system is composed of modules which provide the following features: (1) blast and chemical attack simulation; (2) creation of hazard distribution maps; (3) analysis of risk propagation. Apart from hazard information, which maybe obtained from the simulation modules as well as inserted manually, the system collects and integrates data from several external sensors. The latter include a satellite ground station, oil spill simulation models, a radar and Automated Identification of Ships (AIS). The open, modular structure of the system allows for easy inclusion of different data sources, such as Multibeam Sonar Systems (MBSS) and echosounder. The paper presents case studies of the system applications for analysis, visualization and mapping of threats in the coastal area of the city of Gdansk, Poland. [C2420]

### "Tracking a non-cooperative mobile target using low-power pulsed Doppler radars"

Most target tracking applications developed for wireless sensor networks thus far employ passive sensors which detect the target's emissions. Their performance is thereby dictated by the magnitude of the target's signal and the receivers' sensitivity. Instead, we propose using a network of low-power Doppler radars that actively measure the target's radial velocity. Nodes combine their measurements to solve a system of nonlinear equations that estimate the target's position and velocity. Because these equations have no closed-form solutions we solve

them using numerical methods. These methods however can lead to local minima or even diverge in the presence of even small measurement noise. For this reason we couple the proposed numerical method with an Extended Kalman filter that models the target's movement along a straight line. Clearly the target does not always follow a linear path and so we augment this simple Kalman filter with a method that detects the target's turns and updates the filter's dynamical model accordingly. The combination of the two approaches improve tracking accuracy compared to the numerical solution alone. Results from simulations and a prototype implementation suggest that the combined solution can effectively track a mobile target with average localization error as low as 25 cm in a 10x10 m outdoor field. [C2421]

### "High frequency radar for coastal marine monitoring of currents and vessels"

Use of shore-based high frequency (HF) radar systems for environmental monitoring have become widespread in many countries around the world. In the U.S. various regions, such as the west and northeast coasts, have been instrumented. In California alone, some 50 radar stations contribute to the realtime monitoring of surface currents as part of the state's Coastal Ocean Currents Monitoring Program (COCMP). As recent events in the Gulf of Mexico highlight, environmental security can often hinge upon maintaining comprehensive monitoring systems that are in place and contributing to modeling and response systems at the time of any incident. Beyond real-time surface current maps, low-cost HF radar systems have the potential to contribute to offshore vessel tracking out to ranges of 180 km from the shoreline. Instrument networks that contribute multi-use functionality, such as HF radar networks, provide for effective and efficient long-term installations. [C2422]

### "Net based waterside security applications: From small solutions to maritime security networks"

The protection of military harbours is a complex task. A force protection system integrates several sensors and databases for ashore and waterside surveillance: • passive sensors (acoustic, magnetic, CCTV, IR, FO fence) • active sensors (Radar, Diver Detection Sonar) • remote / autonomous vehicles for inspection and surveillance • chart database • information database Additionally a network-based waterside security application should integrate several additional sources and services e.g.: • WEB based Automatic Identification System (AIS) • Satellite based AIS • Access to online databases e.g. weather information, ship register data • C4I data e.g. MCCIS (NATO C4I system) or JoCIS (EADS export C4I system) Also, new technical possibilities of modern multi touch HMI approaches and aspects of user centric man machine interface design will be discussed. [C2423]

### "SCANTER 5000 and 6000 Solid State Radar: Utilisation of the SCANTER 5000 and 6000 series next generation solid state, coherent, frequency diversity and time diversity radar with software defined functionality for security applications"

Coherent, Solid State Radar technology has been available for decades, however, it did not penetrate into harbor surveillance, VTS and related applications for cost and technical reasons. Technically, the main challenge is that dynamic requirements to radar in littoral waters and build up regions are much higher than to other radar applications. Those challenges have now been met and combined with well-renowned advantages from the Terma SCANTER product range. Methods are further refined and implemented on a new technology platform. The result is a software-defined radar series, tailored to individual market segments, virtually unrestricted by dynamic constraints. The digital radar concept with software-defined functionality makes the set-up of the radar easy. Furthermore, Interference rejection against disturbance from radars on ships passing nearby the radar has also proven effective, and the dynamic range has proved to be sufficient to eliminate any artefacts from a high number of large buildings and other structures in an operational area. Operational tests have been performed with impressive results. [C2424]

### "Multiple sensor fusion for effective abnormal behaviour detection in counter-piracy operations"

We propose a two-stage method based on multiple distributed sensors for detection of piracy operations at sea. The proposed method is based on fusion of evidence from radar and optical sensors as well as AIS signals. The sensors are land based, air based and space based. In the first stage, a number of detectors perform recognition of low-level events, such as vessel speed, direction, size and identification. Their outputs act as input to the second stage, which performs fusion and disambiguation of the first-stage detections taking into account multiple sensor fusion, multi temporal fusion and distributed fusion. The result should be effective abnormal behaviour detection, by which we mean a method that is able to detect piracy operation at an early stage, i.e. close to the time, or possibly before, the attack has occurred. A numerical example with a pirate attack is presented and discussed. [C2425]

### "Multi-frequency radar systems for monitoring vital signs"

This paper presents a theoretical and experimental analysis of multi-frequency radar systems for monitoring vital signs. The main advantage of using a multi-frequency architecture is the possibility to improve the detection sensitivity of heart beats and breathing rate while cancelling the body movement with signal processing. Simulations were carried out using ADS software for three systems operating at 5.8, 24 and 35 GHz. Different parameters such as antenna gain, mixer conversion loss and LNA gain were considered in the simulations for each system in connection with their system effects. It is shown that by using adequate correlation functions of received signals, it is possible to improve the detection accuracy. Experimental results are presented to validate the analysis and proposed approach. [C2426]

#### **"Detection of SSR signals in multipath airport environments by a multichannel receiver"**

Multipath propagation is a serious problem with Secondary Surveillance Radar (SSR) systems at airport apron and taxiway areas. In this approach, effective suppression of interference (garbling) by multipath components, using a multichannel receiver is presented. Thereby the SSR header format is exploited to detect multipath components, which are then eliminated by subspace based signal suppression. Extensive tests at Frankfurt international airport show the potential of the proposed approach to significantly improve reception at problematic sites. [C2427]

#### **"An experimental study of novel scanning system suitable for UWB radar application"**

In this paper, we present a novel electrical antenna scanning system suitable for short-range UWB radars. We have developed our previously proposed UWB impulse array antenna (IAA) and experimentally verified its usefulness. This antenna scanning system features two new technologies. First, each antenna element is equipped with an impulse generator. Second, the time control between the antenna elements is realized by using tapped delay lines and by transmitting trigger signals. An experimental UWB array antenna and a trial radar have been designed and fabricated. The measurement results show excellent performance of this antenna as a scanning antenna and as a short-range radar system. Thus, it is expected that this UWB antenna scanning system will contribute to the performance improvement, size and cost reductions of short-range radar systems such as obstacle detectors, anti-collision sensors and through-wall radars. [C2428]

#### **"A 0.8-13.4GHz combined voltage-controlled oscillator with an exclusive-OR in 130nm SiGe BiCMOS"**

Wide-tuning-range voltage-controlled oscillator (VCO) design is motivated by applications in broadband communications, radars, phase-locked loops and clock generation/distribution. In this paper, post-layout simulation results of a ring quadrature VCO (QVCO) combined with an exclusive-OR (XOR) to double the frequency in 130nm SiGe BiCMOS technology are presented. The combined VCO can be tuned from 0.8 to 13.4GHz. At 0.8GHz, the VCO consumes 13.98mW of power and generates -45 dBm (32nW) of output power into 50 Ohm loads. At 13.4GHz, it consumes 15.52mW of power and generates -30 dBm (1μW) of output power. In the tuning range, the XOR consumes ~11mW of power. The VCO phase noise at 10MHz offset frequency is -100.1dBc/Hz and -91.5dBc/Hz at 0.8GHz and 13.4GHz, respectively. The VCO figure of merit (FOM) is in the range of -127 to -142. The microchip area is 450μm<sup>2</sup>. [C2429]

#### **"Azimuth estimation in periodic linear sparse array by modified amplitude comparison monopulse radar"**

Estimation of direction of arrival (DOA) of a radar backscatter signal by means of an amplitude comparison monopulse estimation scheme (ACMES) is a common high precision technique. But due to spatial undersampling in a sparse array architecture the conventional ACMES results in azimuth ambiguity. In this paper it is proposed that azimuth ambiguity due to sparse array can be mitigated by replacing the sum beam in ACMES with a flat-top beam while keeping the difference beam unchanged. This approach was adapted and simulated for a naval HF Surface Wave Radar (HF SWR) with an array sparsely distributed among 4 mobile platforms each with a dense 9 element primary array. For a single target scenario the results confirm that the proposed approach achieves a precise angular estimate using a periodic sparse linear array. [C2430]

#### **"Millimeter wave FMCW radar system simulations including a 3D ray tracing channel simulator"**

In this paper a millimeter-wave radar system simulation environment for frequency-modulated continuous-wave (FMCW) radar using a 3D ray tracing channel simulator is presented. Therefore we use Agilent's RF design environment ADS® for system simulation and calculate the channel impulse response based on the data received from a 3D ray tracer in a Matlab®-co-simulation. To reduce computing time the whole signal flow is processed in a complex baseband representation and scattering center models are used as substitute for

complex polygon targets as further improvement. Nevertheless all effects occurring at harmonic bands and at DC due to nonlinearities in the transmitter and receiver circuits are well reflected in the simulation. A typical road scenario is simulated and the results show the capabilities of the simulation technique in terms of speed and accuracy. [C2431]

### **"An improved image-based Near-Field-to-Far-Field Transformation"**

An improved approach to determination of radar cross section (RCS) of electrically large targets from the scattered field measured with a monostatic radar over a circle in the near-field of the targets is presented. The frequency- and azimuth-domain scattering data are used to calculate a reflectivity map (radar image) of the target, from which RCS of the target is determined. The characteristic features of the proposed version of Near-Field-to-Far-Field Transformation (NFFFT) are the use of the calibrated signal from the network analyzer as the input data in the transformation and an improved focusing operator for producing reflectivity maps. The combination of these features is expected to result in a practical and more accurate approach to the analysis of scattering properties of electrically large targets. [C2432]

### **"Iterative DEM retrieving from multi-baseline interferometric SAR with MIMO"**

In the recent years, there has been growing interest in exploiting multi-baseline synthetic aperture radar interferometry (MB-InSAR) to solve layover effects and phase unwrapping problem of long baseline. In this paper we propose a novel system concept for MB-InSAR based on Multiple-Input Multiple-Output (MIMO) configuration. Alamouti space-time coding scheme based on two transmitters is introduced into multi-baseline InSAR system. We investigate its performance and processing features based on our space-borne multi-baseline InSAR simulator and iterative multi-baseline data fusion algorithm. The simulation results shows that the received signal to noise ratio (SNR) and the precision of iterative multi-baseline data fusion algorithm are significantly improved under Alamouti scheme. [C2433]

### **"Fish heart motion measurements with a body-contact Doppler radar sensor"**

This paper presents preliminary results demonstrating detection of cardiac motion and monitoring of fish heart rate using a contact antenna as a less-invasive alternative to surgical electrocardiogram (ECG) measurements. Ringtail Surgeonfish were used as initial test subjects with pcb patch and spiral antennas. The frequency of operation, 2.4 GHz, was chosen as a tradeoff between antenna size and propagation. The data show the importance of antenna placement for satisfactory heart motion detection. Measured heart rates varied with time and sedation level, generally near 60 bpm. Of the antennas used, the spiral antenna-provided signal most closely matched that seen with human test subjects. [C2434]

### **"Highly-integrated multi-channel radar sensors in SiGe technology for automotive frequencies and beyond"**

Nowadays, radar based safety- and comfort features for motor vehicles are available from nearly every car maker. For the final breakthrough highly-integrated and low-cost radar sensors are required. Current developments based on silicon germanium (SiGe) heterojunction bipolar transistors show the potential to become the technology of choice for the mass market. In this contribution beside regulatory issues and radar basics, state-of-the-art concepts and semiconductor circuits for highly-integrated multi-channel radar sensors at automotive frequencies around 77 GHz and beyond at 94 GHz and 120 GHz, are summarized. Novel concepts allow, e.g., the realization of integrated multiple-input multiple-output sensors, phased array transmitters, and digital beamformers. RF signal generation, based either on fundamental frequency oscillators or on frequency multiplier techniques, is applied in monostatic or bistatic radar configurations with homodyne or heterodyne receiver concepts. Above systems were all demonstrated by using Infineon Technologies' automotive qualified B7HF200 SiGe technology. By using a modified and advanced technology applications at 120 GHz are also presented. The shown components form the basis for next generation automotive systems as well as for industrial applications, which take advantage of the commercial availability of integrated radar frontends. [C2435]

### **"Compressive sensing for high resolution radar imaging"**

In this paper we present some preliminary results on the application of Compressive Sensing (CS) to high resolution radar imaging. CS is a recently developed theory which allows reconstruction of sparse signals with a number of measurements much lower than what is required by the Shannon sampling theorem. This method has already found its way in a number of applications where the sampling rate or the acquisition time are prohibitive for real time applications, such as high resolution medical and optical imaging. Actual demonstrations of CS with experimental radar data are still very few, and therefore in this paper we apply CS to two-dimensional radar imaging with experimental data. The measurement setup contains a small number of corner reflectors which are

illuminated using a stepped sequence of frequencies, over a range of aspect angles. The CS approach uses only a random selection of frequencies and angles, to reconstruct the two-dimensional image. The results obtained with CS are compared with the one achieved with conventional focusing (Matched Filter). The results show that the corner reflectors are properly reconstructed, with a significant reduction in the amount of measurement samples. [C2436]

#### "On the polarization response using resonances for target recognition"

In most studies concerning resonance based target recognition, targets are usually excited and measured using a linear polarized basis and at the same time ignoring the cross polarization component. In this paper, the possibility of using circular polarization in this context is investigated. Numerical results of some simple wire targets demonstrate that it would be easier to fully excite all of the important resonances using a circular polarization basis with due consideration of the co- and cross-polarized directions. [C2437]

#### "Pulse reduction method for circularly polarized synthetic aperture radar"

Many types of data compression for SAR raw data have been developed during the past 30 years. Since most of them focus on reducing the number of bits required to store signal information onboard, the resulting complexity has been a great hindrance to the implementation of an efficient compression algorithm. We propose a new method of data compression that can be carried out onboard a small-sized platform. The method imposes no additional requirement on the antenna size by reducing the number of pulses needed to produce an image and compensating the missing pulses based on information provided from other pulses. The most complicated task of reconstructing the missing pulses can be performed in the ground station, not onboard the small platform. Because fewer pulses are needed, less power will be required for transmitting and receiving the pulses. This is advantageous for reducing the pulse repetition frequency (PRF), which normally becomes higher for smaller antennas. This method will be applied to our circularly polarized synthetic aperture radar (CP-SAR) system, which is currently being developed toward a mission onboard a microsatellite. [C2438]

#### "Resonant frequency optimization of coaxially fed rectangular microstrip antenna using Particle Swarm Optimization algorithm"

Coaxial probe fed rectangular microstrip antenna is a popular type of patch antenna having applications in communication and radar systems. Particle Swarm Optimization (PSO) is a popular optimization algorithm and recently it is being used for design optimization of microstrip patch antennas. In this paper PSO has been used for optimization of resonant frequency of coaxial probe fed rectangular microstrip antenna. Investigation is made at different microwave frequencies and ranging between 3 GHz and 18 GHz. The optimization problem has three variables namely, patch length, patch width and position of the feed. Results encourage the use of PSO for optimal design. [C2439]

#### "Remarks on the Cramer-Rao inequality for Doppler-based target parameter estimation"

This paper outlines the problem of multi-static Doppler-based target position and velocity estimation. The Fisher information matrix is derived given a separate target illuminator and then given a target-based isotropic signal emission. Some remarks concerning the Cramer-Rao inequality and its relationship to the estimation problem are given. Some results concerning the placement of the receivers are given and some open problems are discussed. [C2440]

#### "Electromagnetic imaging using compressive sensing"

We develop a near-field compressive sensing (CS) estimation scheme for localizing scattering objects in vacuum. The potential of CS for localizing sparse targets was demonstrated in previous work. We extend the standard far-field approach to near-field scenarios by employing the electric field integral equation to capture the mutual interference among targets. We show that the advanced modeling improves the capability to resolve closely spaced targets. We compare the performance of our algorithm with the performances of CS applied to point targets and beamforming. In this paper, we consider two-dimensional (2D) scatterers. However, the results and conclusions can be extended to three-dimensional (3D) problems. [C2441]

#### "Autonomous marine craft navigation: On the study of radar obstacle detection"

Technological advancements over the years have increased the use of Radar technology in the field of robotics, especially in marine robotics to aid obstacle detection algorithms. Obstacle detection comprises of an analytical process in which different algorithms are applied to the field of study to determine the range of objects that are within the reach of a robot. Radar signal analysis and target detection in conjunction with target tracking are

attributes required for autonomous marine navigation. The paper presents a model which converts optimal estimates of radar range values for each range spectra into multiple targets down-range and also presents an approach for power range spectra (range bins) prediction using the radar range equation with adequate information of the signal-to-noise ratio (SNR) of the radar. Obstacle detection in the presence of noise raises certain probabilities of false alarms. Target characteristics are simulated and these are fluctuating targets and non fluctuating targets. Analytical models, simulations and techniques of obstacle detection for autonomous marine craft navigation using a continuous wave radar system were points of discussion in the paper. [C2442]

#### **"Trajectory control of autonomous fixed-wing aircraft performing multiple target passive detection and tracking"**

This paper presents progress made in a previously proposed algorithm for trajectory optimization of autonomous aerial vehicles performing multiple target tracking. The base algorithm, which was described in two earlier papers, involves a variant of the model predictive control approach, built on a partially observed Markov decision process (POMDP) model of the sensor-target system. In this paper modifications and additions made to deal with fixed-wing aircraft dynamics of the controlled vehicles are described and results of simulations involving multiple fixed-wing UAVs, no-fly zones and targets are presented. [C2443]

#### **"Multifunction array lidar network for intruder detection, tracking, and identification"**

This paper describes a novel lidar sensor network based on a small, flat, optical phase array laser aperture. The network of array lidars provides collaborative automatic detection, tracking, acquisition cueing, and intruder type identification, as well as free space optics communication. The lidar consists of four optical phased arrays, each with about 1 million radiating elements in a 1-cm<sup>2</sup> aperture that enable electronic beam steering analogous to microwave array antennas. The four arrays are mounted on four sides of a stalk and have a full 360° field of view. A small number of such stalks can perform target detection over a large area. [C2444]

#### **"Maximum likelihood approach for tracking multiple mobile agents with a moving Doppler radar system"**

Tracking mobile agents with a Doppler radar system mounted on a moving vehicle is considered in this paper. Dopplers modulated from mobile agents on the single frequency continuous wave signals are analyzed in order to estimate the positions and velocities of multiple mobile agents. The measurement noise is assumed to be Gaussian and the maximum likelihood estimation is utilized to enhance the localization accuracy. [C2445]

#### **"Line-based SLAM with slow rotating range sensors: Results and evaluations"**

This paper is concerned with the Simultaneous Localization And Mapping (SLAM) application with a mobile robot moving in a structured environment using data obtained from rotating sensors such as radars or lasers. A line-based EKF-SLAM (EKF stands for Extended Kalman Filter) algorithm is presented, which is able to deal with data that cannot be considered instantaneous when compared with the dynamics of the vehicle. When the sensor motion is fast relative to the measurement time, scans become locally distorted. A mapping solution is presented, that includes sensor motion in the observation model by taking into account the dynamics of the system. Experimental results with real-world 2D-laser scanner data are presented. Moreover a performance evaluation of the results is carried out. A quantitative performance evaluation method is proposed when dealing with a 2D line map and when a ground truth is available. It is based on the bipartite graph matching and combines several criteria that are described. A comparative study is made between the output data of the proposed method and the data processed without taking into account distortion phenomena. [C2446]

#### **"Application of AIS in Marine Search and Rescue Radar"**

Nowadays marine radar detects targets by Constant False Alarm Rate (CFAR). But the search and rescue efficiency is low in poor visibility or serious interference. In this paper, we reference learning mechanism, set up the AIS information for the sample and estimate the threshold  $t$  of the search targets with Maximum Likelihood (ML). Then any ship can be distinguished and searched. Experimental results show that using this method can improve the efficiency and accuracy of marine search and rescue radar searching the targets. [C2447]

#### **"The Research of the Training Assistant Decision-Making Support System Based on Data Mining Technology"**

The key of success in the battle lies in the usual training. Training is very important to the army. The Training assistant decision-making System can sum up the training data, and provides statically result to the officers of the training department. According to the suggestion provided by the training assistant decision-making System,

the training managers can draft the training plan of the next year. Data mining, which emerged about twenty years ago, has been rapidly evolving into a widely used technique for dealing with large amount of data for army to analyze training decisions and alternative. In this paper, we show how data mining methods can be used in the training plan drafting and improve the efficiency of the Training assistant decision-making support System.

[C2448]

### "Plant Species Classification Using a 3D LIDAR Sensor and Machine Learning"

In the domain of agricultural robotics, one major application is crop scouting, e.g., for the task of weed control. For this task a key enabler is a robust detection and classification of the plant and species. Automatically distinguishing between plant species is a challenging task, because some species look very similar. It is also difficult to translate the symbolic high level description of the appearances and the differences between the plants used by humans, into a formal, computer understandable form. Also it is not possible to reliably detect structures, like leaves and branches in 3D data provided by our sensor. One approach to solve this problem is to learn how to classify the species by using a set of example plants and machine learning methods. In this paper we are introducing a method for distinguishing plant species using a 3D LIDAR sensor and supervised learning. For that we have developed a set of size and rotation invariant features and evaluated experimentally which are the most descriptive ones. Besides these features we have also compared different learning methods using the toolbox Weka. It turned out that the best methods for our application are simple logistic regression functions, support vector machines and neural networks. In our experiments we used six different plant species, typically available at common nurseries, and about 20 examples of each species. In the laboratory we were able to identify over 98% of these plants correctly. [C2449]

### "X-band radar based SLAM in Singapore's off-shore environment"

This paper presents a simultaneous localisation and mapping (SLAM) algorithm implemented on an autonomous sea kayak with a commercial off-the-shelf X-band marine radar mounted. The Autonomous Surface Craft (ASC) was driven in an off-shore test site in Singapore's southern Selat Pua marine environment. Data from the radar, GPS and an inexpensive single-axis gyro data were logged by an on-board processing unit as the ASC traversed the environment, which comprised geographical and surface vessel landmarks. An automated feature extraction routine is presented, based on a probabilistic landmark detector, followed by a clustering and centroid approximation approach. With restrictive feature modeling, and a lack of vehicle control input information, it is demonstrated that via the novel RB-PHD-SLAM Filter, useful results can be obtained, despite an actively rolling and pitching ASC on the sea surface. In addition, the merits of investigating ASC SLAM are demonstrated, particularly with respect to the map estimation, obstacle avoidance and target tracking problems. Despite the presence of GPS and gyro data, heading information on such small ASC's is greatly compromised which induces large sensing error, further accentuate by the large range of the radar sensor. This work is a step towards realising an ASC capable of performing environmental or security surveillance and reporting a real-time active awareness of the above-water scene. [C2450]

### "A lidar perception scheme for intelligent vehicle navigation"

In urban environments, detection of moving obstacles and free space determination are key issues for driving assistance systems or autonomous vehicles. This paper presents a lidar-based perception system for passenger-cars, able to do simultaneously mapping and moving obstacles detection. Nowadays, many lidars provide multi-layer and multi-echo measurements. A smart way to handle this multi-modality is to use grids projected on the road surface in both global and local frames. The global one generates the mapping and the local is used to deal with moving objects. An approach based on both positive and negative accumulation has been developed to address the remnant problem of quickly moving obstacles. This method is also well suited for multi-layer and multi-echo sensors. Experimental results carried out with an IBEO Alasca and an Applanix positioning system show the performance of such a perception strategy. [C2451]

### "ATENEA: Advanced techniques for deeply integrated GNSS/INS/LiDAR navigation"

The ATENEA (Advanced Techniques for Navigation Receivers and Applications) project aims to join deeply integrated GNSS/INS receiver architectures and LIDAR techniques to provide an advanced navigation solution. The approach is suitable for a wide range of surveying applications in difficult environments, being Urban Mapping selected as reference case. ATENEA tackles the most challenging issues of this type of applications, showing how the use of Galileo signals, integrated positioning and observable processing can in one shot solve the more severe technical issues (robustness and continuity), increase accuracy and drastically reduce the system cost. The goal of the ATENEA project is to develop an advanced technology concept for seamless navigation at the cm-level regardless of the environment. [C2452]

### "Insights about reliability of Heterojunction Bipolar Transistor under DC stress"

250GHz SiGe(C) Heterojunction Bipolar Transistor (HBT) is a high performance device with low noise figure and high transconductance particularly required in power RF circuits. Applications are various: 77GHz automotive radars, non invasive imaging in airport for example. In order to achieve such specification, aggressive design leads to use of HBT at high collector current and sometime with VCEbias higher than collector emitter breakdown voltage with open base BVCEo. This last bias condition is known to induce progressive degradation with time and must be taken into account in Design-in-Reliability model. While reverse mode has been widely investigated, reliability of direct mode biased HBT is a new research field. It has been recently investigated, the underlying damage physics is now identified, the integrity of EB and BC junctions is known to be impacted as illustrated in the simulation of Fig. 1. The present paper aims at presenting a methodology for characterizing the aging of HBT in time and translating the parameters change of its model card. [C2453]

### "Adaptive polarimetric MIMO radar detection"

This paper mainly deals with the target detecting problem using polarimetric Multiple Input and Multiple Output (MIMO) radar with unknown covariance matrix. And the GLRT-based receiver is devised by resorting to the two-step design procedure. Specifically, the GLRT is devised with known covariance, and then, a suitable estimate of covariance is obtained using secondary data to plug into the derived test. The performance is assessed by several numerical examples, and the results show that polarimetric diversity can be exploited to enhance the performance of detection. Moreover, the adaptive loss is acceptable. [C2454]

### "The KA-MLFMA hybrid algorithm for analyzing the electromagnetic scattering from a 3-D target over random rough surface"

A hybrid algorithm combining the analytic Kirchhoff approximation (KA) and the numerical multilevel fast multipole algorithm (MLFMA) is proposed to calculate the electromagnetic scattering from a composite model of three-dimensional (3-D) perfect electric conducting (PEC) object over Gaussian random rough PEC surfaces. The KA and MLFMA are used to deal with calculations of the Gaussian rough surface and the object, respectively. Meanwhile, an iterative approach is employed to analyze the coupling interactions between the object and rough surfaces. From some numerical results, it can be illustrated that this hybrid algorithm can not only give the reliable results, but also greatly reduce the computational costs comparing with conventional numerical methods. The bi-static difference field radar cross-section (RCS) of a 3-D object above random rough surfaces is also discussed in this paper. [C2455]

### "Fusion method of radar data and IFF data based on NMF"

A new fusion method of radar data and IFF data based on nonnegative matrix factorization (NMF) is proposed in this paper, due to its strong part-based representation capability. The identification data from each sensor are put into one column of the input matrix and the fusion is realized by the converging process of a cost function. The proposed fusion method does not only show better performance in the credential level, but also has the advantage of limited computational load. The proposed method is simulated to validate the effectiveness and significant improvement in comparison with the data fusion algorithm under the framework of D-S evidential theory. [C2456]

### "A frequency synchronization method for hybrid bistatic SAR using direct path signal"

We propose a frequency synchronization method for hybrid bi-static synthetic aperture radar (SAR), which denotes a SAR system with a spaceborne illuminator and an airborne receiver. Due to the high altitude difference, the method based on extracting the direct path signal is employed. The mathematical model to compute the frequency offset between the two sides' oscillators is given. Among the model, a novel method for estimating the Doppler centroid for hybrid bi-static SAR is proposed. Error analysis is carried out, and the result indicates that under normal signal to noise ratio and frequency stability level the estimation error is within the acceptable value. A simulation was performed and the result shows that the imaging result is favorable after compensation. [C2457]

### "A forward-looking 3-D SAR imaging model using unequally spaced array"

A forward-looking 3-D SAR imaging model using an unequally spaced array is proposed in this paper. Firstly, based on the problems that a real equally spaced array suffers, like heavy calculation, the couple between antenna elements, an unequally spaced array with optimized element positions, is obtained by Simulated Annealing. Compared with several different types of arrays, the unequally spaced array has obvious advantages: when the lengths of arrays are the same, it successfully avoids the presence of grating lobes in the beam

pattern, and needs much less number of array antennas than the real array does; when the number of array antennas is fixed, it has narrower main-lobe than the real array. Furthermore, the signal model of the forward-looking 3-D SAR is analyzed and using BP algorithm the simulation results are presented, validating and verifying the feasibility of this model to reconstruct a 3-D scene. [C2458]

#### "An EKF multi-baseline phase unwrapping algorithm"

This paper presents a phase unwrapping algorithm based on the extended kalman filter (EKF) for multi-baseline SAR interferometry. This algorithm achieves simultaneously noise filtering and phase unwrapping by combining an EKF with a conventional path-tracing strategy. The simulation data processing results validate the effectiveness of proposed method, and show a significant improvement with respect to some conventional algorithms in some situations. [C2459]

#### "Ionospheric phase contamination correction method using Generalized S-Transform"

This paper analyzes the instantaneous frequency (IF) estimation properties of S-Transform (ST) and proposes the reason of the poor estimation performance for ST at low frequencies. A Generalized S-Transform (GST) which has better performance than the ST at low frequencies is therefore introduced in the IF estimation. It is the first time applied in the phase contamination correction of Over-the-horizon-radar (OTHR) in this paper. The effectiveness of the GST has been studied by using the data of high frequency surface wave radar (HFSWR) with artificially added phase perturbations. Through the comparisons on the calculation complex and the effectiveness of contamination correction with the Pseudo Wigner-Ville Distribution (PWVD) method and the Modified Adaptive Short Time Fourier Transform (MASTFT) method in the referred literatures, the GST method used in this paper has much better performance. [C2460]

#### "Compressed sensing moving target detection for MIMO radar with widely spaced antennas"

The moving target detection based on compressed sensing (CS) multiple-input multiple output (MIMO) radar with widely separated antennas is studied. The centralized processing is considered. The traditional centralized MIMO radar requires an exhaustive search on every possible two dimensional target velocity, resulting in huge computational complexity. In this paper, we adopt the CS technique to drastically reduce the computational burden and evaluate the reduction of the required complexity. We derive the moving target detector for the CS MIMO radar. The performance of the proposed detector is analyzed, and the receiver operating characteristic (ROC) curves are provided. [C2461]

#### "Coexistence studies for TD-SCDMA with radar system in the band 2300-2400 MHz"

Because of the lack of sufficient frequency bands, the TD-SCDMA system is possibly deployed in the same band with other existing communication systems. In this paper, the coexistence studies for the TD-SCDMA system with the radar system, which has been widely deployed in the band 2300-2400 MHz, is presented. The dynamic system simulation methodology is utilized in the coexistence studies, and simulation results of the impacts on the system performance with different isolation distance and frequency spacing are given. The feasibility of the coexistence between TDSCDMA and the radar system is investigated and some useful conclusions are also presented. [C2462]

#### "Retrieval of oriented vegetation parameters based on experimental data of PolInSAR"

Polarimetric SAR interferometry (PolInSAR) can be used to inversion of vegetation parameters and a two-layer coherent scattering model composed of a random volume over the ground is applied usually. However, the propagation of the electromagnetic waves is anisotropic because the extinction coefficients are highly polarization dependent, the random model is inapplicable. In this paper, a new vegetation model composed of an oriented volume over the ground is employed and experimental data about the true scene can be gained through the microwave anechoic chamber. Finally, the oriented vegetation parameters are retrieved by using three-stage method. [C2463]

#### "Modeling and simulation of chaff cloud interference to SAR"

As a typical passive jamming, chaff cloud have a strong moderating effect on various radar systems. It's also one of typical interference to synthetic aperture radar (SAR). In order to study the impact of chaff cloud on the SAR, based on mathematical expression of SAR reflection deduce the formulation of single chaff reflection, obtained that there is the incoherent Gaussian white noise interference with all band in the azimuth direction. Then from single chaff reflection mathematical expression deduce the chaff cloud mathematical expression, obtained that there is the coherent interference in the radial direction. Give the calculation method of jam power.

At last show the simulation result of chaff cloud interfere. [C2464]

### "Statistical MIMO radar based on coherent signals"

Multi-Input and Multi-Output (MIMO) radar was a new radar technology in the recent years, which used spatial diversity gain of the signal instead of coherent gain in traditional phased-array radar. Using the ideal point source model, this paper made an analysis of these two kind gain's contribution to radar detection system, which was divided into two classes: the contribution to system robustness and the contribution to improve the signal-to-noise ratio. Based on this, proposed that the MIMO radar's space diversity gain could make more contribution to signal-to-noise ratio, which rationality was showed by the modification of the statistical MIMO model. The above theory was verified by simulation. [C2465]

### "Chaotic signal reconstruction with application to noise radar system"

In this paper, we present a new method that is accurate and has low computational complexity to estimate the initial condition of chaotic signal. Then the estimation method is applied to a noise radar system using noncoherent reception scheme. In the new scheme, the received signal correlates with the estimated transmitted signal by the estimation method proposed in this paper. The new scheme avoids a difficult problem that how to accomplish the transmitted signal delayed by delay lines when the signal band is large. Finally, computer simulations are performed to illustrate the effectiveness of the proposed scheme. [C2466]

### "Study of Common Simulation Platform of Pulse-Compression Radar Signal Processing: A Method of Studying Radar System"

Pulse-Compression radar signal processing simulation platform provides a new way on radar digital signal processing, which is not only low-cost, easy maintenance, as well as the characters of standardization, modularization, scalability and restructure. In this paper, we present a Pulse-Compression radar echo signal processing simulation framework and module structure based on pulse compression approach, and analyze the system's data stream through a set of simulation data in interaction, encapsulation and generalization. [C2467]

### "Passive multi target tracking with GM-PHD filter"

This paper considers the challenging problem of multitarget tracking with passive data, obtained here by geographically distributed cameras. We use a Gaussian Mixture Probability Hypothesis Density filter approach to solve this difficult problem. As we make no spatial assumptions for the birth process, we use a slightly modified filter to obtain our results. We first describe the modified filter and detail our application before we present some results obtained on a realistic test scenario. Our simulations demonstrate that the proposed Probability Hypothesis Density filter is a promising candidate for three dimensional passive multi target tracking in clutter. [C2468]

### "Active clutter reduction through fusion with passive data"

Active and passive sonar systems often provide complementary information. Active systems generally provide good localization but are subject to high rates of clutter from bottom and volumetric scatterers. Passive systems generally have good resolution only in bearing and only can detect objects that emit acoustic energy. By fusing measurements from both types of systems, the passive data can be used to reduce the clutter in the active data. The result is improved target tracking, as shown in two examples, including the injection of a single target into a recorded active clutter dataset. [C2469]

### "Gaussian Mixture initialization in passive tracking applications"

This paper describes the approximation of a nonlinear posterior density by a Gaussian Mixture (GM). The GM is used to initialize a bank of Kalman filters. For each Gaussian term, a Kalman filter is started. The basic conditions and the quality of the approximation are discussed. Examples from different tracking applications, the multistatic tracking and passive emitter localization using TDOA measurements, are investigated. The results are discussed and compared with existing approaches. The RMS error of the estimate is used as an evaluation criterion. The performance of the Gaussian Mixture approach is analyzed in Monte Carlo simulations. [C2470]

### "Simultaneous navigation and SAR auto-focusing"

Synthetic Aperture Radar (SAR) equipment is an all-weather radar imaging system that can create high resolution images by means of utilising the movement of the flying platform. Accurate knowledge of the flown trajectory is essential in order to get focused images. Recently SAR systems are becoming more used on

smaller and cheaper flying platforms like Unmanned Aerial Vehicles (UAV). Since UAVs in general have navigation systems with poorer performance than manned aircraft, the resulting images will inevitably be unfocused. At the same time, the unfocused images carry the information about the platforms trajectory that can be utilised. Here a way of using SAR images and their focus measure in a sensor fusion framework in order to simultaneously obtain both improved images and trajectory estimate is presented. The method is illustrated on a simple simulated example with promising results. Finally a discussion about the results and future work is given.

[C2471]

### "A general approach for altitude estimation and mitigation of slant range errors on target tracking using 2D radars"

When target tracking using polar (azimuth and slant range only) measurements is performed, the most usual approach is to simply ignore slant range errors and perform target position estimation on a 2D plane. In reality, slant range errors are very significant and can seriously impair tracking. 3D target tracking can mitigate the effect of slant range errors, and, in some cases, even allow altitude to be estimated. This paper analyzes previous approaches on 3D target tracking using 2D radars and their drawbacks, and proposes efficient methods (based on EKF, UKF and AMM-EKF) that can be used on realistic scenarios, without significant increase on computational cost. A robust filter initialization technique is also proposed for these methods. [C2472]

### "Parameter estimation of K distribution based on second-kind statistics"

The parameters of K distribution are estimated in this paper, and the log-cumulant estimator is proposed based on second-kind statistics. The performance of the log-cumulant estimator is tested on the Monte Carlo simulations. Parameter estimation results demonstrate that the log-cumulant estimator leads to high estimation accuracy for the small values of the shape parameter. [C2473]

### "Robust sensor fusion in real maritime surveillance scenarios"

This paper presents the design and evaluation of a sensor fusion system for maritime surveillance. The system must exploit the complementary AIS-radar sensing technologies to synthesize a reliable surveillance picture using a highly efficient implementation to operate in dense scenarios. The paper highlights the realistic effects taken into account for robust data combination and system scalability. [C2474]

### "GMTI tracking using signal strength information"

Signal strength information is a standard output of a modern radar system. Provided the amplitude of the target returns exceeds the false alarm background, the consideration of signal strength may lead to improved target estimates, depending on the scenario. In this paper a Bayesian tracking algorithm is presented which incorporates the signal strength information. In contrast to previous approaches, the knowledge on the target's signal strength is not only used for an improved calculation of the association probabilities, but it enters into the algorithm as a random variable which is sequentially estimated. By this approach it is not only possible to discriminate closely-spaced targets and improve the track continuity, but also to support possible classification and identification tasks. The signal strength fluctuations of the target returns are modeled by the Swerling-I and Swerling-III cases. As a first performance evaluation, numerical results are presented based on a multi-target simulation scenario. [C2475]

### "A simulation framework for testing GMTI trackers"

Trackers for Ground Moving Target Indicator (GMTI) radar have to be benchmarked in order to yield good results. For many benchmarking purposes, the usage of real data may become expensive and in-feasible. It may also lack of knowledge of the ground truth. Simulating GMTI situations is a less-expensive alternative to real measurements. In order to get a realistic scenario, the motion and radar cross section (RCS) of ground targets, the motion of sensor platforms and the properties of GMTI sensors have to be simulated. In this paper, considerations for a realistic motion and sensor model are presented. Then, an implementation of a framework for simulation is shown, together with first experiences in tracker benchmarking using this framework. [C2476]

### "Applying optimal search theory to inland SAR: Steve Fossett case study"

Steve Fossett, a famous adventurer, disappeared on 3 September 2007 in a remote area of Nevada during a solo pleasure flight in a small aircraft. An intense search conducted by both private parties and multiple government agencies was eventually suspended with negative results. Fossett's wreck was discovered in California's eastern Sierra Nevada mountains by a hiker almost one year later. This paper describes an independent effort to direct search efforts using probabilistic search theory and optimization techniques. Using

field data from various sources, several scenarios were constructed to establish a prior distribution of the crash site. Search efforts were assessed to generate a posterior of the crash location for future search efforts. [C2477]

### "Constrained multi-object Markov decision scheduling with application to radar resource management"

Hierarchical radar resource management uses multi object Markov decision scheduling with a constraint on the resources. In this paper we give a detailed description of constrained multi-object Markov decision scheduling in its general form and the separation that is achieved in the dynamic programming level using Lagrange multipliers. We then apply this general model to obtain a simultaneous beam and waveform scheduling method for radars based on an objective function that depends on both state and action. This method extends on a previous hierarchical method for beam scheduling with an objective function defined only on state. We further improve the objective function based on entropy reduction. This criterion makes the resource management to be more flexible in favor of measurements that carry more information. [C2478]

### "Efficient multilateration tracking with concurrent offset estimation using stochastic filtering techniques"

Multilateration systems operate by determining distances between a signal transmitter and a number of receivers. In aerial surveillance, radio signals are emitted as Secondary Surveillance Radar (SSR) by the aircraft, representing the signal transmitter. A number of base stations (sensors) receive the signals at different times. Most common approaches use time difference of arrival (TDOA) measurements, calculated by subtracting receiving times of one receiver from another. As TDOAs require intersecting hyperboloids, which is considered a hard task, this paper follows a different approach, using raw receiving times. Thus, estimating the signal's emission time is required, captured as a common offset within an augmented version of the system state. This way, the multilateration problem is reduced to intersecting cones. Estimation of the aircraft's position based on a nonlinear measurement model and an underlying linear system model is achieved using a linear regression Kalman filter [1, 2]. A decomposed computation of the filter step is introduced, allowing a more efficient calculation. [C2479]

### "Integrated GMTI radar and report tracking for ground surveillance"

The fusion of information gathered from multiple sources is essential to build a comprehensive situation picture for ground surveillance. In this paper, an approach which performs data correlation and fusion for ground moving target indicator (GMTI) radar data and SALUTE reports is described. GMTI data are simulated based on the ground truth of a military exercise and processed by a GMTI group tracker employing a Cardinalized Probability Hypothesis Density (CPHD) Filter. Multi source fusion is performed by combining the GMTI tracker and report tracker using our data fusion architecture. The scenario used in the experiment is tracking of closely spaced ground targets by GMTI, supplemented with some collected SALUTE reports. The challenges include tracking ground targets moving across foliage and tactical movement (start-stop mode). Using the designed test scenarios, this paper looks into different aspects of benefits by performing cross fusion with GMTI data and SALUTE reports. [C2480]

### "A new co-located MIMO radar system for multi-target tracking and localization"

Multiple Input Multiple Output (MIMO) radars are a new generation of radar systems that bring with them many benefits compared to traditional phased-array and multistatic radars. Target localization using MIMO radars with co-located antennas has been recently discussed in the literature. It has been shown that the maximum number of targets that can be uniquely localized in one cell is bounded. This paper presents a new application of MIMO radars in Multi-Target Tracking (MTT) problems. Firstly, the previous model for co-located MIMO radars is modified in order to guarantee the observability in received measurements. Afterwards, it is shown that using prior information about the motion of targets relaxes the limitation on the number of uniquely localized targets. For filtering part, an Un-scented Kalman Filter (UKF) algorithm is used to update states of targets. Simulation results confirm the superiority of proposed approach in estimating states of multi-targets falling in the same resolution cell. [C2481]

### "Radar cross section of the human heartbeat and respiration"

This paper describes an experimental approach for finding the radar cross section (RCS) of human heartbeats and respiratory movements. A measurement setup, a calibration routine and required processing steps are presented. Using a 2-3GHz Ultra Wideband (UWB) radar, heartbeats and respiration of a human subject were recorded from a distance of 1.14m. Combining the recorded data to measurements with a calibration sphere, the

calibrated human heartbeat and respiration RCS was detected. [C2482]

### "UWB Microwave Monopulse Radar System for breast cancer detection"

The concept of an Ultra Wideband (UWB) Monopulse Microwave Radar System for detection and location of breast cancer is described. The system uses a two-element Tapered Slot Antenna (TSA) array accompanied by a UWB 180° hybrid which scans the breast. When the breast tissue features symmetry with respect to the array axis and the hybrid enables the 180° out phase feeding operation, the array automatically eliminates background while extracting information about an off axis target. The data obtained from the scan is post-processed using a novel imaging algorithm to locate the target. The design of the required 2-element UWB array antenna and the 180° hybrid is presented. The validity of the proposed breast cancer detection method is demonstrated in an example of a simple breast phantom formed by a cylindrical plastic container filled with a vegetable oil and small cylindrical targets. [C2483]

### "A secured chaos encrypted mode-S aircraft identification friend or foe (IFF) system"

This paper introduces a new technique for aircraft identification friend or foe (IFF). The technique is based on using a proposed Chaos Advanced Encryption Standard (AES) with mode-S IFF. AES has a key size of 128 bits and a substitution-linear transformation network with 10 rounds. The sensitivity of the chaos initial condition gives the algorithm the ability to use as a second key. The first key was assigned using a soft look-up table used periodically. The second key was assigned using the date of the current day by both interrogator and the transponder. This technique gives the system more security and confidentiality which is compatible with mode-S IFF interrogation and reply messages format. It requests a new data on the reply signal. This data increase the radar performance for detection and tracking the friend targets in active and passive jamming environments. The results obtained from this technique on the simulated interrogator and transponder signals shows that this scheme can be easily implemented and provide the air defence system a secured aircraft authentication.

[C2484]

### "Search Aid System Based on Machine Vision and Its Visual Attention Model for Rescue Target Detection"

The prompt search and rescue of lifesaving target is very important in the case that a marine casualty occurs. To detect the small target in the wide views over the sea, we have proposed a machine vision system to aid search and rescue on the sea, which combines remote sensing, radar, infrared with visual light technology. One of the detection methods in this system, which is based on visual attention mechanism, is proposed in this paper to find rescue target from visual light image. The color information, image intensity and other image properties are used to generate the feature maps that form the saliency map subsequently with the weighted integrating strategy. The experimental results show that the proposed method is efficient to detect the small target in cluttered ocean scene. [C2485]

### "SAR Images Despeckling via Bayesian Shrinkage Based on Nonsubsampled Contourlet Transform"

We propose a novel and efficient SAR image despeckling via Bayesian shrinkage based on nonsubsampled contourlet transform, which has been recently introduced. Despeckling by means of contourlet transform introduce many visual artifacts due to the Gibbs-like phenomena. Nonsubsampled contour let transform is a flexible multiscale, multidirection and shift-invariant image decomposition that can be efficiently implemented via transform. A Bayesian estimator is applied to the decomposed contour let coefficients of the logarithmically transformed image to estimate the best value for the noise-free signal. Experimental results show that compared with conventional wavelet despeckling algorithm, the proposed algorithm can achieve an excellent balance between suppresses speckle effectively and preserves image details, and the significant information of original image like textures and contour details is well maintained. [C2486]

### "Path Planning for UAV in Radar Network Area"

This paper mainly introduces a path planning algorithm for the unmanned aerial vehicles (UAVs) to avoid radar network. The radar network contains several radars which have different detection ranges. In this algorithm, firstly, according to the theory of the Delaunay triangulations, a directed graph is constructed based on the locations and the detection ranges of the radars. Secondly, the Dijkstra algorithm is used to search an initial path for the UAV. Thirdly, the optimization approach is used to calculate the optimal control vector which the UAV needs when the UAV navigates to the goal position along the initial path. The simulation results showed that the paths which are planned by the algorithm not only could guide the UAV to avoid the radar network, but

also satisfy some task-required constraints, which include temporal, spatial, and UAV maneuverability constraints. [C2487]

### "Electromagnetic absorbing nanocomposites including carbon fibers, nanotubes and graphene Nanoplatelets"

Nanocomposites loaded with different types of micro/nanofillers are developed and characterized for use in electromagnetic radar absorbing materials with minimum thickness. It is demonstrated that the tailoring of the desired EM properties can be achieved by the proper choice and combination of both the filler and the matrix. In particular, graphene Nanoplatelets dispersed in a bisphenol-A based epoxy matrix feature a loss tangent lower than a few percent and tailored dielectric permittivity. The designed bilayer absorbers entirely made with nanocomposites have thicknesses of 2 mm and 1.5 mm for the X-band and Ku-band respectively. [C2488]

### "FPGA based design and implementation of an Adaptive Binary Integrator"

Binary detection integrator is characterized by its simplicity, resistance against asynchronous interference, and its good detection performance. It suffers from detection loss due to non-homogeneous background. To overcome the limitations of binary integration, the Adaptive Binary Integrator (ABI) is used. ABI achieves the advantages of automatic detection and adaptive thresholding over the binary integrator. The presented adaptive binary integrator is designed and implemented using field programmable gate arrays (FPGAs). The performance of the proposed ABI is evaluated through the Receiver Operating Characteristic (ROC). The implemented hardware is evaluated experimentally under different conditions of noise, asynchronous interference, sea clutters, and rain clutters. High probability of detection is achieved by designing the Constant False Alarm Rate (CFAR) processor which is the first stage in the proposed ABI for relatively high probability of false alarm. The final probability of false alarm is then reduced by the effect of integration. [C2489]

### "Estimating polynomial structures from radar data"

Situation awareness for vehicular safety and autonomy functions includes knowledge of the drivable area. This area is normally constrained between stationary road-side objects as guard-rails, curbs, ditches and vegetation. We consider these as extended objects modeled by polynomials along the road, and propose an algorithm to track each polynomial based on noisy range and bearing detections, typically from a radar. A straightforward Kalman filter formulation of the problem suffers from the errors-in-variables (EIV) problem in that the noise enters the system model. We propose an EIV modification of the Kalman filter and demonstrates its usefulness using radar data from public roads. [C2490]

### "Radar tracking performance when sensing and processing compressive measurements"

Radar tracking performance is improved when using waveforms at high delay-Doppler resolution with concentrated ambiguity functions. High resolution measurement acquisition and processing, however, requires high rate sampling and intensive processing. Alternatively, compressive sensing and processing can be used to significantly reduce data rates with no loss in resolution. The drawback is, however, that using compressive measurements increases ambiguity function sidelobes and thus tracking error. In this paper, compressive sensing and processing is applied to single target tracking. The effect of compressive sensing and processing on the ambiguity function sidelobes is examined. Moreover, estimation using compressively sampled and processed Bjojrck CAZAC sequences is shown to be improved over estimation using linear frequency modulated waveforms sampled at the Nyquist rate. This shows that low-rate acquisition and processing maintains reliable tracking performance at high resolution, while simplifying the receiver and reducing computational expense. [C2491]

### "Effects of high-power and transient disturbances on wireless communication systems operating inside the 2.4 GHz ISM band"

This paper deals with special HPEM sources and their effects on wireless communication systems operating inside the 2.4 GHz ISM band. Different measurements have been performed to investigate the effect of UWB and radar pulses on the receiver of a digital wireless communication system. First the coupling of UWB and radar pulses into a typical bar antenna usable for the 2.4 GHz ISM band has been measured. Based on the coupling measurements the effects in the baseband of a typical wireless receiver is being investigated for different radar and UWB pulses. Finally a worst-case analysis by using a HF switch is being investigated for a WLAN and Bluetooth system. The results show how possible interferences with different interference durations and interference repetition rates can cause effects on the performance of a wireless communication system. [C2492]

### "Parallel processing techniques for the processing of synthetic aperture radar data on FPGAs"

This paper presents a design for the parallel processing of synthetic aperture radar data using one or more Field Programmable Gate Arrays (FPGAs). Our design supports real-time computation of a two-dimensional image from a matrix of echo pulses and their corresponding response values. Components of this design include: (a) central processing pipeline to perform back projection calculations, (b) pre-fetch cache to minimize external memory access latency, (c) memory bridge that serves as the primary on-chip storage for pulse data, and (d) a pixel queue to direct image data in and out of the pipeline. Design parameters may be adjusted to achieve optimum performance, and multiple instances of this design may be replicated on-chip to achieve prespecified performance objectives. We provide a complexity analysis as a function of the input and output parameters. Simulation results based on an implementation of this design show that our design achieves 160 GFLOPs per instance on a simulated Altera Stratix III EP3SL150 FPGA, and scales well for output image size ranging from 500 × 500 pixels to 5,000 × 5,000 pixels. [C2493]

### "Real time processing of a Lattice Wave Digital matched filter"

Based on the theory of wave digital filters (WDFs), an algorithm to represent a single pulse matched filter for radar applications is described. This matched filter is obtained by calculating the coefficients of a Lattice Wave Digital Filter (LWDF) adaptors by getting the filter transfer function that results from the arbitrary amplitude transfer function method. In this paper, we are interested only in the main loop of the matched filter frequency response and its pass-band edges locations. The design methodology permits the realization of the system for real-time applications. [C2494]

### "Analysis of signal characteristic and resolution in ground forward scattering radar"

In this paper, the target magnitude signature and Doppler signature characteristics are analyzed in detail. Based on the Doppler signature, the target motion parameters can be extracted. Combining the magnitude signal and Doppler signal, the target convoy resolutions in ground forward scattering radar (FSR) are analytically obtained, which is different from the conventional shadow inverse synthetic aperture radar (SISAR) resolution. Finally the experimented results fully verify the correctness of theoretic analysis. [C2495]

### "Wide area search munition delivered by the intermediate carriers"

This article introduces a new concept of SEAD systems-wide area search munition delivered to the zone of enemy air defense by the expendable intermediate carriers. It is assumed that the expendable intermediate carriers will replace conventional aviation in SEAD missions or at least reduce the risk for conventional aircrafts. Wide area search munition agents (mini-UAVs), delivered by expendable carriers, will extend SEAD actions to the territory controlled by the enemy IADS. The proximity of the enemy radars will increase the effectiveness of the SEAD efforts and allow countering the LPI radars. [C2496]

### "Adaptive clutter map detector in nonhomogeneous environment"

The Ordered Data Variability (ODV) technique is introduced into hybrid clutter map/L-CFAR technique, which is used to process the echoes on the clutter map spatially. The new method is called as Clutter Map/ODV (CM/ODV) technique. An analytic expression of detection probability in homogeneous environment is presented, and detection performance in three different situations in nonhomogeneous environment is analyzed. The CM/ODV can censor interfering targets adaptively and prevent the masking effect, moreover, it doesn't need any priori information, so the new kind of clutter map technique performs robustly. [C2497]

### "Self-calibrated method for distributed small satellite SAR systems"

In practice, the performance of the Distributed small satellite synthetic aperture radar (DSS-SAR) systems is affected seriously by the unavoidable array errors. In this paper, the phase and position errors are considered with the gain error calibrated by the adaptive processing. The clutter echo usually has Doppler (azimuth) ambiguities which is caused by lower pulse repetition frequency (PRF) in such systems. The array error estimation method is given based on the Doppler ambiguities. By analyzing the conventional method in which the phase error and the position error are estimated by iterating between each other, we find that: the steering vector of one Doppler ambiguity associated with the zero Doppler bin is conjugate to its opposite one. So the phase error can be directly obtained though the position error exists. The proposed method is given based on this. It estimates the position error independently without iterations between them. The proposed method can perform approximately as well as the conventional method but with less computation load. Simulations can verify its effectiveness. [C2498]

### "Prominent point InSAR processing"

The statistical property of prominent points in SAR interferometry is discussed after the derivation of the probability density function of Hermitian product of two correlated Rice class SAR signals. A simple processing strategy is then provided for better phase unwrapping performance based on prominent points. The validity of the proposed method is demonstrated by ENVISAT data. Our initial results show the advantage of such algorithm over conventional ones. [C2499]

### "Point target reference spectrum of bistatic SAR with parallel flight paths"

The precise point target reference spectrum of bistatic SAR has been a difficult problem for a long time. Many of the current available algorithms have approximation during deducing. This paper deduces the precise expression in Doppler-Frequency domain with the configuration of parallel flight paths and constant velocity of each platform. At last, simulations are given to demonstrate the good focusing performance. [C2500]

### "A new method of motion estimation and imaging interval selection of ISAR system based on geometry invariance of rigid target"

In this paper, a new method of motion estimation and imaging interval selection of ISAR System is proposed. In this method, based on the 1D-to-3D reconstruction algorithm, the motion path of the rigid target can be reconstructed firstly using the 1D range data of some scatterers extracted from the high-resolution range image of ISAR. Then according to the inertia of the target, the reconstructed motion path is fitted as a smoother trace with the rotation angles estimated effectively. Finally, the Hough Transform is utilized to extract a section of linear path on the 2D plane of the two rotation angles as the selected optimum interval of the ISAR imaging. Simulation results confirm that the method we proposed is effective and can be applied flexibly in current ISAR imaging techniques. [C2501]

### "A novel algorithm for synthetic aperture radar imaging based on compressed sensing"

To achieve high-resolution images, synthetic aperture radar (SAR) faces considerable technical challenges such as huge amount of data samples and high hardware complexity. Compressed sensing (CS) theory shows that the super-resolved images can be reconstructed from an extremely smaller set of measurements than what is generally considered necessary by Nyquist/Shannon theorem. In this paper, a new algorithm of SAR imaging based on the concept of CS is presented, in which a random fractional Fourier transform (FRFT) matrix is used as the sensing matrix. By utilizing the FRFT matrix the demodulator for de-ramping the linear frequency modulation signal can be eliminated. Simulation results with both simulated and real data exhibit the validity of the proposed algorithm. [C2502]

### "Method to determine CPI for ubiquitous radar"

Ubiquitous radio: is a new radar system that provides continuous and uninterrupted multifunction capability within a coverage volume. Continuous coverage from close-in "pop-up" targets in clutter to long-range targets impacts selection of waveform parameters. The CPI (Coherent Processing Interval) must be long enough to achieve a certain signal-to-noise ratio (SNR) that insures the efficiency of detection. This paper analyzes the condition of detection in the case of low SNR, discusses three different cases that would occur during integration and presents a method to determine the CPI. The simulation results show that it is available to determine the CPI for targets detection with SNR as low as -26dB in the experimental system. [C2503]

### "Study of array collocation for MIMO radar based on beampattern synthesis"

The beampattern of MIMO (Multiple-input Multiple-output) radar is the product of transmitter and receiver beam pattern. Exploiting uniform linear array, the beampattern has no grating lobe when a certain relation between the space of transmitter element and receiver element is met. Moreover, this kind of collocation takes on maximum virtual array aperture. Exploiting non-uniform linear array, the beampattern will have better performance. Giving the restriction of array aperture and the number of element and constructing objective function based on minimum side lobe, we make use of GA (generic algorithm) to optimize the element position and then get the non-uniform linear array collocation scheme. Simulations verify the validity of the proposed method. [C2504]

### "New target detection method in strong active jamming background for polarimetric radar"

A new method of target detection for polarimetric radar in the presence of strong active jamming is proposed. Based on analysis of the polarization characterizations of the signals received by polarimetric radar, the target detection is achieved through testing on the polarization information. Comparing with the traditional method of

target detection made in time-frequency domain, the detection performance of the new method is improved because the influence of the strong active jamming is avoided. The performance of the new method is analyzed by simulation. Its validity is verified through outdoor experiment carried out by X-band polarimetric radar. [C2505]

#### "Using target radial length for data association in multiple-target tracking"

Data association plays an important role in multi-target tracking. The traditional data association algorithm uses the nearest neighbor distance method. It will make mistake in larger echo density. Feature aided data association algorithm is tend of development in multi-target tracking. Incorporating target kinematics information and feature information can increase the information dimension, and enhance the association accuracy. In this work, feature aided nearest neighbor algorithm based on radial length of target is proposed. Comparing the traditional data association algorithm, the proposed algorithm can increase the times of correct association when targets move in parallel or move crosswise, and improve the performance of data association algorithm for multi-target tracking. [C2506]

#### "A novel CFAR detector for terminal guidance coherent radar"

In different Doppler channels, the amplitude distributions of sea clutter received by terminal guidance coherent radar are different. The Rayleigh distribution and Weibull distribution can be used to describe the amplitude distribution of different Doppler channel. A novel CFAR detector is proposed. Its performance is compared with column-window CFAR detector. The simulation results confirm that the proposed CFAR detector has a better detection probability compared with column-window CFAR detector. [C2507]

#### "Analysis and suppression for nonstationary clutter in airborne conformal array radar"

The characteristics of clutter nonstationarity for airborne radar with conformal antennas array (CAA) are analyzed, and an improved angle-Doppler compensation method is proposed based on above analysis. Unlike the uniform linear antennas array (LAA), the elements of CAA distribute in three-dimension space which lead to that the clutter angle-Doppler spectrum distribution should be described in four-dimension space. According to this theory, the clutter nonstationarity for airborne radar with CAA is firstly analyzed and the nonstationary nature of it is given. Then an improved STAP method for airborne radar with CAA which compensates the mainlobe clutter in four-dimension frequency domain is proposed. Finally, the simulation shows the effectiveness of the novel method for clutter suppression in airborne radar with CAA. [C2508]

#### "A novel approach of countering centroid jamming by using INS information in terminal guidance"

During anti-ship missile (ASM) tracking ship in terminal guidance phase, echo in monopulse radar seeker receiver was generated by modeling chaff and ship as Swerling II and Swerling IV in chaff centroid jamming scenario, respectively. A generalized likelihood ratio test (GLRT) algorithm was then proposed for chaff detection in the main-beam. When the presence of the jamming was detected, one can combine target position forecast with inertial navigation system (INS) navigation solution to accomplish the homing guidance of ASM, and then when the absence of the jamming was detected, radar seeker capture and track target again, which could help achieve one's purpose of anti-jamming. Simulation showed that this method was effective and feasible due to its preferable anti-jamming performance. [C2509]

#### "Application of compressive sensing in 3D radar imaging"

By using compressive sensing technique, the data rate needed in radar imaging can be remarkably reduced. Phase reservation is the key issue for compressive sensing based radar imaging algorithm. In this paper, we propose a phase-reservation CS based pulse compression algorithm after investigation of the radar signal sparsity property, and then apply the algorithm to 3D radar imaging. Simulation results show that the phase information after CS range compression could be well preserved so as to realize 2D and 3D radar imaging. [C2510]

#### "Real-time measurement in compressive radar imaging based on AIC"

Compressive sensing techniques have been shown to reduce the number of data samples beyond the Nyquist theorem, achieving perfect reconstruction of the original signal. In this paper, we implement a real-time compressive measurement operator, based on Analog-to-Information Converter (AIC). The simulation results conform that the measurement operator works well and has as well performance as random matrix. [C2511]

#### "A TBD algorithm based on dynamic-programming for dim radar target detection"

When the received echo signal energy reflected from a target is quite small, the target cannot be detected reliably with traditional accumulation and detection method. In this paper, based on the stable factor, an improved method is proposed, which utilizes the difference of correlation characteristics between clutter and target to suppress clutter spike. Then the track-before-detect algorithm based on dynamic-programming is applied to dim radar target detection. Compared with the combination method of coherent and non-coherent integration, the predominance of the algorithm is obtained on dim radar target detection. [C2512]

#### "Multilayered diffraction tomography algorithm for ground penetrating radar"

A multilayered diffraction tomography algorithm for ground penetrating radar is derived in this paper. The algorithm considers the planar air-soil interface and uses the thought of the equivalent speed to solve the problem of multilayered medium. The first Born approximation and the dyadic Green's function are adopted to construct a linear forward model that inverted by fast Fourier transform to meet the requirement of small calculation, so we can real-time reconstruct the buried objects. Simulation results are provided to illustrate performance of this algorithm. [C2513]

#### "On separating the information of slow-mode angular motion of projectile"

The information on angular motion of projectile can be expressed by the Amplitude Modulation (AM) index of radar echo. In order to separate the information of slow-mode angular motion, a method based on Empirical Mode Decomposition (EMD) is proposed. Three issues are discussed in this article. First, the angular motion of projectile is approximated as a fast-mode circle superposing over that of the slow-mode according to the theory of exterior ballistics. Next, the characteristics of AM index that can represent the angular motion are discussed. Considering the effects of Discrete Fourier Transform (DFT) and the interference of noise, the index of AM is modeled as nonstationary time series in which the slow fluctuation corresponds to the slow-mode circular motion. Then an EMD-based separating method is suggested to obtain the index of the slow-mode motion. It includes two steps. The first step is to divide the index into a series of Intrinsic Mode Functions (IMFs) and the residual item. The second step is to reconstruct the index of the slow-mode motion with the components of the lower frequency IMFs and the residual by utilizing the prior knowledge about the difference in the periods. Compared with theoretical value and the result of stationary wavelet transform, as well as the in-flight experiment, the results show the validity and effectiveness. [C2514]

#### "Active cancellation stealth analysis of warship for LFM radar"

Active stealth of warship is an important developing direction in modern stealth technology field. Based on scattering properties of warship and characteristics of linear frequency modulated (LFM) signal and its matched filter, the cancellation signal was designed. Warship stealth was achieved through interference cancellation between cancellation signal and radar echo signal. Simulation results show that complete stealth of warship can be achieved through canceling LFM echo signal, and the scattering field of warship can be reduced by almost 10 dB even with some cancellation error. The proposed method can provide important reference for warship's active stealth in project realization. [C2515]

#### "Two methods of 3-D scattering center extraction for targets with micro-motion"

Aiming at the problem of three-dimensional scattering center extraction based on high resolution range profile (HRRP) sequence, two methods based on projection equation solving and spherical fitting were presented in this paper. Equation solving method was to solve the matrix equation based on the algebraic relations between the 1-D radial distance and 3-D position. Spherical fitting method was to extract scattering centers from the mapping graph according to the spherical distribution of 1-D projection data. In addition, a way of turning precession parameters into angle parameters indirectly was proposed for the difficulty of getting the look angle of the radar. Two methods were all verified by experiments developed with simulated and measured data. Finally, the features and performance of two methods were compared in the paper. The result indicates that the spherical fitting method is better than the equation solving method by 15dB under the same SNR. [C2516]

#### "A novel adaptive learning method for low-sidelobe step frequency waveform designing"

For a step frequency waveform, high range resolution can be achieved by inter-pulse synthesis processing and its sidelobe level can be controlled by weighting in frequency domain. However, high range sidelobe arise when the frequency steps is sparsely spaced. For this, low sidelobe can be obtained in two ways. One is by signal processing after receiving. And the other is to design the waveform with low sidelobe. In order to avoid the SNR loss, The latter is more effective. In this paper, a novel adaptive learning method is given. The method can adaptively adjust the frequencies by max sidelobe discrepancy between the matched filtering out of present and the ideal one. The result of simulation shows that it can approach the optimal frequencies for which the max

sidelobe is lowest. [C2517]

#### "A real-time algorithm for signal detection based on autocorrelation at low SNR"

In an electronic detecting system, how to capture non-cooperative signal at low SNR is always a challenging work. This paper puts forward a real-time algorithm named Shifted-N points-Correlation Algorithm for detecting LFM (Linear Frequency Modulation) pulse signal based on digital autocorrelation. Applying a gliding window of proper length to truncate infinite signal into finite length, then calculating the autocorrelation function of the signal in the window, choosing the Nth point as the current output, finally, an envelope which represents the position and intense of the signal can be obtained, while the noise can be eliminated according to its non-relativity. This is especially suitable for detecting weak signal with unknown parameters under the background of band-limited noise. Moreover, when the parameters of the receiving system have been determined, an optimum algorithm can be found for specified system based on the MSNR Criterion. Besides, it can achieve recursive operation, which is easy for hardware to apply. [C2518]

#### "Oil spill detection from polarimetric SAR image"

A new combined feature is proposed based on polarimetric features extraction. Moreover, a new oil spills detection method is developed based on the combined feature and max entropy segmentation. The application to NASA/JPL SIR-C data shows that the new combined feature and detection method are effective to oil spills detection. [C2519]

#### "Ship detection based on compound distribution with Synthetic Aperture Radar images"

Considering the variability of Synthetic Aperture Radar (SAR) imaging (different sensor, resolution) and complex condition of sea surface, the traditional single statistical model may be no longer a good choice to fit the distribution of actual sea clutter in SAR image. Based on the characteristic of Gamma distribution which is suitable to model uniform area, and G0 distribution which is adaptive to the general homogeneous and heterogeneous area, this paper established a compound distribution of G0 and Gamma model to fit the characteristics of various types of sea conditions, and use the moment estimation to improve the computational efficiency as well. Meanwhile, the algorithm combines the Constant False Alarm Rate (CFAR) detection based on dichotomy method in order to figure out the difficulties in solving the analytical expression of compound distribution. TerraSAR-X and ERS-2 images were adopted for investigating the algorithm. Experiment results illustrate that the method can achieve good performance. [C2520]

#### "New approach for improving Mutual Information in POLSAR image registration"

Aiming at the problem that information source of similarity measure is limited to image intensity usually in multi-polarization SAR registration, we propose an improved Mutual Information (MI) based on the multiple correlation information between the same polarized channels (HH, VV) in multi-polarization SAR images. In this method, by analyzing the correlation characteristics of three polarized channels in multi-polarization SAR, and using channel correlation information extracted from polarimetric covariance matrix, we compute MI in multi-polarization SAR to improve the similarity measure. Finally, the simulation results show that, in the multi-polarization SAR image registration, similarity measure information sources affect the performance of similarity measure. We compare the similarity measures with different information sources in curve sharpness and noise immunity. The results prove that the measure based on the correlation of the same polarized channels for multi-polarization SAR performs excellently. [C2521]

#### "Research on adaptive beamforming for airborne phased array radar"

PD mode is usually adopted in airborne phased array radar. However, there are two problems which severely degrade the performance of adaptive beamforming. One is the ground clutter return in the training data, the other is the target return in the training data. Therefore, in this paper, the two problems above are analyzed in detail, and then the methods suitable for engineering realization are presented. Computer simulation results are presented for illustration. [C2522]

#### "Unsupervised classification of PolInSAR image based on Shannon Entropy Characterization"

In this paper, we propose a new method for unsupervised classification of polarimetric synthetic aperture radar interferometry (PolInSAR) images based on Shannon Entropy Characterization. Firstly, we use polarimetric H (entropy) and a parameters to classify the image initially. Then, we reclassify the image according to the span of Shannon Entropy Characterization. Finally, we fuse the results of the two previous steps and merge them to the specified number of clusters. The effectiveness of this method is demonstrated on CETC38 PolInSAR data and

E-SAR PolInSAR data. [C2523]

### "Radar angular superresolution algorithm based on Bayesian approach"

Angular resolution is the key parameter of radar. Conventional means of increasing angular resolution are dependent on the size of the antenna aperture. In framework of maximum likelihood, this paper presents an iterative algorithm to restore the target location information and then to obtain angular superresolution. Theoretical analyses indicate that algorithm accelerates convergence speed and achieves angular superresolution efficiently, and computational burden is relatively small. Simulation results show that the algorithm can efficiently attenuate the effect of antenna pattern convolution and highly enhance angular resolution; test data results show an order of improvement in angular resolution over real aperture image, also confirm that the method could obtain angular superresolution. [C2524]

### "A modified anti-RGPO jamming algorithm"

An algorithm which integrated triple threshold test with nearer range selection method is presented to deal with the deficiency of RGPO jamming in this paper. The triple test has minimum probability of error decision. Nearer range selection to data association can eliminate the effect of the RGPO and clutter simultaneously. The experiment results demonstrated that the method proposed in this paper has better performance and obvious improvement on tracking precision when suffering RGPO jamming compared to the present methods. [C2525]

### "The inversion of sea state based on the micro-Doppler analysis of sea-clutter"

The real sea-clutter data are always hard to analyze due to their instinct complexity, large scale non-stationary, and lack of fundamental understanding of the natural dynamics. Measurable modeling of sea clutter is an important precondition in many research areas and practical applications, such as salvage and marine radar signal processing. However, few works have been down on the time-frequency analysis of sea clutter, especially no effective method for sea state inversion from sea clutter has been proposed. In this work, the author take into account the motion model of sea surface in typical scenarios via time-frequency and micro-Doppler effect analysis. Different contributions of the waves' velocity may provide intuitionistic ISAR images and contain certain motion parameters, from which certain sea state parameters might be inverted. Both theoretical simulation and experimental results indicate the usefulness of the model and method proposed in this work. [C2526]

### "A fast range alignment algorithm for ISAR imaging"

The envelope correlation algorithm and the minimum entropy algorithm are widely used in range alignment of inverse synthetic aperture radar (KAR) imaging. However, these types of algorithms have heavy computation burden mainly caused by the searching operation. Aiming at reducing the burden, a fast range alignment algorithm is presented in this paper. Firstly the mean location of each range profile is calculated. Then we fit the trajectory of them with linear regression model. Based on the straight line trajectory of range shift, range alignment can be accomplished. The proposed algorithm avoids the searching operation which is usually used in traditional algorithms. The computational complexity analysis shows that the computation burden of the novel algorithm is proportional to the data volume. Finally, the comparison between the proposed algorithm and the envelope correlation algorithm with real data demonstrates the validity and efficiency of the fast algorithm. [C2527]

### "A review of space target pose external measurements"

3D pose is the important parameter to express the space target motion states, which has vital meaning in application to target tracking and identification. This paper summarizes various external measurements to the 3D pose of space target, and introduces the application of the various ways, then analyzes and compares, finally, points out the trend of the 3D pose external measurements. [C2528]

### "Orthogonal waveforms design and performance analysis for MIMO sonar"

In this paper, a Multiple-Input Multiple-Output (MIMO) sonar system which can deal with multiple targets is discussed, where orthogonal waveforms are transmitted simultaneously. According to the requirement of waveform orthogonality, the orthogonal frequency division pseudo-random signal (OFD-PR), orthogonal frequency division determinant signal (OFD-LFM) and the spread-spectrum code-based signal (Gold-BPSK) are designed. The Maximum Likelihood (ML) DOA estimator and CRB for MIMO sonar is described. The performance of MIMO sonar based on different waveforms is analyzed via experiments in an anechoic water tank. Simulation and experimental results show that the waveforms which we design possess the higher resolution for multiple source DOA estimation than its phased-array and they could resolve the two targets with

a separation of 1/2 beam width at low SNR. The analysis of DOA estimates and experimental results show that the OFD-PR signal has much better performance than others. [C2529]

#### "A new method of denoising processing for synthetic aperture radar return signal"

In this paper, a denoising processing method for synthetic aperture radar raw return signal is proposed based on the DFT-DWT transform. Compared with presented transforms of DFT and DWT, the DFT-DWT transform is more efficient to extract the SAR raw return signal which is a complex 2-D signal with different properties between the two directions. After removing the out-of-band and high-frequency part of the SAR return signal's DFT-DWT transform, the noise can be eliminated efficiently. Experimental results verify that the SAR denoising processing method has a practical value for suppressing the suppression jamming and detecting the weak targets. [C2530]

#### "Interference suppression method for space-time navigation receivers based on samples selection Householder multistage wiener filter"

Due to suppression the influence of impulsive noise spikes (outliers) from desired signal direction of arrival in GPS signals. The Householder multistage wiener filter was improved, a samples selection Householder multistage wiener filter was proposed. The enhanced algorithm employed by space-time anti-jamming processing in GPS receiver, with the ability of avoiding the impulsive noise spikes influence of weights calculation, and hold the desired signal unchanged. Simulation results indicate the algorithm achieved favorable anti-jamming performance. [C2531]

#### "Overlaying orthogonal coding for sidelobe suppression in HFSW radar"

Strong sidelobes not only lead to false alarm, but also affected the target detection. By overlaying an orthogonal coding over any analog or digital signal, we can completely remove most of the ACF (auto correlation function) sidelobes without any increase to the mainlobe sidelobes. In this paper, we discuss how to choose the original signal for HFSW radar and give the affection of different overlaying matrix. [C2532]

#### "Random weighting filtering algorithm and its application in SINS/SAR Integrated Navigation System"

Strap-down Inertial Navigation System (SINS) is a typical navigation system with strong independence. To improve its performance in space, time and precision, a new Random Weighting Filtering algorithm (RWF) is proposed in this paper which adopts random weighting method. By studying its application in SINS/SAR Integrated Navigation System and comparing with other algorithms, it can be seen from the experiments that the proposed Random Weighting Filtering algorithm could significantly improve the performance of SINS/SAR Integrated Navigation System. [C2533]

#### "The combination of ACDA and FCM for Data Association in multi-target tracking"

For improving the performance of ACDA (Ant Colony Data Association) for data association in multi-target tracking, we propose the combined method of ACDA and FCM. Since FCM is a determinate algorithm, in nature based on NN (Nearest Neighbor), it could generate reasonable results in any case, which is a backup when ACDA becomes divergent. Experiments have been done in three cases-ACDA as data association method only, FCM only, and the combined method of ACDA and FCM. The results show that the performance of the combined method is superior to the other two methods. [C2534]

#### "A mover detection method based on 2-D fuzzy entropy in SAR images"

In this paper, a new technique for the moving targets detection combining incoherent and coherent information of the Synthetic Aperture Radar (SAR) images is proposed based on the measure of a two-dimensional (2-D) fuzzy entropy principle. Firstly, it extracts incoherent and coherent information from images in pixel and builds a 2-D histogram. Secondly, according to 2-D fuzzy function, image pixels are fuzzy classified into two groups: changed and unchanged then 2-D fuzzy entropy is calculated. Finally, Differential Evolution (DE) algorithm is used to maximize the entropy and the optimal parameters of the fuzzy function are obtained, which procures effective moving target detection results. [C2535]

#### "Parameter estimation of moving target for stepped-frequency radar under temporal-correlated clutter"

Proposed is a maximum likelihood (ML) estimation method to estimate the parameter of the moving target for

high range resolution stepped-frequency radar in strong clutter background. In this study the temporal correlated clutter is used. By transmitting frequency-hopping waveform and using the spectrum density of the clutter, the method may accurately estimate the moving target parameter in strong clutter. Numerical experiments illustrate the effectiveness of the proposed method. [C2536]

#### "Architecture design of spaceborne SAR imaging processing system"

The significance of on-board spaceborne SAR imaging processing is expatiated first. By analyzing the characteristics of spaceborne SAR imaging processing, a dual-layer, scalable, reconfigurable and fault-tolerant on-board spaceborne SAR real-time imaging processing system architecture, which the top layer adopts data partition parallel processing and the bottom layer adopts multi processors fine granularity close coupling, is put forward. System running efficiency is pointed out to analyze the whole system's efficiency; two system bottom realizable structures of bus sharing and bus distributing were designed. [C2537]

#### "Singularity detection of TWR echoes based on correlation"

This paper introduces a modified algorithm of singularity detection based on modulus maxima for through-wall radar (TWR) targets detection. By tracking the wavelet transform modulus maxima (WTMM) at fine scales, singularities can be detected, and the important information of human target is also selected. According to the singularities of TWR A-scan signal, it can be commendably given prominence to the targets. Finally, singularity detection based on modulus maxima was successfully realized. [C2538]

#### "Analysis of inner-pulse Doppler effect for the echoes of inverse synthetic aperture LADAR"

Inverse synthetic aperture LED AR is an active imaging system, which can achieve high resolution real time imaging for moving targets. For the traditional inverse synthetic aperture radar, the inner-pulse Doppler frequency will reduce the quality of image obviously only when the target has high speed. However, due to the ultra-high frequency and ultra-wide bandwidth of the laser signal, the influence of inner-pulse Doppler cannot be ignored even for the low speed moving targets in the ISAL. This paper analyzes the inner-pulse Doppler effect of the ISAL echoes and presents an echo model for the ISAL. Via the conventional motion compensation method, in which the accurate estimation of reference point's track is obtained after range realigning and phase focusing, the inner-pulse Doppler effect can be removed and then the image of target can be achieved. Finally, some simulation results are given in the paper. [C2539]

#### "Parameter estimation for stepped-frequency radar under temporal-spatial correlated clutter"

Proposed is a maximum likelihood (ML) estimation and minimum target error function (TEF) method to estimate the parameters of the moving target for high range resolution stepped-frequency radar in temporal-spatial correlated clutter background. The compound-Gaussian model is used for the temporal-spatial correlated clutter. Both of the velocity and range of the moving target can be accurately estimated for stepped-frequency radar. Numerical experiments illustrate the effectiveness of the proposed method. [C2540]

#### "SAR image target extraction based on 2-D leapfrog filtering"

This paper reveals that the classical R-D imaging algorithm can not remove the strong noise and extract the objects in R-D imaging image by their range and azimuth matching filters. Though 2-D DCT-DWT or 2-D DFT-DWT can be a 2-D filtering for the issue, while the algorithms need huge computation amount, they can not process SAR image real time. To solve the problem, this paper develops a new 2-D filtering algorithm based on 2-D leapfrog filter, which is good at extracting the SAR image target clearly. The 2-D recursive filter is of few multiplications for SAR image each pixel to realize fast and real-time image filtering. Practical experiments of SAR image processing have shown that the approach and algorithm are correct, effective and pragmatical. [C2541]

#### "Micro-Doppler effect analysis based on inverse synthetic aperture imaging LADAR"

Although the micro-Doppler (m-D) effect can provide additional information for target recognition, the microwave radar cannot afford enough resolution to detect the m-D effect of small targets and long distance targets. To obtain high range resolution for the extraction of the fine m-D signatures, inverse synthetic aperture imaging LADAR (ISAIL) is used here. Because of the frequency modulation continuous wave (FMCW) laser signal is used in ISAIL, the m-D effect of ISAIL is different from the microwave radar. In this paper, the m-D effect of ISAIL is analyzed and compared with that in X-band radar. The experiment results show that ISAIL can offer sufficient information of micro-motions when the feature of motions is tiny. [C2542]

### "Inverse Synthetic Aperture Radar Imaging at Low Signal-to-noise Ratio"

Inverse synthetic aperture radar (ISAR) imaging at low SNR ratio is not resolved completely. The SNR increases in time-frequency domain over the one in the time or the frequency domain alone both theoretically and numerically. This shows advantage of time-frequency analysis technique for ISAR imaging at low SNR. The reassigned Gabor spectrogram time-frequency distribution is proposed for ISAR imaging at low SNR. Finally, the real data demonstrated the validity of the method proposed. [C2543]

### "Estimation of UWB radar scattering center with GTD-based 2D state-space method"

A GTD-based 2D state-space method is presented in this paper for estimating the parameters of the scattering centers on a moving target under the ultra-wideband conditions. Firstly, this method constructs the GTD-based impulse response from the moving target in the state space equation, and then arranges the impulse response of different frequency at different time into a Hankel matrix. Next, the range and the range rate are estimated by using the Hankel matrix singular value decomposition (SVD), which effectively solves the range aliasing problem when the ranges of different scattering centers are overlapped. It occurs in the ID state space when the range is estimated only. At last, the type parameter and intensity of the scattering center are solved out by this method. The effectiveness of the method is verified by comparing the result of processing the echo data from the rotating conical target with the CRB on parameters estimation. [C2544]

### "Research on airborne chaff centroid jamming to ground radar"

In radar passive countermeasure, Chaff centroid jamming plays an important role. Whether chaff cloud is diffusing or has diffused, its RCS and position change as time goes. Chaff cloud model is constructed accordingly. The plane and centroid motion model are constructed respectively too. Based on the searching and tracking mode of the ground radar, detailed research on chaff centroid jamming is made. Simulation results show that airborne chaff centroid jamming to ground radar has a good effect. [C2545]

### "Feature evaluation and selection for polarimetric SAR image classification"

This paper presents an evaluation of different features for polarimetric SAR (PolSAR) image classification. Firstly, we select several of the polarimetric features to give a summary on them. Then we give an insight into their classification performance together with a texture feature using the support vector machine (SVM). Finally, we employ a feature combination and selection strategy that optimizes the trade-off between the feature dimension and precision. The experimental results on PolSAR data of the CETC38 demonstrate: i) the strategy works effectively in the reduction of redundant feature dimensions; ii) in comparison with the unselected feature, the classification performance and computation efficiency of the selected one are improved by this approach. [C2546]

### "General clutter modeling for airborne radar"

Clutter returns in airborne radar applications spread in Doppler frequency because of platform motion. The clutter characteristics should be analyzed in detail for designing clutter suppression algorithms. In this paper, clutter modeling method for conventional phased array airborne radar, multiple-input-multiple-output (MIMO) airborne radar, and hybrid MIMO-phased array airborne radar, all with arbitrary antenna array, is presented. Modeling of clutter intrinsic motion, sensor error, subarraying is also considered. [C2547]

### "Time delay and doppler shift estimation accuracy analyses of moving targets in non-cooperative bistatic pulse radar"

According to the characteristics of non-cooperative bistatic pulse radar systems and the issue that the doppler mismatched loss of the cross-correlation detection of moving targets is serious, two fast methods for joint time delay and doppler shift estimation of moving targets, based on segment correlation-FFT processing and modified partial segment correlation-FFT processing, are proposed, after analyzing the common methods for cross-ambiguity function processing such as direct calculation, FFT, Zoom-FFT method. The processing performance of direct calculation and partial segment correlation-FFT processing of LFM pulse-series is analyzed in theory and by simulation. And the simulation shows that the weak moving target can be detected effectively and the time delay and doppler shift can be fast estimated by the methods presented in this paper. [C2548]

### "An FPGA based semi-parallel architecture for higher order Moving Target Indication (MTI) processing"

The design and implementation of a higher order Moving Target Indication (MTI) engine is presented. This is part of a single chip radar signal processor also incorporating the subsequent algorithms. The bottleneck in use

of higher order filters for MTI is not an algorithmic one but one related to implementation. Thus the challenge is to minimize area utilization and achieve the required speed. The proposed architecture employs the use of multiple offchip memory banks for achieving the required memory bandwidth and use of dedicated FPGA resources for area minimization. The requirement of stacking a large number of radar returns in memory and then reading them all for filtering within a single return time demands a parallel memory reading and data processing approach. But this demand has to be balanced with the requirement to consume as little area as possible to leave room for the following algorithms. Considering these constraints, a semi parallel architecture employing multiple filters, each built around a DSP48 slice configured as a Multiply Accumulate (MACC) unit in a time shared manner is used. An analysis of various factors that affect speed and area is also made. The architecture is implemented on a Virtex-4SX35 FPGA using Xilinx XtremeDSP Kit. The design is tested using unprocessed baseband data from a TA-10K air traffic control radar. Results show a marked improvement in the clutter suppression capability of the radar. The design achieves the required speed using only 7% of the available FPGA slices. Thus, not only can the other algorithms be implemented on the same chip but there is room for enhancements as well. [C2549]

### "Approach for airborne radar ISAR imaging of ship target based on generalized keystone transform"

High resolution image of ship target under low SCNR condition is unable to be obtained by conventional ISAR imaging methods when long coherent integration time needed. To overcome this problem, a novel approach for imaging the ship target by airborne radar is proposed in this paper. Firstly, the generalized keystone formatting is applied to compensate the range curvature induced by long integration time. Secondly, the quadratic term of slow time in phase is eliminated by estimating the target motion parameter using Radon-Ambiguity Transform (RAT) scheme. Next, generalized keystone formatting method is used again to eliminate the residual linear range walk. Finally, the high resolution image of ship is obtained by employing the Relax algorithm. Results of both simulation and real data are presented to confirm the validity of the proposed algorithm. [C2550]

### "Research of unsupervised image change detection algorithm based on 2-D histogram"

Change detection in images of a given scene acquired at different times is one of the most interesting topics of remote image processing. In this paper, a novel image change detection algorithm is proposed based on the clustering characteristic of 2-D histogram. First, the best segmentation direction of 2-D histogram is ascertained by using Fisher criterion. Secondly, a kind of new 2-D entropy is defined to search the best threshold and segment the 2-D histogram into unchanged region and change region. Then the change area in different image is detected based on the change region of 2-D histogram. Finally, the proposed algorithm is compared to traditional algorithm. The theoretical analysis and experiment results confirm the effectiveness of the proposed means. [C2551]

### "Range Cell Migration Correction using texture mapping on GPU"

Range Cell Migration Correction (RCMC) is a key step in the imaging procedure of Synthetic Aperture Radar (SAR). The performance of RCMC affects the final SAR image quality greatly. Traditionally, RCMC is carried out via an interpolation operation on CPU, and is a time-consuming phase in the whole processing flow. In this paper, a novel RCMC technique using texture mapping is proposed. The texture mapping operation is implemented on the Graphics Processing Unit (GPU), which accelerates the operation by special hardware structure. The proposed RCMC technique can achieve a higher speed compared with the traditional methods designed for CPU. [C2552]

### "A new polarization filter based on weighted combination"

Conventional polarization filters can mitigate an interference by using the orthogonal vector of the interference polarization, but leading to distortion of the target signal in its amplitude and phase. A null phase-shifting polarization filter can reconstruct the original target signal. However, it needs some complex operations, such as a linear polarization-vector translation and compensations in amplitude and phase. In this paper, a weighted combination polarization filter is proposed, which retains the original target signal while suppressing the interference within one step. The simulation results show that the new filter is an effective means to remove the interference in the polarization domain. [C2553]

### "An improved joint subspace projection method for InSAR interferogram filtering"

In this paper, an improved joint subspace projection method for synthetic aperture radar interferometry (InSAR) interferogram filtering is proposed. Benefiting from the new formulation of joint data vector, the method does not need to calculate the noise subspace dimension before estimating the InSAR interferometric phase, thus

avoiding the effect on the estimation of the InSAR interferometric phase due to the inaccuracy of the noise subspace dimension. The method can auto-coregister the SAR images and reduce the interferometric phase noise simultaneously. [C2554]

### "Matrix transpose methods for SAR imaging system"

Matrix transpose is a very crucial procedure in the synthetic aperture radar(SAR) imaging system. This paper analyzes the existing matrix transpose methods in the signal processing of SAR imaging and proposes two new matrix transpose methods, meanwhile, the implementation steps of new methods are also introduced. Finally, an example which uses the matrix transpose methods described in this paper is given as a demonstration and the results and analysis are also presented. [C2555]

### "Spread clutter mitigation via knowledge-aided STAP in multiple-input single-output system"

In Multiple-Input Single-Output (MISO) HF surface wave radar system, the fact that bistatic operation and the movement of the receiver platform causes the nonstationarity and spreading of sea clutter, which will lead to the difficulty in detecting those immersed targets. The space-time distribution of sea clutter in different geometry is firstly investigated; and a knowledge-aided STAP scheme is proposed for mitigating the clutter. The weights of different range bins are acquired from both the clutter priori and the prefiltered training data by direct data domain (DDD) algorithm. Numerical simulation shows the proposed scheme effective. [C2556]

### "Impacts of Keystone formatting on Space-Time Adaptive Processing in airborne radar"

Keystone formatting (KF) has the capability of compensating multiple targets' (including ground clutter) range walk simultaneously without using any specific knowledge of the target motion. However, due to serious Doppler ambiguity of the fast moving targets, KF will affect the distribution of the clutter and degrade the Space-Time Adaptive Processing (STAP) performance. Based on the above reasons, the impacts of KF on the clutter distribution are analyzed firstly, and then the impacts of KF on STAP are analyzed. The conclusions obtained are helpful to figure out better methods for fast dim air moving target detection. [C2557]

### "Real-time data compression bias estimation on netted radar"

Interest in netted radar has grown tremendously in the last few years, and registration is the necessary process of radar network system. A real-time data compression Kalman filter registration algorithm is presented to correct the dynamic systematic errors based on local measurements. It is accomplished by constructing pseudomeasurements of the radar biases with additive zero-mean, white noises. Then the netted radar bias estimates are obtained dynamically by employing data compression Kalman filter algorithm. Finally, Monte Carlo simulations are employed to evaluate the performance of the proposed algorithm. Results show that the new algorithm is efficient. [C2558]

### "2-dimensional DOA estimation using ESPRIT algorithm in ARM confronting coherent decoy"

Because of the intrinsic defect of passive radar seeker (PRS) of ARM, it can't distinguish coherent decoys from far distance. Using extended-aperture confronting coherent decoys for ARM is proposed in this paper, and a new 2-dimensional DOA estimation ESPRIT algorithm is presented. This algorithm uses the characteristic of a new special array to construct a special covariance matrix. With this algorithm the DOA of coherent decoys can be estimated without spatial smoothing techniques and spectrum peak searching. Elevation and azimuth estimations can also be paired automatically. Simulations demonstrate the effectively to distinguish radar and bait from the directions of arrival and the significant performance gain realizable by this method for ARM confronting coherent decoys. [C2559]

### "The distributed passive radar 3-D imaging and analysis in wavenumber domain"

This paper studies the distributed passive radar three-dimensional (3-D) imaging under the 3-D configuration formed by the illuminators of opportunity and the distributed receivers. The echoes received by the distributed channels actually constitute the target wavenumber-domain coverage, whose characteristics such as range, uniformity and compactness greatly affect the inversion performance. Generally, the wavenumber-domain coverage of the passive radar system is small-scale, sparse and nonuniform, in which case the traditional IFFT method becomes invalid. Therefore, we propose a novel imaging method, named Spherical Coordinates Method (SCM). Furthermore, so as to get higher resolution and better imaging quality, a broader, more uniform and compact coverage in wavenumber domain is required and this can be achieved through the following three methods: increasing the number of the receivers, making use of the motion information and optimizing the disposition of the receivers. Numerical simulations verify the effectiveness of the presented method and the

rationality of the theoretical analysis. [C2560]

#### "A novel STAP method for the detection of fast dim air moving targets"

Space-time adaptive processing (STAP) is an effective method for moving target detection in airborne radar. In this paper, a novel STAP method for fast dim air moving target detection is proposed. The new method suppress clutter in the received data firstly, and then apply Keystone formatting (KF) to compensate the target's range walk. Finally, target is accumulated by the conventional space-time beamforming. Effectiveness of the new method is verified via simulation examples. [C2561]

#### "Water extraction in SAR images using GLCM and Support Vector Machine"

Traditional methods to extract water regions in SAR images usually rely on image binarization with a specified threshold. However, because of the inherent speckles in SAR images, finding an appropriate threshold is very difficult. In the paper, we propose a new method for water region extraction in SAR images using GLCM (gray-level co-occurrence matrix) based features combined with SVM (Supported vector Machine). The characteristics of water and non-water regions are distinctively depicted by GLCM based features, which are fed into the SVM classifier to extract water regions. Experiments on synthetic and real SAR images demonstrate that the proposed method achieves better results compared with two other ones. [C2562]

#### "A modified two-scale fractal sea model of the non-fully developed full-range sea spectrum"

The determination of backscattering coefficients is important to analyze echoes objective signals. To describe a rough sea surface naturally, a non-fully developed full-range sea spectrum (NDFSS) is reconstructed, and a fractal sea model based on NDFSS is presented. Based on the conventional two-scale model for backscattering coefficients, a complementary term is added for considering the skewness of sea waves. The additional part is proportional to the surface bispectrum and it is a critical part in explaining the scattering difference between upwind and downwind observations. The numerical results show this modified model is consistent with the real radar data. [C2563]

#### "A new approach to distributed passive radar imaging by 2-D NUFFT"

This paper studies distributed passive radar imaging of two-dimensional (2-D) scene. The echoes and the reflectivity of target are confirmed to be a Fourier transform pair. However, due to the space configuration based on the illuminators of opportunity, the echoes are sampled non-uniformly, which lead to the non-equispaced property of space-spectrum distribution. In this case, direct 2-D FFT reconstruction doesn't apply now. To retain the fast computing of image reconstruction like FFT, non-uniform fast Fourier transform (NUFFT) is introduced to avoid complex interpolation. We generalize NUFFT to 2-D NUFFT to tackle the problem that the space-spectrum is unequally-spaced in both directions of  $\mu$  and  $\nu$ . This new 2-D NUFFT method is compared with polar-coordinate method in efficiency and accuracy using both the analytical and numerical approaches. Simulations demonstrate that 2-D NUFFT can reduce the computational complexity while ensuring image reconstruction accuracy. So it's a promising strategy for realtime imaging of distributed passive radar. [C2564]

#### "The FAA handbook on microprocessor selection and evaluation in airborne systems"

Under the management of the Aerospace Vehicles Systems Institute (AVSI), the FAA initiated a project to study the safety concerns surrounding the use of complex commercial off-the-shelf (COTS) microprocessors and systems-on-chips (SoC) in safety-critical airborne systems. Additionally, several aerospace companies cooperated with the FAA in providing oversight, direction and technical contributions throughout the course of this project. The major product of this work is the "Handbook for the Selection and Evaluation for Microprocessors for Airborne Systems" to be published by the FAA as a set of recommendations for both regulatory personnel and systems manufacturers. This paper describes the technological trends occurring in modern COTS microprocessors and SoC that have prompted the FAA to better understand the implications of their use in airborne systems. This paper also briefly describes the purpose and structure of the Handbook and provides supplemental information regarding the evaluation platforms and analyses that were the basis for its recommendations. [C2565]

#### "Integration of a 2.5D radar simulation in a sensor simulation suite"

Recently DLR's sensor simulation toolkit F3S (flexible sensor simulation suite) has evolved from a mere proof-of-concept demonstrator to a versatile collection of sensor simulations. The main aspect of the software is to provide real-time simulation for sensors like millimeter wave radar and laser based sensors in an environment for testing enhanced vision concepts. We achieve this by making heavy use of graphics hardware acceleration

as available in recent computer hardware. The latest addition to the set of sensor simulations is a 2.5D/3D scanning radar. Other than traditional 2D radars simulating such a sensor raises some special challenges when most of the calculations should be done by the graphics hardware. We present a custom solution that extends our previous approach to 2.5D and 3D sensors while maintaining real-time in the sense that the simulation runs at least as fast as real existing sensors. [C2566]

#### "Enhancement in realism of ATC simulations by improving aircraft behaviour models"

This paper addresses the challenge to provide realistic aircraft behaviours in air traffic control simulations. Many simulation environments lack actual information on aircraft, airline or airspace-specific operational procedures: they resort to generic procedures to navigate the simulated aircraft, which may result in unsatisfying aircraft behaviours. A methodology has been developed by EURO-CONTROL to improve the aircraft behaviour model in its large-scale and real-time air traffic management simulation system, by identifying specific aircraft operation parameters from historical radar data. The simulator has been adapted to take these aircraft operation parameters into account, and the methodology was applied and tested during the last two simulations which took place at the EUROCONTROL Experimental Centre in 2010. The results of using operationally-tuned parameters during those simulations demonstrate that the analysis of flight recordings can bring valuable information about numerous flight behaviour parameters, and that the use of detailed flight behaviour models based on the parameters identified from the recordings can improve the accuracy of aircraft modeling enough that air traffic controllers liken the simulated traffic to a real traffic. [C2567]

#### "TCAS surveillance performance analysis"

The Traffic Alert and Collision Avoidance System (TCAS) Version 7 surveillance requirements were developed in the mid-1990s with the use of limited radar data. Recently, a more comprehensive radar data source has become available, enabling a thorough analysis of TCAS surveillance performance throughout the National Airspace System (NAS). This paper uses a high fidelity simulation to characterize TCAS surveillance performance in six high traffic terminal environments. Transponder utilization due to TCAS and TCAS surveillance range are compared with the interference limiting design requirements. The effect of TCAS surveillance activity on Air Traffic Control (ATC) ground radar performance is also investigated. Results indicate that the surveillance algorithms perform as intended and that TCAS has a minimal impact on ground radar. Areas of concern are noted for future investigation. [C2568]

#### "High-throughput hardware architecture of MQ arithmetic coder"

A novel byte-out architecture in MQ arithmetic coder is proposed and the new MQ-coder hardware architecture which use the novel byte-out architecture is presented, in which it can encode two CX-D pairs per cycle. The coder is described with Verilog HDL at RTL. Synthesis, fitter, assembler and timing analyzer are conducted with Quartus II 9.0. The results of timing analyzer show that the architecture can efficiently improve the throughput and clock frequency, the throughput can achieve  $117.12 \text{ MCxD} \cdot \text{s}^{-1}$  and the clock frequency can achieve 58.56 MHz. [C2569]

#### "Multiple/Distributed Target Detection for HRR"

Side lobe suppression is extremely important in precisely determining the weak echo scattering region in the presence of range side lobes. This paper addresses the signal design problem for the detection of multiple/distributed targets in high resolution radar (HRR) application with improved side lobe suppression ratio. The simulation results indicate a significant improvement in terms of noise tolerance for HRR target detection; compared to conventional binary sequences. [C2570]

#### "Correlation radar signal processing on basis of probability Kravchenko weight functions"

In this report the combined method of correlation radar signal (RS) processing based on the theory of atomic functions (AF) is examined. Examples of using of new probability Kravchenko weight functions (WF) designs are presented. Quality functional for estimate accuracy and efficiency of RS processing for concrete physical models is constructed. It is shown that the proposed approach significantly improves the quality of the coherent analysis of the RS. [C2571]

#### "The Surface Operations Data Analysis and Adaptation tool: Innovations and applications"

This paper describes the Surface Operations Data Analysis and Adaptation (SODAA) tool, which has been developed by Mosaic ATM and NASA. The SODAA tool provides database management of multiple aviation data sources including both airport surface surveillance data, flight data, flight operator-originated data and many

other aviation data sources. The paper describes the design of the SODAA system, as well as many analyses that have been conducted using SODAA. [C2572]

### "The phase statistical characteristic of InSAR image at the isolated point"

Current researches on the phase of interferometric Synthetic Aperture Radar (abbreviated as InSAR) images are restricted to the homogeneous scene with spatially constant backscatter coefficients. But in reality, there are many unknown targets or sealers with high backscatter coefficients in the ground scene, which produce several bright spots (called isolated points) in the SAR image. The phase statistical characteristic of interferogram at the isolated point is not available recently. Based on the InSAR system, the phase distribution characteristic of SAR image at the isolated point is analyzed. Furthermore, the interferometric phase probability density function at the isolated point is deduced and the phase statistical characteristic at the isolated point is analyzed in theory which is confirmed by the simulations. Finally the conclusion is obtained that the existence of isolated point can improve the interferometric phase estimation precision which establishes the theoretic foundation for calibrating the InSAR system with the interferometric phase at the sealer. [C2573]

### "An improved GVF snake model and its application to linear feature extraction from SAR images"

In this paper, an improved GVF snake model that allows controllable snakes is proposed. Two kinds of external constraint forces are exploited in the model. The first one can pin specified points on the snake and determine the basic shape of a snake. The second one avoids generating ears during curve evolution. It ensures that the curves are smooth and won't grow in a wrong direction. The improved snakes are employed to close gaps in linear feature extraction since they can fix the connection points during the deformation and provide smooth linking curves rather than straight lines. The experimental results of ridge (and ravine) extraction and road extraction from real SAR images increase the correctness and quality of extracted results. [C2574]

### "Evaluation of separation performance with ADS-B at the Philadelphia key site"

The Federal Aviation Administration's (FAA) Surveillance and Broadcast Services (SBS) Program Office has implemented one of the first enablers of the Next Generation Air Transportation System (NextGen) by installing a ground infrastructure that supports the Automatic Dependent Surveillance-Broadcast (ADS-B) data service. One of the main applications for this infrastructure is to enhance air traffic control (ATC) separation through more frequent and accurate data about aircraft. As part of the initial assessment activities, the ADS-B data was incorporated into four different automation platforms in four different key sites. One of these key sites was the Philadelphia Terminal Radar Approach Control (PHL TRACON) which uses Standard Terminal Automation Replacement System (STARS) to process and display radar data to controllers. The Philadelphia STARS was updated to accept ADS-B data in its native format. Beyond just accepting new surveillance data, however, PHL TRACON is the first location that went operational where ATC used system track positions (so called- "fused" targets) published to the ATC display to allow controllers to separate aircraft, a paradigm shift from current operations where controllers use radar "plot" positions. As part of the SBS evaluation, a working group was created that worked specifically to evaluate the end-end performance of separation services with the new data flow-ADS-B avionics, ADS-B surveillance service on the ground, and the updated STARS software. The evaluation used a comparative approach with current monopulse secondary surveillance radar (MSSR) systems as a baseline; if the new system performed as good or better than MSSR systems in separation applications, then the system was acceptable for operation. This paper describes the efforts of the SBS working group to evaluate the operational performance in Philadelphia, including the metrics used, assumptions made operational scenario development, and results from several analyses, including simulation, flight testing, and targets of opportunity operating in the TRACON airspace. [C2575]

### "Frequency modulated radar signals based on high dimensional chaotic maps"

High dimensional chaotic maps have more complicated structures and better anti-jamming performances. Frequency modulated radar signals based on high dimensional chaotic maps are proposed. The signal model is presented, characteristics are analyzed, and comparison among 1D Bernoulli map, 2D Cat map and uniform random noise with different series length is made in the paper. Simulations show well performances of the proposed signal. [C2576]

### "Toward System Oriented Runway Management"

Decisions about what airport configuration should be used and when the configuration should be changed are currently made manually by personnel in the Air Traffic Control (ATC) Tower (ATCT) or Terminal Radar Approach Control (TRACON). Over time, each airport has adapted unique local procedures related to airport configuration management, creating a challenge for both studying airport configuration management and

developing decision support technologies. At many airports, the airport configuration decision is based primarily on the weather forecast and historical experience. While configuration changes to respond to weather changes are relatively straightforward, when traffic demand motivates a configuration change, the change is often made in reaction to observing aircraft queues and delays, or not made at all, rather than proactively based on forecast traffic situations. Consequently, significant opportunity exists for automation to support airport configuration decisions that will improve airport capacity and efficiency. Moreover, NextGen technologies and procedures will cause the definition of airport configuration to expand to include how metroplex resources other than the runways are utilized. As the metroplex configuration decision space becomes more complex, the need for supporting automation will become even greater. System Oriented Runway Management (SORM) is a concept in which the configuration and use of metroplex resources are explicitly planned with a holistic perspective of the operations within the metroplex as well as the needs of the metroplex within the context of the overall National Airspace System (NAS). System Oriented Runway Management is also a significant new research initiative by the NASA Airspace Systems Program that addresses the need for automation to achieve the SORM concept. This paper introduces the SORM concept and initial research to develop automation to support airport configuration planning. [C2577]

#### **"Target detection of high-resolution radar in non-Gaussian clutter"**

The high-resolution radar echo is modeled as a range-spread target. Based on the generalized likelihood ratio test design procedure, the range-spread target detection in spherically invariant random vector clutter is addressed. And a binary integrator with constant false alarm rate property is proposed to detect the whole range-spread target, after single target scatterer detection in each range cell. Finally, the performance assessment shows that, the detection performance is improved as the number of sensors used or the clutter spike increases, while it is robust to the clutter correlation. [C2578]

#### **"The principle of synthesizing HRRP based on a new OFDM phase-coded stepped-frequency radar signal"**

Orthogonal Frequency-Division Multiplexing (OFDM) phase-coded pulse is a wideband signal, of which the range resolution is inversely proportional to the bandwidth. However, it is a challenge to synthesize large bandwidth for OFDM phase-coded pulse since wide instantaneous bandwidth and high sampling rate requirements. To solve this problem, this paper proposes a new radar signal called OFDM phase-coded stepped-frequency (OFDM-PCSF) signal, of which the pulse train is stepped frequency, and each pulse is implemented with OFDM phase-coded chips. The property of OFDM-PCSF signal is analyzed at first. And then, the mathematical expressions of the high resolution range profiles (HRRP) are derived, assuming an elementary scenario of point-scattering targets. It mainly presents the influence of velocity on HRRP and investigates the parameter design and velocity compensation, which is helpful for the realization of OFDM imaging radar. Finally, the simulation results demonstrate the validity of the conclusions. [C2579]

#### **"Target detection with distributed radar sensor networking systems (DRASENS)"**

An innovative radar sensor networking system is introduced for effective target detection. By using orthogonal coding waveforms, the number of radar echoes generated by the radar network from the same target is maximized for the best fusion processing result. Several centralized signal detection schemes are investigated for the networking system and their performances are evaluated. [C2580]

#### **"Fast one-dimensional least squares matching of InSAR images"**

Image matching is one of the key steps in Processing of InSAR. In order to improve the reliability and the rate of matching, a fast least squares matching algorithm with one-dimensional azimuth searching was proposed. The interferometric SAR images obtained by space-borne ERS-1/2 and by airborne dual-antenna system were employed to do experiments of matching. The results show that the proposed one-dimensional least squares matching algorithm was fast and effective. [C2581]

#### **"Radar track-before-detect algorithm of dim target based on track test"**

This paper proposes a track test-based track-before-detect algorithm for radar target detection. Track test is used to estimate the target motion model. The implementation of this scheme on the search tracks and the detection strategy on the energy accumulation values of tested tracks are presented. Simulation results show the proposed algorithm have better detection performance and tracking performance, compared with the dynamic programming-based track-before-detect algorithm. [C2582]

### "Parameters estimation of target with precession based on combined feature"

It is beneficial for the recognition and classification of targets to obtain geometrical and motional parameters simultaneously. This paper proposes a new method to estimate parameters of target with precession based on combined feature, which is generated by Doppler feature and high range resolution feature of target from a new radar-OFDM radar. Expanded Hough transform (EHT) is employed to establish the combined feature with range and motion information of scatterers. The paper mainly presents the principle to establish the combined feature and the estimation of precession angle, target posture and target length. Finally, the results from simulations and anechoic chamber data prove the validity of the method. [C2583]

### "Study of continuous wave radar for human motion characteristics measurement"

Human motion characteristics study based on radar is a new technique developed in recent years. This paper firstly analyzes the model of human radar returns, and then designs an X-band continuous wave radar for human motion characteristics measurement. Experiments for measuring the human motion characteristics have been performed based on the radar. The Doppler features of human motion are extracted with time-frequency analysis from actual measured data generated by the radar, which verifies the validity of the measurement data. [C2584]

### "Compressive sensing MIMO radar imaging based on inverse scattering model"

From the view of inverse scattering imaging, the paper gives basic principle of MIMO radar imaging, then applies compressive sensing (CS) to two methods. The first method is sampling and receiving echoes randomly in both frequencies and channels. The second method is sampling echoes randomly only in frequencies, and controllable space intersection is done in channels to increase the practicability. Both methods can achieve high image resolution using few echo samples. The first method has better imaging quality, but the second method is more controllable. Ulteriorly, the simulation gives detailed analysis of imaging quality and reconstruction successful probability, which is beneficial to applications of CS to MIMO radar imaging. [C2585]

### "The improvements on the enhanced WRS-88D storm identification and tracking algorithm"

SCIT is a classic algorithm in storm identification, tracking and forecasting. In this paper, we try to employ disjointed set ADT to improve the efficiency of storm identification firstly, and then try to improve the performance of SCIT tracking and forecasting strategy by optical flow methodology. [C2586]

### "A novel ISAR algorithm for the imaging of ship targets based on AM-LFM model"

Rang-Instantaneous-Doppler (RID) processing is widely used in ISAR imaging of maneuvering target and acceptable image can be achieved when the amplitude modulation effect of scatterers echoes can be neglected during intergation time, whereas, the RID method based on the assumption above does not work properly when the variant amplitude modulation of scatterers' echoes involved, such as ship target. In this paper, a multicomponent amplitude modulation and linear frequency modulation (AM-LFM) signal model developed and a fast parameter estimation technique-DechirpClean method proposed. To achieve the best quality in DechirpClean ISAR image, a new effective optimum imaging interval selection scheme addressed. The performance of proposed method is verified by comparing the result with the image produced by conventional RID method from the real data processing. [C2587]

### "Cram r-Rao bounds for estimating velocity and direction with a bistatic MIMO radar"

We derive Cramer-Rao bounds (CRB) expressions for the velocity (Doppler shift), and direction of a point target using a bistatic multiple-input multiple-output (MIMO) radar in this paper. First, we introduce the signal and noise models which satisfy the space-time separability conditions. Then, general CRB expressions are derived for a narrowband signals with the above signal and noise models. We find that the directional parameters are uncoupled with Doppler shift for the space-time separable signal and noise models. However, the directional parameters are usually coupled with each other, i.e., the direction-of-departure (DOD) with direction-of-arrival (DOA) and the azimuth angles the elevation angles are ordinarily coupled. Fortunately, the uncoupled direction estimation can be gotten by the specifical antennas placement. [C2588]

### "Detection of moving target based on fractional Fourier transform in SAR clutter"

Based on the analysis of the characteristics of SAR target echo and the time excursion of fractional Fourier transform (FRFT), the Article has put forward a time-delay balance method based on FRFT to detect the slowly moving target in SAR echo according to the characteristics of SAR ground clutter. Calculation on the FRFT of echo signal and the FRFT of echo signal after short delay time results in two complex signals, in which, the

modules of static backgrounds are just totally same, and in the range of moving target, the amplitude of module will cause an offset, therefore, when calculate the difference of the modules of two complex signals, the static background could be balanced and the moving target could be detected effectively. Simulation analysis indicates that the method in the Article shows its advantages in a background with strong clutter. [C2589]

#### "Radar imaging based on compressed sensing by random convolution"

Compressed Sensing (CS) theory provides great possibilities for resolving problems associated with traditional high resolution radar, such as high sampling rate, too many data and difficulties of real time processing. Sensing by random convolution is a universally efficient data acquisition strategy and easy to realize. This paper focuses on radar imaging technique based on CS by random convolution, researches into several different random downsampling strategies. Experiments from simulated data and real data verify the validity of the proposed imaging method, also the influences of SNR and downsampling strategy on imaging performance are analyzed and compared. Finally the problems need further research are pointed out. [C2590]

#### "Design method of parameters for pulse doppler signal to nullifying the interference of negative frequency"

This paper describes how the negative-frequency portion of the pulse doppler (PD) radar signal's spectrum extends into positive frequency and causes interference in signal processing. A novel design method of the parameters of pulse doppler signal is presented to nullifying this interference. The key idea of nullifying the interference is to place a null of the negative-frequency portion's sidelobes to the place where the interference exists. This method encounters the problem of frequency aliasing in conventional process of PD signal and it no longer works. An improved filtering process is proposed to solve this problem. Some computer simulation results are presented to illustrate the performance of the proposed parameters designing method and the improved filtering process. [C2591]

#### "Spinning targets imaging based on OMP algorithm with radial basis function"

A new radar imaging method is proposed for spinning targets in space. The rapid spin motion of the target induces multi-period sinusoidal modulation of the radar echoes in both range and doppler domain, which causes Range-Doppler (R-D) algorithm invalid in conventional radar imaging. The presented method analyzes the echo model of the target spinning around an arbitrary axis. An exponential radial basis function (RBF) is then constructed from the scatters' range profile based on a distance-weighted criterion, and the image is rebuilt by recovering the projection of the target base on orthogonal matching pursuit (OMP) algorithm with the radial basis matrix. The simulation results show that the proposed method can obtain the radar image more effectively for the target with a uniform speed spin motion. [C2592]

#### "Multi-carrier frequency MIMO HF radar using convex optimization beamforming"

In order to enhance HF radar angle resolution, and overcome target RCS scintillations, we adopt the transmitting and receiving antennas sparse deployment under bistatic pattern, the element intervals far less than range from the target to transmitters and receiver, the transmitters emit multi-carrier frequencies. In this paper, we apply CVX theory to solve the optimal weights of each element at different frequency, take advantage of multi-carrier frequency signal phase changing offset the side lobe each other. The beampattern has better angle resolution, and achieves lower side lobe. In the end, we analyze that the different frequency echo amplitude and phase impact side lobe and direction errors. [C2593]

#### "Inverse synthetic aperture ladar imaging with the Range Instantaneous Doppler algorithm"

Inverse synthetic aperture ladar (ISAL), which operates at visible or infrared wavelength, is more sensitive to maneuver than inverse synthetic aperture radar (ISAR). In this paper, we propose the Range Instantaneous Doppler (RID) algorithm for very high resolution ISAL imaging of maneuvering targets. The Wigner-Ville distribution (WVD) and the Radon transform are used for computing the time-varying Doppler spectrum of maneuvering targets. The data processing of the RID algorithm is illustrated. The simulation shows that the RID algorithm can reconstruct a clearer ISAL image of the maneuvering target than the conventional rang Doppler (RD) algorithm. This is a crucial step in developing a real ISAL system. [C2594]

#### "Deception jamming method for ISAR based on sub-Nyquist sampling technology"

Fast sampling of wideband RF signal and real time processing of vast data are great difficulties in the engineering implementation of deception jamming to ISAR. This paper proposes a sort of Sub-Nyquist Sampling-Based Method for Jamming ISAR Systems. First introduces the deception jamming technique based on false

target for ISAR. Then investigates the jamming principle of sub-Nyquist sampling modulation. Through modulating false target information on radar signals intercepted by sub-Nyquist sampling, the resulting signal can produce a train of vivid false targets. The proposed method can greatly reduce the demands on sampling rate and processing speed, its jamming performance is analyzed in detail and verified by simulation experiments. The conclusions here have certain significance to the manufacture of ISAR jammer in practical engineering. [C2595]

#### "A new cross-range scaling algorithm based on FrFT"

Inverse synthetic aperture radar (ISAR) generates two dimensional high resolution images of targets in range-Doppler domain. In order to determine the cross-range dimension of the target or implement polar formatting to reconstruct more focused ISAR images, estimation of the rotation angle is required. A new algorithm for cross-range scaling (CRS) is proposed to estimate the rotation angle, which makes use of the information hidden in the chirp rate of echoes from the scattering centers. A technique based on Fractional Fourier transform (FrFT) is used to estimate the chirp rate, simulation and real data analyses are provided to verify the effectiveness of the proposed algorithm. [C2596]

#### "A general multi-channel radar echo simulator"

A general-purpose multi-channel radar echo simulator is researched and proposed in this paper to satisfy the various needs of the radar signal processor testing. The specificity of target echo model is the main problem to achieve the generalization for a simulator. The simulator will give priority to the issue of the generalization because the generalization is always the most attractive feature for any device. Therefore, it will lose some other performance. For example, the accuracy of the target distance will be reduced since we consider the target will not move in a coherent integration frame to reduce the computation and complexity of the echo modeling. At last, implementation of a specific simulator based on FPGA and DSP is introduced, including hardware design and software processing methods. [C2597]

#### "An improved nonlinear chirp scaling algorithm with capability motion compensation for one-stationary BiSAR"

This paper deals with the imaging problem of one stationary bistatic Synthetic aperture radar (BiSAR) with motion error. Since a motion error is the main phase error source in the aircraft SAR, the motion errors have to properly be compensated during the SAR image reconstruction. The nonlinear chirp scaling (NLCS) algorithm is one of the typical algorithms in the practical radar system. An improved NLCS algorithm which can compensate motion error for One-Stationary BiSAR is proposed. Specially, the proposed method is based on the constant acceleration movement and the sub-aperture technique. [C2598]

#### "The imaging research of the ground moving targets in forward scattering radar"

The present shadow inverse synthetic aperture radar (SISAR) imaging algorithm is derived based on some assumptions for air moving objects such as long baseline, large target size and so on. For the forward scattering radar (FSR) system to detect ground moving targets, the assumption conditions are often unsatisfied because of relatively small objects size, the strong ground clutter and the short baseline length. Furthermore, the assumptions will result in distorted imaging results for the extraction of profile median line and height difference using the present imaging algorithm. To obtain the accurate imaging results of ground moving target, the more accurate signal model for ground moving target is first time presented based on Fresnel-Kirchhoff diffraction formula and high order phase approximation methods, and the modified imaging algorithm is also proposed for the accurate profile reconstruction of ground moving target. Finally, the effectiveness is verified by simulation results. [C2599]

#### "Research on Scan-GMTI technology of airborne MIMO radar based on STAP"

Through successive azimuth scanning with narrow beam steered to different angles, Scan-GMTI technology provides a significant way to implement wide-area surveillance and track a particular target simultaneously. Applying MIMO mode to Scan-GMTI, abundance channel and frequency resources provide significant advantages for STAP algorithm to implement. The space-time-frequency joint processing will provide an effective approach for improvement of detection of slowly moving targets, reduction of Doppler ambiguities and blind velocities. [C2600]

#### "An improved algorithm of velocity measurement using burst error function"

Based on modulated frequency stepped signal model, the interference phase which impacts the precision of the least burst error velocity measure method is analyzed in this paper, phase correction factor is given to improve

the accuracy of the least burst error velocity measure method for moving targets, finally the signal processing flow is given and the performance is verified by computer simulation. [C2601]

#### "The algorithm of SAR speckle noise suppressing by using generalized multi-scale CB morphology"

During forming synthetic aperture radar (SAR) image, the inherent speckle noise severely affects the application result of SAR images. To deal with this problem, based on the contour bougie morphology (CB morphology) and the generalized multiple structuring elements morphology, a novel series morphological filter was constructed to suppress the speckle noise in SAR images. Firstly, by use of the omnidirectional multiple structuring elements the generalized multi-scale morphology open-max filter was adopted to filter the noise at the cost of minimal loss of image geometrical details, and then a CB open and a CB close series filter were used to filter the remained speckle noise. Thus it can not only effectively suppress the speckle noise in images but also preserve more detailed information of the images. Lastly, the simulated SAR images and the actual SAR images are simulated, and the results prove that the algorithm presented in this paper can efficiently suppresses the speckle noise in SAR images. [C2602]

#### "Exploitation of SRTM DEM in InSAR phase unwrapping problem"

A novel approach is proposed in this paper to exploit the Shuttle Radar Topography Mission (SRTM) digital elevation model (DEM) in the interferometric synthetic aperture radar (InSAR) data processing. The proposed algorithm includes three steps: the first step is to patch the void cells in the SRTM DEM; the second step is to determine a one-to-one correspondence between the interferogram and the SRTM DEM; the third step is to eliminate the phase trend between the original and simulated interferogram. This algorithm can be applied to facilitate phase unwrapping problem. Conventional techniques approach phase unwrapping as an optimization problem, where the total branch-cuts or the gradient errors, etc. are to be minimized. Generally speaking, they consider phase unwrapping as a blind procedure, i.e., without any external guidance. The purpose of this paper is to fill this gap by introducing the SRTM DEM as guidance for phase unwrapping. Some experimental results with JESR verify the theoretical analysis and show that the method can improve the performance of the phase unwrapping to a great extent. [C2603]

#### "Relationship of target identification performance and waveform parameters"

In this paper, we established rigorous relationship between target recognition performance and the parameters of a fixed waveform via Kullback-Leibler information number of single observation (KLINs). The method we proposed takes advantage of the methodology of sequential hypothesis test. It depicts the target recognition efficiency of certain radar waveform parameter in the metric of average number of necessary signal (ANS) transmission. Compared with the traditional simulation methods in literature, it is a more efficient and valuable one to find the optimum values of a certain waveform parameter. Simulation results about the parameters of LFM signal show the validity of the method. [C2604]

#### "A quadrature Doppler radar system for sensing human respiration and heart rates"

In this paper, a Doppler radar system for cardiopulmonary detection will be described. The idea of our design is to use inexpensively commercially available motion sensor detectors. So a quadrature receiver board from AD-8347 is used. Experiment results indicate that this system can extract respiration and heartbeat rates at a short distance with digital signal processor. [C2605]

#### "Algorithm for unknown SNR estimation based on sequential Monte Carlo method in cluttered environment"

In target tracking, radar or sonar sensors provide amplitude information as well as kinematic information, e.g., range and bearing. Considering the amplitude information with kinematic information, tracker can more effectively distinguish measurement origin in cluttered environment. The tracker utilizes the amplitude information in the form of signal to noise ratio (SNR). However, a major challenge comes from the fact that the SNR is often fluctuated according to the target's aspect and effective radar cross section. So the certain level of uncertainty of SNR should be reduced. Focused on the point, we propose a novel SNR estimation algorithm based on sequential Monte Carlo method. Finally, estimated SNR is applied to the probability data association filter with amplitude information. Simulation results demonstrate the effectiveness and high accuracy of the idea of exploiting SNR estimation in heavy cluttered environments. [C2606]

#### "On performance enhancement of a following tracker using stereo vision"

A stereo vision system has a distinctive advantage capable of obtaining exact and wide range of the distance

information. The use of stereo vision system has been increased due to the advances in hardware technology. This paper deals with design of the active vision system which acquires the distance and the direction information of the target using the stereo vision system. This paper also implements the tracker that follows the main tracker, which we call a following tracker, without identifying the target. In addition, the CAMShift algorithm which tracks the target based on the color information is used to acquire the center point of the object. A following tracker algorithm generates the control input that makes the following tracker aim the same target based on the sensing results from the active vision system. A following tracker needs the exact distance information between the system and the target to track the object accurately. We first build the mathematical model of object tracking system and following tracker, design the system controllers, and then compare the tracking accuracy under the two conditions: the presence and the absence of the distant information. [C2607]

#### **"Advanced obstacles detection and tracking by fusing millimeter wave radar and image sensor data"**

Reliable object detection and recognition for Adaptive Cruise Control (ACC) by multi-sensor and multi-algorithm have attracted much attention recently. Aiming at the calibration complexity problem, a novel calibration method is proposed to calibrate the millimeter wave radar data and the CCD camera data using a homography. The proposed method does not require estimation of rotation and translation between them or intrinsic parameters of the camera. And the calibration can be done without any manual manipulation. Tracking of the detected object by radar is done in image plane as the radar is insensitive to object size and has a low object recognition rate as well. A new tracking algorithm based on Mean Shift(MS) algorithm with Unscented Kalman filter (UKF) is proposed to track the detected objects in the image plane, in which UKF is used to predict the initial position of iteration for MS algorithm. Then MS is applied to find out the accurate position of the object and positions of objects are mapped to radar plane to judge it is a new object or old one. We demonstrated the validity of the proposed methods through experiments. [C2608]

#### **"On the Signal Processing in the Life-Detection Radar Using an FMCW Waveform"**

The progresses and difficulties faced in the life-detection radar signal processing are introduced in the paper. First, the progresses in signal processing are shown, including obtaining the breathing and heartbeat frequency by using self-correlation process and composing the mode vector to discriminate a life by using time-spectrum analysis and singular value decomposition. Then, the difficulties faced now are discussed. Echoes from the obstructions in the direction of radar antenna are main interference. How to control the interferences are discussed and a combinative approach of body movement and life information detection is brought forward in the paper. [C2609]

#### **"Chirp Sub-pulse Stepped Frequency Radar Signal Processing"**

Chirp-SF signal is a new kind of high range of resolution signal. This paper firstly points out that the traditional signal processing methods will cause "ghost images" when there is more than one scatter in a distance unit. Then a new method which including interfacing each sub-pulse in the Timeline and frequency shifting to constitute a FM signal is proposed. We can solve this problem and have a high range resolution by execute the pulse compression on the synthetic signal. In the end, the simulation result is shown to prove the correction of the Algorithm. [C2610]

#### **"Future voyage data recorder based on multi-sensors and human machine interface for marine accident"**

Voyage data recorders (VDR) enable accident investigators to review procedures and instructions before an incident and help to identify the cause of any accident. The Future data recording should be capable of recording data audio and video during day and night. The recording should be of high integrity, digital as well as independent of ship supplies. Voyage data recorder, popular name black-box, is used for recording all kinds of navigation information. VDR is a data recording system designed for all vessels required to comply with the International Maritime Organization IMO's and International Convention safety of life at sea SOLAS requirements (IMO). Data from various sensors on board the vessel is collected, digitized, compressed and then stored in an externally mounted protective storage unit. The protective storage unit is a tamper-proof unit designed to withstand the extreme shock impact, pressure and heat, which could be associated with a marine incident (fire, explosion, collision, sinking, etc). This research realizes the importance of obtaining these stored data for accident analysis. This paper considers a real case accident, by downloading and replaying the data of real black box for a sunken ship in the red sea. Eventually, video recorded data of the accident will be more helpful to the investigation. [C2611]

### "Analysis of data structures used for storing and processing 3D LADAR data"

This paper compares the use of a point cloud data storage structure with a voxel based storage structure for 3D data collected with LADAR. The motivation for this work is to support the development of a classification system to model the environment of an autonomous vehicle operating in an unstructured natural setting. The classifier should be able to detect trees, bushes, and ground based on the data. Most LADAR sensors provide accurate 2-D range information in a plane, but we generate 3-D data from the sensor by articulating it using a pan-tilt mechanism. A 3-D grid of voxels is used with each voxel representing a cubic region in space with an associated value to indicate the region's occupancy. We discuss how this voxel representation compares with a point cloud representation in the process of data collection, data storage, and data processing and also look at the complexity of merging new data with old data in the same region. There are two main contributions. The first is comparing a possible voxel based data representation with one possible point cloud data representation. The second is determining reasonable parameters (voxel size, LADAR pitch angular velocity, and distance to the target) to facilitate classification of the voxel data. The scope of this paper is confined to analyzing data size, scanning time required for accurate classification, and processing efficiency. Experimental data size, density, and classification performance results are presented. [C2612]

### "Complex permittivity estimation from free space RCS measurement"

Non-destructive and non-contacting estimation of the complex permittivity of the solid materials has been proposed using the monostatic RCS measurement from the specular reflection surface. In order to isolate the surface reflection contribution from the total scattering response, time gating method is utilized. The frequency domain RCS is measured first at a certain frequency band, and the corresponding time domain result is calculated via inverse Fourier Transformation. After identifying the surface reflection contribution and selecting it with a certain time width, Fourier transformation is used to obtain the desired surface response in the frequency domain. These RCS results are then utilized to estimate the surface reflection coefficients and their permittivities. The proposed method has been tested to evaluate the permittivities of cubic granite and synthetic phantom material, and the results are compared with those obtained by a coaxial probe method. Good agreement has been found between them and the validity of our method has been confirmed. [C2613]

### "Terrain classification based on structure for autonomous navigation in complex environments"

One of the main challenges for autonomous navigation in cluttered outdoor environments is to determine which obstacles can be driven over and which need to be avoided. Especially in off-road driving, the aim is not only to recognize the lethal obstacles on the vehicle's way at all costs, but also to predict the scene category thereby giving a better decision-making framework for vehicle navigation. This paper studies terrain classification based on structure relying on sparse 3-D data from LADAR mobility sensors. While most of recent methods for LADAR processing are purely found on the local point density and spatial distribution of the 3-D point cloud directly. We, on the other hand, introduce a new approach to analyze the point cloud by considering local properties and distance variation of pixels inside edgeless areas. First of all, the edgeless areas are extracted from segmenting the 3-D point cloud into homogeneous regions by Graph-Cut technique. Secondly, the neighbor distance variation inside edgeless areas (NDVIE) features are obtained by calculating the euclidean distance of neighbor distance variation inside each region. Through extensive experiments, we demonstrate that this feature has properties complementary to the conditional local point statistics features traditionally used for point cloud analysis, and show significant improvement in classification performance for tasks relevant to outdoor navigation. [C2614]

### "MIMO radar with spatial-frequency diversity for improved detection performance"

The Multiple Input Multiple Output (MIMO) radar concept exploits the independence between signals at the array elements unlike beamforming which presumes a high correlation between signals either transmitted or received by an array. Radar Cross Section (RCS) of a complex target varies with both transmitted frequency and target geometry. By widely separating transmit and receive antennas, MIMO radar systems observe a target simultaneously from different aspects resulting in spatial diversity, thus improving the detection performance. Also by utilizing different frequencies, independent RCS of the target can be observed, thus resulting in frequency diversity. In this paper, the spatial and the frequency diversities are studied together to bring out the combined benefits. The system proposed will not only have several antennas appropriately spaced but also several operating frequencies appropriately spaced, providing a better detection performance than conventional MIMO radar systems for the same transmission power. The simulation results exhibit a better detection performance of the proposed system as compared to MIMO radar systems with only spatial diversity. [C2615]

### "Range tracking filter using measurements with uncertain delays"

In modern marine range tracking systems, both Doppler radar and range sensors are often used to enhance the detection and tracking performance against sea clutters. Due to the delays in communication links, however, the measurements of the sensors do not arrive simultaneously to the data processor where the tracking filter operates. Moreover, the magnitudes of the delays vary irregularly. To cope with this problem of uncertain time delays, in this paper, we propose a new range tracking filter algorithm by adding a ZSB (zero-scan-back) MAP (maximum a posteriori) delay estimator to conventional Kalman tracking filter. Computer simulations are carried out to demonstrate the performance of the proposed filter. [C2616]

#### "A novel method for indoor location identification"

Radio Frequency Identification (RFID) is used in different applications. RFID technologies are getting considerable attention not only from academic research but also from the applications for enterprise. One of the most important applications of RFID research is the indoor position location. Many researchers have used varied technologies to perform the action of indoor position location tracking. In our research, we will propose methods using RFID tags to perform indoor position location tracking. First, we use RFID to collect Received Signal Strength (RSS) from reference tags beforehand, and then use multiple neuron networks models to do the indoor position location learning. Finally, when the track tags are set up in indoor environments, they can find the position of neighboring reference tags by using the neuron networks and an arithmetic mean to calculate the position location values; with this method we are able to break figures down to track tag position locations. We conducted this experiment to prove that our methodology can provide better accuracy than the LANDMARC system. We conducted the experiments to test the system accuracy. [C2617]

#### "Particle Swarm Optimization aided unscented kalman filter for ballistic target tracking"

Tracking of a ballistic target in its reentry phase by considering the radar measurements is a highly complex problem in nonlinear filtering. Kalman Filter (KF) is used to estimate the positions of the target when the measurements are corrupted with noise. If the measurements (range and bearing) are nonlinear then Unscented Kalman filter (UKF) can be used. For obtaining reliable estimate of the target state, filter has to be tuned before the operation, which is offline. Tuning is the process of estimating the process noise covariance matrix (Q) and measurement noise covariance matrix (R) of the filter. This paper presents tuning of UKF using Genetic Algorithm (GA) and Particle Swarm Optimization (PSO) for ballistic target tracking. Simulation results show that the superiority of PSO tuned UKF over conventional UKF. [C2618]

#### "Study on the Signal Detection Algorithm of Weak Laser Radar Target Based on Wavelet Transform"

According to the different transmission characteristics under the wavelet transform (WT) domain and the different distribution characteristics of frequency domain of the signal and noise, a novel approach for detecting weak signal laser radar target based on wavelet transform has been proposed. In many cases, wavelet decomposition has been used to de-noise a digital signal submerged by mass noise. Differently in our approach, we applied the wavelet decomposition and the modulus maximum to detect the locations of laser radar echo signal. Simulation shows that the proposed algorithm is more efficient than only utilizing wavelet decomposition in a clutter environment. [C2619]

#### "Doppler radar vital signs monitoring using wavelet transform"

An algorithm using wavelets is used to detect heartbeat rate from a phase modulated Doppler radar signal. It is shown that the heartbeat rate can be detected up to 1.5m from the radar in a noisy environment without the need of filtering. Also the property of wavelet transform to preserve both time and frequency information is utilized to analyze the phase modulated Doppler radar signal giving information about changes in heart beat over very small intervals of time. [C2620]

#### "Key technology research of CHINA Advanced Metering Infrastructure"

This paper defines content of Advanced Metering Infrastructure (referred to as AMI), make comparative analysis of the similarities and differences between domestic and foreign AMI. This paper describes the status of China AMI related technology system and China power using information collection system architecture; proposes typical structure of China AMI; analyzes AMI related communication technologies and their applications which includes power composite optical fiber communication, power line broadband communication technology and wireless communication technology. This paper also analyzes the metering sensor networks, interoperability, digital metering, distributed generation bi-directional metering, local and remote smart control technology, demand response and other key technologies; proposes the technical requirements of smart energy meter and

smart interactive terminals, data management system. [C2621]

### "Compact microstrip antenna design for microwave imaging"

An ultra-wideband microstrip antenna design is considered with respect to applications in breast cancer detection. The underlying design concept is based on ground penetrating radar (GPR). Simulated and measured prototype performance show excellent performance in the input impedance and radiation pattern over the target range from 4 GHz to 8 GHz. The 4 GHz to 8GHz frequency band for microwave imaging perform better in comparison with other microwave frequencies. The antenna also shows a reasonable uniform radiation performance in the broadside direction which contributes to the reduction of clutter levels, thus aiding the reconstruction quality of the final image. [C2622]

### "Automatic detection of reflexion hyperbolas in gpr data with neural networks"

In order to locate cylindrical objects like pipes and cables buried underground using ground penetrating radar it is necessary to detect reflexion hyperbolas in the measured radargrams. In practice, this task is in many cases complicated due to different geological environments, incomplete or disturbed hyperbolas, and first of all the fact that nearby objects lead to hyperbolas interfering with each other. In this paper we present an automatic detection system based on a specially connected neural network using receptive fields. We show that with an adequate definition of training data the system is capable of reliably detecting reflexion hyperbolas even in those challenging situations. [C2623]

### "An environment monitoring system for valuable chinese herbal medicine growing based on wireless sensor networks"

The wireless sensor network, which refers to the combination of sensors, embedded system, MEMS, distributed information processing and wireless communication network has become a hot topic in the research field because of its wide application prospect. This paper propose the design of an environmental monitoring system for valuable medicinal herb growing based on wireless sensor network, which gives a real-time monitoring of the environment information on the target area, such as soil temperature, humidity, light intensity, soil components. This paper describes architecture of the monitoring system and gives a design of hardware platform for sensor nodes and workflow as well as the terminals of monitoring management system. [C2624]

### "Application of GPRS technology in water quality monitoring system"

The method of water quality monitoring applied by XueYe reservoir is sampling in the scene and analyzing at the laboratory at present. Based on analyzing key problem of water quality monitoring, automatic water quality monitoring system based on GPRS is provided in this paper. Considering features of water quality monitoring, the general structure and network framework of the system, and the way of access to GPRS of data monitoring center are designed based on GPRS technology. Water quality parameters collected by multi-parameter water quality probe are transmitted to data processing and monitoring center through GPRS wireless communication network of mobile. The system collects, transmits and processes water quality parameters automatically, so production efficiency and economy benefit are improved greatly. Practice has proven GPRS technology can achieve well within the complex environment of poor water quality unmonitored, and more specifically applicable to the collection point, data transmission automatically generate the field of water analysis equipment data transmission and monitoring. [C2625]

### "A new approach for classification of data transmission media in power systems"

Smart Grid denotes the integration of all elements connected to a power grid with a communication infrastructure. Recent communication systems are developed by multi layer architecture. The lowest layer in such systems is transmission media. The characteristics of the communication systems will be seriously influenced by the characteristics of its media. This paper classifies communication media of power systems as dependent or independent ones. A dependent media is part of power system which is normally owned by Independent System Operator (ISO) or distribution companies. In contrast, as an independent media, it is not normally part of power system and can be public or provided by data service providers. In this paper, first, a brief summary of popular media used in power systems is presented. Then, the two main classes of media are compared with each other. [C2626]

### "A fully integrated 77-GHz radar transmitter based on a low phase-noise 19.25-GHz fundamental VCO"

A 77-GHz automotive radar transmitter is presented. The transmitter is based on a 19.25-GHz Colpitts voltage

controlled oscillator, that feeds two cascaded frequency doubler stages. In a following medium power amplifier (MPA) the signal recovers after frequency transformation. Finally a power amplifier (PA) adds 6 dB to the power level after the MPA. In addition, an emitter follower stage connected to the oscillators output drives a switchable divide-by-16/32 stage realized in emitter-coupled-logic (ECL). [C2627]

#### "A 77-GHz down-conversion mixer architecture with built-in test capability in SiGe technology"

A 77-GHz double-balanced mixer in a 200 GHz ftsilicon-germanium technology is presented. The proposed mixer architecture is capable of simultaneous direct up- and down-conversion of two separate input signals without additional power consumption. An up-converted low-frequency test signal is coupled back into the receiver RF input path to enable a built-in functionality test of the down-conversion path of the mixer. The circuit exhibits a conversion gain of 20 dB and draws 22mA from a 3.3V supply. The fabricated chip occupies an area of 1028 Ч 1128µm<sup>2</sup>. [C2628]

#### "Weak Signal De-noising Method Based on Accumulation in Frequency Domain and Wavelet Transform"

Bioradar echoes are often very weak and submerged in noise. The SNR of radar signal is very low. Therefore, echo signal denoising is indispensable for extracting life information. In this paper, the method of weak signal denoising based on the combination of accumulation in frequency domain and wavelet transform is proposed. First, the effectiveness of frequency domain in accumulation and wavelet transform in denoising is presented respectively. Then, the combination of two methods was used to remove noise and extract useful information on the situation of Gaussian white noise. Simulation results show that the method can restrain the noise and extract useful signal effectively in low SNR. [C2629]

#### "Simulation of transient electromagnetic fields on a finite-element mesh"

This paper presents a full-wave 3D electromagnetic transient simulation method which uses an unstructured finite-element mesh. The mesh elements have a range of sizes and orientations such that, rather than forming a regular grid, they conform to the geometry of the model, respecting all its details. This paper will discuss the method and present some examples of applications. [C2630]

#### "3D simultaneous multi-beams radar processing by using planner array antennas"

In this study a planner array with beam forming and beam shaping techniques are designed in order to develop and simulate 3D simultaneous-multi-beams (3DSMB) radar. Two targets are obtained, firstly developing 3D radar with 4 simultaneous-pencil beams, secondly, developing 3D with 4 simultaneous-different beams, such as Pencil, Fan, Transmit, and Intermediate beams. The new development in this paper provides in conjunction with enhanced processing techniques superior innovative war-fighting solutions to the dramatic change in the nature of threats (i.e. Missile, Anti Radar Missile, Jammers, and heavy clutter). A new software package is developed for the 3DSMB Radar in order to obtain the lobbing pattern coverage for a complex topography, because the previous studies didn't obtain the lobbing pattern for the 3D radar. Also, the cost will be much cheaper for the new mentioned development because instead of using different radars for different tasks and different targets platforms, the new development will be one radar processing different tasks and different targets platform at the same time, in addition to minimizing size and increasing processing speed and saving processing time. [C2631]

#### "Modeling of 3D pencil beam radar (PBR) volume coverage and 3D DMC"

The actual three dimensional radar purposes are to detect the target in three dimensions range, height and azimuth angle. The objective target for this paper is to simulate and study the three dimensional 3 D radar pencil volume coverage and the evaluation of the 3 D detection map contours (DMC) in complex environment. Also, the 3D DMC and 3D volume coverage are examined for different polarizations, such as horizontal, vertical, and circular. The results show that greater DMC and volume coverage are obtained in case of using horizontal polarization than the vertical and circular polarizations, also the vertical polarization produces greater ranges and greater DMC than the circular polarization assuming that the same radar parameters and same environment for the two cases, the free space and interference conditions. Also the accuracy measurements for the elevation and azimuth angles are better when using the Pencil beam coverage. The applications of the 3D (PBR) are widely used and interested for ATC radars and the EWR for homeland defense and protection because they are offering the prediction of radar performance and radar sitting. The detection and tracking facilities are obtained simultaneously which improve the target processing time and minimizing the cost. [C2632]

#### "Optical Image and SAR Image Matching Based on Scattered Edge Feature"

In this paper, we propose a novel algorithm for matching optical image to synthetic aperture radar (SAR) image based on scattered edge feature using relaxation Hausdorff distance combined with genetic algorithm. A method is presented to extract scattered edge feature from low signal to noise ratio (SNR) SAR image via statistical and ratio model. Based on the scattered edge image from SAR and optical image, relaxation Hausdorff distance is adopted as a similarity measure because it is insensitive to noise. Genetic algorithm is used as searching strategy to achieve high computation speed for its intrinsic parallelism. Experimental results using real SAR and optical images demonstrate that the algorithm is feasible, and can achieve high matching accuracy. [C2633]

#### "The Adaptive Detector of MIMO Radar and Its Performance"

Aiming at that the echo signal lies on the target characteristic in target detection of MIMO radar, namely the RCS of target determines the echo intensity, MIMO radar adaptive detector is based on the GLRT MIMO radar. It samplings in the radar receiver, makes the test be related to the SNR and sample size, and overcomes that the amplitude of echo effect detector's performance. then The better detector is achieved. The relative entropy, which is used to test the detection performance can represent the effect of the sample size on the detection performance. It is proved by the entropy that the MIMO detector is feasible and advanced. [C2634]

#### "Nonlinear Control System Intelligent Identification Using Optimized Support Vector Machines"

Nonlinear control system identification is studied using neoteric optimized Least Squares Support Vector Machines (LS-SVM) in this paper. Firstly, a multi-layer adaptive optimizing parameters algorithm is developed for improving learning and generalization ability of least squares support vector machines. According to different learning problems, the optimization approach can obtain appropriate LS-SVM parameters adaptively. Then, a nonlinear control system is identified by improved LS-SVM. The results show that the optimization approach can acquire best-optimized parameters for LS-SVM, and optimized LS-SVM can provide excellent control system identification precision and excellent convergence. And also, the multi-layer adaptive optimizing parameters algorithm may be appropriately extended to other types of support vector machines. [C2635]

#### "A Novel Velocity Compensation Algorithm by Graph Matching Method"

A novel velocity compensation algorithm is proposed. By extracting all potential scatters of two range profiles as two point patterns, the algorithm matches the point patterns by means of graph matching method. The velocity is estimated by the distance of correspondent points. The simulation experiments on range profiles with varying SNR, false scatters, and clutter aiguilles show the robustness of the new algorithm. [C2636]

#### "Track-Before-Detect Based on Two-Stage Sampling Particle Filter"

A modified track-before-detect based on two-stage sampling particle filter is proposed for detection and tracking of a target with low signal-to-noise ratio in an image sequence. According to each component's impacting on measurement directly or not, the state vector is partitioned into two parts. Then a higher-dimensional sampling problem in TBD can be changed into two successive lower-dimensional sampling problems. This improves the efficiency of state sampling. Results on simulated data show a higher gain in performance of detection and tracking. [C2637]

#### "Design and Implementation of a 1.5Gsps Digital Channelized Receiver"

Based on the derivation of the efficient implementation structure of the frequency domain polyphase filter digital channelized receiver, a digital channelized receiver was achieved on the hardware platform with I/Q sampling, 1500Msps, 64channels. In order to ensure good performance of the system, optimization of the processor speed and processor resources was fully considered during the design process of the whole system. The actual ultra-wideband signal test results show that the digital channelized receiver is in good performance. [C2638]

#### "One Vehicular Information Service System"

This article deals with several kernel technologies applied in vehicle information service. The technology referring to GPS (Global Positioning System), GPRS (General Packet Radio Service), GIS (Geographical Information System), and Computer Network etc, as we have studied, is believed to be able to construct a Vehicle Information Service System which faces the public. Synthesizing the technologies including GPS,GPRS, GIS, image capture and compress based on ARM9 processor and embedded system to establish a intelligent vehicle service model, which emphasizes U-V-S (User-Vehicle-Server) interaction. It is a integrated application in embedded system and its application software runs on relatively real-time and multi-mission operating systems. [C2639]

### "The Eye Movement Experiment and the Usability Evaluation of the Fighter Cockpit Digital Interface"

The relationship between the eye movement experiment and the quantitative evaluation of the visibility and usability of the fighter cockpit digital interface is put forward. After analyzing the data of the eye movement experiment of simulated fighter cockpit digital interface, we can demonstrate that the four kinds of quantitative data of the eye movement which include the pilot's gaze point coordinate, the gaze point number, the pupil frequency and the event time are very sensitive to the visibility and usability evaluation of the cockpit digital interface, and that the figure of gaze point sequence can apply to the usability evaluation of the interface very well. Furthermore, we infer that the eye movement experiment can reveal the pilot's visual process and cognitive activity, which will have a great practical significance to evaluate the usability and optimize the interface. [C2640]

### "IR revolution 360 infrared panoramic camera the ultimate solution for perimeter security"

Throughout the world, security issues are becoming increasingly important due to the current political and economical situation. Formerly reserved to the Defence sector, surveillance technologies for site monitoring are now required in many sectors. To this aim, very often a multitude of sensors using different technologies are installed, i.e. radar, intensification light cameras, CCTV, infrared barriers, lasers, IR cameras. These are spread around or within the monitored area in order to secure it. [C2641]

### "Highway road traffic information and monitoring system"

Road traffic, by dimensions, weights and speeds of vehicles which is moving is a danger that requires precise deployment rules, advanced technical systems for safe movement, an appropriate infrastructure etc. Road safety is an issue of interest to all citizens, each of which can contribute to improving safety on public roads. Although the measures taken in this area have proven, road accidents remain unacceptably high. One of the main causes of serious accidents is the failure of its speed and road weather conditions. For this reason in this paper we present an electronic road traffic information and monitoring system. The system consists of a traffic information system and detection equipment and weather monitoring, video imaging to speeding vehicles and the weight permitted for movement on public roads. [C2642]

### "Direction-of-Arrival estimation for uniform sensor arrays"

The Direction-of-Arrival estimation is a ubiquitous task in array signal processing with applications in radar, sonar, acoustics, astronomy, communications, medical imaging and military applications. For this reason, several techniques were developed for estimating the arrival direction of signals. The initial methods for estimating the direction of arrival were Bartlett and Capon, but the Multiple Signal Classification (MUSIC) algorithm is one of the most popular subspace-based techniques for estimating the directions-of-arrival of multiple signal sources. This paper is making a study of techniques for estimating the signals at arrival, when at the reception a linear array of antennas is used. The presented techniques are based on the estimation of the spectrum obtained at the reception. It shows a comparison between the methods implemented: Bartlett, Capon and MUSIC. [C2643]

### "A New Range Profile Identification Method Based on Multi-Scale Entropy Feature"

In high resolution radar, one dimensional range profile supplies detailed information of targets, but it is sensitive to direction, translation and intensity. To get direction, translation and intensity invariable features, a wavelet based multi-scale entropy feature is proposed. As entropy is not dependent on the shift of range profiles and is insensitive to the direction variation, the entropy feature has a translation and direction invariable property. In the paper, the entropies of neighbor two scales were divided to eliminate the intensity sensitivity of profiles. When the proposed feature was applied into real data for target identification, good result has been obtained, which is much better than conventional methods. Therefore, the proposed multi-scale entropy feature is an effective feature for range profile identification. [C2644]

### "Study on Command Control Network Cooperation Measurement of Network Centric Artillery Combat"

Firstly, the computing method of network centric artillery combat command control network cooperation measurement is studied. Secondly, the network relationship of artillery battalion command control nodes is analyzed in detail. Thirdly, the time delay of command control system influenced by the network complexity and a combat example are also studied. The results show that the network complexity and its corresponding network cooperation affect greatly the time delay of system. This research can provide good decision-making support for artillery command control network nodes deployment and optimization. [C2645]

### "The Case Study of a Diffusion Theory Model of Adoption and Substitution for Successive Generations of Mobile Internet"

Norton model is a diffusion model to use for a substitution for successive generations of a product. There are many hypotheses on this model, one of them is that only the next generation product can substitute this generation of product, and the first several generations cannot affect the diffusion of this generation product. In fact, successive generations of a product influence each other when they diffuse in the same market, so this paper takes the factors of the influence of successive generations of a product into account Norton model, and defines the substitution influence coefficients, then constructs the extended Norton model. This paper takes the adoption and substitution for successive generations of the mobile Internet in Taiwan as an example for the application of the extended Norton model. The results is satisfied after comparing with Norton model. In the end, the paper draws a conclusion that the extended Norton model is reliable, and the fitness and the forecasting is better than that of Norton model. [C2646]

### "Research on FOA and TOA Estimation Algorithm of Galileo SAR Signal"

In order to estimate FOA and TOA accurately in Galileo Search and Rescue system by considering that the message bit width and the phase edge time are unknown, we present a new FOA and TOA estimation algorithm which combines the algorithm based on Multiple dimensions Joint Maximum Likelihood Estimation criterion and Barycenter calculation algorithm. The FOA and TOA estimation errors of this algorithm can be limited within 0.03 Hz and 12 us in the condition that carry-to-noise rate (CNR) equals to CNR treatment threshold which is 34.8 dBHz and phase edge time is 250 us for received signals. Theoretical analysis and measurement results have proved the effectiveness of this algorithm. And the algorithm has been applied to the Galileo MEOLUT station. [C2647]

### "An algorithm for detecting a maneuvering target based on TFR and Viterbi algorithm"

An algorithm for radar signal detection method based on a time-frequency representation (TFR) and Viterbi algorithm (VA) is proposed. Two TFR methods are considered, Short-time Fourier Transform (STFT) and S-method (SM). Performance and detection ability of the proposed algorithm was investigated on real radar signals of a single maneuvering target with added Gaussian noise and signal-to-noise ratio from -15 dB to -2 dB. The results show that the proposed algorithm works well even in very low SNR values. [C2648]

### "A novel multi-dimensional spectrum estimation technique"

Conventionally, to multi-dimensional spectral estimation techniques, each data snapshot in space is captured simultaneously in time. The size of the antenna array is dependent on the area of interest. In this paper, we propose a data measurement technique, which does not collect data samples within each snapshot in space simultaneously but sequentially along a predefined path, and a spectral estimation technique, which is based on the Discrete Fourier Transform (DFT), for the collected data. The key idea of these techniques is to create a large synthetic antenna aperture by displacing a small antenna array and by assuming uniform plan impinging waves. The performance is evaluated by simulation. The applications of the proposed techniques include synthetic aperture radar, radar processing and sonar systems. [C2649]

### "Performance analysis of LFM-UWB radar based on Doppler frequency"

This paper analyzes the detection probability of LFM-UWB radar based on Doppler frequency. The LFM-UWB radar system consists of a transmitted part and a received part and uses AWGN channel. The system model is verified through analysis and simulation. Frequency offset occurs in the received part caused by the mismatching between the received signal and the reference signal. Performance degradation of detection does not occur in LFM-UWB radar, with 30cm resolution when the margin of Doppler frequency is about 120Hz. [C2650]

### "Self-optimization of capacity and coverage in LTE networks using a fuzzy reinforcement learning approach"

This paper introduces a solution to enable self-optimization of coverage and capacity in LTE networks through base stations' downtilt angle adjustment. The proposed method is based on fuzzy reinforcement learning techniques and operates in a fully distributed and autonomous fashion without any need for a priori information or human interventions. The solution is shown to be capable of handling extremely noisy feedback information from mobile users as well as being responsive to the changes in the environment including self-healing properties. The simulation results confirm the convergence of the solution to the global optimal settings and that the proposed scheme provides up to 20% performance improvement when compared with an existing fuzzy logic

based reinforcement learning approach. [C2651]

### "A novel maneuvering target tracking algorithm based on moving slide window"

We propose a novel tracking algorithm called slide window tracker (SWT) suitable for maneuvering target. To efficiently estimate trajectory of moving target, we adopt a sliding piecewise linear window which includes past trace information. By adjusting the window parameters, the proposed algorithm is to reduce measurement noise and to track fast maneuvering target with little computational increment as compared to  $\alpha$ - $\beta$  tracker. Throughout the computer simulations, we verify outstanding tracking performance of the SWT algorithm in noisy linear and nonlinear trajectories. Also, we show that the SWT algorithm is not sensitive to initial model parameter selection, which gives large degree of freedom in applying the SWT algorithm to unknown time-varying measurement environments. [C2652]

### "Target detection with MSN algorithm for the bistatic radar using digital broadcasting signals"

In the bistatic radar, it is important to suppress the undesired signals such as the direct propagated signal from transmitter and its multipath components. Conventionally, the suppression method by subtracting the replicas of the undesired signals is often used. However, it requires the precise delay times of the undesired signals. In this paper we propose a new method to detect the target without any information on the undesired signals' delay times in digital terrestrial TV-based bistatic radar, the signal of which is based on orthogonal frequency division multiplexing(OFDM). This kind of the radar is called "passive bistatic radar." We adapt a scheme based on maximum signal to noise ratio(MSN) algorithm, which makes signal to interference plus noise ratio(SINR) maximum for the certain delay component. The maximum sensitivity is steered along the delay which relates to the target position, as if the search beam is steered along the direction in array signal processing. The sensitivity is steered by the weight applied to the received signal in the frequency domain. We obtain the method to estimate the weight to achieve the maximum SINR in the delay estimation which also includes the compensation for the reduction of the weight's length caused by decorrelation among the delay components. The simulation results show our proposed method without any information on the undesired signal's delays provides the sufficient performance compared to the conventional one. [C2653]

### "DOA with linear array antennas based on MoM"

Direction estimation of signal of interest has been an important issue in radar and communication system. Generally, DOA(Direction Of Arrival) methods have been researched in the field of signal processing with ideal array sensors. However, there are some problems in array antennas such as the input signal distortions in amplitude and phase, due to the mutual coupling between array elements. Therefore, the compensation techniques of mutual coupling effects in the array antenna are required for the accurate estimation of DOA. In this paper, we propose a new method of the compensation of the mutual coupling effects for the DOA estimation in the dipole array antenna by using the method of moment (MoM). Also, the proposed method is applied to the estimation of azimuth ( $\Phi$ ) and elevation ( $\theta$ ) angles using uniformly linear dipole array under noisy environments. [C2654]

### "Model-based decentralized embedded diagnosis inside vehicles: Application to Smart Distance Keeping function"

In this paper, the deployment of a fault diagnosis strategy in the Smart Distance Keeping (SDK) system with a decentralized architecture is presented. The SDK system is an advanced version of the Adaptive Cruise Control (ACC) system, implemented in a Renault-Volvo Trucks vehicle. The main goal of this work is to analyze measurements, issued from the SDK elements, in order to detect, to localize and to identify some faults that may be produced. Our main contribution is the proposition of a decentralized approach permitting to carry out an on-line diagnosis without computing the global model and to deploy it on several control units. This paper explains the model-based decentralized solution and its application to the embedded diagnosis of the SDK system inside truck with five control units connected via a CAN-bus using "Hardware In the Loop" (HIL) technique. We also discuss the constraints that must be fulfilled. [C2655]

### "Enabling roaming management in GPRS and WLAN networks based on SIP"

In the wireless networks technologies, the concept of Next Generation Networks (NGN) focuses on environments in which IP technology provides transparent connectivity. It includes the roaming and mobility management between mobile users in heterogeneous networks. We compare two roaming models in order to integrate communication and session control from GPRS to WLAN 802.11 using SIP signaling protocol. The approaches follow the classification for service composition of the SAHARA project: Cooperative Model and Brokered Model. The solutions are based on loose coupled integration and IP mobility, which provide mobile applications and

mobile services. Contributions include the selection of the better model, the design of SIP broker agent and the implementation of roaming management following the IETF specifications. [C2656]

### "Retrieval of Ground Deformation Based on TS-DInSAR Technique"

Time series interferogram analysis is an upgrade of the traditional 2/3/4-pass differential interferometry, and has been widely used to map ground deformation associated with urban subsidence, landslide, earthquake and so on. This paper analyzes some key steps in TS-DInSAR processing, including selection of high-coherent points, extraction of linear deformation, separation nonlinear deformation phase and atmospheric phase. Finally, an experiment based on TS-DInSAR technique is conducted over Taiyuan area using totally 14 ENVISAT ASAR scenes in the time span of 2003-2007, and the result of derived deformation shows good agreement with the leveling data with mean square root error of 3.1mm, demonstrating that the TS-DInSAR technique is accurate and efficient in deformation mapping over urban areas. [C2657]

### "A new parameter for FMCW radar under external interference"

Recently, ITS (Intelligent Transport System) has been studied actively which is useful for smooth traffic and safety drive of the various vehicles. Though the laser or imaging camera sensor was used for ITS, they have unstable performances and high complexity. Therefore, FMCW radar using millimeter wave has been proposed recently. Actually, 47, 60, 77, 94 and 139 GHz are assigned for the vehicle radar frequency in Europe and Japan. In this paper, FMCW radar was simulated and modeled with interference. Also, RER(Range Error Rate) was proposed to estimate the performance error due to the interference. [C2658]

### "Closure monitoring in Potash Mines using LiDAR"

Underground soft rock mines are constantly deforming-this is a normal rock response to mining excavation. Once a mine opening has been excavated or cut, the opening begins to deform into the excavation. This rock displacement, or room closure, could occur quickly or much more slowly depending on the stress changes caused by mining pattern, rock mechanical properties and in-situ rock pressure. Of particular importance to Mining Engineers and Rock Mechanics specialists is the rate of this closure and where it is occurring within the mine. Room closure is traditionally measured using simple displacement transducers; these instruments give readings only at the points where they are installed. This paper proposes the use of Laser Range Finders (LRF) in generating 3D models of the mine areas where closure needs to be monitored. With this approach, closure can be measured at many points in the room, not just at individual instrumented stations. A procedure is presented using automatic scan registration to obtain a 3D model of an area using an inexpensive 3D LRF. Test results are presented from the Allan Potash Mine. It is shown that this procedure produces results consistent with a standard closure meter in a real mine environment. The difference between the average closure measured with LRF and the closure rod ranged from 3 millimetres to 13 millimetres (4% to 14% of total displacement change). [C2659]

### "FDI(R) for satellite at Thales Alenia Space how to deal with high availability and robustness in space domain?"

European leader for satellite systems and at the forefront of orbital infrastructures, Thales Alenia Space is a joint venture between Thales (67%) and Finmeccanica (33%) and forms with Telespazio a Space Alliance. Thales Alenia Space is a worldwide reference in telecoms, radar and optical Earth observation, defense and security, navigation and science. Thales Alenia Space has 11 industrial sites in 4 European countries (France, Italy, Spain and Belgium) with over 7,200 employees worldwide. Satellite evolution and wish to design more autonomous mission imply an enhancement of satellite architecture and to pay special attention to the FDIR. Nevertheless the constraints on the FDIR technique and strategy stay still invariant: robustness, reactive detection, quick isolation / identification and validation. This paper gives first the current context of FDIR by describing the approach implemented on Telecommunication satellite and more precisely one of the most FDIR sensible subsystem: the AOCS (Attitude and Orbit Control System). Following current state of FDIR in the Space domain, some perspectives will be introduced like a centralized distributed FDIR strategy for next generation of autonomous satellites and some research tracks like active diagnosis and hybrid diagnosis. [C2660]

### "Development of farming PDA based on the zigbee wireless sensors network and GIS"

It is the basic needs for carrying out precision agriculture to acquire the farmland information in real-time. Farming PDA is developed based on wireless sensors network and GIS technology. Farming PDA integrates the Zigbee coordinator module, GPSOEM module, GPRS module, and embedded GIS module as a whole mobile intelligent farming solution. Zigbee module is used for coordinating and managing the field wireless sensors

network and for collecting the farmland information through the network. GPS module is used for collecting and managing the geographic location information of each sampling point and for collecting the boundary geographic information of the target sampling field. GPRS module is used for the remote communicating and transferring the farmland information between the farming PDA and the host PC. The farming PDA can exchange information with the host PC in real-time so that it can be used to collect the farmland information in real-time. [C2661]

### "Application of particle filter for angle measure"

In anti-ship terminal guidance radar tracking system, the target echo is always corrupted by the sea clutter. When sea clutter is large at high sea state, the signal-to-noise ratio (SNR) of the target echo is usually relatively low as a result of the effect of sea clutter. The precision of angle error extraction in radar tracking servo is low, while the fluctuating error of angle measure is large in low SNR region. The radar antenna has to adjust itself very frequently to keep tracking its target. While it leads that the radar can not always hold on tracking the target steadily. To improve the precision of angle error extraction and steady off-boresight angle measure of the target, a novel angle measure method based on particle filter is proposed, which achieves off-boresight angle estimation by approximating the posterior probability diversity with particle set, and the steps of algorithm are presented. Finally the simulation experiment confirms the valid of the proposed algorithm. [C2662]

### "Noise analysis and restrain in the fusion process of remote sensing"

Considering the noise problem of multi-spectral images and SAR, several image noise models are described in this paper. The idea of non-negative matrix factorization and rough set are used to carry out the fusion experiment. Non-negative factorization is a matrix factorization method in the restrictive condition which all elements are non-factorization. The theory of rough set is mainly about the combination between knowledge and classification, which has an effect on de-noising aspect to the image noises. On the other side, the HIS and wavelet algorithm are adopted to the multi-spectral image fusion. It can not only hold more spectral information but also improve the spatial resolution greatly. The results from the experiment on the images specified the different types of noise, and get the conclusion in the help of some evaluation methods. [C2663]

### "Adaptive network fuzzy inference system used in interference cancellation of radar seeker"

The method of adaptive network fuzzy inference system (ANFIS) applied to the interference cancellation system of radar seeker was described in this paper. When the antiaircraft missile, which adopts the pulse Doppler radar seeker, attacks the low altitude target in the down-looking mode, the seeker of missile will receive strong ground clutter. As we all know the ground clutter will seriously affect the seeker's properties of target detecting and real-time tracking. To dealing with the seeker signal, the model of clutter should be constructed firstly. But it is difficult to handle because of the uncertainties and non-completeness characteristic of the clutter model. In order to solve the problem and overcome these, the nonlinear model, which used for clutter signal processing by the ANFIS is accepted in the interference cancellation system. In some researches, it was proved that the artificial network based on ANFIS not only has the ability of nonlinear mapping but also has the function of self-learning. Especially, ANFIS has small calculating costs. In my study, to possess a desired robust model, the adaptive side lobe clutter cancellation system depended on ANFIS was introduced. Through the side lobe clutter cancellation, the signal noise ratio (SNR) of echo signal got obviously improvement. The simulation results of experiments showed that the method of ANFIS can sharply improve the detecting performance of pulse Doppler radar seeker's looking for lower altitude target. [C2664]

### "A two-stage gating algorithm for joint probability data association filter"

Gating techniques for maneuvering target tracking using a joint probability data association filter (JPDAF) are considered in this paper. A way of estimating the gate size via the performance of the data association filter has been proposed recently, by which the gate size can be estimated by looking for the optimal performance of the data association filter. Combining the elliptic tracking gate with the direction tracking gate, a modified performance estimation function was proposed. As a feasible implementation, a suboptimal two-stage gating algorithm has been proposed also. Simulation results show that the suboptimal algorithm can offer advantages of decreasing the number of the feasible association events and reducing the calculation load of JPDAF, especially in a heavy clutter and/or false alarm environment. [C2665]

### "Ballistic missile precession frequency extraction by homomorphic filtering"

In order to extract the precession frequency, which is an important feature parameter in ballistic missile target recognition, we first establish the dynamic Radar Cross Section (RCS) signal model for a conical ballistic missile warhead with precession motion. A homomorphic filter is designed to remove the scintillation effect in the RCS signal. Simulations show the practical usefulness of the proposed method in extracting an estimate of the

precession frequency. [C2666]

### "Methods and experience of using Matlab and FPGA for teaching practice in digital signal processing"

Digital Signal Processing is a curriculum closely integrated by theory, implementation and application. With the development of microelectronics technology in recent years, the emergence of variety of chips makes digital signal processing widely used in various fields. Therefore, almost all of the electronic and computer engineering departments are now offering the digital signal processing courses. The main content of this course is abstract signal processing and transforming, involving a large number of mathematical knowledge and basic theory. The Matlab software can make the signal be presented in the form of visualized graphic image. Besides, FPGA, DSP and other high-performance chips can make digital signal processing technology widely used in various fields. Leading Matlab and FPGA into the teaching of digital signal processing is useful to improve the students' mastery of the knowledge points and enhance interest in learning. In this paper, for the purpose of radar real-time processing system application, methods of using Matlab and FPGA for teaching knowledge points such as bandpass sampling, polyphase filters, FFT processing, etc. are introduced. [C2667]

### "The Applications of GPRS in the Mine Monitoring and Control System"

Remote monitoring system based on GPRS is a modern monitoring system which is composed of radio communication technology, signal collection and computer network technology. This article introduces a wireless coal mine monitoring system based on GPRS communications technology. This system proposed in this paper has achieved a good result in the test. [C2668]

### "Travel Time Forecasting Based on Phase Space Reconstruction and SVM"

Travel time forecasting is an important content of dynamic traffic navigation. Dynamic traffic data collection is the precondition of forecasting. Many traffic data collection methods have been adopted, such as loop inductive vehicle detector, radar detector, video detector, GPS floating car and so on. Due to the widely distribution, GPS floating car has become the most efficient mean to collect instantaneous traffic information. How to take use of the collected GPS floating car data to forecasting the travel time is a popular research topic. In this paper, we develop a travel time forecasting method with the combining phase space reconstruction theory and SVM. Phase space reconstruction theory is used to determine the number of forecasting variable. SVM is used to forecast the future travel time value. The efficiency of the method is illustrated through analyzing Jinan urban traffic data. [C2669]

### "Tracking Maneuvering Target on Airport Surface Based on IMM-UKF Algorithm"

Aiming at tracking maneuvering target of SMR (Surface Movement Radar), this paper establishes a constant acceleration motion model, constant turn motion model and constant velocity motion model according to the actual movement of aircraft. On the base of these models, the IMM-UKF filter tracking algorithm is designed by introducing Unscented Kalman filter (UKF) into the interacting multiple model (IMM) algorithm. And IMM-UKF is compared with IMM-EKF (extended Kalman filter) algorithms. Simulation results show that IMM-UKF algorithm has good stability, and it overcomes the divergence problem of the EKF filter. The tracking accuracy and the model of transition speed are better than IMM-EKF algorithm. [C2670]

### "Design and Implementation of an Embedded Diagnosis System for Radar Built-in Test Equipment"

This paper describes a kind of embedded diagnosis expert system for radar built-in test equipment (BITE). Based on gradation diagnosis model and fault separation tree, diagnosis knowledge is represented by integrated framework, and the direct inference, reverse inference and hybrid inference diagnosis strategy are carried out in radar system. Site test results showed that the diagnosis system could improve fault diagnosis accuracy and speed for modern radar fault diagnosis. [C2671]

### "A Novel Algorithm of Velocity Ambiguity Resolution for Wind Profiling Radar"

Wind Profiling Radar can be used to detect the distribution of atmospheric three-dimensional wind, the quality of velocity information affects its performance directly. Compared to other weather radar, wind profiling radar's velocity ambiguity is particularly prominent when used to detect signal. Multiple PRF (pulse repeat frequency) is often used in radar system in order to solve the ambiguity problem. In this way, radar system has a variety of solutions for ambiguity algorithm in signal processing. In this paper, Doppler frequency series (DFS) algorithm can recover target's true velocity from the coupling velocity estimating directly. Simulation results proved the effectiveness of the method, and show us the DFS algorithm for speed estimation performance. Finally,

optimization of one-dimensional set of algorithms-compare screening algorithm and DFS algorithm to ambiguity-resolving, given the speed estimated in the DFS algorithm superiority. [C2672]

### "Efficient parallel computation of the estimated covariance matrix"

Computation of a signal's estimated covariance matrix is an important building block in signal processing, e.g., for spectral estimation. It involves a sliding window over an input matrix, and the summation of products to construct any given output-matrix element. Any given product contributes to multiple output elements, thereby complicating parallelization. We present a novel algorithm that attains very high parallelism without repeating multiplications or requiring inter-core synchronization. Key to this is the assignment to each core of distinct diagonal segments of the output matrix, selected such that no multiplications need be repeated, and exploitation of a shared memory (including L1 cache) that obviates the need for a corresponding awkward partitioning of the memory among cores. Implementation on Plurality's shared memory many-core architecture and, in order to demonstrate additional benefits, also on the x86, reveals linear speedup and a 130-fold power-performance advantage over x86. [C2673]

### "Tunnel Construction Safety Inspection and Polymer Grouting Technology for Tunnel Quick Maintenance"

In this article, the monitoring and measuring of the Xuejiazhuang tunnel of Lingnan freeway is introduced. The fitting regression analysis for the data of curve was done. And the surrounding rock stability is studied with the regression analysis of the convergence displacement data. In order to maintain the existing void between initial lining and surrounding rock, the ground-penetrating radar nondestructive testing technology and polymer grouting technology is presented. The field test results show that the use of polymer grouting technology can repair the tunnel distress and provide an ideal manner for tunnel quick maintenance. [C2674]

### "Signal separation based on Paired-Echo Theory"

Signal separation plays a very important role in radar signal processing. The separation of radar signal and the background signals has great influence on radar signal processing. The traditional method has little efficiency when the background signal is nearly the same as the radar signal. Therefore, a more efficient method is needed. This paper is devoted to design a new type of mismatch network to modulate the transmitted signal of an active radar transponder (ART). With the help of the mismatch network, the reflected ART signal can be effectively distinguished from background signals. [C2675]

### "Research on correlation description and processing method of multi-sensor fusion"

The correlation and dependence among information from different sensors usually increase the difficulty of data fusion. Through analyzing the correlation of multi-sensor, three correlation models are deduced. They are strong-correlation, weak-correlation, and maybe-correlation. Three different methods are used corresponding to the above three correlation models. Finally, an example is enumerated to show the whole fusion process. [C2676]

### "An algorithm of signal sorting and recognition of phased array radars"

This article uses the radar beams scan characteristics of the phased array radar, and proposes an algorithm based on the rough sets theory to sort the signal of phased array radars. From the research of the character of the phased array radar's beam scanning manners, and use the PDW received from sensors as the set of attributes. So we can sort the phased array radar signal from the environment. [C2677]

### "A robust method for PRI modulation recognition"

One of the main problems of radar identification in electronic warfare support system is analysis of pulse repetition interval (PRI) modulation. In this paper a robust method of recognizing the PRI modulation type of radar signals is proposed to improve robustness of previous recognition methods as well as to reduce the complexity. Simulation results show that the proposed method achieves much better error recognition rate in case of missing and spurious pulses than other methods such as autocorrelation based techniques and the Noone method. [C2678]

### "The facilitation of SRTM DEM-derived interferogram to accurate DEM reconstruction"

A novel approach is proposed in this paper to exploit the Shuttle Radar Topography Mission (SRTM) digital elevation model (DEM) to improve the accuracy of digital elevation model (DEM) reconstruction in interferometric synthetic aperture Radar (InSAR). The proposed algorithm can be applied to facilitate the DEM reconstruction

problem, i.e, the raw and simulated interferograms can be fused by introducing a user-defined weighting factor, that is, in regions of higher coherence, the raw interferogram with the interferometry method are remained, and in regions of lower coherence, the interferogram is updated with the simulated one. Some experimental results with ERS data verify the theoretical analysis and show that the method can improve the performance of the DEM reconstruction to a great extent. [C2679]

### "Life detection based on Correntropy Spectral Density"

A life detection method based on Correntropy Spectral Density (CSD) is proposed. Because correntropy contains second and higher-order moments of the probability density function due to the nonlinearity of the kernel, it is capable of yielding higher output Signal to Noise Ratio (SNR) in non-Gaussian background when compared with traditional life detection algorithm based on the Power Spectral Density (PSD). The simulation with synthetic data and experimental results illustrate the superiority of the method. [C2680]

### "Track clustering based data association for sky-wave Over-the-horizon Radar"

The multipath propagation and low measurement precision in sky-wave Over-the-horizon Radar (OTHR) pose new challenges to data association. Aiming at the formation of ships, this paper presents a new method of data association. Firstly the plane measurement model is established, and the transformation between radar and ground coordinates is deduced according to the given ionospheres state, which leads to different propagation modes. Then measurements observed from radar are transformed to ground coordinates considering all possible propagation modes, and the transformed points in ground coordinates for each measurement are called hypothetic points. Max-min distance clustering method is adopted to divide these hypothetic points into multi-classes. The feasible classes are selected using the restriction of propagation modes, and the geometry center of clustering can be calculated by averaging the points of feasible class. Finally, the nearest neighbor method is used to associate the geometry centers of clustering among different scans and further find the correlation of measurements, propagation modes and targets. Simulation results indicate that the proposed algorithm can associate the tracks in the formation of ships effectively, and the influence of radar detection probability on the algorithm is also analyzed. [C2681]

### "Influence and compensation of target motion on monopulse estimation in PD radar"

Pulse Doppler (PD) radar system with monopulse estimation can effectively acquire the location information of weak target, since it combines the advantages of coherent integration and monopulse technique. However, as it takes some time to realize the coherent integration, target motion will result in the decline of integration efficiency, thus affects the angle measurement precision. This paper investigates the principle of monopulse estimation in PD radar and the influence of target motion on angle measurement. A modified expression for angle measured value is presented when target has tangential motion, which can be interpreted as the midpoint angle of target motion track. Moreover, the target radial motion can be compensated by envelope interpolation method in time domain with the prior information of velocity, or by Keystone transform method in frequency domain without velocity information. Finally, the availability of the modification and compensation is verified by simulation. [C2682]

### "Research on the linear frequency diverse array performance"

The application of the linear frequency diverse array (LFDA) provides the more freedom for the waveform design in time, frequency, amplitude and phase domain. The antenna pattern of the LFDA is analyzed firstly. The main-lobe width of the antenna pattern is narrower and narrower with the increasing of the frequency interval between antenna elements. The ambiguity function of both LFDA and the conventional broadband linear frequency modulation (LFM) signals is compared. The blur between range and Doppler of the LFDA ambiguity function is improved evidently. The simulation and assay indicate that the application foreground of the LFDA is comprehensive. [C2683]

### "A quick and unitary algorithm for imaging radar jamming effect evaluation"

It is complicated to effectively and quickly evaluate jamming effect on imaging radar. Based on the concept of Euclid range space, a modified jamming effect evaluation technique for imaging radar has been proposed in this paper. Difference from previous methods, the most advantage of this method is that it has quick, accurate and unitary characteristics and it resolves the problem of timeliness that anti-jamming facing urgent need. It satisfies modern warfare's high demands and real-time need and has broad application prospects. Because this method make the evaluation standard of jamming effect quantify from zero to one, according to the evaluation coefficient value size, whether the jamming mode is effective can quickly and easily be given and the jamming intensity exerted to target can be known quickly. The jamming simulation has been done with the real and raw imaging

radar data. The result demonstrates the method is effective. [C2684]

#### "Mean shift track initiation algorithm based on Hough transform"

To solve the problem of initiating tracks for multi-target in dense clutters environment, a Mean shift track initiation algorithm based on Hough transform is proposed. In the algorithm, firstly, hough transform is applied to transform observation points from input space, referred to as feature space into curves in a special parameter space; then a Mean shift clustering algorithm is executed to cluster the items gained in the parameter space, and the problem of peak seeking is also solved adaptively. Furthermore, a fuzzy influential factor, which is based on the vote number of accumulation matrix and distance between items in the parameter space and clustering center, is defined to design kernel function of Mean shift; thus clutters are removed more effectively. Experimental results show that proposed algorithm has high detection accuracy and can initiate tracks effectively. [C2685]

#### "A novel method on radar 3-D imaging"

To realize perception to local lunar surface under the condition of relative stationary before soft landing during moon discovery, a novel 3-D imaging method is proposed. The method is based on receiving digital beamforming and modulated frequency stepped radar signal processing. The outstanding feature is this method can realize 3-D imaging without relative motion between radar and target. Simulation results indicate that it can obtain coordinates of strong scattering centers accurately and reconstruct 3-D image of scene successfully. [C2686]

#### "Research on SR\_UPF ground moving target tracking algorithm using road information"

A kind of tracking algorithm using square root unscented particle filter is proposed to solve nonlinear problem caused by maneuverability of target and low measurement update rate in ground moving target tracking. Unscented transform is used to transfer state estimation and covariance matrix, where the covariance matrix has been extracted. From this, importance sampling used in particle filter can be gained. Then, the state estimation which is obtained through particle filter is projected to road according to road information if it is off road. Using one ground moving target indication sensor to track a target on road, simulation results show that the proposed algorithm can effectively solve nonlinear problem in ground moving target tracking. Compared with the conventional particle filter algorithm, the proposed algorithm not only advances the tracking precision, also reduces the needed number of particles which mean less run time will be taken. Another way, tracking performance can be further improved due to using of road information. [C2687]

#### "Three-dimensional microwave imaging with adaptive single-input-multiple-output SAR"

Three-dimensional single-input-multiple-output synthetic aperture radar (SIMO-SAR) imaging method is proposed in this paper based on Capon adaptive beam-forming technology, and we have designed the downward-looking geometry architecture and signal echo model of the imaging system. Imaging algorithm is derived from the model and simulated. The advantages of three-dimensional imaging with SIMO-SAR are shown by the simulation results that it can get the height information of the targets besides the azimuth and range information, thus the targets can be located accurately and viewed in a stereogram. Furthermore, the algorithm can give better three-dimensional resolution. [C2688]

#### "Study of Anti Jamming of Radar Signal Based on Sparse Decomposition"

In order to distill the features of radar echo-signal affected by strong jamming noise, the sparse decomposition method and BPDN (Basis Pursuit Denoising) algorithm are used to remove the noise and recover the radar echo-signal. Based on the theory analysis, the reconstruction of the radar echo-signal with different SNR and anti-jamming effect of the method is studied by the simulation. The simulation results show that the proposed method is effective for anti-jamming of radar signal. [C2689]

#### "Identifying ship echoes in CODAR HF radar data: A Kalman filtering approach"

Coastal nations have an interest in maritime domain awareness for applications in national security, coastal conservancy, fishery and stewardship of the exclusive economic zones (EEZs) along their coastlines. Maritime situational awareness involves knowing the location, speed and bearing of ships and boats in the EEZ. HF radar is a useful tool in providing ship information in real time. It is especially effective when combined with ship-borne AIS beacons. Our previously developed HF radar and AIS ship detection models estimate signal to noise ratio (SNR) as a function of range, including ducted propagation for the AIS radio signals. However, ship detection is hampered by the high variability of HF echoes from ships. This is due in part to the aspect dependence of ship

radar cross-section and to the presence of clutter bands at known Doppler shifts from both the ground and ocean waves. Tracking ships using their HF radar echoes becomes the means for effectively monitoring the presence of ships in the coastal ocean. We explore the application of Kalman filtering to the ship tracking problem, following the techniques described by J. V. Candy. This approach is described and demonstrated with a simple example. [C2690]

### "Software beam forming for ocean radar WERA features and accuracy"

The WERA system (Wave RADar) is a shore based remote sensing system to monitor ocean surface currents, waves and wind direction. This long range, high resolution monitoring system based on short radio wave radar technology. The vertical polarised electromagnetic wave is coupled to the conductive ocean surface and follows the curvature of the earth. This over the horizon oceanography radar can pick up back-scattered signals from the rough ocean surface (Bragg effect) from ranges of up to 200 km. The direction in azimuth is defined by means of the phase of the incoming electro-magnetic wave. That means the accuracy of this measured azimuth strongly depends on the quality of this phase measurements. The described Software Beam Forming method combines best accuracy with the highest temporal resolution for ocean radar applications. Compared with other beam forming methods the flexibility of this method provides more degrees of freedom for the radar site planing and makes it much easier to identify suited site locations. [C2691]

### "Characteristics of internal waves in the South China Sea Observed by a shipboard coherent radar"

In 2005 and 2007, a coherent, X-band radar was deployed in the South China Sea on two different ships. In both cases, the two parabolic antennas of the radar were fixed at grazing angles of approximately  $2^\circ$  looking toward the bow of the ship. The radar transmitted and received through a single antenna but alternated between the two antennas approximately every half second. One antenna was horizontally polarized and the other was vertically polarized. The data were analyzed by computing normalized radar cross sections and scatterer velocities as a function of ground range and time. Surface signatures of the internal waves were obvious in both types of image and at both polarizations as regions of enhanced cross sections or scatterer velocities. The collected imagery showed that at least two different types of internal waves exist in the South China Sea: small, nearly sinusoidal trains of waves and large soliton-like waves. These different types travel at very different speeds and interact with each other. The small nearly sinusoidal waves travelled at phase speeds near 1 m/s that increased as the small wave trains were overtaken by the faster solitons. Combined with other shipboard measurements, the radar measurements yielded the widths, maximum velocities, and strain rates of the solitons as well as the dependence of phase speed on amplitude. When the speeds of both the ship and the solitons were removed, the measurements showed that soliton full-widths at half-maximum ranged from about 0.5 to 4.5 km. These widths showed a dependence on the amplitude of the soliton. The phase speeds of the solitons also depended on their amplitude, reaching 3 m/s in deep water but only about 1.2 m/s in shallow water. CTD profiles were used to estimate an interface depth for a two-layer fluid model of the propagation of the solitons. The phase speeds predicted by this model agreed well with the observed dependence of the soliton phase speed on amplitude in both shallow and deep water. [C2692]

### "Surface measurement by using a fixed antenna microwave pulse Doppler radar in Sagami-bay off Hiratsuka in Japan"

A sea surface measurement system by using a microwave pulse Doppler radar has been developed. It can measure sea surface waves, sea surface currents and a sea level at one time only with the use of mathematical relations without the necessity of using any empirical relations. From September 2009 to January 2010, sea surface conditions had been measured by using a X-band microwave pulse Doppler radar at 1 km off Hiratsuka in Sagami-bay, Japan. Algorithms for obtaining of sea surface conditions from the backscattering microwaves measured by a pulse Doppler radar and some measurement results are shown in this paper. The radar measured shoaling phenomena clearly. The increasing rate of wave height became larger in proportion to the square of the wave orbital velocity. [C2693]

### "Temporal error analysis for compact cross-loop direction-finding HF radar"

Surface currents and ocean swell are measured using an HF radar with a compact cross-loop antenna design. This unique direction-finding radar has been widely used for long-term monitoring and for coastal oceanography applications over the last ten years. Numerous studies have evaluated errors associated with these devices under a host of environmental and seasonal conditions, and reliable comparisons between HF radar surface current measurements and those from other technologies indicate a range of 0.08 to 0.15 ms<sup>-1</sup>, while internal error estimates that are made using the spread of data values in a time series or spectrum from the radar systems generally lead to errors of around 0.2 ms<sup>-1</sup>. These error estimates are typically based on manufacturer-

recommended operating parameters that can include up to 25 specific parameters or assumptions made about the data. In particular, one of the dominant parameters in computing ocean surface currents from SeaSonde devices is the averaging time of both the power spectra and the computed radial components of the surface current vectors. This paper explores the relative effect of temporal averaging for two SeaSonde stations in Western Australia. By analysing 31 days of radial data, we evaluate the statistical characteristics of noise in the spectra and determine the limits to the assumption that it represents a stationary ensemble of independent samples. The improvement in accuracy as we integrate over different time intervals from 10 to 180 minutes is determined by these characteristics. These results are applied to error analysis for the radial components of surface currents and compared with the errors in the gridded values of the radial components. Finally, the effects of calibrated and uncalibrated antenna patterns on the radial components is evaluated in the context of the temporal and spatial errors. [C2694]

#### "Using a dynamic ocean surface to perform a geometric calibration of a bathymetric lidar"

A geometric calibration of an airborne lidar is an essential component to any bathymetric survey. A poorly-aligned system leads to erroneously reported depths, diminished system resolution and internally inconsistent point clouds. While most calibration procedures depend on the use of cultural features (like gabled roofs), one recently suggested methodology requires only a single broad, flat surface. Given the potential difficulty in identifying such a surface on land, this paper investigates the possibility of using the ocean surface instead. Simulations are performed to examine the anticipated influences of both surface waves and tidal variation. Finally, oceanic results are compared with the likely topographic alternative: using a narrow airport runway as the calibration surface. [C2695]

#### "Comparison of SAS processing strategies for crabbing collection geometries"

This paper presents a number of different processing strategies for generating synthetic aperture sonar (SAS) imagery when data collection suffers from significant sideways crab (where we define crab as the angle difference between track and heading). Whilst large amounts of sideways crab do not present fundamental limitations to the SAS method, the assumptions SAS processing chains are built upon are often violated under such conditions. We discuss typical assumptions and compare alternate image formation strategies. We also provide a short discussion of the fundamental limitations to crabbing systems. We found that the adjustments to our standard wavenumber-based imaging kernel increased crab-tolerance from approximately 7 degrees up to approximately 30. [C2696]

#### "The influence of rainfall upon Scatterometer estimates for sea surface stress: Applications to boundary layer parameterization and drag coefficient models within tropical cyclone environments"

The use of satellite scatterometers to probe the winds in and near strong tropical cyclones (TCs) is a valuable tool for both numerical weather prediction (NWP) and weather forecasters. The presence of widespread rain in these storms complicates the estimation of surface winds from the satellite. Improvements in the techniques to infer surface winds from the satellite observations, which remove the effects of rain contamination at the ocean surface, will improve the modeling efforts as they pertain to the prediction of TC intensity. We demonstrate the use of collated and simultaneous high-resolution rain measurements obtained from nearby Next-Generation Radar (NEXRAD) and NASA Quick Scatterometer (QuikSCAT) measurements, respectively. Through the application of the National Oceanic and Atmospheric Administration (NOAA)/Atlantic Oceanographic and Meteorological Laboratories (AOML)/Hurricane Research Division (HRD) TC wind analysis (H\*WIND; Powell and Houston [1996] ), we will study the dependence of a surface normalized radar cross-section (NRCS) on the TC wind-speed and rain-rate. The objective is to better observe and understand the dependence of the drag coefficient upon the surface stress across a wide range of conditions and spatial scales within these storms. [C2697]

#### "Worldwide internet based data acquisition from remote platforms"

A novel concept for using a low power web server integrated in a data acquisition platform for transferring data using "http" (hypertext transport protocol) has been developed by SAIV. The data is directly transferred from a field station to the end user without any intermediate links via the Global System for Mobile Communications (GSM). [C2698]

#### "Train Conformity Check System; Technology and current operation experience"

An overview is given of the technology and the performance of "Train Conformity Check System". The system provides a modular set of defect detection functions for rail vehicles, including the detection of three-dimensional profile limits violations and of overheated components. Other available defect detection systems can be

integrated to identify and arrest trains with hazardous defects, to support rolling stock maintenance planning and to increase railway lines availability. [C2699]

### "Spilled Oil Tracking Autonomous Buoy"

We are developing Spilled Oil Tracking Autonomous Buoy System (SOTABS), which is composed of a land base and several spilled oil tracking autonomous buoys (SOTAB), to detect and track spilled oil autonomously, sending real time data around them to the land base. This paper firstly deals with steady sailing performance of SOTAB-II with a sailboat shape for tracking spilled oil on the sea surface by controlling the rudder angle, and the area and direction of the sail, and then sea trials using a model of SOTAB-II with a cylindrical buoy shape to obtain its fundamental characteristics on motion. [C2700]

### "Improving target tracking performance by incorporating classification information"

This paper presents approaches for incorporating classification information into target tracking algorithms, specifically in a multistatic active sonar context. In addition, this paper describes the framework designed for simulation and classification of return time series from simulated targets and clutter in a realistic underwater environment. The simulated target and clutter returns are integrated into an existing contact-based tracking dataset (TNO Blind dataset) for which time series are unavailable. Simulations compare the integrating classification of contacts at different stages of tracking algorithms. Results show improvements in some tracking metrics with no degradation of the others. [C2701]

### "National Data Buoy Center (NDBC) support of the Integrated Ocean Observing System (IOOS)"

The National Data Buoy Center (NDBC) began implementing Integrated Ocean Observing System (IOOS) principles in 2001, when they partnered with the Gulf of Maine Ocean Observing System (GoMOOS). NDBC and GoMOOS collaborated on a project to transmit meteorological and oceanographic data from the GoMOOS buoys to NDBC in real-time. NDBC's data quality control, data format, and communications services were then used to transmit the data to the NWS Telecommunications Gateway (NWSTG), which disseminated the data to the Weather Forecast Offices (WFOs) in the region. As IOOS has matured and Regional Associations (RAs) have developed, NDBC has been a partner. NDBC shares ocean observation expertise, develops data management techniques and quality control algorithms, and keeps the RAs and IOOS informed by participating in Regional Association meetings and workshops. Using a scalable system that is able to receive increasing numbers of observations, while maintaining quality control, NDBC has increased the number of partner data providers to more than 40 and the number of partner platforms to more than 600. Many of the providers are members of RAs and Ocean Observing Systems (OOSs). The number of observations handled by NDBC will approach 10 million a year by the end of 2010. As NDBC and partner data are quality controlled at the gateway, any data that do not meet the stringent quality control algorithms are automatically assigned quality flags. The flagged data are transmitted to NDBC, where analysts reexamine the data. NDBC has also been involved in the IOOS effort to establish the technical infrastructure, standards, and protocols needed to improve delivery of ocean data through the Data Integration Format (DIF). NDBC, along with NOAA's Center for Operational Oceanographic Products and Services (CO-OPS) provide these services. Services include the NDBC Sensor Observation Service (SOS), which provides ocean temperatures, salinities, currents, waves, and winds from NDBC Coastal Buoys, IOOS Regional Coastal Ocean Observing Systems, and TAO moorings. In addition to these data, high Frequency Radar derived coastal surface currents are available through the NDBC THREDDS Data Server. A new partnership between NOAA's National Oceanographic Data Center (NODC) and NDBC will lead to the capability to preserve all of NDBC's marine datasets to meet the standards for climate observation requirements established by NOAA and the Global Climate Observation System (GCOS). Taking advantage of new techniques using Ocean Geospatial Consortium (OGC) Inc. standards and the SOS described above and funded by NOAA's IOOS Program, will enable a new degree of interoperability within and between NDBC and NODC and properly archive all NDBC Partner observations. [C2702]

### "Low resource demanding FOTA method for remote AtoN site equipment"

This paper presents a method for firmware update in memory constrained low-power controllers used in marine aids to navigation (AtoN) and telematics systems. The developed method allows carrying out firmware updates regardless of the communication channel used. This approach differs from other similar methods mainly by its low requirements to hardware and high flexibility; hence it is applicable to relatively small microcontrollers. The paper is concluded with experimental results performed on operational marine buoys. [C2703]

### "The NANOOS Visualization System (NVS): lessons learned in data aggregation, management and reuse, for a user application"

The mission of NANOOS is to coordinate and support the development, implementation, and operations of a regional coastal ocean observing system (RCOOS) for the Pacific Northwest region, as part of the U.S. IOOS. A key objective for NANOOS is to provide data and user-defined products to a diverse group of stakeholders in a timely fashion, and at spatial and temporal scales appropriate for their needs. To this end, NANOOS developed the NANOOS Visualization System (NVS), which aggregates, displays and serves meteorological and oceanographic data, derived from buoys, gliders, tide gauges, HF Radar, meteorological stations and satellites, as well as model forecast information in such a way that it presents end users with a rich, informative and user friendly experience. First released in November 2009, NVS has already undergone several significant updates. While its original focus and continued strength is on near-real-time (NRT) observations from stationary platforms (buoys, coastal stations, etc.), it has evolved to include other types of observations as well as forecast information. NVS integrates data from a wide diversity of providers across the region, ranging from county agencies, private industry and regional partnerships, to core IOOS federal programs, and state agencies and academic groups that are principal partners in NANOOS' Data Management and Communication (DMAC) efforts. Regional and national feedback confirms that NVS has been well received by ocean observing and stakeholder communities alike. This paper discusses, in detail, NVS 2.0, which was released in August 2010. In particular, we provide an in depth look at the database schema, metadata, data harvesting, and component communication. In addition, we discuss the NVS data management and communication approach in the context of the IOOS DMAC interoperability and standards-based efforts, highlighting the strengths and weaknesses of application-focused vs. strong-interoperability-focused approaches. Lessons learned both from technical and project management perspectives are also presented. Lastly, we discuss future plans for NVS. Anticipated improvements include automating asset metadata discovery and processing using IOOS standard protocols, and a NANOOS implementation of ERDDAP that will support NVS by replacing multiple, data-source-specific data harvesters with more generic and easier-to-maintain NERDDAP harvesters; and by enabling customized data subsetting and download capabilities that will be accessible through the NVS user interface. [C2704]

#### "Active position security through dynamically tunable radar"

Acquiring and securing position information is of fundamental importance in vehicular ad hoc networks and their applications. Recently, it has been shown that securing position information can be achieved by enlisting the help of on-board radar devices that have seen a phenomenal penetration of the vehicular market. However, most on-board radar devices have a static range and this can cause a number of insecurities and can add to communication delay. The main contribution of this work is a novel low-cost radar model which can dynamically tune its range by changing the signal sample size. As it turns out, the dynamically-tunable radar considerably enhances position security. [C2705]

#### "Miniature, low power, generic Doppler sonar"

The Oceanographic Systems Laboratory at Woods Hole Oceanographic Institution has developed a small, low power, single-axis, range-gated pulse-coherent Doppler sonar, that is primarily intended for boundary layer turbulence studies. This instrument is composed of a receiver-transmitter, a 24MHz analog-to-digital converter, a down converter, and a low power Digital Signal Processor (DSP). The system is capable of autonomous operation from a variety of stationary platforms, such as buoys, moorings, and bottom frames, and small mobile platforms, including gliders, profilers, towed bodies and autonomous underwater vehicles (AUVs). [C2706]

#### "Wavelet Transform and its Application to ICESat-GLAS Full Waveform Data"

Based on wavelet transform (WT), this paper proposed an approach to extract ICESat/GLAS full waveform characteristics. Through wavelet decomposition of the full waveform data, setting the threshold function and reconstructing signal, the filtered waveforms were achieved. All comparisons were performed on simulated LiDAR full waveform signals with typical back scattering noise. In the simulation and comparison, the root mean square error (RMSE) of the coefficients dropped by 0.7188 in this way, and the Signal-to-Noise Ratio (SNR) increased by 16.17 dB. The results showed that the wavelet transform method was better than the Gaussian method on de-noising and the signal by wavelet transform reserved useful information of the echo waveform. In the filtering process, the wavelet transform can effectively suppress the waveform "overlay" problem. [C2707]

#### "Research on the Optimal Disposition of Near Space Multi-sensor Platform"

In this paper, to solve the cooperative detection problem of ground observation for near space multi-sensor platform, put forward the index of multi-sensor platform optimal disposition, and the genetic algorithm is used to analyze the calculation process, finally, through an example shows the utility and value of the index and algorithms, implemented the optimal disposition of the multi-sensor platform. [C2708]

### "What can HF radar contribute to the salvage of a grounded ship?"

The area around the grounding site of the Shen Neng 1 in Great Barrier Reef waters On 3 April 2010 was monitored by an HF radar and several Acoustic Doppler Profilers. The HF radar is shown to compare well with the Profilers at the mooring sites. The radar data was used to produce a time series of surface currents at the site during the grounding and throughout the subsequent salvage and clean-up. The spatial and temporal surface current maps are ideally suited for Lagrangian tracking of notional zero buoyancy water parcels starting from the grounding site. Lagrangian 'parcels' were released at two-hour intervals after the grounding in order to identify locations of flotsam or spills. Releases at two-hour intervals through a tidal cycle followed similar tracks until, on the fifth day, a significant change in the meso-scale meteorology and oceanography occurred. It is shown that the meso-scale change had a stronger control on the destination of 'parcels' than tides. HF radar has much to offer in nudging real-time hydrodynamic models used for predictions of currents during a maritime incident like this. [C2709]

### "Comparisons of a fully coherent and coherent-on-receive marine radar for measurements of wave spectra and surface currents"

A new coherent solid state marine radar has been developed for short range coastal ocean remote sensing applications. It has been applied to the measurement of coastal ocean currents and ocean wave spectra, examples of which are reported here. The radar is based on a standard marine radar package, but using a solid state power amplifier incorporated as part of the transceiver subassembly. The solid state transceiver subassembly was developed based on a SMA-connector component prototype that was reported on at the Oceans 2019 Biloxi meeting. A series of parallel tests were run with a prototype coherent-on-receive radar, which is based on modifications to a standard Koden marine radar. For the latter, the leakage signal of the transmitted pulse is used as the reference for realigning the phase of the received echo. Due to the non-coherent nature of magnetron sources used for marine radars, the pulse-to-pulse stability of the transmitted frequency of such a system creates problems with pulse-pair phase-differencing estimates of Doppler shifts. This effect creates a rather noisy Doppler image, and mean Doppler estimates over many rotations can be in error. Data were collected with the pair of radars during the passage of 2-m waves up to 13-s period at the FRF pier in Duck NC. We report on differences in Doppler estimates for the fully coherent and coherent-on-receive marine radars for data collected during this storm, comparing with FRF measurements of wave spectra and surface currents. [C2710]

### "Frequency diversity for active sonar/radar application and optimal receiver design"

MIMO (Multiple Input Multiple Output) concept has been explored for radar/sonar application recently for improving target detection and estimation performance. The existing work in this direction mainly investigates the spatial diversity and waveform designs based on the assumption of the same carrier frequency for multiple transmitters. In this work, we investigate the frequency diversity by using multiple narrowband transmitters of different center frequencies. We prove that the ambiguity function for such signal is not an optimal receiver, and propose an optimal receiver for signals with different frequency components. [C2711]

### "On the use of time-frequency domains for the improvement of the Stochastic Matched Filter Pulse Compression scheme with a high speed computing architecture"

In several domains of engineering technologies, such as telecommunication, sonar imaging, positioning systems, radar, medical imaging ..., the main problem is to identify a transmitted useful pulse in a noise-corrupted received signal. A solution to this problem consists in using a modulated pulse for emission and a matched filter for reception. Such a concept is known as pulse-compression. Taking into account the main assumptions of the matched filter theory, the use of the bandpass transmitted pulse as matched filter's impulse response is only available if the useful signal is well known and if the noise is white, which is not the case in practice. For this reason, it has been recently proposed an alternative to the classical pulse-compression scheme taking into account the random nature of the useful signal and the coloration of the noise. This new principle is known as the SMF-PC. Although, this method allows a great improvement in terms of signal to noise ratio compared to the classical pulse-compression technique, the SMF-PC appears under optimal due to stationary assumptions. In this context, the purpose of this paper is to propose an improvement of the SMF-PC by coupling this technique with a time-frequency method. Results obtained on synthetic and real data are proposed and discussed. [C2712]

### "Microwave backscatter of ship signatures on SAR imagery"

Speckle characteristics was analyzed by computing the ENL (Equivalent Number of Looks) for sub images of 30 by 30 pixels from four RADARSAT-2 dual polarization products, two single look complex (SLC) products acquired

in wide swath single beam mode with dual polarization of HH+HV and two ScanSAR Wide (SCW) products acquired in ScanSAR Wide beam mode with dual polarization of HH+HV, which lie in the sea area around Iberian Peninsula. The speckle analysis indicates that ENL value combined with the intensity value of the SAR image should be a feasible short cut to find ship signatures out of SAR image. Based on the ENL analysis of speckle characteristics, a data set for ship signature has been derived, from which the ship signature was measured by polarimetric synthesis since the polarimetric SAR signature is an effective way of utilizing the amplitude and phase information to characterize the polarization properties of microwave backscatter. Driven by the need for a realistic microwave backscatter of ship signature model, the detailed behavior of a single ship in different polarizations and different incidence angles will be investigated by the Ray-Optical method which was developed by Burkholder et al. The purpose of this paper is to pave the way for a further improved scatter matrix model. [C2713]

### "Front matter"

The following topics are dealt with: deep ocean survey; oceanographic instruments; optical communication system; data visualization; autonomous underwater vehicles; sonar signal processing; acoustic systems; SAR imagery; water quality sensor; deepwater horizon oil spill; and marine renewable energy. [C2714]

### "Integrated Coastal Observation Network (ICON) for real-time monitoring of sea-level, sea-state, and surface-meteorological data"

National Institute of Oceanography (NIO) has established an Integrated Coastal Observation Network (ICON) of in-house designed and developed Internet-accessible real/near-real time reporting cellular based sea-level, sea-state, and surface meteorological (Met) stations at several locations on the Indian coasts & Islands (<http://inet.nio.org>). Subsurface pressure sensors and downward-looking microwave radars are incorporated in the sea-level station network. Sea-level, Met, and surface wave parameters are acquired using dedicated Linux based data loggers and uploaded to an Internet server at 5-, 10- and 30-min intervals, respectively with the use of GPRS cellular modems. The sensors and data loggers are powered from sealed lead acid batteries, which are charged through solar panels. The ICON provides graphical presentation of sea-level information (observed sea-level, predicted tide, residual sea-level); significant wave height and wave direction; and Met information (vector-averaged wind speed & direction, barometric pressure, atmospheric temperature, solar radiation, relative humidity, and rainfall). Installation of sea-level sensors free from the influence of stilling-wells and long narrow tubes renders the measurements ideal for tsunami and storm-surge studies by preventing waveform distortion and non-linearity of large-amplitude short-period signals. The network maintains accurate time-stamp of the dataset through Internet-time synchronization using network time protocol (NTP). Real-time reporting capability of ICON yields several benefits, such as (i) remote monitoring of proper working condition of individual stations; (ii) implementation of repair/maintenance in the shortest possible time, thereby minimizing break in the time-series data stream; (iii) periodic arrival of data stream from all stations at a single central server, thus yielding backup for the data from all the stations; (iv) access to the latest in-situ information; (v) allows possible-- use of data with automated real-time running numerical models for operational forecast. In contrast to the limited bandwidth provided by INSAT transmitters, coastal observations at high bandwidth at significantly low cost have become realizable using cellular GPRS network. The NIO-network allows, Internet based real/near-real time tracking and monitoring of sea-level, sea-state, and meteorological conditions along the Indian coasts and islands and from almost anywhere--an issue of considerable practical significance during natural disasters such as storm, storm-surge, and tsunami. [C2715]

### "Modeling and simulation of sea surface radar observations"

This paper describes a methodology to model and simulate the reflectivity measured by radar observing a maritime environment. The simulation principle consists of reproducing the acquisition of a Real Aperture Radar (RAR) moving along its axis. Pulse after pulse, high range resolution profiles are successively computed by summing the contribution of backscatters comprised in the radar footprint. The scatterer contributions are calculated from typical statistical distribution estimation. The simulation output, called raw data, is the concatenation of time profiles (short time) successively obtained for each radar pulse (long time). A SAR algorithm is then applied in order to form a high resolution image. The generation of the sea surface is achieved by a multi-scale model. This approach takes into account phenomena at different scales (from long wave to small objects), all in interaction in a hydrodynamic environment. It is thus possible to focus locally on contributions considered as more significant. To improve the processing time some contributions can also be retrieved from Look-Up Tables. Hence, our method performs a realistic simulation of electromagnetic interactions in a maritime environment. [C2716]

### "A network based attenuation correction system for networked dual polarization radar observations"

Electromagnetic waves backscattered from a common volume in networked radar systems are attenuated differently along the different paths. A network based attenuation correction system for a network of dual polarization radars can be developed by combining the conventional network approach and the conventional differential propagation phase based attenuation correction technique. The network based attenuation correction system proposed here has been evaluated by data from the Adaptive Sensing of the Atmosphere (CASA) Integrated Project 1 (IP1) radars, which is a radar network that can observe a weather event simultaneously by multiple radars in different locations. The preliminary results show that the network based attenuation correction algorithm retrieves reflectivity and differential reflectivity properly. [C2717]

#### "Real-time buried object detection using LMMSE estimation"

We present the application of linear minimum mean square error (LMMSE) estimation to GPR data for achieving buried object detection. Without employing any empirical assumptions, nonstationary form of Wiener-Hopf equations is applied to GPR signals to estimate the next sample in normal conditions. A large deviation from this estimation indicates the presence of a buried object. The technique is causal, which allows it to be used in real-time applications. Our approach is theoretically optimal in linear minimum mean square error sense, and it is also validated with the tests that are carried out on a comprehensive data set of GPR signals. [C2718]

#### "Sub-band phase calibration in stepped frequency GB noise SAR"

The paper describes a method of band synthesis in a stepped frequency ground-based (GB) noise synthetic aperture radar (SAR) in case the of phase offset between reference and surveillance channel changing along with the carrier frequency switching. The method is based on receive channel calibration using crosstalk signal between transmitting and receiving antenna, dominating over the scene echoes. The paper shows a method of phase offset estimation and correction and results of its application to SAR data obtained with a radar system constructed using universal commercial off-the-shelf (COTS) measurement instruments. [C2719]

#### "Performance of an ultra wideband radar for detection of water accumulation in the human bladder"

This paper presents an Impulse Radio Ultra Wideband (IR-UWB) radar for detecting water accumulation in the human bladder. The goal is to monitor the level of urine in patients who suffer from urinary incontinence. This is achieved by detecting the reflected UWB signals from the boundaries of human tissues such as muscle and urine. The reflection properties are investigated both in a simulator with a bladder model and through measurements with a phantom model. The performance of the vivaldi antenna is investigated with regards to the pulse distortion due to the near field effect and signal attenuation in the far field. The simulation and the measurement results show the potential of water detection of the human bladder by using UWB pulses. [C2720]

#### "Simulation study of relationships between Doppler-polarimetric parameters at microwave remote sensing of precipitation"

This paper studies the relationships between recently introduced differential Doppler velocity and other parameters of radar signal reflected from rain. Analytical calculation and simulation methods are used mostly. The results are checked by measurements in special cases. Some possibilities to derive information on distributed object structure are shown. [C2721]

#### "Illumination properties of multistatic planar arrays in near-field imaging applications"

The achievable illumination quality in microwave and millimeter-wave images using multistatic planar arrays is discussed. The geometrical relations between the array effective aperture and the illumination boundaries caused by the specular reflections are introduced. Afterwards, the variations in the processing gain due to diffuse and specular reflections are analyzed and verified experimentally. [C2722]

#### "Pseudo-noise waveform synthesis for SAR applications"

The paper presents the research carried out at Warsaw University of Technology on area of waveform design for Noise Synthetic Aperture Radar (SAR). The aim of the article is to present the method of creating complex pseudo-noise waveform with reduced side lobes of autocorrelation function in observation area. [C2723]

#### "Enhanced monopulse radar tracking using empirical mode decomposition"

Monopulse radar processors are used to track targets that appear in the look direction beamwidth. The target tracking information (range, azimuth angle, and elevation angle) are affected when manmade high power interference (jamming) is introduced to the radar processor through the radar antenna main lobe (main lobe

interference) or antenna side lobe (side lobe interference). This interference changes the values of the error voltage which is responsible for directing the radar antenna towards the target. A monopulse radar structure that uses filtering in the empirical mode decomposition (EMD) domain is presented in this paper. EMD is carried out for the complex radar chirp signal with subsequent denoising and thresholding processes used to decrease the noise level in the radar processed data. The performance enhancement of the monopulse radar tracking system with EMD based filtering is included using the standard deviation angle estimation error (STDAE) for different jamming scenarios and different target SNRs. [C2724]

#### "A Fit-to-Sine based processing chain to handle multiple-target scenarios"

The full coherent processing of non-equidistant sampled data has been the topic of many research activities. In this paper we propose a processing chain based on such an algorithm, the Fit-to-Sine function, which is able to handle multitarget and target/clutter radar signals. Starting from the computation of a least squares cost function in dependency of frequency, followed by a feature extraction method and the suppression of unwanted sidelobes, we conduct a simple noise/target distinction by utilizing basic fuzzy logic characteristics and operations. Finally we exemplify our processing chain and the achievable results on a real radar scenario with a target moving in strong clutter. [C2725]

#### "Submillimetric high resolution passive imaging system using synthesis aperture technique"

This paper presents a G-band [140-220 GHz] high resolution passive imaging system for personal security applications. The spatial resolution depends on the size of the antenna. Since a spatial resolution of 1 cm, at a distance of 5 m requires a very large aperture antenna equal to 1 m at 140 GHz, so it is difficult to achieve a compact system. The synthesis aperture technique allows to reduce the size of the system, while keeping a good spatial resolution. To apply this technique, the studied system is a Y-shaped radiometric interferometer. One of the advantages of such a system, is that there are no moving part, and the size of the synthesized aperture is easily expandable to meet more uses. The system design, simulated performances, and realized monolithic microwave integrated circuits results are presented. [C2726]

#### "Evaluation of a high accuracy range detection algorithm for FMCW/phase radar systems"

The FMCW radar is the most versatile radar principle used today. Depending on the system configuration, it is possible to use an FMCW radar to detect targets in the range from hundreds of kilometers down to a few centimeters. This paper describes an algorithm, which can be applied to improve the FMCW range accuracy down to a few mm. Numerical system simulations are used to evaluate the possibility of using a combination between an FMCW and a phase radar for a line based range detection at 24 GHz. [C2727]

#### "A 94-GHz receiver front end for passive millimeter-wave imaging"

We have designed and fabricated the passive millimetre-wave imaging system for receiving radiation energy from the an object and a human body. The lens and front-end of the receiver are important in the system to detect input thermal noise signal. Passive millimetre-wave imaging system required of high sensitivity and wide broadband to detect input thermal noise. The LNA module of the imaging system has gain of 65.8 dB in average linear gain and 11 GHz in bandwidth to enhance sensitivity for thermal noise and to receive it in wide-band width as well. The zero-bias Schottky diode has been used for the detector circuit to convert amplified millimeter-wave signals to DC output. [C2728]

#### "EM estimation of a generic 2D object model based on a sparse set of incomplete ISAR images"

This paper addresses the estimation of a two-dimensional model of an object, based on measurements with a network of High Range Resolution (HRR) scanning surveillance radars. While considering a dynamic radar scene, the data collected from the multiple radars at multiple scans of the antenna provide a wide, but highly sparse, coverage in 2D space. The multi-radar multi-scan data are treated as asynchronous. Inverse Synthetic Aperture Radar (ISAR) 2D imaging is independently performed within the narrow angular sector which is covered during each single radar scan. Each of the formed ISAR images is a rotated and incomplete version of the 2D profile of an extended object. The multi-look images are aligned and incoherently fused in a common 2D space. Their complementary information content is thus combined in a unique composite image. The Expectation-Maximization (EM) algorithm is further applied for parametric estimation of a low-dimensional 2D object model. This model constitutes a feature vector, useful for object classification. The local-only use of the phase in this overall sparse, but locally dense, sampling scheme accelerates significantly the de-ghosting of the formed 2D target images. Quicker convergence to an unambiguous estimate of the generic 2D object model is achieved, as compared to a purely incoherent processing of the sparse dataset. [C2729]

### "A Kalman smoothing approach for surface deformation monitoring in differential SAR interferometry"

This paper presents a Kalman smoothing approach for estimating the temporal evolution of terrain deformations, using a chronologically ordered sequence of differential synthetic aperture radar interferograms spanning a long time interval. The proposed method assumes that the interferograms are formed with respect to the same master image and that the data pairs used to generate the interferograms can have orbital separations (i.e. baselines) up to the decorrelation baseline or even larger. The algorithm presented next applies to every highly coherent pixel (known as permanent scatterers) in the image and it is independent of the interferometric processing of the SAR images; so it is essentially a post-processing step. Since it's supposed that all the SAR images are available for batch processing, the proposed algorithm is naturally a smoother. The Kalman smoother reported thereafter can be exploited successfully to estimate the line-of-sight surface deformation of a vast area. This technique has been tested on simulated deformation data and it has demonstrated an excellent capability to track the ground deformation dynamics with a high accuracy. [C2730]

### "Microwave ocean scattering at low-grazing angles with the GMoM"

The radar cross section from a rough surface becomes very small at grazing incidence, since most part of the energy travels in the forward direction. Therefore, building a model that can estimate it accurately is challenging. Here, a rigorous model is presented, based on a specific integral formalism, and tested on sea surfaces. We plan to apply this model to time-varying ocean surfaces at microwave frequencies, under a small slope assumption. The sea surfaces patches are to be tank measurements, or generated numerically. We aim at comparing the resulting Doppler spectra to first order approximate methods. [C2731]

### "HYCAM-a software-defined testbed for experimentations of new S band surface radar concepts"

In 2008, ONERA started developing a radar designed for experimental studies on new concepts for naval and surface applications. The project is called HYCAM. The aim is to be able to be representative of most of the categories of surface radars (multi-function radars, surveillance radars, target analysis systems, NCTR radars, tracking radars, weather radars,...). To achieve such a versatility, a modular and software defined architecture has been proposed thanks to modern and high performance digital technologies (FPGA, DAC, ADC). Moreover, micro-wave front-end/antennas are reconfigurable. The device is expected to be validated in 2011. In this paper, radar definition and specifications are detailed. [C2732]

### "Comparative analysis of two techniques for moving target velocity estimation"

In this paper two different algorithms for target velocity estimation are considered and compared. Traditional approaches for detecting and tracking moving targets typically rely on a multiphase strategy in which target detections are feed to a Kalman-filter-based tracker. In the present paper, two techniques for target velocity estimation in the framework of Hough Transform (HT) detection scheme are considered. The experimental results are obtained by means of numerical analysis. The quality parameter is estimated using the Monte Carlo simulation approach. A comparative analysis of the two velocity estimation techniques is done based on same parameters of the surveillance radar. The research work is performed in MATLAB computational environment. The obtained analytical results can be used in both, radar and communication receiver networks. [C2733]

### "Characterisation and cancellation of medium grazing angle sea clutter"

High grazing angle sea clutter data were collected and characterised using two different airborne radars with HH and VV polarisations. The ability to cancel sea clutter using single-channel and multi-channel coherent signal processing is investigated. [C2734]

### "Signal detection in multi-frequency Forward Scatter Radar"

The peculiarity of Forward Scatter Radar (FSR) is the absence of range resolution. As a consequence, possible low signal-to-clutter ratio is the most limiting factor in FSR detection. In this paper we will discuss non-coherent and coherent FSR Doppler signal processing and consider an alternative cross-correlation approach, which could be called 'quasi-coherent' processing. Multi-frequency radar enables correlation of Doppler output of one of the channels with another which can be considered as the matching waveform, or the reference signal, to the first signal. This leads to a compression of the FSR return by cross-correlation with enhanced processing gain, and, consequently, enhanced detection. [C2735]

### "Method of automatic target angle tracking by sum-and-difference monopulse radar invariant"

### against the polarization jamming"

Method of automatic target angle tracking by sum-and-difference monopulse radar covers radiolocation sphere and specifically monopulse direction finding systems. It can be used in order to increase guidance accuracy, for example, for anti-aircraft missiles and of unmanned aerial vehicles (UAV) to radar targets such as: radio beacons; aerial vehicles reflecting the radio signal that illuminates them; aerial vehicles and ground-based devices radiating radio signals and jamming signals. The aim of the method consists in the assurance of reliability and stability and in the enhancement of guidance accuracy of automatic target angle tracking due to elimination of automatic tracking losses and great errors arising during the influence of the signals of orthogonal polarization or polarization close to it. The proposed method provides full protection from polarization jamming for all types monopulse radars. [C2736]

### "Microwave gauging with improved angular resolution"

Angular resolution of a microwave level gauge may have positive impact on the robustness of the target detection. Therefore, an azimuthal scan can be performed with the aid of electronical or mechanical beam-steering methods. The present paper provides an overview and a comparison of signal-processing methods which improve the angular resolution of such measurements. For a given antenna, improvements can be achieved well beyond the limit of the half-power beam-width (HPBW) of that sensor. Among others, the performance of the Wiener filter and the Kalman filter for a motion-free channel is examined in greater detail since their application exhibits promising improvements on the angular resolution in both, simulations and measurements. In addition, the advantage of using a Kalman filter for a channel with statistical fluctuations is shown in simulations. [C2737]

### "Nonparametric signal detection algorithm using permutation statistics of signal partial likelihood ratios"

This paper presents a new approach to design radar signal detection algorithms that are applicable when a priori information is limited. The problem is formulated as testing the hypothesis of the kind of a density function. A new method that uses nonparametric statistics of partial likelihood ratios and allows adopting a permutation test in a practical algorithm is suggested and researched. The results can be used for signal detection and processing in different radar systems. [C2738]

### "A modular 24 GHz radar sensor for digital beamforming on transmit and receive"

A compact modular 24 GHz imaging radar sensor for digital beamforming is presented. Besides digital beamforming on receive, the advantage of multiple switched transmitters is used for increasing the angular resolution, which requires less hardware effort. The presented FMCW radar sensor provides up to eight switchable transmitters and eight receiver channels for parallel receiving, allowing digital beamforming on transmit and receive. A new switching technique via switchable amplifiers is proposed. Within the scope of this paper an overview of the whole radar sensor's architecture, design and realization is given. The performance of the sensor is successfully demonstrated and evaluated by measurements. [C2739]

### "Simulation of the PARSAX dual-channel FMCW polarimetric agile radar system"

Polarimetric agile radar can be used to estimate all elements of the polarization-dependent backscattering matrix (BSM) simultaneously. Stringent requirements, such as amplitude and phase matching between channels, cross-channel isolation and polarization isolation, for a dual-channel polarimetric agile radar system have to be investigated. The radar system simulation is a practical and effective approach to evaluate these requirements. This paper presents the modelling and simulation of the dual-channel FMCW polarimetric agile radar system by using Agilent Advanced Design System (ADS) simulation software. The paper focuses on investigating the limitations of cross-channel isolation and estimating the error of BSM components in polarimetric agile radar system simulations. [C2740]

### "2D image fuzzy deconvolution and scattering centre detection: Model and real-time FPGA implementation for automotive application"

A new non-conventional technique based on fuzzy deconvolution for scattering centre detection (F-SCD) is proposed together with its implementation in FPGA for real-time deployment in automotive collision avoidance application. F-SCD emulates the human being interpretation of radar images using fuzzy measurement of features of the radar Point Spread Function (PSF) differently from other classic detection techniques. The first stage of F-SCD detects signal from noise using image oversampling and binary integration technique. The second stage uses a fuzzy description of the radar PSF in order to discriminate among scatterers and side lobes

in the radar image. The method/IP have been implemented in FPGA and tested with a FMCW 77 GHz radar prototype in real automotive benchmarks showing high POD, low FAR and high rejection of ambiguities even with poor time-space variant PSF. [C2741]

### "Circular polarization selectivity of space-fed arrays using element rotation"

Microstrip array antennas with spatial feed can be designed to act as curved mirrors and lenses by applying appropriate phase shifts. If the array acts on circular polarization, the phase shifts can be obtained by element rotation. Arrays of this type are analyzed and it is shown that the mirror or lens effect is different for each hand of incident circular polarization. This effect is demonstrated by a prototype array lens. [C2742]

### "A wide field of view radar for Sense and Avoid on UAV using space coloring waveforms"

Up to now, UAV are employed in crisis or war times. For training purposes, some areas are especially attributed for UAV deployment in a limited space area and in a limited time slot. In the future, both for emerging civilian applications and for training purpose, these limitations will no longer be acceptable and UAV will have to be inserted in the general Air Traffic. Thus, "Sense and Avoid" systems will be mandatory. The radar is the most pertinent non-cooperative "all-weather" sensor because it provides, by essence, accurate ranging, direction and closing speed. In this paper, we propose a low cost radar solution based on space coloring waveforms. This design allows the implementation of the radar within the UAV airframe without any moving parts. [C2743]

### "2D image fuzzy deconvolution and scattering centre detection"

A new innovative technique based on fuzzy deconvolution for scattering centre detection (F-SCD) is proposed together with its implementation in FPGA for real-time deployment in UAV and automotive collision avoidance application. F-SCD emulates the human interpretation of radar images using fuzzy measurement of features of the radar Point Spread Function (PSF) differently from other classic detection techniques. The first stage of F-SCD detects signals from noise using an image oversampling and binary integration technique. The second stage uses a fuzzy description of the radar PSF in order to discriminate among scatterers and side lobes in the radar image. The method has been implemented showing high POD, low FAR and high rejection of ambiguities even with poor time-space variant PSF. [C2744]

### "New generation Doppler radar processing: Ultra-fast robust Doppler Spectrum Barycentre computation scheme in Poincaré's unit disk"

In case of short time series, we prove that we can replace classical Radar Doppler processing chain based on FFT by a new generation processing based on Lie Group Theory. We have defined a robust and ultra-fast computation of Doppler Spectrum Barycentre based on "Median Spectrum" estimation through an regularized autoregressive identification in lattice and ladder form like BURG algorithm. [C2745]

### "Passive detection and tracking of maneuvering targets with particle filter techniques using DVBT broadcasting"

We present a complete and practical particle filter-based scheme to detect, classify and track multiple maneuvering targets using DVBT-based passive radar. As in the conventional radar signal processing, the proposed technique first detects the target Doppler and bi-static range considering the outputs of long-term correlation matched filters whose level exceeds an adaptive threshold. The detections are then followed by a bank of particle based-filters. Each filter tracks a detected target and estimates its position and velocity from the analysis of short-term correlations. [C2746]

### "Antenna size versus sea clutter rejection: A new analysis of coastal radar performances and optimization"

In the field of coastal surveillance radar, and more generally in maritime environment, the overall radar performance for the detection and tracking of small target is primarily linked to the capability of the radar to reject the sea clutter. Sea clutter is the radar signal return of the sea surface illuminated by RF waves and can often be as strong as the target radar return. A conventional method to counter sea clutter is to use very large antennas providing high angular resolution trying to optimize the signal to clutter ratio in the radar processing by defining the smallest possible illuminated cell of sea surface. This paper provides an in depth analysis of the pro and cons of large slotted waveguides antennas and shows that bigger is not better: Parasitic effects, correlated to antenna dimensions, in the beam forming process of big antennas tends to degrade the antenna performance and leads to the conclusion that the optimal antenna size is often smaller than the one currently used on existing coastal surveillance radars. [C2747]

### "On wideband MIMO radar: Extended signal model and spectral beampattern design"

MIMO radar systems can increase the radar resolution, the number of targets that can be identified, and the flexibility in beampattern design in comparison with standard phased array radars. To date, most of the work on MIMO radar has been performed assuming the signals are narrowband. However, wideband signals can improve radar resolution, among other benefits, and are sometimes unavoidable when stringent range resolution specifications must be met. In this paper, we present a method for extending the MIMO narrowband model to a wideband model. Next, from the exact expression of the spatial power distribution involving the CSDM (Cross-Spectral power Density Matrix), we propose a suboptimal transmit beampattern synthesis technique, which can be used in the context of wideband signals. [C2748]

### "Multiposition bistatic radar system using radio signals of geostationary satellites for hydrometeors parameters determination"

The method using geostationary satellites to determine hydrometeors parameters and to diagnose hazardous occurrences, such as: showers, hail formations, lightnings, turbulences, etc are presented. The advantage of the multiposition bistatic radar system is a capability of detecting small objects (turbulences) owing to a sharp increase in the value of Radar cross-section of objects close to base line and its environmental safety. [C2749]

### "Strategies for sub-optimal air to air STAP in forward looking configuration"

This paper deals with the selection of adequate sub-optimal strategies for air to air STAP in a forward looking configuration. The particular scenario is characterized by: (i) need of real-time operability; (ii) strong range dependency of the clutter statistics. To overcome these two aspects, a reduction of the overall number of degrees of freedom (DOFs) has to be performed, thus sub-optimal STAP approaches must be used. In addition, the range dependency of the clutter limits the overall number of available secondary data for clutter covariance matrix estimation. Three strategies for secondary data collection are presented and the corresponding performances are compared for a sample scenario. [C2750]

### "Automatic target recognition in SAR images using multilinear analysis"

In this paper, we investigate an approach based on multilinear analysis for synthetic aperture radar automatic target recognition (SAR/ATR). High resolution SAR images are the composite consequences of multiple factors: bearing angle, grazing angle, number of views and polarisation. Linear methods like principal component analysis (PCA) require to reshape images into a high dimensional vector. This vectorisation processing breaks natural structure and correlation in the original data set. Moreover the PCA, based on a matrix singular value decomposition (SVD), allows only one factor to vary in the image database. Multilinear analysis provides a powerful mathematical framework to analyse ensembles of images resulting from the interaction of underlying factors and preserves their original shapes. In this paper, we propose a method based on multilinear principal component analysis (MPCA) to classify unlabeled targets. We form a tensor with the images of the training set and use the higher order singular value decomposition (HOSVD) to reveal interesting patterns and dependencies between images. HOSVD is also used to compress the data and remove all information belonging to the background. A multilinear projection algorithm projects the unknown target into multiple basis which characterize learned classes. Tests using real SAR images database show that the multilinear approach provides very good recognition performance with a very high compression rate. [C2751]

### "Effects of the SNR of the signal replica in LMMSE-based filtering"

A general issue in radar processing is amongst other ones to separate targets. Several advanced techniques have been developed to fulfill this objective, such as linear minimum mean square error based processing (LMMSE). Nevertheless they depend heavily on the signal replica known at the receiver, and exhibit degraded performance when this reference is not noise-free. And this is also true for the classic matched filter (MF). As such the replica used for correlation receiver can be described with a signal to noise ratio (SNR). The analysis of the effects is done for a multi-target scenario where targets are close enough for the sidelobes of a target to interfere with the main lobe of another target, and close-by weaker echos are also present. This paper shows some experimental and simulation results illustrating the effects when there is such a discrepancy between the echoing signal and the signal reference used in the processing. Also shown is the improvement when countermeasures to this problem are taken. [C2752]

### "Backscattering of wide-band HF signals from evolving ocean-like surface: 2-D direct numerical simulations and analysis"

Direct numerical simulations are used to calculate wide-band HF radar backscatter from evolving ocean-like surfaces in 2-D space. With the attainable spatial resolution of about 15 m, the large-scale wave pattern is visible in range-time plots of backscatter magnitude. The double Fourier transform of the signal magnitude or power in range and time reveals strong harmonics located along the dispersion curve of the propagating long waves. The signature is not predicted by the 1st-order Small Perturbation Method, and considering the next, 2nd order is required. It is shown that the spectral components along the expected dispersion curves in the  $\omega$ - $k$  domain can be used to retrieve the deterministic wave height of the surface. [C2753]

#### **"DC-offset compensation in a bistatic 77GHz-FMCW-radar"**

In this paper the necessity for a DC-offset compensation in a bistatic 77GHz-FMCW-radar is discussed. Measurements of DC-offset voltages of a pseudo monostatic system, with two receiver and two transceiver channels, are presented and conclusions for a bistatic application are drawn. Two reasons for DC-offset are differentiated. First, DC-offset due to the characteristics of the radar circuit itself. Second, DC-offset caused by reflections of the near environment of the radar, such as bumpers. [C2754]

#### **"Angular measurements in azimuth and elevation using 77 GHz radar sensors"**

The availability of highly integrated cost-effective 77 GHz SiGe-MMICs creates new possibilities for different applications of radar sensors in the automotive area. The ability to measure angles in azimuth and elevation will be a relevant feature for the upcoming radar generations. We present a beamforming solution for angular measurements in both directions with one single sensor, using a combination of series fed arrays and a cylindrical dielectric lens. With this solution amplitude and phase information are split up and independently used to get the azimuth respectively the elevation angle. [C2755]

#### **"W-band antenna-reflector combined in a lens"**

Automotive radars are becoming widespread for safety reasons. However their effectiveness remains doubtful since even a metal car does not have strong RCS over all angles of its body. For reduction of traffic accidents, the solution is not only surveying around car-body but also making vehicles easily visible to drivers by means of radar and other luminous sources. This paper introduces a lens antenna double as a reflector for radio and light waves as vehicle equipment. [C2756]

#### **"Through the wall detection and localization of a moving target with a bistatic UWB radar system"**

This paper presents a method for detecting and locating a moving target behind a wall with a bistatic UWB radar system. This method not only can locate a moving target, but can also be used to estimate certain parameters of a wall (dielectric constant and thickness). [C2757]

#### **"Sentinel-1 C-SAR calibration"**

The ESA Sentinels constitute the first series of operational satellites responding to the Earth Observation needs of the EU-ESA Global Monitoring for Environment and Security (GMES) programme. The GMES space component relies on existing and planned space assets as well as on new complementary developments by ESA. This paper describes the in-orbit calibration aspects for the Sentinel-1 mission. It provides an overview of the calibration requirements, and a potential technical concept for the implementation. [C2758]

#### **"Solid state pulse Doppler radars for maritime traffic surveillance-Review of architecture and trade-off analysis"**

Maritime traffic surveillance radars are in use for several decades, they are mostly based upon magnetron pulse emitters and simple non coherent signal processing. While the lack of coherent signal processing capabilities is compensated by strong pulse power, there is still a demand for improving detection and tracking performances especially in front of heavy sea clutter for detecting small and evasive targets. The solutions that address such demands are based upon the use of solid state transceivers which allow to generate and to process specifically designed waveforms incorporating for example frequency or phase codes. [C2759]

#### **"Medium-PRF detection by non-coherent integration"**

The document describes a detection and inherent ambiguity resolution scheme for Medium-PRF waveforms. Medium-PRF waveforms are characterized by ambiguous measurements of both range and doppler. Ambiguities are resolved by changing the pulse repetition frequency (PRF) from burst to burst and by combining the ambiguous results of adjacent bursts. The classical binary integration procedure applies a detection threshold on

burst level and combines detections from burst to burst including unfolding of the ambiguities. In this paper the more optimum method of non-coherent integration from burst to burst with inherent ambiguity resolution is discussed. The method provides a significantly improved detection performance. Of particular interest for non-coherent integration is the appearance of ghost targets. The paper proposes a method for deghosting. [C2760]

#### "Bio-radiolocation method at chest wall motion analysis during tidal breathing"

Influence of chest wall surface motion in bio-radar signal during tidal breathing was researched. A high-speed camera and multi-frequency radar with signal step modulation were simultaneously applied. The model of chest motion during quite breathing was used. Pairwise correlation coefficients for all the markers on the chest wall given in the model were calculated. The correlation of data from high-speed camera and bio-radar was found. Two methods were compared. [C2761]

#### "Radar polarimetry using sounding signals with dual orthogonality-PARSAX approach"

The article describes specific aspects of the radar polarimetry using sounding signals with dual-orthogonality. Such signals provide the unique opportunity to measure all elements of the polarization back-scattering matrix simultaneously, during one sweep/pulse period of radar signal. This approach has been implemented in the IRCTR PARSAX radar system, the fully polarimetric high-resolution Doppler FMCW radar. The digital architecture of the radar starts from intermediate frequency and makes the radar fully reconfigurable in terms of sounding waveforms and processing algorithms. [C2762]

#### "A radar oriented ionospheric channel model based on ray-tracing theory"

A ionospheric channel model based on raytracing theory is here proposed. Several HF ionospheric channel models based on statistical approach have been presented. The here proposed model combines the statistical method with the deterministic method, using a raytracing approach. By means of raytracing we are able to simulate any ionospheric channel condition by varying the transmission frequency in the HF band, the elevation angle, the transmitter geographical coordinates, the season, the time of day and the solar activity. The here proposed model is a useful tool to simulate a signal received by an OTH (Over-The-Horizon) radar, that uses the ionosphere as transmission channel. [C2763]

#### "Submillimeter-wave power measurements with commercial infra-red detectors"

In this paper, we present studies of the capability of commercially available infra-red detectors at submillimeter-wavelengths. The detection is based on pyro- and thermoelectric effects. These technologies have been developed to a mature level for applications in infra-red regime. The detectors are low-cost, compact, and robust-qualities that a typical submm-wave power detector does not possess. The IR detectors are not confined to be operated only in infra-red regime. The principle of power detection remains the same also at submm-wavelengths. Results of measurements at 625-814 GHz with commercial IR detectors compared to dedicated submm-wave power detectors are presented. Sensitivity and noise-equivalent power of the pyroelectric detector is estimated to be 600 V/W and 0.6  $\mu\text{W/Hz}^{1/2}$  at 784 GHz at 20-Hz chopper frequency. [C2764]

#### "A complete indoor positioning system implementing six-port interferometers"

This work presents a complete in-door microwave localization system based on six-port interferometry. Using two planar fan beam antennas and an interferometer with power detectors, the angle of arrival (AOA) from a 2.4 GHz ISM-Band transmitter is determined. With two receivers the position of the transmitter is computed from the direction angles and displayed on a PC. The manufactured prototype detects and localizes a transmitter inside a room with an accuracy of about 10 to 20 cm. It is proposed to use the system for the telemetry control of small unmanned aerial vehicles inside closed buildings where GPS systems are not available. [C2765]

#### "Radar and radio data fusion platform for future intelligent transportation system"

We present a software-defined data fusion system which integrates both radar (sensing) function and radio (communication) function within a single transceiver platform. In the proposed architecture, the radar mode and the radio mode operate in different time slots. The required modulated waveform is generated with the help of a direct digital synthesizer (DDS) that is able to control signal parameters such as amplitude, frequency and phase with very high resolution. For the radar mode, a specially arranged trapezoidal frequency modulation continuous-wave (TFMCW) modulation scheme is adopted, which combines three time intervals, namely an up-chirp, a constant-frequency period and a down-chirp. As such, range-velocity ambiguity can be resolved. Moreover, a constant-frequency period follows the radar cycle in the transmitted signal, which can be encoded with information data using different modulation schemes such as ASK, FSK, PSK, and some combinations among

them. A low-frequency prototype for the 5.9-GHz dedicated short range communication (DSRC) system was designed and prototyped. Both system simulation results and preliminary measurement results have proved the proposed concept. The presented system has demonstrated such advantages as low cost, low complexity, and versatile functionality, which promises to play an important role in the design of future intelligent transportation system. [C2766]

#### **"Monostatic scattering from an object near an ocean-like surface from an efficient fast numerical method"**

The rigorous computation of the monostatic scattering from an object near a one-dimensional sea surface (2D case) needs to solve a problem involving a high number of unknowns. By using a recently developed fast numerical method, called E-PILE+FBFA (Extended Propagation-Inside-Layer Expansion combined with Forward-Backward Spectral Acceleration), the monostatic scattering of such a complex scene can be investigated. Two canonical objects are considered in this paper: the cross and the cylinder. Results allow us to understand the physical mechanisms involved in the coupling between the object and the sea surface. [C2767]

#### **"Side-lobe suppression techniques for a uniform circular array"**

This paper provides a comparison between two different techniques for the array pattern side-lobe reduction in a passive radar system based on a circular array. The first method retrieves the phase modes pattern for the reference array and then applies a conventional tapering for the side lobe suppression of the obtained virtual uniform linear array. The second approach foresees instead an optimization algorithm in order to obtain the desired level of the side lobes. Both techniques have been adapted for being used with an 8 elements FM-based circular array for passive radar applications developed at TNO-Defence, Security and Safety in The Hague. The effect of the directional elements has been also considered for the array pattern synthesis. The different advantages of the algorithms are described and a distinction about the possible fields of application is retrieved. [C2768]

#### **"Modular RF design for QUASAR Ku-band polarimetric SAR system"**

A new compact fully polarimetric Ku band SAR system (SBK) is being developed by INTA radar Laboratory as an advanced payload for QUASAR project, which involves INTA new SAR developments for small platforms and UAV's. SBK design is based on previous developments of INTASAR program for his X-band SAR prototypes, RIX and RBX, focusing work on units miniaturization and new RF payload development. SBK RF development comprises the design of a modular KU-band RF payload mostly consisting on a highly stable Tx/Rx module, a Ku-band front-end and a planar antenna. RF design for the whole system and each of the RF related modules is shown including RF internal calibration capabilities of SBK. [C2769]

#### **"Microwave-range imagery with an ultrawideband time reversal-based RADAR"**

This work presents a new RADAR prototype built for the purpose of imaging targets located in a cluttered environment. The system is capable of performing Phase Conjugation experiments in the ultrawideband [2-4] GHz. In addition, applying the D.O.R.T. method to the inter-element matrix allows us to selectively focus onto targets, hence reducing the clutter contribution. The system has been validated by physically backpropagating the focusing wave into the medium all over the frequency band and observing the expected focusing properties. [C2770]

#### **"Calibration and characterization of a CW radar for blade tip clearance measurement"**

The calibration and characterization of a blade tip clearance sensor is proposed for gas turbine applications. This sensor is based on continuous-wave microwaves that operates at 6GHz in the version for large frame turbines. The calibration of such a sensor is a difficult problem because of the complex interaction between the microwaves and the blade tip geometry. Different geometrical parameters can influence the calibration results, which drives us towards using both the actual blade geometry and probe positioning. This study presents the calibration process of this sensor using a precision test setup. Moreover, the optimization of probe positioning is discussed in order to limit the measurement errors due to axial shift of the rotor during engine operation, which is the major source of errors for tip clearance measurement. Finally, the measurement error corresponding to an optimal probe positioning is characterized. [C2771]

#### **"MPAR: Waveform design for the weather function"**

An integrated target/weather surveillance at medium range, i.e. for the Terminal Manoeuvre Area (TMA) in the frame of Air Traffic Control (ATC) and regional weather monitoring, is made possible by MPAR (Multifunction

Phased Array Radar) techniques, allowing a single technology to satisfy different requirements. The guidelines for system design, needed for cost/benefit analysis, were described in a previous EuRAD paper. As in many other radar applications, pulse compression is a key element to achieve the required MPAR performances with low-cost solutions using relatively low-peak-power Transmit/Receive modules. This paper describes a preferred novel solution for the waveforms to be used in the weather function of the MPAR. Performance comparison with more traditional codes is also presented. [C2772]

#### "Monitoring open-pit quarries by interferometric radar for safety purposes"

A novel Ground Based Synthetic Aperture Interferometric radar was set up for slope stability monitoring in open pit quarries. It is a wide view angle system which is easily adapted to the typical geometry of a quarry, and it automatically generates interferometric DEMs of the area under investigation. The system was tested during a 40 days field survey in a stone quarry in Tuscany, Italy. [C2773]

#### "Million element ISIS array"

The DARPA ISIS Program is developing and demonstrating technologies to enable a stratospheric airship-based dual-band active-array radar system. The antenna is a UHF and X-band shared aperture with backend digital beamforming. ISIS achieves unprecedented airborne radar performance through use of a large antenna aperture instead of high transmit power. The low-power-density aperture has an areal mass density of only 2 kg/m<sup>2</sup>. A conceptual future system achieves 360° azimuth coverage using a cylindrical antenna of 36m height and 50.5m diameter. A small demonstration system scheduled for launch in 2013 has a UHF antenna cylinder 8m high and 22m in diameter. A 98m<sup>2</sup> rectangular section of this cylinder is populated with active X-band elements. The dual-band array has total receive and overhead power consumption, including off-array components, of only 5W/m<sup>2</sup>. [C2774]

#### "AMSAR-A France-UK-Germany success story in active-array radar"

DGA, BWB and D&ES initiated a radar project, called AMSAR (Airborne Multi-role Solid-state Active-array Radar) to demonstrate the enormous potential of Active Electronically Scanned Array (AESA) radar. This paper describes all the stages of the AMSAR project and the results obtained. The AMSAR demonstrator is still the only European, forward-looking multichannel active array radar with the capability of recording the outputs of more than 4 quadrants. [C2775]

#### "Copyright page"

The following topics are dealt with: phased array systems and technology; array design; radar; beamforming; calibration; measurement; testing; wideband and multifunction; communication system; MIMO array system; widefield radio astronomy arrays; overlapped subarrays and nonregular arrays; adaptive arrays; and direction finding arrays. [C2776]

#### "Gap free CONUS surveillance using dense networks of short range radars"

Dense networks of short-range radars having the potential for improved surveillance of weather and airborne targets are described. Such networks overcome the earth-curvature blockage suffered by long-range radars. This enables surveillance from the region beneath the radar coverage of today's national radar infrastructure, up through the tops of storms and flight levels. Such networks have the potential to supplement-or replace-the long range radar networks in use today. [C2777]

#### "Phased array systems and technologies in SELEX-Sistemi Integrati: State of art and new challenges"

This paper is a follow-on of [1] and [2], presented at 1996 and 2003 IEEE Intl. Symposium on Phased Array Systems and Technology, respectively. After a brief recall of 3D Long Range phased array concepts, already presented in [2], the focus is on the G-band multifunction radar systems and on the technological capabilities that SELEX-Sistemi Integrati is developing by taking advantage of its Research and Development facilities. At the end, future trends about new challenging applications and technological issues are presented and discussed. [C2778]

#### "Progress of phased array systems in Japan"

This paper reviews the research and development on the phased array antennas (PAAs) for several applications in Japan. First, the author shows the historical overview of the PAA for radar, satellite and mobile

communication uses. Then, the author introduces a millimeter-wave PAA, an optical beam forming, and an ultra wideband antenna element as modern applications of PAA systems. [C2779]

#### "Phase continuous radar test set"

A method of generating phase-continuous, coherent radar target returns is described which leverages existing Commercial Off-The-Shelf (COTS) Radio Frequency (RF) channel simulator technology. This hardware-in-the-loop system avoids the generation of unintentional spurious signals due to the discrete range steps typically utilized in traditional radar test sets. The time delay, Doppler, and amplitude variations are entirely phase continuous, replicating the true analog behavior of a real target return. Digital signal processing techniques are employed to interpolate the RF propagation and scattering effects. The interpolation smoothes the motion dynamics to ensure a pure analog signal return to the radar. The radar test set also provides physics-compliant Doppler characteristics by time domain expansion/compression of the modulation as well as the RF carrier. Often, Doppler is simply emulated with a shift in the carrier frequency only. Doppler shifts on the modulation result in degradations in radar signal processing such as pulse compression fidelity. Without properly imparting time domain expansion/compression, these degrading effects are not tested. Further, the radar test set provides correlated range/Doppler dynamic motion without discrete phase discontinuity artifacts enabling superior test performance. [C2780]

#### "Synthetic ultra-wideband radar range profile based on stepped frequency pulse trains"

In this paper, stepped frequency pulse trains are utilized to synthesize ultra-wideband radar range profile. Because of the errors of measured target velocity, the synthesized range profile still has range migration and power divergence. Therefore, a new method, called iterative dimidiating approach, is proposed. By exploiting this new technique, the range migration and range spread along range dimension can be neglected. The simulation results prove the validity of the method. [C2781]

#### "Tunable low-pass filter using fractal shaped complementary split ring resonator with ultra-wide stop-band and excellent selectivity"

This paper presents novel Hilbert fractal shaped complementary single split ring resonator (CSSRR) with a tunable transmission zero realized by negative effective permittivity of it and multi-band property attributes to Hilbert fractal geometry. Transmission characteristics of several CSSRR cells have been assessed by using full-wave electromagnetic simulation. Also miniaturization performance as well as its equivalent circuit model has been deeply investigated. Then a tunable assembled low-pass filter by periodically loading the Hilbert shaped CSSRR has been designed and simulated. Simulated results show that the designed filter has good performances such as low insertion loss (maximum 0.5dB) in passband, ultra-wide stop-band (from 2.47 up to 25GHz) as well as steep rejection with sharp transition band (2.2 to 2.47GHz) out of band. Excellent property of it has demonstrated the correctness and effectiveness of the designed concept. [C2782]

#### "Compact bandpass filter based on fractal shaped composite right/left handed transmission line with ultra-wide band, deep out-of-band suppression and enhanced passband performance"

In this paper, a novel ultra-wide band (UWB) bandpass filter (BPF) based on combined technology has been detailed researched. The proposed filter is constructed by composite right/left handed transmission line (CRLH TL) and Sierpinski carpet shaped six-staged stepped impedance lines for the first time. CRLH TL mainly consists of Koch loop shaped defected ground structure (KDGS) etched in the ground plane and series capacitive gap in the conductor strip. Equivalent circuit model is put forward and lumped parameters are also extracted for deep insight into the operation mechanism. Consistent results between electrical and EM simulation have confirmed the accuracy of the proposed equivalent circuit model. Simulated results show that the designed BPF with relatively bandwidth 129.4% owns many good performances, i.e., compact in size, relatively low insertion loss (less than 1.5dB) and comparable low return loss (better than 17.2dB) in pass band, deep suppression (better than 60dB) out of band. Thus indicate a giant application in future small size wireless communication system. [C2783]

#### "Time of arrival estimation for range-based localization in UWB sensor networks"

Accurate Localization has gained significant interest within sensor networks recently and positioning systems based on Ultra-Wideband (UWB) technology have been considered, because the UWB signals have a very good accuracy due to the high time resolution (large bandwidth). Time of Arrival (TOA) estimation of the first path is usually used for range-based localization in realistic environments within UWB sensor networks, which can be challenging in dense multipath environments. In this paper, TOA algorithms for range-based localization in UWB

sensor networks are analyzed and two new TOA estimation methods are proposed. One is the constant false alarm rate (CFAR) method, which is based on the CFAR detection theory in Radar systems. The other one is the maximum probability of detection (MPD) method, which determines the TOA estimation according to a comparison of the detection probabilities of a number of different possible TOA estimations. The performance of the proposed methods is evaluated and compared with several existing methods by computer simulation using realizations of IEEE802.15.4a channel models. [C2784]

### "Design and mutual coupling analysis on wideband wide-angle scan step-constant tapered slot antenna array"

Active reflective coefficient is a kernel design parameter in the process of ultra wideband antenna research and optimization. Mutual coupling effect, wideband and wide angle scan characters according to active reflective coefficient are analyzed in the step-constant tapered slot antenna design and fabrication for RF integrated. Measured results demonstrate that proposed antenna can achieve a bandwidth of 6-18GHz with VSWR < 2 and possesses 120° half-power beam width. [C2785]

### "Latest update of UWB regulation and standardization for medical healthcare and ITS"

A body area network (BAN) and a vehicle radar are latest applications of UWB wireless technology in microwave and millimeter wave bands, respectively. The speaker has been heavily involved in a regulatory committee on UWB and in international standardization on wireless PAN IEEE802.15.3a, 4a and BAN 802.15.6. In this keynote, background and essence of UWB regulation and standard will be introduced as well as remained problems for research, development and business. [C2786]

### "Never ending saga of phased array breakthroughs"

3, 4, 6 face "Aegis" systems developed by China, Japan, Australia, Netherlands, USA. Israel and Australia "Aegis" AESAs have an A/D at every element, a major breakthrough. GaN advancing rapidly. Will be helped by use for PCs, notebooks, cell phones, servers. Extreme MMIC: 4 X-band T/Rs on 1 SiGe chip for DARPA ISIS program; goal < \$10/TR. Raytheon funding development of low cost flat panel Xband array using COTS type PCB. MA-COM/Lincoln-Lab. development of low cost Sband flat panel array using PCB, overlapped subarrays and a T/R switch instead of a circulator. Purdue Un. developing S-band low cost Digital Array Radar; GaN PA and A/D at every element. Revolutionary 3-D Micromachining: integrated circuitry for microwave components, like 16 element Ka-band array with Butler beamformer on 13 x 2 cm<sup>2</sup> chip. Ultra low cost 77 GHz radar on 72 mm<sup>2</sup> chip together with >8 bits 1 GS/s A/D and 16 element array. Valeo-Raytheon 24 GHz phased array now available for blind spot detection in cars for just \$100's. Lincoln Lab using 2 W chip increases spurious free dynamic range of receiver plus A/D by 20 dB JPL's SweepSAR provides wide swath SAR from space with 1/6 th power required by ScanSAR. Metamaterials: 1. Can now focus 6X beyond diffraction limit at 0.38  $\mu$ m Moore's Law marches on. 2. Used in cell phones to obtain antennas 5X smaller and have 700 MHz-2.7 GHz bandwidth. 3. Provide isolation between closely spaced antennas and antenna elements. [C2787]

### "Low-profile ultra-wide band antenna array element suitable for wide scan angle and modular subarray architecture"

A planar topology of UWB wide-scan array is presented, based on the class of the aperture coupled stacked patches. Performance is aimed at achieving both wide-band and wide-scan capabilities for multifunction C-X band radar applications that require modular subarray antenna architecture. The theoretical and technological aspects that affect correct design and effective realization of the array structure are addressed. An 8x8 tile has been manufactured and a multi-element waveguide simulator has been built to validate the experimental results. The relevant results show very interesting features as concerns band and scanning characteristics. [C2788]

### "RF on Flex tile for L Band phased arrays"

Passive and active L Band phased array tiles based on RF on Flex interconnect have been successfully demonstrated. The tile is a modular building block for light weight, high performance phased arrays to be used in space based radar applications. Each tile contains 6 radiating elements with a maximum radiated power per element of ~2 W. Each tile includes two beamformers and two T/R modules per radiating element so that any transmit polarization may be formed and both V and H polarizations may be received. Each tile weighs 0.41 kg (3.9 kg/m<sup>2</sup>). In order to minimize production cost the tile is designed to be fabricated on an industry standard Printed Circuit Board assembly line and the T/R modules are packaged as Plastic Encapsulated Modules (PEMs). A thirty tile build has demonstrated high yield and a path to meeting the tile high volume production cost goal of \$50K/m<sup>2</sup>. [C2789]

### "Phase-only tapers for regular planar arrays, a heuristic nonlinear-FM approach"

We present a simple approach to constructing phase-only tapers for regular planar arrays that is analogous to the instantaneous-frequency approach classically used to construct FM-chirp waveforms with high time-bandwidth products. Design experiments for a large triangular-grid array show that the crude results yielded by this method when aperture-beamwidth products are modest can sometimes be "tweaked" into reasonableness. We conjecture that such a taper would improve upon the usual uniform-weight starting point for a nonlinear-optimization approach that seeks out a local optimum. Specific design examples presented here nominally aim to approximate a brick-wall beam and a variant of a Gaussian beam. [C2790]

### "System considerations for passive radar with GSM illuminators"

The increasing number of communication transmitters makes passive radar an attractive and simple alternative to active radar systems. GSM base stations as illuminators for passive radar enjoy the advantage of digital waveform, frequency diversity and global availability. The problems with these transmitters are the low transmit power and the more or less directive transmit patterns. These limit the achievable range. This paper studies how a useful system can be designed by fusion of bistatic systems using multiple transmitters. [C2791]

### "Electronic protection for digital shared aperture array radar"

We have developed a digital shared aperture array radar architecture which supports sub-aperture partitioning of a conformal array to improve time energy management for achieving radar search and track functions over 360 degree azimuth coverage. The digital array system consists of a plurality of digital transmit sub-arrays and digital received sub-arrays. For transmit operation, different frequencies or orthogonal waveforms can be employed for different apertures using the array control commutator. For receive operation, the sub-arrays are selected for different apertures using the receive data commutator. Essentially, the digital shared aperture supports dynamic partitioning of the aperture for multifunction applications. In this paper, we address these capabilities in the electronic protection (EP) against electronic threats, i.e. jamming and deception. Digital array radar provides digital degrees-of-freedom (DOFs) for transmit as well as for receive. These DOFs are selected by the commutators to support transmit and receive electronic protection. The receive DOFs are used for adaptive processing in jammer cancellation. These DOFs can be exploited in a number of ways through sector selection and digital beamforming to support several advanced processing architectures and algorithms. The digital array capabilities can also be exploited in monitoring jamming spectrum and estimation of the corresponding directions-of-arrival (DOAs). Digital array radar has transmit DOFs which can be used to form a transmit beam with nulls towards the deceptive jammers and separate decoy beams formed towards the deceptive jammers. [C2792]

### "Light weight digital array SAR"

A light weight SAR has been designed, suitable for short range tactical UAVs, consisting of a fully digital receive array, and a very compact active transmit antenna. The weight of the complete RF front is expected to be below 3 kg, with a power consumption below 30 W. This X-band system can provide image resolution down to 10 cm at up to 5 km range. The system makes use of FMCW technology and digital beam forming in the horizontal direction, with 24 receive channels. A switchable transmit antenna is designed, to allow wide coverage with sufficient antenna gain. RF electronics for the receive panels have been realized and tested, as well as a low phase noise transmitter. Detailed antenna design has been performed, and critical issues such as bandwidth and transmit-receive isolation have been assessed by simulation. [C2793]

### "Analog beamspace super-resolution radar processing"

Current monopulse radar does not resolve multiple sources within the main beam, a scenario that arises in a number of radar applications such as ballistic missile defense, where the incoming missile complex consists of a large number of objects; air defense, where a detection may correspond to a single plane or multiple planes; cruise missile defense for low angle target tracking in multipath; etc. This paper describes a superresolution technique designed for radar applications requiring resolving multiple targets within the main beam given a single snapshot of multiple beam data. The technique enables the practical implementation of such super-resolution algorithm by first forming multiple beams in the analog domain to provide data and degree-of-freedom (DOF) reductions without significant loss of information. Super-resolution is then achieved through the use of matrix processing techniques operating on the digitized beamspace data. The overall procedure can be considered a generalization of the monopulse processing scheme to the multi-target case. [C2794]

### "The fundamental input/output structure of a linear, time-varying array receiver"

A single-output array receiver based on static antenna elements of arbitrary geometry that drive linear, time-invariant signal processing is well known to be fully characterized by a frequency response dependent on direction-of-arrival (DOA). This paper develops the generalized characterization that results when the time-invariance requirement is removed. The special case based on periodically varying signal processing is further derived and shows such a system to be fundamentally, structurally incapable of realizing a long-sought goal in navigation engineering: a frequency shift smoothly dependent on DOA. Self-contained developments of time-varying continuous-time linear systems and of a 4D Fourier-transform view of propagating electromagnetic waves are given in the appendices. [C2795]

#### "Ultrawideband VHF/UHF dipole array antenna"

A linearly-polarized ultrawideband dipole array antenna has been developed for coverage in the VHF/UHF frequency range for communications or radar applications. The antenna design utilizes a horizontally polarized array of thick tubular dipole elements above a ground plane. Numerical electromagnetic simulations were used to analyze and optimize the antenna parameters prior to fabrication. Measurements of a 24-element ultrawideband dipole array prototype in an anechoic chamber demonstrate the antenna's return loss and gain pattern performance over a wide bandwidth. [C2796]

#### "Digital Array Radar panel development"

The Army Digital Array Radar (DAR) project's goal is to demonstrate how wide-bandgap semiconductor technology, highly-integrated transceivers, and the ever-increasing capabilities of commercial digital components can be leveraged to provide new capabilities and enhanced performance in future low-cost phased array systems. A 16-element, S-band subarray has been developed with panel-integrated, plastic-packaged gallium-nitride (GaN) amplifiers, multi-channel transceiver ICs, and digitization at the element level. In addition to full digital beamforming on transmit and receive, the DAR subarray has demonstrated efficient RF power generation exceeding 25 Watts per element, in-situ, element-level calibration monitoring and self-correction capabilities, simultaneous transmit and receive operation through subarray partitioning for an indoor target tracker, and more. An overview is given of these results and capabilities. [C2797]

#### "Parameter estimation of moving target based on linearly constrained space-time adaptive monopulse technique"

Technique of space-time adaptive processing (STAP), which is usually employed by airborne radar to reject the ground clutter and jamming and at the same time, detect the ground moving targets, can not estimate the spatial-temporal parameters of the corresponding targets. Monopulse technique, as a mature method for parameter estimation can be used on airborne radar, however, the estimation performance of this method is dramatically effected by the ground clutter and jamming components present, even when these components falls into the mainbeam interval. By combining the STAP technique with the monopulse technique, a new method for estimating the spatial-temporal parameters of moving targets is proposed and referred as to LC-STAM in this paper. Additionally, the proposed method utilizes the beam null, monopulse slope, and decoupling constraints to remove the worse influence on the beam shape from the mainbeam clutter, maintain the characteristic of the monopulse ratio, and increase the veracity of parameter estimation. Simulation results illustrated that the LC-STAM method possesses the excellent estimation performance of the spatail-temporal parameters by comparing with the other similar methods. [C2798]

#### "Adaptive cancellation of impulsive interference in phased array radar"

Performance of a pulse-Doppler radar may be severely degraded by high-power pulses emitted by other nearby radars operating in the same frequency band. Typical approaches to mitigating the resulting impulses in the received radar data may impose stressing requirements in the areas of probability of impulse detection, throughput, and estimation error. This paper proposes an adaptive nulling approach to mitigation of impulsive interference. This approach ameliorates the disadvantages associated with conventional impulse mitigation. By exploiting prior knowledge about this type of interference, the effort may be decomposed into two separate nulling stages. This provides a novel application for the Two-Step Nulling (TSN) algorithm, which has previously been used in Space-Time Adaptive Processing (STAP) applications. [C2799]

#### "Nonlinear Kalman filtering for self-calibration of airborne arrays"

The calibration of a millimeter-wave antenna array mounted on an aircraft wing is considered. The theory and implementation of nonlinear Kalman filters, which are optimal for the desired minimum mean squared error (MMSE) criterion, are considered. Numerical results are provided for a field experiment employing a 32-element Ku-band antenna array. The implementation of the algorithms is sub-optimal due to limitations in available

computational power, which reduces the model order and the accuracy of the required calculations, but the technique is effective in calibrating the array. [C2800]

#### "A carrier-based UWB transceiver in CMOS 90nm for biomedical radar sensing and sensor communications"

This paper describes a carrier-based multi-band UWB transceiver front-end in CMOS 90nm designed for full UWB band biomedical radar sensing and sensor node communications. The transceiver operates in band 3-10GHz. The transceiver consists of a transmitter and a receiver. The transmitter includes a pulse generator, a mixer, a VCO, and a driver amplifier. The receiver includes a filter bank, a ultra wideband LNAs, mixers, integrators, and decision-making circuits. The system was simulated using CMOS 90nm technology to verify functions for both the sensor communications and radar sensing. The overall power consumption is 62.75mW. [C2801]

#### "MMIC based phased array radar T/R modules"

In order to lower the cost of basic MMIC components and modules for commercial and civilian phased array applications dramatic cost reductions when compared to the present military must be realized. These cost reductions can only be achieved by employing highly integrated RFICs which are produced on high volume process lines for low cost using GaAs MMICs and Silicon based technologies where appropriate, exploiting high volume plastic packaging technologies for both low cost and high performance, and employing commercial printed circuit board and module manufacturing technologies. The viability of these approaches is already being demonstrated on a number of phased array radar projects ranging from L-Band to X-Band. Results for an ongoing S-Band Phased Array effort are the basis for this work. In this project, M/A-COM Technology Solutions' high performance pHEMT MMIC processes to produce highly integrated Tx and Rx ICs are being employed. Logic control is realized in standard low cost CMOS technology. These ICs are packaged in industry standard PQFN packages. The packaged ICs are then surface mounted to realize the T/R Module. [C2802]

#### "Optimization of multistatic passive radar geometry based on CRLB with uncertain observations"

In the present paper, we derive the Cramer-Rao Lower Bound (CRLB) with uncertain observations, namely for  $P_d < 1$ , for the 2D position measurements of a multistatic passive radar, to optimize the geometry of the system. This is an extension of the enumeration method CRLB to the multisensor case, where it is considered that the multiple receivers could detect or miss the target independently of one another. This version of the CRLB with uncertain observations is the correct measure for the realistic performance assessment of a passive radar, since typically passive radars show low values of  $P_d$  and neglecting the target miss probability, in the standard evaluation of the CRLB, provides unreliable performance assessments. The obtained CRLB is then used inside the multistatic passive radar optimization scheme derived by the authors in, to select the broadcast transmitters and the receiver locations providing the highest accuracy. The proposed approach is illustrated by means of a case study: a multistatic passive radar based on two transmitters of opportunity and a single receiver. For this case, we analyse how the Signal to Noise Ratio and the detection probability affect the measurement accuracy and the estimation accuracy and, finally, we use the theoretical CRLB to select the two transmitters among the available ones and choose the receiver location, for a target flying a specific trajectory. [C2803]

#### "S band radar target detection in an extreme advection duct event"

Mesoscale numerical weather prediction models coupled with modern parabolic equation radar performance models have allowed the resolution of four dimensional radar performance in challenging non homogeneous near surface refractivity fields at the time and location of the modeller's choice. Large scale offshore flow of warm and dry air over colder seas produces strong surface ducting. Large land-sea temperature differences can produce near shore sea breezes and surface based ducts. This paper describes modelled radar performance in such a complex ducting structure over the Persian Gulf during large scale northwest flow. The refractivity field was resolved by the Coupled Ocean Atmosphere Mesoscale Prediction System and the notional radar performance was modelled by the Advanced Refractivity Effects Prediction System. The results indicate strong spatially dependent enhancements and degradations in radar performance relative to a standard atmosphere. [C2804]

#### "Wireless indoor localization using dynamic monopulse receiver"

This paper proposes a dynamic monopulse receiver (DMR) for wireless indoor localization. By electrically steering the radiation beams to  $N$  discrete angles,  $N$  sum-difference ( $\Delta$ - $\Sigma$ ) curves can be generated in the desired field of view (FOV). The target angle can be precisely estimated using the proposed selection-and-

average algorithm. The 1-D and 2-D localization experiments were conducted, which demonstrate precise location with mean distance error as low as 0.33 m for 75% cumulative probability. [C2805]

### "Multistatic passive radar geometry optimization for target 3D positioning accuracy"

The paper presents a design procedure for a multistatic passive radar system, that aims at its performance optimization, in terms of 3D positioning accuracy. Specifically, the proposed procedure considers the main features of the considered air traffic control scenario and the main physical and geometrical features of the passive radar receivers and guides the designer to select the geometry that maximizes the three-dimensional target positioning accuracy. The procedure can be applied to any type of sources of opportunity, the final accuracy results being inversely scaled by their frequency band occupancy. The proposed procedure has been applied to two different air traffic control scenarios, namely an en-route flight and an approach path. The results show that a multistatic passive radar system with just two or three transmitters of opportunity and a single receiver is able to localize targets with positioning accuracy comparable to conventional air traffic control systems. [C2806]

### "A model-based track-before-detect strategy"

This paper addresses adaptive detection and tracking of a point-like target in thermal noise plus clutter which is assumed to be heterogeneous from one range cell to another. To this end, a track-before-detect scheme is derived and assessed; its design relies on autoregressive modeling of noise returns. A preliminary performance assessment, based upon Monte Carlo simulation, shows that it can outperform previously proposed TBD strategies. [C2807]

### "Precise radial velocity estimation using an FMCW radar"

This contribution addresses radial velocity estimation with a frequency-modulated continuous-wave (FMCW) radar system. The estimator we propose aligns the up- and downchirp information of adjacent sweeps including the phasing of the chirps. The resulting one-dimensional signal depends on the radial velocity and can therefore be used for estimation purposes. Because the phase information between nearby chirps is preserved, the accuracy is seriously increased compared to estimators that evaluate only the frequency shift due to the Doppler effect. Additionally, the range of velocities that can be estimated without ambiguity constraints is extended considerably when compared to a standard range-Doppler procedure. [C2808]

### "Fractal based detection using blind box-counting method in high resolution radars"

Sea clutter refers to the radar returns from the sea surface. Accurate modelling of sea clutter and detection of low observable targets within sea clutter are major problems in remote sensing and radar signal processing applications. Recently fractal geometry is applied to the analysis of high range resolution radar sea clutters. The box-counting method is widely used to estimate fractal dimension but it has some drawbacks rarely considered in literature. We explain the problem of box size range and present a novel method to select an appropriate range. [C2809]

### "MetaSensing compact, high resolution interferometric SAR sensor for commercial and scientific applications"

For the first time in the world airborne Frequency Modulated Continuous Wave (FMCW) Synthetic Aperture Radar (SAR) images have been acquired in interferometric mode. The paper reports on the X-band images collected by the new high resolution, compact MetaSensing interferometric SAR sensors in 2009. MetaSensing approach allows cost-effective SAR mapping by employing small, readily available Cessna 172/182 or similar in order to drastically cut the costs of current radar campaigns for scientific and commercial applications. MetaSensing X-band SAR sensor is able to transmit more than 1.4 GHz of bandwidth and its versatile two receiving channels allow along-track and cross-track interferometric acquisitions. A fully polarimetric L-band sensor is in the final test stage and is available from the third quarter of 2010. The new MetaSensing approach is an optimal solution for commercial and scientific application which requires SAR mapping on local areas. [C2810]

### "Improving SAR images: Built-in geometric and multi-look radiometric corrections"

SAR systems installed on small aircrafts and UAVs suffer from trajectory deviations and instabilities of antenna orientation. These kinds of motion errors lead to significant geometric distortions and radiometric errors in SAR images. In the paper, we describe a time-domain multi-look stripmap SAR processing algorithm with built-in geometric and multi-look radiometric corrections. Geometric correction is performed due to azimuth reference

functions and range migration curves specially designed to produce SAR images directly on a rectangular grid on the ground plane. Radiometric correction is based on multi-look processing with extended number of looks. The proposed techniques have been successfully tested with a Ku-band SAR system installed on a light-weight aircraft. [C2811]

### "Fractional Range Doppler Algorithm for SAR imaging"

Synthetic Aperture Radar systems are normally used to form high resolution images from radar backscatter. The Fractional Fourier transform (FrFT), which is a generalized form of the well-known Fourier transform, has opened up the possibility of a new range of potentially promising and useful applications that involve the use and detection of chirp signals including pattern recognition and SAR. In this paper the FrFT is applied to the well established Range Doppler Algorithm in order to obtain a superior result in terms of resolution and noise rejection. The results confirm that the FrFT can be useful to perform high resolution SAR processing and to reduce the speckle noise while enhancing the resolution and focusing accuracy. [C2812]

### "A multiple target doppler estimation algorithm for OFDM based intelligent radar systems"

In this paper an approach will be presented that allows for estimating the velocity of multiple reflecting objects with standard OFDM communication signals. The proposed technique does not require any specific coding of the transmit signal and provides high dynamic range and low sidelobe levels. This allows for an efficient acquisition of velocity information in joint communication and radar systems. The paper discusses the developed algorithm and a possible OFDM system concept for automotive applications. Measurement results are provided that prove the operability in practical scenarios. [C2813]

### "Arbitrary synthetic aperture motion compensation based on Fast Back Projection"

Back Projection imaging algorithm, whose low efficiency reduces its applications in practical projects, could work with highly nonuniform apertures. According to this reason, many scholars have presented some Fast Back Projection algorithms based on sub-aperture method. But how to compensate the motion error after sub-aperture dividing is awaited for further studying. The motion compensation method for FBP algorithm at different motion error levels is studied in this paper. Three situations denoting different motion error levels, which are only non-uniform in azimuth aperture, tracks of two-dimensional motion error and highly nonlinear even curvilinear flight tracks, are discussed here. Then it comes to a fast back projection imaging algorithm for arbitrary aperture, and this algorithm needs highly precise position information. Finally, an outside experiment is made to prove the algorithm's availability. [C2814]

### "A multi-model track-before-detect algorithm for manoeuvring target detection for Over-the-Horizon Radar"

In this paper a multi-model track-before-detect (MM-TBD) is proposed for the HF Over-The-Horizon-Radar (OTHR) manoeuvring target detection. Multiple hypotheses about target manoeuvres and echo sources are represented in the multi-model-estimation framework with each sub-filter corresponding to one hypothesis. The track output of each sub-filter is obtained based on the maximum likelihood criterion and then a generalized likelihood ratio for hypothesis test is presented to target detection. A numerical simulation is presented to show the effectiveness of the proposed algorithm. [C2815]

### "Characterisation of dismounted combatants radar signature from airborne platforms"

The radar signature of dismounted combatants as observed from a moving airborne radar platform was examined and quantified. The dismounted target presented a characteristic amplitude and frequency modulated signature which proves useful in distinguishing true targets from those due to uncanceled clutter discretely. [C2816]

### "Inter-period compensation algorithm in full-polarimetric FMCW radar"

This paper describes a new type of sounding signals for polarimetric FMCW radar and the corresponding signal processing technique. The inter-period compensation (IPC) algorithm is proposed for isolation increase in radar channels. The novelty concerns the use of orthogonal polarizations of two bi-cyclic LFM-signals having an additional phase shift every second sweep. Summation units proposed for use in the receiver channels allows for reducing the effects of interfering signals due to the specified phase of received signals over two consecutive sweep times. [C2817]

### "Exploiting the joint distribution of amplitude and monopulse ratio for chi-square fluctuating targets for target DOA estimation"

This paper deals with the Direction of Arrival (DOA) estimation for chi-square fluctuating targets. The joint Probability Density Function (PDF) of the amplitude in the sum channel and the monopulse ratio for a chi-square fluctuating targets presented in [1] is here used to derive several DOA estimators. The proposed estimators are obtained by following respectively the Maximum Likelihood criterion, the Method of Moments, and the Maximum Entropy Method. Their performance are characterized in terms of bias and standard deviation error. [C2818]

### "An implementation of step recovery diode-based UWB pulse generator"

Ultra-wideband (UWB) wireless communications and carrierless UWB radar technology use narrow nanosecond or sub-nanosecond pulse as the transmission medium. This paper presents an implementation of sub-nanosecond level pulse generator. The main principle is using the rapid step recovery characteristics of step recovery diode (SRD) to shape the driving pulse, shorten the rise time, narrow the pulse width, then gain the required UWB pulse. The final actual measured pulse width is about 600 ps, amplitude is about 5 V. It is enough for practical applications, but the ringing is a little too big, the amplitude is relatively low. The paper provides a simple method to design UWB pulse generator. Although there is some room for improvement, it has important reference value for the use of SRD in UWB pulse generating in the future. [C2819]

### "Comparison of multi-beam pillbox antennas using leaky-wave and slotted waveguide radiating parts for automotive radars at millimeter-waves"

This work deals with a comparison between multi-beam leaky-wave and slotted waveguide pillbox antennas. The antenna systems present the same pillbox architecture: feeding part, quasi-optical system and radiating part. Two different radiating parts are considered: a leaky-wave solution and an array of slotted waveguides. In particular, an array of slots etched on the uppermost metal layer of the pillbox structure and 23 waveguides with 8 radiating slots are adopted for the leaky-wave and slotted waveguide solution, respectively. The quasi-optical system and feeding part used in both antennas are the same. The quasi-optical system is made by a pin-made integrated parabola and several coupling slots, and is used to shape and focus the energy coming from the input part to the radiating part. Seven pin-made integrated horns are placed in the focal plane of the integrated parabola to radiate seven beams in the far field. The antenna performances in terms of efficiency, bandwidth and scanning capabilities are compared. Both the proposed antennas are low-cost, low profile, compact, efficient and very promising solutions for applications in the millimeter-wave range, especially for long range automotive radars. [C2820]

### "Reconfigurable digital receiver for polarimetric radar with dual-orthogonal signals"

This paper outlines the work on the design of a reconfigurable receiver for the PARSAX radar. The FPGA based digital receiver samples incoming signals at intermediate frequency (IF) and processes signals digitally instead of using more conventional analog approaches. In this way it offers more robust system stability and avoids unnecessary multi-channel calibrations of analog circuits. The processing algorithms implemented in the FPGA chips can be reconfigured adaptively regarding to different transmitted waveforms, and without changing of hardware. The successful development of reconfigurable receiver has been verified by experiment and yields maximum flexibility for the whole radar system. [C2821]

### "77 GHz FM-CW radar for FODs detection"

Foreign objects and debris (FODs) may cause accidents or disasters. The crash of a Concorde jet in France that killed 113 people in 2000 is an example of the danger created by a thin metal strip that fell from another airplane. Recently, FOD detection systems have been developed and tested on airports. Most of them are based on the association of a mm-Wave radar and an optical sensor. This paper describes the investigation, conducted together with the ENRI and LEAT on a wide band mm-Wave radar module. It is composed a 76-81 GHz front-end and a quasi-optical antenna that is a printed Fresnel reflector operating with circular polarization. The purpose of this paper is to compare the measured responses of selected. This work is conducted within a Sakura project funded by the French and Japanese Ministries of Foreign Affairs. [C2822]

### "Spatial (aperture) noise generators"

Spatial noise generators with apertures of 200 mm, 270 mm, 1500 mm were developed in OKB MEI. Spatial noise generators with apertures of 200, 270 mm are Djuar vessels filled up by boiling liquid nitrogen, with metal cylinder, fixed in liquid nitrogen's zone. One of cylinder's founding is cooled by boiling nitrogen. It is covered by radio-absorption material. Another founding, covered by heat protection radio-transparent material, is radiating

aperture of spatial noise generator. Spatial noise generators with aperture of 1500 mm is a collimating system, which consists of the parabolic reflector (part of parabolic) and radiator, which consists of aperture noise generator and additional reflector (contra-reflector). Additional reflector also provides lighting of main mirror (parabolic reflector) and forming of plane parallel collimation beam. Methodology of noise temperature unevenness measurements in the section of the collimation beam is presented. [C2823]

#### "Reconfigurable radar transmitter based on photonic microwave signal generation"

In this paper we propose a photonic technique for a reconfigurable microwave signal generation based on the beating in a photodiode of two laser modes from a regenerative Fiber Mode-Locked Laser (FMML). The excellent performance of this kind of pulsed laser guarantees high stability to the generated microwave signal even at ultra high frequencies (up to W band). Therefore, by using the proposed architecture, the performance of a reconfigurable full digital coherent radar system can be enhanced in terms of Moving Target Indicator (MTI) improvement factor. Moreover, thanks to the achievable high repetition rates and the coherence properties of the FMML, this laser scheme has also been proposed for digitizing the received signal by electro-optical sampling. Thus the advantage of using just one device for signal generation in both the transmitter and receiver chain, makes the proposed solution a cost effective architecture for microwave signal generation. Differently from the microwave synthesizers, whose performance strongly deteriorate with increasing frequencies, the photonic radio frequency generation always shows an excellent spectral purity. The results show excellent spectral purity above 5 KHz for the proposed technique compared to a state of the art Agilent synthesizer even though the timing jitter increases for integration time greater than 10 msec. In order to achieve the same stability performance at both high and low frequencies a Phase Locked Loop between the laser and a synthesizer could be used. [C2824]

#### "Using signals of the global navigation satellites for diagnostics of above land troposphere refraction"

Possibility of global navigation systems using for troposphere refraction coefficient determination is considered. Relation between measured altitude and troposphere state is determined. The method of reflecting sources number, altitude of sources location and troposphere refraction estimation on GPS and GLONASS received signal spectrums of amplitude fluctuation is proposed. [C2825]

#### "Comparison between wavefront-based shape reconstruction and beamforming for UWB near-field imaging radar"

This paper investigates the performances of a wavefront-based shape reconstruction algorithm, known as Envelope, for ultra-wideband (UWB) near-field imaging. In contrast with conventional beamforming, surface estimation is based on identification of wavefronts within the received data and direct transformation from delay time to the target shape. The algorithm is compared with conventional beamforming in terms of both imaging accuracy and speed. The influence of sparsity of data acquisition on the estimated surface image is further compared showing both advantage and problems of the methods. [C2826]

#### "Scan-to-scan sea-spikes filtering for radar"

High range resolution radars are often a solution to the problem of small target detection in the presence of sea clutter, however this solution leads to a high density of sea-spikes echoes. The number of false plots can be very high and need to be regulated in order to be able to control the tracking load and limit the number of false tracks. In this paper a solution for the Coast Watcher 10 and Coast Watcher 100 products is derived. The new patented scan-to-scan algorithm used to filter plots before tracking is presented. It uses the position and Doppler information of the plots on several scans to regulate the number of false plots at tracking level. [C2827]

#### "Detection against the background of non-Gaussian clutter from underlying surface"

The method for the operating characteristics of the radio systems estimation based on using of model of non Gaussian clutter from underlying surface (sea, land plots) is proposed. This method was done by nested semi-Markov based processes. The characteristics of parametric (Neumann-Pearson, adaptive control of threshold and filter band of moving-target indication) and non-parametric (sign and linear rank) detectors are analyzed theoretically and are compared to results of the experimental investigations. [C2828]

#### "OTHR-SW Coordinate Registration method based on sea-land transitions: Clutter model definition"

In previous works we proposed a Coordinate Registration (CR) method of the received echo by pulsed, monostatic Over The Horizon Sky Wave Radar (OTHRsw). This method takes advantage from the a priori geo-

morphological knowledge of the surveillance area (especially the coastline profile) and from the pronounced difference between the sea and land normalized backscattering coefficients. In this paper we present a model of surface clutter, its software implementation and its role in the simulation tool under development intended to recreate the complex OTHR scenario in order to analyze the performances of the proposed CR method. A brief introduction about the radar scenario is given; the main clutter model hypotheses are outlined; the adopted space-time distributions processes are motivated; the key-parameters for the model configuration are described; some examples of simulated clutter scenarios are proposed; the achieved results are finally shown. [C2829]

#### **"Comparison of accurate and simplified sub-entire-domain basis function methods in RCS computation of large-scale periodic structures"**

Accurate sub-entire-domain (ASED) and simplified sub-entire-domain (SSED) basis function methods are introduced and compared in this paper for radar cross section (RCS) computation of large-scale periodic structures. The detailed algorithms are presented and the number of unknowns, CPU time and precision of the two methods are discussed respectively. Numerical results are given to show the differences of the two methods, so that a flexible choice can be acquired for further researches and wider applications of SED method. [C2830]

#### **"Polarization diversity in Ultra-Wideband imaging systems"**

This paper presents an Ultra-Wideband (UWB) indoor imaging system with dual-orthogonal polarized antennas. Both the measurement setup and the algorithm implemented for data processing are introduced. In the presented approach, a 4Ч1 vertically oriented antenna array is used in order to perform 2D scan. For 3D imaging, single antennas are applied. Emphasis is given to the polarization diversity, through which additional properties of objects such as form, surface structure and orientation are investigated. In this way, some objects are detected, which may remain invisible for single-polarized systems. In addition, the presented approach extends UWB-Radar/Imaging with very high resolution to a high-end system with robust target detection, while providing extensive information about the environment. Such a system can be of great interest in applications such as indoor search-and-rescue operations, motion tracking and indoor navigation. [C2831]

#### **"Cost effective Wafer Level Chip Size Package technology and application to the next generation automotive radar"**

Cost effective 77GHz transmitter and receiver MMIC's, that use a three-dimensional MMIC technology optimized for flip-chip implementation, are presented. The MMIC structure incorporates inverse TFMS lines so that a ground metal can be applied to cover the whole chip surface except for interconnect pads. Four metal layers including the ground metal are formed between and the top surface of polyimide layers each of which is SiN coated for humidity proof. Hence, these MMIC chips require no package, as well as can be directly assembled on printed circuit board. The transmitter MMIC is composed of an Ч8 multiplier chain (9.5GHz/38GHz MLT, 38GHz AMP, and 38GHz/76GHz MLT), and a driver+power amplifier. A saturated output power of 14dBm has been obtained between 76 and 77GHz from this transmitter MMIC. A portion of the 38GHz amplifier output is split for the receiver mixer. The receiver MMIC is composed of multi LNA+MIX blocks and a common Ч2 multiplier block that provides a 10dBm of LO power. A receiver gain of 10dB and a noise figure of 7.8dB for a baseband frequency at 10MHz were obtained. The die size of the transmitter is 1.5mm Ч 2.0mm and the chip area of the receiver is 1.9mm Ч 1.3mm. [C2832]

#### **"Improved wide-band dual-linear polarization compact microstrip antenna array for Microwave Image system"**

This paper provides a wide-band dual-linear polarization compact antenna array for P-band Microwave Image system, where the center frequency is 400 MHz with a 200 MHz of bandwidth (50% from 300MHz to 500MHz), and the size is smaller than 1600mmЧ400mm. The array system has dual-linear polarization with a maximal gain of 14.3dB at the center frequency, a minimum gain of 10.2dB at two ends of the band and the cross-polarization level is much less than -50dB over the frequency band. In the antenna design, compactness and stability of the presented antenna array is considered firstly, which is very important in practical airborne environment. Furthermore, one of the most excellent achievements is to develop a simple wide-band match structure composed with three independent parts. [C2833]

#### **"Odd-Symmetry Template based three-step detector for IR-UWB radar"**

The detection scheme for robust detection and target location in the presence of interference is presented. The problem of detecting the slow-moving target at noisy background is addressed in this paper. A novel kind of Odd-Symmetry Template Correlation (OSTC) process is developed as the first-step of the detector. The OSTC

method has a better performance due to interference suppression than traditional ones. The Range-Extended Constraint and Threshold Feedback technique is proposed as the second-step for detecting range-extended target and controlling the false alarm rate. The Multi-Cycle Fusion method completes the third-step detection procedure, and improves the detection reliability by reducing false alarms. Experimental results are given to demonstrate the efficiency of this approach. Moreover, the effectiveness of this method allows for real-time execution. [C2834]

#### **"An improved IPCP detector of UWB radar signals based on adaptive searching window"**

The research on detection of range-extended targets has been a focus of UWB radars. The paper introduces weighted accumulation and adaptive searching to the IPCP detection, and theoretical value of detection threshold is derived in detail. Related experiment and simulation confirm that weighted accumulation increases SNR effectively and adaptive searching basically eliminates the negative effects on detection performance caused by unknown extended range of the target echoes, which guarantees the reliability and stability in practical application. [C2835]

#### **"A low-cost handheld integrated UWB radar for shallow underground detection"**

In order to fit the demands of low cost and miniaturization for ground penetrating radar (GPR), a handheld integrated high resolution UWB GPR system was developed. The design methods of the low-cost RF module with the impulse transmitter, the sequential receiver and the UWB antenna were described, and the structure of the embedded control module with the radar control unit, the data acquisition and the image process unit were also introduced. The integration improves the convenience and the stability of the system. Several experiments were carried out with the prototype. The experimental results show that the system could detect shallow underground objects effectively with high resolution. [C2836]

#### **"Power handling and temperature compensation design for passive Microwave devices"**

Summary form only given. Modern communication and radar transmitter systems require high performance RF/Microwave devices and components, to improve communication and detection range. The increase in range is accomplished by increased transmitted power and higher receiver sensitivity. The increased transmitted power requires the engineer to estimate the transmitter's power handling capability as part of the design process. In addition, the engineer has to meet several competing requirements at a specified pressure level, such as containment of transmitted bandwidth (wide or narrow, i.e., reduce adjacent channel spill over), minimize group delay variations, and reduce performance drifts with environmental condition changes (e.g., temperature, pressure, and humidity). When designing devices for these high power operations, one often has to take into account the following effects: multipactor and ionization breakdown, passive intermodulation interferences and thermal-related issues such as temperature compensation. This talk will elaborate the physics background, technical challenges and design methodologies. It will also cover the clever use of both circuit and electromagnetic modeling techniques. Numerous examples will be presented from those widely used in the industry. The method presented is general and is applicable to all device types. [C2837]

#### **"Possibilities of cloaking and invisibility at microwaves"**

Summary form only given. Recently, the topic of making objects "invisible" for electromagnetic radiation has gained much attention, following new ideas of using engineered electromagnetic materials with unusual properties for this purpose. This lecture provides a comparative review of the recent developments in this field and discusses the potentials of utilizing these ideas for various microwave and antenna applications. The lecture starts from a review of the notions of invisibility and cloaking and their relations to the classical stealth technologies of reducing radar cross section of targets. Next, we make a historical overview of earlier approaches to techniques allowing reduction of scattering from various objects. Recently proposed solutions for cloaking of objects are reviewed and compared, with the emphasis on the fundamental limitations of their performance. This topic is closely linked to the problem of creating of artificial materials with engineered electromagnetic properties. In particular, materials with equal values of relative permittivity and permeability are of interest. The lecture presents our recent developments of such materials based on mixtures of spiral inclusions and their use for cloaking applications. Furthermore, we discuss the use of electrically dense meshes of transmission lines as cloaking devices. It is shown how new cloaking techniques can be used for applications not necessarily related to cloaking of objects, for instance in new microwave lens antennas or in the design of matched absorbing layers. [C2838]

#### **"The conductivity of unidirectional and quasi isotropic carbon fiber composites"**

This paper describes a novel technique to predict the variation of the conductivity of carbon fiber reinforced

polymer versus frequency. Free space transmission/reflection and radar cross section measurements are utilised to confirm this prediction. The results indicate that the conductivity of unidirectional carbon-fiber is dependent on the polarization of the incident electric field and increases with increasing frequency for a particular polarization. [C2839]

#### **"A way to modern and cost effective packaging for RF frontends for use from microwave through millimeter wave frequencies"**

This paper describes the way from a cost intensive status of development of RF electronics to modern cost effective concepts. Military RF electronics as e.g. receivers, transmitters or complete radar frontends historically have been realized using expensive technologies to reach outstanding RF performances and reliability. Many advances in technologies, but also tradeoffs are a way to overcome expensive solutions. [C2840]

#### **"Boresight gain optimization of an UWB monopole antenna using FDTD and genetic algorithm"**

Printed planar monopoles are promising ultra wideband (UWB) antenna and can be easily integrated in communication systems by fabrication onto printed circuit boards. These planar monopoles become popular for wireless communication due to their broad bandwidth and appropriate radiation pattern. However because of the dependence of the antenna gain and the antenna aperture, as the frequency increase, the wavelength decreases, the boresight gain decreases and its variation is very large. In this paper, a new UWB elliptical monopole antenna with a printed structure fed by a microstrip line is presented. The antenna is analyzed by using the finite-difference time-domain (FDTD) method and the parameters of the shape of the antenna are determined by utilizing the genetic algorithm (GA). Through a novel ground structure of the substrate, the boresight gain equals to approximately 2.4dB in the frequency band ranges from 3GHz to 9GHz. Details of the proposed antenna design and simulated results are presented and discussed. [C2841]

#### **"Welcome to the 13th European Microwave Week 2010"**

EuMW continues its series of successful events with the 13th European Microwave Week 2010 which will be held at the CNIT la Défense, Paris, France from 26 September to 1 October 2010. This conference series has continued to grow and is now the premier event in this field in Europe. This event gathers all the international microwave community around four themed conferences:-The 40th European Microwave Conference (EuMC)-The 5th European Microwave Integrated Circuits Conference (EuMIC)-The 7th European Radar Conference (EuRAD)-The 3rd European Wireless Technology Conference (EuWiT) [C2842]

#### **"A low phase-noise SiGe Colpitts VCO with wide tuning range for UWB applications"**

An integrated differential common collector Colpitts VCO with a wide tuning range is presented in this paper. The circuit was designed and fabricated in the IHP Technologies SGB25V 250 nm SiGe:C BiCMOS process. It provides a superior low phase noise performance of -115 dBc/Hz covering the frequency range of 6.7 to 8.7 GHz for UWB pulsed frequency modulated secondary radar application. An additional common collector output buffer was implemented as well. The circuit provides an overall output power of -10 dBm single-ended with a power dissipation of 47 mW including the on-chip buffer. This paper also shows the modifications and improvements done at the mm-wave topology to reduce size and to improve the tuning range. [C2843]

#### **"Design of a passive radar network"**

This paper presents a pair of tools that can be use for design of a passive radar network (PRN). The one is called RAVLA and it is suited for searching potential sites for receivers among transmitters of opportunity as well as building up a passive radar surveillance network. The other one is called PAVA and it can be used for searching potential transmitters of opportunity for the receiver located at the certain site. Both tools presume that the properties of the transmitters and the receiver are known as well as the number of bistatic bases which are needed for the location of the target. Finally, some intermediate results of the design process of a DVB-T based passive radar network in Southern Finland are considered. [C2844]

#### **"Comparison of the time-reversal and SEABED imaging algorithms applied on ultra-wideband experimental SPR data"**

This paper presents a comparison study between a simple time-reversal algorithm (designed at LEAT) and the SEABED algorithm (designed at Kyoto University) with their application to multiple-target experiments. Data are collected with an eight element ultra-wideband antenna linear array connected to an eight port vector network analyzer, working in a frequency bandwidth starting from 1.5 GHz up to 8 GHz. Several target configurations demonstrate the advantages and disadvantages of both algorithms. [C2845]

### "UWB radar signal processing for through wall tracking of multiple moving targets"

Through wall tracking can be very helpful in the situations where the entering of a room or a building is considered hazardous and it is desired to inspect its interior from outside through the walls. In majority of such cases, the tracking of multiple moving targets is needed. The radar signal processing for this application has to deal with several supplementary tasks in comparison with a single target tracking. Their solution is included in the complex signal processing procedure introduced in this paper. The experimental results obtained by the real radar signal processing confirm good performance properties of the proposed procedure. [C2846]

### "Wind farm Gapfiller concept solution"

This paper describes a Gapfiller concept solution to mitigate the potential negative effect from a wind farm upon a military surveillance radar system. The problem is described as well as the technical solution to mitigate the problem. This paper does not describe signal processing techniques that can be applied to the main surveillance radar, but it describes some important technical requirements and a Gapfiller solution that can be used to complement a surveillance radar system. The application of a Gapfiller deployed within an offshore wind farm is described and other relevant applications are suggested. [C2847]

### "Calibration of a 2.45 GHz indoor Direction of Arrival system based on unknown antenna gain"

In this paper we discuss the calibration procedure and effectiveness for an indoor Direction of Arrival (DOA) positioning system based on a switched six-beams antenna operating at 2.45 GHz. The introduced calibration procedure consists in optimizing the radiation pattern parameters of the antenna to minimize DOA estimations error, over a limited set of known positions. The estimations are obtained by the multiple signal classification (MUSIC). We demonstrate that in a realistic indoor environment the mean errors for the DOA estimations are less than 4.9 deg for both the DOA coordinate angles  $\theta$  and  $\phi$ , with a peak error of 8 deg, while a DoA estimation accuracy less than 3 deg was observed. [C2848]

### "Quasi-Analytical method for estimating low false alarm rate"

This paper proposes a new approach for estimating low false alarm rate (FAR) using Quasi-Analytical (QA) method. The results from both theoretical analysis and simulation show that QA estimation is unbiased with obvious simulation speed improvement with respect to Monte Carlo (MC) and Conventional Importance Sampling (IS) for typical application cases. Furthermore, unlike IS approaches that rely on complex optimization procedures for optimal IS parameters or sub optimal parameters, the QA is simple to implement and computationally effective. [C2849]

### "High range resolution DVB-T Passive Radar"

Passive Radar systems, also referred to as Passive Coherent Location systems (PCL), exploit reflections from illuminators of opportunity (IO) in order to detect and track objects. Digital waveforms like DVB-T and UMTS signals offer wide bandwidth channels which allow achieving good spatial resolution. Moreover, they have spectral properties which are nearly independent of the signal content. Such waveforms exhibit an ambiguity function with a thumb-tack shape and bandwidth that is constant in time. This paper focus on the usage of multiple channels of the same IO (e.g.: DVB-T or UMTS channels) in order to improve range resolution and make target recognition and radar imaging feasible. Specifically, two different architectures based on the exploitation of multiple DVB-T channels have been considered. A DVB-T transmission system has been simulated with a Simulink® model compliant to. Simulation results are presented and discussed in order to evaluate the system performance in terms of spatial resolution. [C2850]

### "FPGA implementation of UWB radar signal processing for automotive application"

A radar signal processor of 24GHz UWB pulse radar for automotive short-range application is presented. A FPGA-based architecture for this signal processor is proposed to fulfil the real-time system requirement. The high performance of the proposed architecture was feasible since the employment of parallel hardware processing modules, like a 64-point FFT, a CFAR processor, and other extra processing modules. Also our signal processor supports the external DDR2 memory in order to speed up the data transfer between the signal processor and a memory. Also in this work, our radar system was simulated as our radar working scenarios using the variable pulse length and the phase modulation. Experimental results of the FPGA implementation are presented. [C2851]

### "Welcome to the 13th European Microwave Week 2010"

EuMW continues its series of successful events with the 13th European Microwave Week 2010 which will be held at the CNIT la Défense, Paris, France from 26 September to 1 October 2010. This conference series has continued to grow and is now the premier event in this field in Europe. This event gathers all the international microwave community around four themed conferences: -The 40th European Microwave Conference (EuMC)-The 5th European Microwave Integrated Circuits Conference (EuMIC)-The 7th European Radar Conference (EuRAD)-The 3rd European Wireless Technology Conference (EuWiT) [C2852]

### "Design and implementation of sub-GHz transmitter for ultra-wideband through-wall radar"

Ultra-wideband (UWB) transmitters for through-wall radars operating in sub-GHz frequency may enable better penetrating ability and lower attenuation than devices utilizing signals above 1 GHz frequencies. In this paper, the crucial parameter of sub-GHz unipolar pulse width is investigated by theoretical analysis and experiment. Based on these parameter data, in order to radiate the signal effectively and reduce the ringing, we design a fifth-order parallel LC high-pass filter. It shapes the unipolar pulse into the bipolar pulse which has no direct current component and slight ringing. The transmitter circuit is implemented and tested. Results indicate that it generates sub-GHz UWB pulses with 2.6 ns temporal width and 744 MHz frequency bandwidth, which appears to be suitable for the through-wall radar. [C2853]

### "UWB front-end for SAR-based imaging system"

A planarly fed UWB leaky lens antenna is presented integrated with wide band transmit and receive front-end electronics, to be used in a SAR-based imaging system. The unique non-dispersive characteristics of this antenna over a very wide bandwidth, together with the dual band front-end electronics based on 'off the shelf' components and integrated using standard PCB technology makes them very attractive as transmit-receive element for a MIMO array configuration. Design and measurement results of the leaky lens antenna characteristics are presented, and design considerations for the integrated mm-Wave electronics are discussed. [C2854]

### "A gain-enhanced semicircular disc antenna with a quasi-planar surface-mounted short TEM horn"

A constant-gain ultra-wideband semi-circular disc monopole with a quasi-planar surface-mounted short TEM horn and a semi-circular reflector is proposed. The total length of the antenna is only 70 mm i.e. nearly  $0.67 \lambda$  at 2.86 GHz. The gain of the antenna is nearly constant:  $6.5 \pm 1.1$  dBi from 2.86 GHz to 15 GHz, and  $6.5 \pm 0.7$  dBi from 3.1 GHz to 10.6 GHz. It has broad azimuth pattern and its compact integrated configuration is suitable for several ultra-wideband (UWB) wireless and radar applications. [C2855]

### "SAR-like localization of RFID tags for non-uniform trajectory"

In this paper we present a new principle for localization of backscatter RFID tags. A new algorithm comparable to synthetic aperture radar on a non-uniform trajectory is proposed. The performance is verified with measurement data acquired by a multi sensor platform which comprises radar, imaging and RFID. The identified RFID transponder positions are presented with augmented-reality visualization. The new radar approach called SAR-like is shown to have similar performance as SAR at an apparently lower computational cost. [C2856]

### "SAR-like localization of RFID tags for non-uniform trajectory"

In this paper we present a new principle for localization of backscatter RFID tags. A new algorithm comparable to synthetic aperture radar on a non-uniform trajectory is proposed. The performance is verified with measurement data acquired by a multi sensor platform which comprises radar, imaging and RFID. The identified RFID transponder positions are presented with augmented-reality visualization. The new radar approach called SAR-like is shown to have similar performance as SAR at an apparently lower computational cost. [C2857]

### "A modular 24 GHz radar sensor for digital beamforming on transmit and receive"

A compact modular 24 GHz imaging radar sensor for digital beamforming is presented. Besides digital beamforming on receive, the advantage of multiple switched transmitters is used for increasing the angular resolution, which requires less hardware effort. The presented FMCW radar sensor provides up to eight switchable transmitters and eight receiver channels for parallel receiving, allowing digital beamforming on transmit and receive. A new switching technique via switchable amplifiers is proposed. Within the scope of this paper an overview of the whole radar sensor's architecture, design and realization is given. The performance of the sensor is successfully demonstrated and evaluated by measurements. [C2858]

#### "Fidelity criterion for UWB medical diagnostic"

In this paper an Ultra Wideband (UWB) system based method is introduced, which permits to analyze and to extract information from the back reflected time domain signals originated by a UWB Radar signal impinging on the human body. The criterion is based on the fidelity parameter. In the paper the developed method is firstly mathematically introduced and then measurement results are presented. [C2859]

#### "A novel UWB Radar super-resolution object recognition approach for complex edged objects"

In this paper a novel approach for object recognition (OR) by backscattered Ultra Wideband (UWB) signals on the basis of a reference data set is presented. The aim of this robust OR is succeeded by UWB imaging, classifying and finally applying a maximum probability recognition algorithm. To provide super-resolution even under multi-scattering conditions, an advanced wavefront detection algorithm with subsequent high resolution imaging technique is performed. After postprocessing a joint moment based feature, texture feature and geometrical feature recognition algorithm is applied. The simulation-based performance evaluations show a very precise imaging and a perfect maximum probability recognition rate with additional outstanding robustness. First tests using an m-sequence UWB Radar indicate the feasibility of this concept. [C2860]

#### "A 79-GHz LTCC laminated waveguide to metallic rectangular waveguide transition using high permittivity material"

An integrated laminated waveguide (LWG) to metallic rectangular waveguide (RWG) transition based on low temperature co-fired ceramic (LTCC) technology is presented in this paper. The transition is designed for the 76-81 GHz radar frequency band using a high permittivity material ( $\epsilon_r = 7.4$ ). An additional secondary LWG structure improves both impedance matching and bandwidth. The bandwidth at -10 dB return loss is more than 5 GHz. The measurement results of the fabricated prototype agree closely with the simulation. This compact and backshort-free waveguide transition allows low-cost integration and offers the possibility of measuring E-Band radar components based on ceramic substrate. [C2861]

#### "Metamaterial matching of high-permittivity coatings for 79 GHz radar sensors"

Future automotive radar sensors in the 79 GHz regime are intended to be integrated behind painted, plastic fascia. This integration has to be carefully studied, concerning reflections coming from the bumper in line of sight of the sensor. To reduce these reflections, impedance matching of multilayer structures with high permittivities (e.g. metallic paints) is mandatory. Besides conventional matching techniques, metamaterials are a possibility to realize a matching layer. Based on an adopted parameter extraction algorithm for multilayer dielectrics, a bandwidth evaluation of a possible metamaterial design is shown. The measurement results show that for a bandwidth up to 3.8 GHz the metamaterial outperforms the benchmark. [C2862]

#### "Second order extension of power amplifiers behavioral models for accuracy improvements"

In the design process of reconfigurable radars, it is required to study the interaction between antennas and the power amplifiers in order to quantify the distortion and predict the performances of power amplifier (PA) on TX-chains. This paper presents an accurate behavioral model for PAs, based on nonlinear scattering functions, which allows taking into account large output loading impedance mismatches, i.e. Voltage Standing Wave Ratio (VSWR) up to four. First application presented is a black box modeling technique limited to Taylor first order expansion dedicated to moderate VSWR ( $VSWR \leq 3$ ). Unfortunately, the first order model is not efficient enough, so a second application is presented, showing an accurate model expanded to Taylor second order in the case of large VSWR ( $VSWR > 3$ ) which allows predicting circuit performances at system level and establishes a mixed simulation tool for a bilateral communication between amplifiers and antennas. [C2863]

#### "Session D4: Sensing and medical imaging; collision, ground-penetrating and through-wall radars"

{no data available} [C2864]

#### "Design of two flare UWB antenna dedicated to the research of alive buried victims"

This document presents the antenna design for the detection of alive victims buried under thick layers of rubble. The antenna is used with UWB Radar techniques in order to locate buried alive victims. The detection is based on the signature of alive persons by using Doppler analysis of movements and respiration. Detecting victims in this environment is very difficult due to the large dynamic range of signal levels. In fact, the reflected signal caused by the buried alive victim is very low behind other reflected or disturbing signals such as mobile phones, vegetation movements, water, rescuers... A two flares UWB antenna, light weight and easy transportable has

been specially design for the research of buried victims beneath building rubble. This paper focuses on antenna design, simulation and measurement. These measurements have been made by IETR and CEA. The experimental results show a good comparison between measurements and simulations. [C2865]

#### "Simulated and experimental wavelet-based detection of breast tumor using a UWB radar"

The objective of this work is the detection and localization of breast cancer by means of microwave imaging using Ultra Wide Band (UWB) techniques. The proposed method consists in detecting the time-of-flight signal backscattered by the tumor using continuous wavelet transform. The feasibility of this method is investigated from several simulated and experimental results using a phantom with a UWB pulsed radar. [C2866]

#### "Design of wearable communication device for body protection from EM wave using the EBG structure"

This paper presents a wearable communication device for body protection from electromagnetic wave using a electromagnetic bandgap (EBG) structure at a WCDMA band. Since wearable wireless communication devices are worked in the proximity or contact of the human body, a health risk from a electromagnetic fields generated by body worn devices is important. The EBG structures can suppress the propagation of surface current and act as a perfect magnetic conductor. Thus, it is capable of preventing a undesired electromagnetic wave from the wireless communication devices. The proposed wearable communication device has the PIFA with the EBG structure at a WCDMA band, frequency generator for the SAR testing and a dielectric case. It is a kind of watch phone worn on the human wrist. Simulation and experimental results demonstrate S-parameter, radiation pattern and the SAR value of the proposed structure. [C2867]

#### "Measurement verification of dual-orthogonal polarized UWB monopulse radar system"

In this work the practical verification of the UWB-monopulse radar is presented. Based on measurements of the antenna impulse response the look-up table is created. For radar measurements three targets are placed in vertical plane, at different angles and distances in respect to the antenna. The signals received in sum and difference beam are processed and compared with the look-up table. The presented system maintains a high range resolution delivered by UWB-technology and precise estimation of angular direction of the target. The sensing is performed with simple data processing, where no additional mechanical or electrical scanning of the antenna beam is required. [C2868]

#### "A low phase-noise SiGe Colpitts VCO with wide tuning range for UWB applications"

An integrated differential common collector Colpitts VCO with a wide tuning range is presented in this paper. The circuit was designed and fabricated in the IHP Technologies SGB25V 250nm SiGe:C BiCMOS process. It provides a superior low phase noise performance of -115 dBc/Hz covering the frequency range of 6.7 to 8.7 GHz for UWB pulsed frequency modulated secondary radar application. An additional common collector output buffer was implemented as well. The circuit provides an overall output power of -10dBm single-ended with a power dissipation of 47mW including the on-chip buffer. This paper also shows the modifications and improvements done at the mmwave topology to reduce size and to improve the tuning range. [C2869]

#### "Dual frequency & dual-linear polarization integrated Antenna array for application in Synthetic Aperture Radar"

This paper presents the design and realization of a dual frequency antenna array for application in Synthetic Aperture Radar. The array consists of 64 C-band elements interleaved with 4 L-band elements incorporated with feeding network in one integrated, multilayer, LTCC compatible structure. The Antenna has been designed to operate with dual-linear polarization in both frequency bands. The achieved bandwidths are 100 MHz in L-band and 400 MHz in C-band. Several techniques for suppressing orthogonal polarization has been implemented to achieve very low cross-polarization coefficient in both frequency bands. The beam forming network has been designed to provide modified cosec<sup>2</sup> radiation pattern suitable for radar applications. [C2870]

#### "A single bias 20W S-band HPA for radar applications"

The development of a single bias S-band MMIC HPA designed for radar T/R module applications is reported. The chip was fabricated with a low-cost 0.5 $\mu$ m GaAs PHEMT process and is composed of two stages, with a final stage of 29 mm gate-width periphery. The MMIC power amplifier is designed by using a zero gate bias configuration and therefore is attractive due to the size and cost reduction. In the frequency bandwidth 2.4-3.6GHz, the HPA biased at  $V_d=10V$  delivers an output power of 20W @ 4dB of gain compression, with an associated PAE of circa 28%. [C2871]

### "Original identification technique of passive EM sensors using loaded transmission delay lines"

This paper presents a proof of concept of an original identification technique of passive EM sensor cells. Previous works published by the authors have shown the feasibility of high sensitivity passive sensor Microsystems based on the electromagnetic transduction principle. More, other works, published by the same authors, have demonstrated the feasibility of a wireless interrogation technique of such passive measurement units. This interrogation technique is based on the measurement of the Radar Cross Section (RCS) level of the system composed of the sensor connected to an antenna. In this communication and for the identification purpose, a smart solution combining the sensor cell and a loaded transmission delay line is proposed. The length of the transmission delay line attributes unique identifier to the EM sensor cell. As it will be shown, the measured Beat signal Level spectrum, obtained by using an FMCW Radar reader, is composed of a two parts: one part related to the structural mode (which gives information about the antenna position) and a second part composed of the antenna mode (which gives us information dealing with the sensor measured value and the sensor identification in case of multiple sensor configuration). [C2872]

### "LNA and mixer for 122 GHz receiver in SiGe technology"

The paper presents 122 GHz receiver circuits including a low-noise-amplifier (LNA) and a mixer fabricated in SiGe BiCMOS technology. The design takes advantage of a novel transmission line structure with thick metal ground-shield on top of the MMIC. The LNA utilizes a two-stage cascode topology and the mixer is a Gilbert cell with additional current injection in the RF-path. Measurements of the receiver frontend show a gain of 12 dB and a noise figure below 13 dB at 121-129 GHz. The power consumption is 165 mW from a 3.5 Volt supply. The receiver frontend is intended for the use in ISM-band radar and communication systems, wide-band communication systems and in radar imaging systems. [C2873]

### "Design and development of a millimetre-wave novel passive ultrasensitive temperature transducer for remote sensing and identification"

The millimetre-wave passive temperature transducer consists of micro bimorph cantilevers (Au-Silicon) and split ring resonators, operating around 30 GHz. The temperature change causes a deflection on the bimorph cantilevers, thus results in a shift of resonant frequencies of the split ring structure. The design achieves sensitivity of 2.62 GHz/ $\mu\text{m}$  in terms of frequency shift response to cantilever deflection, corresponding to a sensitivity of 498 MHz/ $^{\circ}\text{C}$ , three order of magnitude higher than existing sensors. In terms of deflection versus temperature, the material choices for the bimorph cantilevers can be varied and adapted to different applications including those operating in harsh environments. To demonstrate proof-of-concept, a scaled prototype operating around 3 GHz is presented with Radar Cross Section measurements for remote identification. [C2874]

### "79GHz BiCMOS single-ended and differential power amplifiers"

This paper presents the performance of 79GHz power amplifiers (PAs) for automotive short range radar (SRR) application. A single-ended four stage common emitter circuit topology and a differential PA with integrated baluns are fabricated using 0.13 $\mu\text{m}$  SiGe BiCMOS process. The design and the measured results of the monolithic integrated low-voltage PAs are reported. The 79GHz differential PA, which the design is based on the single-ended PA, delivers 18dBm of maximum output power and 13.5dBm output power at 1dB compression (P1dB). The differential circuit achieves 21.5dB gain and shows 8.2% of power added efficiency (PAE) from a 1.8V supply voltage at 79 GHz. The power amplifier was fully integrated including matching elements, bias circuit and very small baluns. The chip occupies an area of 0.46mm<sup>2</sup> and 0.7mm<sup>2</sup> for the single-ended and differential configuration respectively. [C2875]

### "SAR computation in a real-sized car: Multi-exposure scenarios"

In this study, investigations have been carried out into the variation of whole-body averaged SAR values for 4 humans (one driver + three passengers) inside a realistic real-sized car. Transmitting devices used in the simulations had multiple frequencies making it a multi-exposure environment. These devices (e.g. Bluetooth, Universal Mobile Telecommunications System (UMTS) and WiMax) use differing operating frequencies and can be used in semi-echoic environments such as cars, trains, planes, etc. Results showed that the whole-body averaged SAR is below exposure limits provided by international standards and guidelines when there is 1 of each transmitter present. The results also show the whole-body averaged SAR when 2 active transmitters are simultaneously in use. Computed values are shown to be within the ICNIRP recommended limits. [C2876]

### "X-band cavity-backed slot antennas and coupled oscillator systems"

In this paper, substrate integrated waveguide (SIW) cavity-backed antennas and coupled oscillator systems are proposed. The cavity-backed structure permits to overcome potential problems such as heat dissipation and unwanted surface wave modes in large array implementations, and may provide better phase noise performances. Moreover, it provides a design parameter to control coupling among the oscillator elements. Full-wave FEM-based and harmonic balance (HB) analyses are used to design passive antennas and active antenna oscillators, whose frequency responses have been evaluated for different values of certain geometrical parameters. Based on the results obtained, different configurations of two-element coupled oscillator antenna systems have been proposed. Compact, single substrate prototypes are presented. These low cost implementations could be useful in radar and communication applications. [C2877]

#### "Information-theoretic algorithm for waveform optimization within ultra wideband cognitive radar network"

A novel information-theoretic approach for designing the excitation ultra wideband (UWB) waveforms within a cognitive radar network is developed. This method utilizes the mutual information (MI) between subsequent radar returns to extract desired information from the radar scene. With this approach, the radar system constantly learns about its surroundings and adopts its operational mode accordingly based upon the MI minimization criterion. Subsequently, the positioning algorithm makes use of this information about the radar scene to generate more accurate location estimates. Numerical results demonstrate an improvement in the probability of target detection even at low values of receive signal-to-noise ratio (SNR). The proposed algorithm also promises a better delay-Doppler resolution of the target, which can be analyzed through the radar ambiguity function (AF). Simulation data show an improvement in the target discrimination ability in the presence of noise and clutter. [C2878]

#### "50W X-Band GaN MMIC HPA: Effective power capability and transient thermal analysis"

This paper reports the performance of a two-stage X-Band MMIC GaN HPA designed for radar applications. At 20V drain voltage bias and 3dB compression point the HPA delivers more than 20W of pulsed RF power with a PAE of 35% over the 8-10.5GHz frequency range, whereas at  $V_{ds}=35V$  the MMIC provides more than 50W and 30% of PAE, with a peak power value of 58W at 9 GHz. In order to evaluate the effective HPA power capability in a real system environment and the related thermal management issues, the HPA transient thermal response for pulsed bias conditions has been investigated by means of IR thermo-camera measurements. [C2879]

#### "Integrated X-band FMCW front-end in SiGe BiCMOS"

An integrated X-band FMCW front-end is reported. The front-end unites the core functionality of an FMCW transmitter and receiver in a 0.25  $\mu m$  SiGe BiCMOS process. The chip integrates a PLL for the carrier generation, and single-side band and image-reject mixers for up- and down-conversion of the waveform. The front-end has been designed to co-operate with COTS integrated direct digital synthesizers and ADCs. The measurements show an output power of 0 dBm, P1dB at the receiver input of -11 dBm and a side band suppression of the mixer in the transmit chain of >40 dBc. The MMIC measures 1.8x1.5 mm<sup>2</sup>. This integrated front-end paves the path for future planar 2D integration of FMCW phased-array radars at X-band. [C2880]

#### "Comparative study of 2.4 GHz and 10 GHz vital signal sensing Doppler radars"

Performance and implementation complexity between 2.4 GHz radar system with homodyne and 10 GHz radar system with super-heterodyne are compared and discussed. In particular, recently proposed architectures are examined, which are implemented by identical PLL and VCO. Both the operation of two different architectures and the superior performance of these radar systems can be understood by observing what level of signal is received based on same signal conditions. 10 GHz approach yields better performance in terms of RCS and antenna gain, but at the cost of increased implementation complexity. [C2881]

#### "G-band low noise amplifier and oscillator for synthetic aperture applications"

This paper presents the results of G-Band Monolithic Microwave Integrated Circuits (MMIC) for passive imaging applications. The studied system is a Y-shaped interferometer. This kind of system provides both high resolution and a compact system. MMIC were made using a 70 nm GaAs metamorphic High Electron Mobility Transistor process from OMMIC (France). A Low-Noise Amplifier performances are presented, measurement results provide a noise figure of 5 dB with a gain of 20 dB on 10 GHz bandwidth around 140 GHz. The second circuit is an oscillator, measurement results give an oscillation frequency close to 146 GHz. [C2882]

#### "T/R-module technologies today and future trends"

After many years of development the active electronically scanned array (AESA) radar technology has reached a mature technology level. Many of today's and future radar systems will be equipped with the ASEA technology. T/R-modules are key elements in active phased array antennas for radar and electronic warfare applications. Meanwhile T/R-modules using GaAs MMICs are in mass production with high quantities. Top priority is on continuous improvement of yield figures by optimizing the spread of key performance parameters to come down with cost. To fulfill future demands on power, bandwidth, robustness, weight, multifunctional sensor capability, and overall sensor cost, new emerging semiconductor and packaging technologies have to be implemented for the next generation T/R-modules. Using GaN MMICs as HPAs and also as robust LNAs is a promising approach. Higher integration at the amplitude and phase setting section of the T/R-module is realized with GaAs core chips or even with SiGe multifunction chips. With increasing digital signal processing capability the digital beam forming will get more importance with a high impact on the T/R-modules. For lower production costs but also for sensor integration new packaging concepts are necessary. This includes the transition towards organic packages and using low cost surface-mount soldering technology. [C2883]

#### "Ramp response radar imaging: Analysis of frequency parameters"

Low frequency imaging in radar domain can have applications for stealthy or buried targets. Transient scattering response from a ramp waveform is related to the profile function of the target, namely its transverse cross-sectional area along the line-of-sight, and it thus provides information about the target size, orientation and geometrical shape. Indeed, such profile functions can be used for generating a 3-dimensional image of the target shape. However the required frequency band is very large and may involve difficulties for experiments as well as simulations. That is why, we propose to study the effect of these frequency parameters on targets profile functions and, consequently, on their reconstructed shape. [C2884]

#### "Comparison of target detection schemes in Doppler radar with PSK signals"

The aim of this article is to test the effectiveness of the known CFAR processors in order to detect moving targets in the frequency domain of real records. The purpose is to be chosen optimal CFAR detector for moving target detection. The data are obtained by portable, surveillance, Frequency Modulated Continuous Wave (FMCW) radar with Low probability of Intercept (LPI). In the paper are studied and compared CA, OS, SO, GO CFAR processors. [C2885]

#### "Digital signal processing applied to radar sensors operated in active defense systems"

The active defense (AD) is deemed a very promising way how to protect military vehicles, especially in contemporary fight against terrorism in the Third world countries. Cheap and easily accessible hand-held cumulative missiles (e.g. RPG-7) are able to penetrate up to 300 mm of the hard-hardness armour (HHA). Thus light transport military vehicles equipped typically with less than 10 mm thick armours, used frequently e.g. in Afghanistan are very vulnerable. The AD systems are based on radar sensors that detect approaching missiles and activate a suitable counter-measure able to destroy the threatening missile. The article describes the microwave curtain, which is one of the radar sensors applicable in AD systems, and signal-processing methods used for generation of ignition signals from its output signals. Practical results obtained at army shooting range are also presented. [C2886]

#### "Interferometric quadrature down-converter for 77 GHz automotive radar: Modeling and analysis"

This paper describes a millimeter wave quadrature down-converter module based on the interferometric principle. The computer model of the six-port interferometer is implemented using S-parameter measurements of a 90° hybrid coupler fabricated on thin alumina substrate. This model is validated by full two-port measurements of the six-port. Down-converter error vector modulation results are analyzed using an envelope simulation. The proposed architecture is suitable for low-cost, high-performance, reconfigurable millimeter wave automotive radar and communication front-ends. [C2887]

#### "Optimal sensor placement for multi-bistatic ISAR imaging"

Inverse Synthetic Aperture Radar (ISAR) images are typically used for target recognition and identification purposes. The target projection on the ISAR image plane depends on the target's own motions and on the relative position of target and radar. Since targets of interest are often non-cooperative, the first condition is not under the radar's control. Nevertheless, the relative radar-target position can be somehow controlled or predicted in some cases. Moreover, the use of multiple receivers enhances the likelihood that a desired radar-target position occurs during radar measurements. In this paper, the theoretical aspects of optimal sensor positioning for obtaining desired ISAR image projections are detailed. A mathematical tool will be presented that is able to predict the optimal sensor positions for maximising the probability of obtaining a desired ISAR image. Real data

will be used that demonstrate the effectiveness of the proposed tool. [C2888]

### "MIMO radars. What are they?"

Two classes of MIMO radars are briefly considered. MIMO radars with colocated antennas and coded signals represent a new and prospective concept. MIMO Radars with widely separated antennas ("Statistical MIMO radars") are a particular case of well-known Multisite (Multistatic) radar systems. Most results presented by the authors of "Statistical MIMO radars" were obtained under much more general conditions and published many years ago. Besides, ignoring some specific features of radar by the authors of "Statistical MIMO radars" has led to serious errors. [C2889]

### "Knowledge assistance for ground target tracking and resource management"

Tracking slow moving ground targets from airborne phased array radar is a challenging task. Some of the major issues are heading accuracy of slow moving target and radar resource management in clutter regions. In this paper, we propose a novel tracking framework using digital map and clutter knowledge bases to efficiently track the ground moving target using airborne phased array radar. The proposed technique uses offline processed digital map for fast retrieval of road parameters. Also, the proposed radar data processor provides feedback to populate and update the clutter knowledge-base. A fast yet robust method is employed for ground mapping of targets and to detect map features such as road junctions. Experimental results show (i) the robustness of the map knowledge assisted tracking approach when target moves along different kinds of path (i.e. on/off the road) (ii) better heading accuracies achieved by knowledge assistance and (iii) radar resource management in clutter region with knowledge-base. [C2890]

### "Study on velocity estimation of MCPC signal in wideband radar"

This paper presents a novel scheme for velocity estimation in wideband Multi-Carrier Phase-Coded (MCPC) radar, which has drawn considerable attention recently as a new generation of radar. Conventional narrowband Doppler processing preserves the phase relationship of the received pulses, thus not only increases the Signal-to-Noise Ratio (SNR), but also obtains reliable extraction of the Doppler parameters. However, the rangewalk of moving target due to the wide bandwidth makes things difficult. Additionally, it is a question of interest to researchers that is resolving velocity ambiguity within a single burst. Based on separated processing of subcarriers in MCPC echo signals, we can estimate the radial velocity of the target without ambiguity by Least Squared (LS) algorithm over the linearity curve of Doppler spectrum. The simulation results verify that this scheme can be applied to the fast-moving target efficiently. [C2891]

### "Book of abstracts"

{no data available} [C2892]

### "EuRAD 2010 abstract cards"

{no data available} [C2893]

### "Radar polarimetry for security applications"

We analyse micro-Doppler techniques and the improved performance that fully polarimetric radar techniques can add. We perform fully polarimetric measurements of the varying micro-Doppler signatures of humans as a function of elevation angle and azimuthal angle in order to try to optimize this type of system for the detection of arm motion, especially for the determination of whether someone is loaded. We determine that polarimetric measurements can isolate and highlight the arm motion for a classification as loaded or unloaded. Second, the azimuthal angle of the motion is a critical parameter to consider in ground-based systems. For choke-point observations where the direction of motion is more controlled, polarimetric radar has the potential to determine who is not loaded inappropriately and who should be checked. [C2894]

### "EuRAD 2010 detailed author index"

{no data available} [C2895]

### "Target localization methods for frequency-only MIMO radar"

When the time resolution of the signals is not so good, we can't rely on the time of arrival (TOA) information. On the other hand, if the frequency resolution of the signals is good, than frequency of arrival (FOA) informations

will be more reliable. Localization of a moving, non-maneuvering target is possible by using Doppler-shift measurements in MIMO radar systems. A new method for target localization in frequency-only MIMO radar is proposed and it is compared with previous method. These methods use only received frequencies, and all of other unknown quantities can be written by using locations of the target, the receivers and the transmitters. If the received frequencies are known only, desired area can be searched grid by grid for all possible (x, y) coordinates to find the position of the target in 2D space. [C2896]

#### "Digital antenna unit for DOA analysis in ESM systems"

In this paper, design and characterization of a novel "Direction Finding Antenna" unit (D/F DAU) are presented. The unit has been designed in order to localize electromagnetic emitters with precision direction finding capabilities. The Antenna is employed in the ELT avionics and naval modern ESM sensing system and utilizes an amplitude direction finding scheme. The main characteristic the D/F DAU is the ability to cover the signal pulses visibility in presence of simultaneous CWs emitters. An evidence of the used techniques, electromagnetic simulations, three dimensional outlines, measurements and obtained performances are explained. A paragraph of the article is focused to describe the characteristic of the Antenna to cover the signal pulses visibility in presence of simultaneous CWs emitters. [C2897]

#### "The end of indexes"

{no data available} [C2898]

#### "Millimetre wave radar imaging of mining vehicles"

This paper considers some of the complexities in regard to generating 2D and 3D radar images of mining infrastructure. It examines issues with range interpolation in multi scatterer environments and a method of modelling radar returns from vehicles. [C2899]

#### "Radar and Electronic Warfare cooperation aboard a single or multiple cooperative platforms"

Up to now, combat aircrafts are fitted with Fire Control Radar (FCR), Electronic Warfare System (EWS), and radio links. Each of these systems is dedicated to a particular task and the cooperation is reduced to a minimal exchange of information between them, so far. Major system performance enhancements are to be expected from close co-operations to each other sensors. The future co-operations can be ordered in four stages. The three first ones lead progressively to a common sensor including radar and EW functions. The last one is the deployment, on a given platform, of these common multifunctions sensors on a network basis. Another focus is the cooperation between platforms. Depending on the cooperative application, low, medium or high data rates will be needed. A typical example required by such co-operations is the implementation of "ad hoc" data links using the FCR or the EWS. This kind of co-operations does not need to add specific antennas or other R.F. devices. [C2900]

#### "Non-quasi-static modeling of the intrinsic Y22 for GaN, Si, and GaAs mm-wave FET technologies"

The extraction of accurate transistor models is essential for a reliable and efficient design of transmit/receive modules, which in turn is a keystone for the development of active electronically scanned array radars. The present paper is aimed at analysing the implementation of non-quasi-static effects for advanced millimeter-wave FET models. The non-quasi-static phenomena can be neglected at few GHz but their contributions become more and more dominant by increasing the operating frequencies. In particular, this study is focused on the investigation of the non-quasi-static effects for modeling the intrinsic short circuit output admittance for FETs based on gallium nitride, silicon, and gallium arsenide technologies. Different model solutions are carefully compared and analysed in detail. [C2901]

#### "Estimation of efficiency of a tree structured hierarchical wavelet representation of synthetic database applied to Non-Cooperative Target Recognition"

In this paper, problem of efficient representation of large database of target radar cross section is investigated in order to minimize memory requirements and recognition search time, using a tree structured hierarchical wavelet representation. Synthetic RCS of large aircrafts, in the HF-VHF bands, are used as experimental data. Hierarchical trees are built using wavelet multiresolution representation and K-means clustering algorithm. Criteria used to define these hierarchical trees are described and the obtained performances are presented. [C2902]

### "Dual frequency & dual- linear polarization integrated antenna array for application in Synthetic Aperture Radar"

This paper presents the design and realization of a dual frequency antenna array for application in Synthetic Aperture Radar. The array consists of 64 C-band elements interleaved with 4 L-band elements incorporated with feeding network in one integrated, multilayer, LTCC compatible structure. The Antenna has been designed to operate with dual-linear polarization in both frequency bands. The achieved bandwidths are 100 MHz in L-band and 400 MHz in C-band. Several techniques for suppressing orthogonal polarization has been implemented to achieve very low cross-polarization coefficient in both frequency bands. The beam forming network has been designed to provide modified cosec<sup>2</sup> radiation pattern suitable for radar applications. [C2903]

### "Foreign object debris detection using a 78 GHz sensor with cosec antenna"

This paper presents the results of FOD measurements conducted using a broadband 78 GHz radar sensor. Previous studies with a short-range setup up to 30 m showed promising results. However, to meet the requirements of the intended application, the range has to be increased significantly. As for all radar systems, the range can be extended by increasing the transmitted power and/or the antenna gain. In this work two different folded reflectarray antennas with a cosec-shaped pattern have been used to improve the system performance and range. Together with a CFAR (constant false alarm rate) algorithm and a moving target indication advances could be achieved compared to the previous setup. [C2904]

### "Design of two flare UWB antenna dedicated to the research of alive buried victims"

This document presents the antenna design for the detection of alive victims buried under thick layers of rubble. The antenna is used with UWB Radar techniques in order to locate buried alive victims. The detection is based on the signature of alive persons by using Doppler analysis of movements and respiration. Detecting victims in this environment is very difficult due to the large dynamic range of signal levels. In fact, the reflected signal caused by the buried alive victim is very low behind other reflected or disturbing signals such as mobile phones, vegetation movements, water, rescuers... A two flares UWB antenna, light weight and easy transportable has been specially design for the research of buried victims beneath building rubble. This paper focuses on antenna design, simulation and measurement. These measurements have been made by IETR and CEA. The experimental results show a good comparison between measurements and simulations. [C2905]

### "A high resolution 2D omnidirectional synthetic aperture radar scanner at K band"

In this paper a K-band 360° 2D imaging radar utilizing a synthetic aperture scanning principle is introduced. A small omnidirectional antenna is mounted on a rotating platform to create a circular synthetic aperture. Based on a broadband holographic reconstruction principle a high resolution 360° 2D image is calculated after each turn of the platform. The size of the synthetic aperture and thus the lateral resolution of the imaging system are determined by the diameter of the resulting circular antenna trajectory. In contrast to common radar scanner-concepts that utilize highly directional and thus bulky antennas, the proposed scanner concept has the advantage that it uses a small and lightweight omnidirectional antenna. This results in a much more compact radar system with notably relaxed requirements for the scanning mechanics. In addition it will be shown that the use of an omnidirectional antenna allows for very simple options to transfer energy to the radar on the rotation platform. The performance of the proposed SAR radar scanning method is illustrated with a 24 GHz FMCW radar sensor system. [C2906]

### "Loss mechanisms of folded reflectarray antennas"

Folded reflectarray antennas can provide a good solution for millimeter-wave systems requiring compact, low-cost antennas, e.g. in automotive applications. This contribution investigates different approaches of such antennas with rectangular and composite reflecting elements. Special emphasis is put on gain and antenna loss mechanisms, including increased beam-width and sidelobe level as well as metallization losses. [C2907]

### "Comparison of analog IFM and digital frequency measurement receivers for electronic warfare"

Measurement of the incoming signal's frequency is one of the most important topics of an EW receiving system. The continuous performance and reliability improvement of Analog to Digital Converters and FPGA pushed the operation frequency of these devices up to tens of GHz, thus making possible the design of quasi-full digital wideband EW receiving systems. In this paper a comparison between a traditional analog microwave IFM receiver and a modern digital frequency measurement receiver is carried out, dealing with architectural, technological and performance differences, enhancement capabilities and lifetime. [C2908]

### "Airport radar monitoring of wake vortex in all weather conditions"

To assess maturity and capability of X-band radars to monitor wake roll-ups in all weather conditions, Radar data were collected on airports, near runway at ORLY airport and just under its ILS Interception Area. Additional trials took place on Paris-CDG Airport to benchmark Lidar & Radar Technologies. Continuous Detection, characterization and profiling capabilities of wake vortices, up to a range of 2000 m, have been proved in clear air and rainy weather. Recorded data have been correlated with electromagnetic and fluid mechanical models of Wake Turbulences for better and more accurate understanding of roll-ups radar cross section (RCS) and Doppler signature. X-band Radar has been proved to be a full-fledged alternative, which can make a significant contribution to a wake vortex alert system, but to achieve as much reliability as possible, collaborative Electro-optical & electromagnetic sensors solution is envisaged encapsulated in a Wake Vortex Advisory System. These sensors could be used to permanently monitor wake turbulence on runways. [C2909]

### "A multifunctional 60-GHz system for automotive applications with communication and positioning abilities based on time reversal"

This paper reports a multi-functional 60-GHz system which performs promising performances for short-range automotive applications such as short range RADAR with communication abilities. Experimental results validate the ability of the topology to transmit high speed data in the millimetre-wave (MMW) frequency band using Pulse Position Modulation (PPM). Using the same front-end, a positioning functionality is simultaneously assumed successfully in a Time Difference Of Arrival (TDOA) configuration. Furthermore, the Time Reversal (TR) technique is introduced and its impact on the location accuracy is presented and validated by experimental results. [C2910]

### "Angle of arrival detection using Retrodirective RADAR"

In this paper, experimental results are shown for angle of arrival extraction using an analogue Retrodirective RADAR using PLL to an accuracy of  $2.5^\circ$ . Angle of arrival results from the Retrodirective RADAR were extracted from the low frequency IF phase of the PLL based phase conjugator. The target position can then be determined virtually instantaneously. Therefore the system does not require any complicated DSP post processing, so is able to operate with low power and relatively simple circuitry. This system is ideally suited to real time acquisition of fast moving projectiles. [C2911]

### "Dual-sided phase conjugating surface techniques for imaging"

We describe the principle of operation and study the imaging capabilities of a dual sided phase conjugating lens operating as an imaging sensor in free space or in an environment where significant multipath or scattering may be present. The image formation is based on the wavefront reversal properties of the phase conjugating array. By the means of numerical simulation we show that the characteristic resolution of a single dielectric target in free space is about one wavelength,  $\lambda$ , across the range and  $3-4\lambda$  along the range for CW illumination and about one centre-wavelength  $\lambda_0$  when the target is illuminated with a Gaussian packet. For multiple targets in free space resolution across and along the range is  $\sim 2\lambda_0$  when illuminated by a Gaussian packet. It is shown that a weakly scattering object can only be detected behind a lossy dielectric wall using CW or UWB phase conjugation techniques when the backscattered field from the wall is eliminated. A procedure for achieving this is proposed. Numerical simulations for through-the-wall imaging using the phase conjugating lens technique with wall backscatter elimination demonstrates the possibility for small target high-resolution imaging. [C2912]

### "Riemannian median, geometry of covariance matrices and radar target detection"

We develop a new geometric approach for radar target detection which is based on the notion of Riemannian median and the information geometry of covariance matrices. First of all, we give the definition of Riemannian median and a simple algorithm to compute it. After that, the explicit expressions of reflection coefficients parametrization of covariance matrices are obtained, with which the Riemannian metric on the manifold of covariance matrices has a very simple form. The explicit expressions of geodesics in the manifold are also obtained in order to facilitate the computation of the Riemannian median of covariance matrices. Finally, we give some simulation examples to illustrate the performance of this new method. [C2913]

### "Design challenges for millimeter wave active imaging systems"

Due to the atmospheric absorption in W-band, especially the spectrum around 94 GHz has been the frequency of choice for radar applications in reconnaissance and metrology, but more recently also for indoor security applications. However, for indoor security applications the propagation environment and scale of the application is quite different as compared to the long-range military and scientific applications. In this paper we report on the

work performed at the research group ESAT-TELEMIC on modelling and designing indoor millimeter wave imaging systems that employ coherent multi-parametric illumination in a "flash"-like configuration. We discuss trade-offs between certain system parameters and present two examples of multi-parameter imaging. We show that a 2.5D simulator is a good compromise between computational cost and ability to analyse interference effects such as speckle. We also elaborate on challenges in terms of hardware implementation, and demonstrate experimentally the potential of using printed antennas for millimeter wave security applications. [C2914]

#### "Through the wall MIMO radar detection with stepped frequency waveforms"

In this paper, we present through the wall (TTW) radar detection simulations with an emerging radar architecture which is the multiple-input multiple-output (MIMO) radar. The urban environment, especially in TTW detection, is very tough for radar detection. With the aim of improving the detection performances, we use several spaced antennas in transmission which gives a spatial diversity leading to different points of view of the scene. So as to keep diversity we choose linearly independent waveforms and more particularly we utilize the hyperbolic frequency hop codes. We first begin by introduce the problems and applications of TTW detection. Then we will present the geometric configuration of the scene and the wall attenuation and target modeling. After what, we will expose the waveforms used in transmission and the processing to perform detection. We finish with some preliminary results and conclude about this work. [C2915]

#### "New coastal radar performances: Evolution or revolution"

Based on the legacy of marine radars, historical coastal surveillance sensors were based on the cheap magnetron-slotted waveguide antenna combination and were addressing sea-lane traffic control missions. New regulations in the marine world, such as the SOLAS convention, and increasing requirements for very small objects tracking, put new requirements on radar performance. It triggered an evolution process that is transforming the coastal radar design: From a rough and simple magnetron design, it is now moving into solid state and multi-mission units. This paper addresses the key elements triggering this evolution and puts in perspective the latest developments in this fastly moving field. It addresses a key question: Are we witnessing a market driven revolution in the coastal radar domain? [C2916]

#### "Multistatic, MIMO and networked radar: The future of radar sensors?"

A review is presented of work on multistatic, MIMO and networked radar, explaining the current high degree of interest in these subjects. The enhancement of target signatures in the forward scatter geometry is explained, and some of the principles of Passive Bistatic Radar. The challenge here is to identify applications which offer a clear advantage over conventional radar approaches. Finally, some newer, longer term ideas on networked radar as an intelligent, adaptive distributed sensor system are presented and discussed. [C2917]

#### "Advanced clouds tracking for airborne weather radar & ground primary surveillance radar"

A method for modeling and tracking convective clouds within radar images is presented. An object modeling approach is used, based on the extraction of either morphological or grayscale skeletons from 2-dimensionnal cross-section of 3-dimensional radar data. Grayscale skeletons are appropriate shape descriptors for non-rigid and heterogeneous objects, in which gray-level local maxima correspond to regions of interest. The modeling scheme is enhanced by meta-data linked to some chosen points of the skeleton; this provides a good representation of the weather scene in terms of hazards for an aircraft. Skeletons are stored within a graph structure and tracked among successive pictures by means of relaxation labeling processes. The deduced advection field is used to now cast the clouds evolution. Satisfying results are obtained concerning advection forecasts. Convective activity forecasts are promising, even if they must be carefully interpreted. [C2918]

#### "Possibilities of oil slick detection on the sea surface using radar"

Possibilities of oil films detection on the sea surface and distinction them from natural marine slicks and look-alikes phenomena are discussed. [C2919]

#### "Study of different configurations of tapered-slot antenna arrays for detecting buried objects"

In this paper, results of comparative study of several designs of tapered-slot antennas for subsurface applications are presented. To this end, influence of mutual arrangement of the antennas in bi-static configuration and placed in the antenna arrays has been studied using both simulations and experiments. Major attention is paid to the behaviour of the transmitting-receiving antenna pair near the ground surface. It was found that displacement of the antennas in the array by about a half of the antenna opening suppresses unwanted lateral coupling while the resistive loading strengthens the field radiated by the antenna into the

medium. Antennas with the displacement of about 0.5 of the width of the opening exhibit weak coupling that can be fairly well subtracted. The tapered-slot antenna arrays had been fabricated and tested in a test site for the detection of low-contrasted objects like anti-personnel mines. [C2920]

#### **"MIRA-CLE X: A new imaging MIMO-radar for multi-purpose applications"**

The research field of MIMO radar offers a bunch of new opportunities for various applications. Imaging MIMO radars can be used as a significant supplement to usual SAR and phased array radars and can extend the common applications for radar. MIRA-CLE X is an X-band MIMO radar consisting of 16 transmit and 14 receive antennas. During signal processing, 224 virtual antenna elements are generated to enable 2D radar imaging. This paper presents the radar system, the signal processing approach as well as a detailed analysis of first imaging results. [C2921]

#### **"Characterization of underground objects in UWB GPR by range profiling of phase"**

In this work, a new phase-based data processing method for UWB subsurface radar is presented. The method utilizes extraction of the phase information related to the signal reflected from the particular depth inside the medium under test. This phase depends on dielectric properties of reflecting targets and thus can be used for their discrimination. Both amplitude and phase data is combined further in common GPR image where brightness is related to the amplitude of reflection and the phase profile is represented by color. The phase-extraction algorithm does not employ heavy computations and therefore is well suited for practical applications. Advantages of the method as compared to other data processing methods are shown using simulated data. The method performance is demonstrated also in several experimental examples. [C2922]

#### **"Co-array weighting in minimum-redundancy arrays for radar image enhancement"**

The pronounced lobing of minimum-redundancy arrays-a class of thinned arrays-leads to image degradation in radar applications. Co-array weighting is investigated as a possible cure. Different distributions are considered. A comparative study of pattern degradation caused by random phase errors of the individual array elements is conducted. Multiple target detection-a critical aspect of nonlinear array processing-is addressed as well in this context. The potential of the proposed approach is critically assessed by simulation. The findings are confirmed by Ka-band radar experiments performed with a synthetic array. [C2923]

#### **"Experimental characterization of channel crosstalk in interleaved array antennas for FMCW radar"**

The inter-channel isolation of an FMCW radar with interleaved transmit-receive array antennas is, for the first time, characterized by measurements on an operative system. Theoretical predictions, based on full-wave simulations, are compared to computations from the measured antenna scattering parameters. In both cases, the received signals are re-combined by using ideal equi-phase and equi-amplitude power distribution networks. Two 1 to 32 Wilkinson power dividers are then fabricated and the radar inter-channel isolation is measured directly between the input (transmit) port and the output (receive) port of the system, recording a crosstalk of -34 dB. The effects of the system non-idealities on the antenna isolation are discussed. [C2924]

#### **"Target detection and positioning in correlated scattering using widely distributed MIMO radar"**

Multiple-input multiple-output (MIMO) radars use different sources of diversity to improve the performance of the radar. A MIMO radar in which angular diversity is achieved by using widely distributed antennas has been proposed to reduce the impact of the fluctuations of the target radar cross-section. This type of system is also known as the statistical MIMO radar. Typically, it has been assumed that the scattering amplitudes of the signals received by different antennas are either fully correlated or independent depending on the configuration. However, the antennas may see similar aspects of the target in some situations leading to correlation in the scattering. In this paper, we show how the correlation of the scattering can be exploited to improve the probability of detection and positioning. This is achieved by using a parametric model for the correlation of the scattering. We also investigate how the correlation can be used for estimating the direction of arrival with an uncalibrated MIMO radar system. [C2925]

#### **"New capabilities for PCL system: 3D measurement for receiver in multidonors configuration"**

For more than 15 years, the interest for PCL (Passive Coherent Location) system has been growing. It began with the analog waveforms like TV and FM; now the interest for digital waveform has increased and especially for DVB-T (Digital Video Broadcasting-Terrestrial). Despite all these interesting progress, some new requirements mentioned by several potential users of such PCL systems have appeared like an altitude estimation and especially for low altitude targets. Some works have begun in this area especially for tracking

consideration. In order to illustrate the PCL capabilities, we'll present some elevation measurements using a 2D array with DVB transmitters in a SFN (Single Frequency Network) configuration. The corresponding 3D tracking results will also be presented. These measurements will be analysed according to the "GPS" reference plots. In a second part, after a short description of the main differences between the three main kinds of illuminators (FM, DAB, DVBT), we'll consider the complementarities of these potential donors in order to outline some elementary rules for choosing the most appropriate waveforms according to our final requirements. [C2926]

#### "Radar probing of steep gravity waves. wave tank experiment"

Results of wave tank experiment on radar probing of steep gravity waves are discussed. It was shown that Ka-radar backscatter signal from cm -dm steep surface waves is connected with gentle breaking and parasitic capillary ripples generation; backscatter signal from dm-m surface waves is connected with strong breaking and free ripples generation. [C2927]

#### "An extended NLCS algorithm for Bistatic fixed-receiver SAR imaging"

Imaging of Bistatic fixed-receiver SAR which is azimuth-dependent, is rather different from monostatic SAR, because the relative position between the transmitter and the receiver is slow-time dependent. In this paper, the Range Cell Migration (RCM) characteristics of Bistatic fixed-receiver SAR are analyzed firstly. Then the nonlinear chirp scaling (NLCS) algorithm is presented and the residual phases caused by the NLCS processing are analysed as well. An extended NLCS algorithm based on sub-aperture approach is proposed to handle the case in which the residual phases cannot be ignored for Bistatic fixed-receiver SAR. Finally, a simulation with typical parameters is performed to verify the correctness of the extended NLCS algorithm. [C2928]

#### "SAR-MTI improvement using a-priori knowledge of the road network"

This paper focuses on the SAR-MTI processor improvement by using a priori knowledge of the road networks. The proposed technique is fit for civil applications where the traffic obeys to certain rules, such as being bound to a road with a predefined direction and complying, in average, with a velocity range. This possibility is demonstrated using a mixture of simulated and real data. [C2929]

#### "Accurate time-domain modelling of MEMS antennas for wireless telemetry systems"

A singularity-expansion-method-based technique for the accurate time-domain modelling of reconfigurable MEMS antennas for wireless telemetry applications is presented. Closed-form expressions of the radiated electromagnetic field in time domain are derived in terms of the newly introduced incomplete spherical Bessel functions depending on the complex frequencies of the natural resonant processes occurring in the antenna. [C2930]

#### "3-D calibration of InISAR imaging under a condition of phase ambiguity"

Interferometric inverse synthetic aperture radar (InISAR) imaging is a recently developed powerful radar three-dimensional (3-D) imaging technique, which combines the interferometric technique and the inverse synthetic aperture radar (ISAR). The true 3-D reconstruction of target scattering centers is obtained by interferometric phase processing of different two-dimensional (2-D) ISAR images from the various image planes. However, phase ambiguity is an involved problem in the interferometric process. This paper begins with the discussion on the InISAR imaging principle, followed by the description of three-dimensional calibration technique. By linear fitting phase differences between adjacent scattering centers of the same slant-range cell, the traditional phase ambiguity can be overcome. In the end, simulation results are provided to demonstrate the behavior of the proposed algorithm. [C2931]

#### "Millimeter-wave radar for civil applications"

This contribution gives an overview of civil state-of-the-art and also some novel applications of radar sensors in the millimeter-wave frequency range, together with some general principles and a number of examples of such radar systems. [C2932]

## "Welcome to EuRAD 2010"

I am very pleased to welcome you on the 7th European Radar Conference which is held this year in Paris as part of the European Microwave Week (EuMW). Every year, since the beginning of this conference seven years ago, the interest in the Radar activities grown. This is due mainly to the quality of the papers, workshops and focused sessions which have been proposed during the past conferences. This level of quality has been achieved thanks to the high class research performed in advanced, either from university or from industry laboratories in the world and thanks also to the rigor of the Technical Committee which review and select the papers. The number of proposed contributions has continuously increased during the seven years and EuRAD is now established as one of the largest European and worldwide Radar events. EuRAD submission is now more than 15% of the whole EuMW which creates the necessity to increase the duration of this conference to two full days. [C2936]

## "EuMW2009 rome prizes"

## "Welcome from the president of the European Microwave Association"

It is a privilege to welcome you on behalf of the European Microwave Association (EuMA) to the 2010 European Microwave Week (EuMW) in Paris. EuMA is the organisation behind the Week, we are a non-profit international association based in Belgium, with the mission to promote microwaves in Europe and to foster networking between microwave scientists and engineers in Europe. And the European Microwave Week is the key event serving this purpose. [C2939]

## "Welcome to the 13th European Microwave Week 2010"

EuMW continues its series of successful events with the 13th European Microwave Week 2010 which will be held at the CNIT la Défense, Paris, France from 26 September to 1 October 2010. This conference series has continued to grow and is now the premier event in this field in Europe. This event gathers all the international microwave community around four themed conferences: -The 40th European Microwave Conference (EuMC)-The 5th European Microwave Integrated Circuits Conference (EuMIC)-The 7th European Radar Conference (EuRAD)-The 3rd European Wireless Technology Conference (EuWiT) [C2940]

## "Track-before-detect algorithms for bistatic sonars"

Track-before-detect (TBD) algorithms can improve track accuracy and follow low signal-to-noise ratio targets. A price paid for this increased performance is the high computational complexity of TBD implementations. In this work, we develop a new TBD approach capable of handling raw hydrophone data. In order to learn more about its performance and feasibility when applied to sonar, we use data from the sea trial PreDEMUS'06 with DEMUS sensor array of NATO Undersea Research Centre. As a first step, we introduce the sensor model for a bistatic sonar based on DEMUS receivers. Then, we formulate the TBD problem at hand as a binary hypothesis testing problem and derive a class of adaptive algorithms by using design procedures based upon the generalized likelihood ratio test. Remarkably, such detectors guarantee the constant false track acceptance rate property under the design assumptions with respect to the overall spectral properties of the noise. A preliminary performance analysis is presented. Finally, we discuss its potential to implement automatic track continuation and to prepare automatic classification for temporarily weak targets as these tasks are usually the challenges multistatic sonar systems have to overcome. [C2941]

## "Copyright page"

The following topics are dealt with: intelligent platform networks; adaptive learning algorithms; cognitive radio; spectrum sensing and management; signal estimation and tracking; Bayesian machine learning; cognitive radar

processing; waveform agile intelligent adaptive sensor signal processing; collaborative sensing techniques; learning theory and modelling; and game theoretic tools for cognitive radio. [C2942]

### "Vessel detection and classification: An integrated maritime surveillance system in the Tyrrhenian sea"

In recent years a number of organizations, both national and international, have put significant efforts in developing knowledge-based integrated maritime surveillance (IMS) systems. The final aim is to have a clear picture of the position, classification, identification and movement of cooperative and non-cooperative targets entering and leaving the 200 nautical miles limit of the Exclusive Economic Zone (EEZ). Each sensor (i.e. satellite-based, ground-based, shipborne or airborne) has its own task and, in such a context, high frequency (HF) surface wave (SW) radars are inexpensive tools for long range early warning applications in open waters. They allow maximizing the effectiveness in dealing with fisheries protection, drug interdiction, illegal immigration, terrorist threats, search and rescue tasks. This paper focuses on the possibility of combining automatic identification system (AIS) data with HFSWR data for vessel detection and classification purposes. Three algorithms for target detection in compound Gaussian HF sea clutter are presented and their performance evaluated. The combined use of AIS plots provided by cooperative targets can allow the operator to discriminate non-cooperative targets and possible threats. The concurrent exploitation of AIS and HFSWR data is presented and discussed by means of real data recorded during the NURC experiment in the northern Tyrrhenian Sea in May 2009. [C2943]

### "Metacognition in radar"

An airborne ground looking radar sensor's performance may be enhanced by selecting algorithms adaptively as the environment changes. A short description of an airborne intelligent radar system (AIRS) is presented with an in-depth description of the knowledge based filter and detection portions. A second level of artificial intelligence (AI) processing is presented that monitors, tests, and learns how to improve and control the first level. This approach is based upon metacognition. [C2944]

### "Millimeterwave radar network for foreign object detection"

Millimeterwave radar sensors are netted to cover a sufficient region of an airport and deliver as well information on position as classification of debris. To be able to miniaturize the antenna assembly, which is critical for the vicinity of a runway, the 220-GHz radar band is used. Use of this band also allows to achieve a wide signal bandwidth and consequently a high range resolution. [C2945]

### "The radar system and information flow"

The information flow through a radar system channel is studied for various component design choices including the radar measurement function, signature feature selection, and classifier decision rule. A simplified target scattering model is used to analyze the application of the information theoretical channel model. [C2946]

### "Adapting a MIMO/phased-array radar transmit beampattern to target location"

Proposed MIMO and hybrid MIMO/phased array (HMPAR) radar systems have the potential for tremendous flexibility in the choice of the transmit beampattern, through the selection of multiple transmitted signals. This paper considers how one might exploit that flexibility in light of prior information or uncertainty in target spatial location, for parameter estimation or tracking applications. We first consider an idealized problem of distributing energy across multiple target sites given a prior probability distribution on those sites. It is shown that the optimal allocation of energy would be proportional to the square root of the prior probability. Second, we propose a method to approximate this optimal distribution of energy using a MIMO radar or HMPAR radar system. The method chooses signals that realize an intrapulse beamspace scan over the region of interest, with a nonuniform distribution of scan points matched to the desired distribution of energy. [C2947]

### "Software defined RADAR a state of the art"

A software-defined radar is a versatile radar system, where most of the processing, like signal generation, filtering, up-and down conversion etc. is performed by a software. This paper presents a state of the art of software-defined radar technology. It describes the design concept of software-defined radars and the two possible implementations. A global assessment is presented, and the link with the Cognitive Radar is explained. [C2948]

### "Adaptive radar detection: A subspace identification approach"

We address adaptive detection of Swerling 2 pulse trains by an array of antennas. The disturbance is modeled in terms of a state space model and the ideas of subspace identification are used to come up with a GLRT-based detector. Such detector is compared by Monte Carlo simulation with a Kelly's detector derived assuming that returns are temporally uncorrelated (but spatially correlated) and that a proper set of secondary data is available. [C2949]

### "A unique calibration method testified by X-band polarimetric radar"

This paper explores a unique calibration method for polarimetric radar without requiring any calibration targets. The error of the polarimetric scattering matrix measurement is modeled as antenna distortion matrices and channel distortion matrices. These distortion matrices can be determined using a signal generator in anechoic chamber. The performance of the calibration method is analyzed by simulation. Its validity is verified through the experiment of an X-band polarimetric radar system. [C2950]

### "CFAR detector using GIS information"

In order to realize the constant false alarm ratio (CFAR) processing, the adaptive threshold should be used in radar signal detection. The threshold of the CFAR detector can be calculated using the clutter of range bins nearby the cell under test. In the real world, the clutter environments is always non homogeneous, which result in the performance degradation of the CFAR detector. In this paper, the CFAR detector using geographic information system (GIS) is proposed. With the knowledge of the clutter environment, the performance of the CFAR detector can be improved remarkably. The IPIX radar data are used to validate that the CFAR detector using GIS information is outperform the other conventional CFAR detectors. [C2951]

### "Radar waveform design for detection of weapons"

We present waveform design based on signature exploitation techniques for improved detection of weapons in urban sensing applications. We consider a single-antenna monostatic radar system. Under the assumption of exact knowledge of the target orientation and, hence, known impulse response, matched illumination approach is used for optimal target detection. For the case of unknown target orientation, we propose waveform design based on subspace decomposition of the target impulse response matrix corresponding to the various aspect angles. Numerical electromagnetic modeling is used to provide the impulse responses of an AK-47 assault rifle for various target aspect angles relative to the radar. Simulation results depict an improvement in the signal-to-noise-ratio (SNR) at the output of the matched filter receiver for both matched illumination and subspace waveforms as compared to a chirp waveform of the same duration and energy. [C2952]

### "Study on retrieval methods of soil water content in vegetation covering areas based on multi-source remote sensing data"

Fusion image of SAR (Radar-sat image) combined with visible spectrum remote sensing image (TM image) is used to extract soil and vegetation water content in arid oasis taking the delta oasis of Weigan and Kuqa rivers in Xinjiang as the study area. Based on the Normalized Difference Moisture Index extracted from homochromous visible spectrum remote sensing data, this thesis utilizes "water-cloud model" to wipe off vegetation influence from total backscattering coefficient of radar data and sets up the relationship between soil backscattering coefficient and soil moisture. The Result shows that in arid and semi-arid area where the main crops are cotton and corn, the combination of C- band HH polarization radar data with visible image performs well in the study of removing vegetation influence while retrieving soil water content in medium vegetated areas. [C2953]

### "Rapid waveform adaptation for nearly optimal detection in colored interference"

A cognitive radar can dynamically design its transmit waveform in response to changing environmental knowledge, which may be obtained a priori, estimated online, or both. We consider the detection of targets in wide-sense stationary additive colored Gaussian noise. Cognitive radar has been shown to provide potentially significant improvements for this problem. However, existing algorithms may be too computationally demanding for some scenarios. We present an approach that can be implemented in the most demanding scenarios. This approach trades optimality for reduced computational complexity by computing a large library of nearly optimal waveforms before operation, and retrieving them rapidly at runtime. [C2954]

### "Wind direction manifestation on HF ocean radar echoes"

A direct measure from the spectra of HF radar sea echoes is the ratio of energy in the dominant Bragg peaks. If

a single lobe is assumed for the directionality then two radar stations can be used to provide a closed solution for the direction of the lobe. In this work we examine the potential of using just one radar station to derive directional information about wind fields. It is shown that HF radar Bragg ratios are effective in providing timing and location information for features appearing on Mean Sea Level synoptic charts. [C2955]

#### **"Waves in the Southern Great Barrier Reef"**

A brief description of three different platforms (WAVEWATCH III, Acoustic Doppler Current Profiler mooring and HF ocean radar) with directional wave measurement capabilities is provided. Initial results of directional wave and wind patterns derived from observations within the southern Great Barrier Reef, Australia, show consistency with the WAVEWATCH III model. These early findings are promising for future wind-wave investigations and validation studies in this region. [C2956]

#### **"Can vertical mixing from turbulent kinetic energy mitigate coral bleaching? An application of high frequency ocean radar"**

Coral bleaching is an ecological response to stressful physical conditions observed to occur when strong insolation coupled with stratification of the water column leads to anomalous warming of the surface water. Stratification requires calm winds, the absence of waves, and an absence of currents: conditions which result in limited mixing of the water column and thus confine heat due to insolation at the ocean surface. There is a strong need to identify which of the physical parameters are more significant at any given time and, more importantly, to monitor the physical parameters in near realtime to serve as a tool for long-term planning and management for marine parks and coastal waters. This paper reviews the contribution that currents make to mixing in the water column through the dissipation of turbulent kinetic energy and takes a further step to evaluate the use of surface current data to provide an index of vertical mixing. In this work, when the surface current speed is greater than a critical value, the water column is found to be vertically mixed even in the absence of wind or waves. A phased array HF Ocean Radar deployed in the southern part of the Great Barrier Reef provides a map of surface currents with high spatial resolution (4km) every 10 minutes over the grid. These surface currents are used to predict vertical stratification and mixing which can then be used as an indication for conditions under which bleaching might occur. [C2957]

#### **"Time domain numerical simulation of microwave backscattering from sea surface for radar remote sensing"**

Time domain numerical simulation technique has been developed to understand microwave backscattering mechanisms and evaluate sea surface observation methods. Backscattering coefficients and Doppler spectra can be obtained by this simulation technique. Physical optics approximation is applied to calculate scattering electric fields. The validity of the simulation has been verified by comparing with the results of the experimental basin. The results indicate that the simulation technique is effective to calculate microwave backscattering from the water surface changing in time. As an application of the simulation, we have simulated microwave backscattering with a pulse Doppler radar to evaluate sea surface observation methods. Radar images of backscattering coefficient and Doppler velocity have been generated. The results of the simulation show that radar images of Doppler velocity are more effective than images of backscattering coefficient for sea surface observation. [C2958]

#### **"Rapid deployable HF RADAR for Norwegian emergency spill operations"**

The Norwegian company CodarNor A/S, with funding from the Norwegian Clean Seas Association for Operating Companies (NOFO) and from Innovation Norway through an industrial research and development contract, is developing a self-contained rapid deployment HF radar which can be deployed by helicopter or other means to remote and rugged locations along the Norwegian coast and operate autonomously, communicating surface current data in real time back to operators, the Norwegian Coastal Administration and drift modelers. Large-scale 2-D current maps collected from these rapid-deployable systems will be used to improve spill response efforts by blending data with drift model currents for improved drift predictions and cleanup vessel management. [C2959]

#### **"Towards the use of a team of USVs for civilian harbour protection: The problem of intercepting detected menaces"**

Protecting civilian harbours is a field which has received increasing interest after the attack of September 11th. Exploiting a team of Unmanned Surface Vehicles (USVs) for the protection of harbours is one of the areas under major investigation. Indeed the USVs could be used to perform patrolling around the crucial waterways or to investigate possible suspect vessels, increasing the effectiveness of the security system, while at the same time

decreasing the number of human beings directly exposed to threats. The coordination of such a team of USVs is the goal of an on-going joint research project, the Swarm Management Unit (SMU), between the authors' organization. This work presents the latest results of the SMU project, i.e. a menace interception system composed by the on-line selection of the best interceptor coupled with the off-line optimization of the positioning of the team of USVs. [C2960]

#### "Sea surface current mapping by Radar Doppler Current Profiler"

A Radar based method has been developed to measure surface currents directly. Applied techniques, results, capabilities and applications of this method will be discussed. [C2961]

#### "On the detection of marine mammals with ship-borne polarimetric microwave radar"

Collisions between ships and whales are not rare occurrences. Apart from constituting a major cause of death for whale species which frequent busy oceanic areas such as the North Atlantic, such collisions often result in damage to ships. Thus there is keen interest in finding reliable means of detection of whales at sufficient range to ensure successful collision avoidance. In this paper we present the results of experiments aimed at establishing the potential of polarimetric microwave radar to provide such a means. The key element in our approach is the construction of a polarimetric filter which enhances the contrast between the disturbed sea surface around the whale and the ambient sea. The results suggest that detection can be achieved under conditions where conventional uni-polar radars such as those normally found on merchant ships would fail. [C2962]

#### "X-Band radar derived sea surface elevation maps as input to ship motion forecasting"

Nautical X-Band radars used for navigation can also be used to determine spectral and individual wave properties. The sea surface reflects the incident radar beams and wave fronts become visible as stripe like pattern of high back scatter on the radar screen. When connected to a conventional nautical X-Band radar, the Wave Monitoring System WaMoS II exploits this imaging of waves to detect full directional wave spectra and to derive statistical sea state parameters as well as surface currents. WaMoS II is continuously improved with new features being developed. In particular, the sea surface elevation maps derived by WaMoS II allow to investigate and describe the spatial and temporal development of 3D ocean surface waves. The European Joint Industry Project 'On board Wave and Motion Estimator (OWME)' used this measurement technique to provide the wave information that is required to predict periods of quiescent vessel motions. A task that offers valuable support for various offshore operations like e.g. the tensioning of a tanker or the landing of a helicopter. This contribution gives an overview of the overall OWME system design showing first validation results, focusing on the method to derive wave trains using the WaMoS II system. [C2963]

#### "Waveform design with stopband and correlation constraints for cognitive radar"

One of the main objectives of cognitive radar is to adapt the spectrum of transmit waveforms to certain needs, such as avoiding reserved frequency bands or narrowband interferences. Besides spectral requirements, good correlation properties of the transmit waveforms are also desired in specific applications, such as range compression. Moreover, practical hardware constraints usually require the transmit waveforms be unimodular (i.e. only phase-modulated). In this paper, we propose a new algorithm named SCAN (stopband cyclic algorithm new) to design unimodular sequences with spectral power suppressed in arbitrary bands and with low correlation sidelobes as well. The SCAN algorithm, which starts from random initializations, can generate many sequences possessing similarly good properties. Furthermore, the SCAN algorithm is based on FFT (fast Fourier transform) operations and thus is computationally efficient, which facilitates long-sequence design and real-time waveform update. [C2964]

#### "Perimeter patrol on autonomous surface vehicles using marine radar"

Perimeter patrol enhances the utility of autonomous surface vehicles (ASVs) by enabling many security and scientific missions, including harbor protection, water sampling, and geological survey. We present a novel approach to perimeter patrol that uses only two sensors: commercial off-the-shelf available marine radar and the heading information from a GPS. Our algorithm performs computer vision morphological operations on the radar image to find a suitable path around shore and choose an appropriate next waypoint. Our method has proved robust to a variety of field conditions, allowing us to demonstrate the autonomous navigation of a 3.5 km perimeter lake. [C2965]

#### "Slocum Glider energy measurement and simulation infrastructure"

Autonomous underwater vehicles (AUVs) are indispensable tools for marine scientists to study the world's oceans. Depending on their missions, AUVs are equipped with advanced sensors (sonar, cameras, acoustic communication, bio-sensors), have on-board computers for data analysis (image analysis, data compression), and are capable of on-board decision making (resource planning, swarming). Since AUVs operate solely on battery power, power and energy management is a crucial issue. Mission-critical tradeoff decisions have to be made between energy consumption and sensing, data processing, and communication activities. Mission planning has to consider these tradeoffs when provisioning resources for expected future events, or when dealing with changing environmental conditions such as weather, water currents, and seafloor profiles. Effective power and energy management requires knowledge about the actual energy consumption of each active component within the AUV. Effective planning requires simulators that can predict energy consumptions based on expected future events and environmental conditions. In this paper, we discuss the design and implementation of a power measurement infrastructure for the Teledyne Webb research Slocum glider. This infrastructure can be used for online power/energy management or to better understand the time-dependent energy consumption profile of the active glider components during a particular mission. We also discuss the design of a new simulation environment for the Slocum glider which uses the power/energy data obtained by our measurement infrastructure, in addition to seafloor and coastal radar information. We illustrate the effectiveness of the new tools in the context of planning a glider flight across the continental shelf off the coast of New Jersey. [C2966]

#### "Doppler velocity dealiasing with millimeter wave radar RHI data"

Millimeter wave radar has a unique advantage on detecting cloud microphysical structure. However, it is easy to cause the velocity aliasing due to its short wavelength. Velocity dealiasing is an effective means of detecting wind field information with Doppler radar. This paper reviews the cause of velocity folding and proposed a human-machine interaction method aimed at millimeter wave radar in the RHI scanning. It is concluded that the algorithm is very efficient and can produce high quality velocity data. [C2967]

#### "Simultaneous estimation of AOA and polarization using differently polarized antennas"

This paper explores the simultaneous estimation method of the AOA and the polarization of the signals. Based on two differently polarized antennas, the simultaneous estimation is achieved with consideration of the cross-polar and co-polar patterns of the antennas. The performance of the method is analyzed. The validity is testified by the experiment of P-band radar system. [C2968]

#### "Estimating the parameters of a moving target in MIMO radar with widely separated antennas"

In this paper, we develop a new maximum likelihood (ML) moving target parameter estimation technique for multiple-input multiple-output (MIMO) radar. It is required for this technique that different receive antennas have the same time reference, but no synchronization of initial phases of the receive antennas is needed and, therefore, the estimation process is noncoherent. The target motion within a certain processing interval is modeled as a second-order polynomial whose coefficients are given by the initial location, velocity, and acceleration of the target. The proposed ML estimator is able to jointly process the data collected from multiple consecutive radar pulses. It is shown that the considered ML problem simplifies to the classic "overdetermined" nonlinear least-squares problem. The proposed ML estimator requires multi-dimensional search over the unknown location, velocity, and acceleration parameters. The performance of the proposed estimator is validated by simulation results. [C2969]

#### "An improved monopulse angular tracking method using adaptive digital beamforming technique"

Monopulse radar is widely used for its accurate angle measurement. However, when jamming occurs, especially in mainlobe, the performance of the monopulse technique for target estimation deteriorates greatly. In this paper, an improved method for monopulse angular tracking is proposed, which can be divided into two stages. The first one involves a digital beamforming system which is used to suppress sidelobe jamming while maintaining the mainlobe shape. The second stage is used to suppress mainlobe jamming while maintaining the monopulse ratio undistorted. The computation load of the proposed method is lower compared with that of the same category method. Simulation results are given which demonstrate that the presented approach can suppress jamming effectively, while maintaining the perfect performance with mainlobe undistorted. [C2970]

#### "Session E3: Radar techniques and applications"

{no data available} [C2971]

### "Passive radar imaging of moving targets with sparsely distributed receivers"

We develop a novel passive image formation method for moving targets using measurements from a sparse array of receivers that rely on illumination sources of opportunity. We use a physics-based approach to model the wave propagation and develop a passive measurement model that expresses the measurement at each receiver in terms of the measurement at a different receiver. This model eliminates the need for knowledge about the transmitter locations and waveforms in the proposed image formation method. We formulate the image formation problem as a Generalized Likelihood Ratio Test (GLRT) for unknown target location and velocity using the proposed passive measurement model. We form the image in spatial and velocity space using the space- and velocity-resolved test-statistics. [C2972]

### "3D Electromagnetic imaging using compressive sensing"

We develop the application of compressive sensing (CS) for solving general inverse electromagnetic problems such as three-dimensional (3D) microwave imaging. The goal is to estimate locations of unknown, but sparse targets, hidden inside dielectric bodies. The potential of CS for localizing sparse targets in vacuum or buried in ground was shown in previous work. We extend the proposed schemes by considering arbitrary embedding medium and exploiting dual-polarized measurements. We compare the performance of CS and beamforming in the breast-cancer estimation problem. [C2973]

### "MIMO GMTI radar with multipath clutter suppression"

This paper address ground-moving target indicator (GMTI) radar operation in the presence of strong multipath spread-Doppler clutter (SDC). Spacetime adaptive processing (STAP) for single-input-single-output (SIMO) radar is designed to mitigate direct-path SDC which leaks into the sidelobes of a moving radar platform. However, multipath SDC often returns via the receiver mainlobe and cannot be suppressed in a SIMO radar without also canceling the target. In this paper, we study multipath SDC mitigation using multiple-input-multiple-output (MIMO) GMTI radar. Clutter loci and adaptive array patterns for MIMO GMTI are presented in multipath SDC. By achieving range-dependent nulling on transmit, the effectiveness of MIMO GMTI radar at suppressing multipath SDC is shown. [C2974]

### "A miniaturized broadband four-port antenna based radar detection system"

A novel compact four-port antenna based receiving radar detection system is presented. Emphasis is placed on the antenna and pattern transform algorithms development. The antenna, with size of  $113 \times 113 \times 33.7\text{mm}^3$ , operated within 1.0-1.8GHz ( $S_{11} < -10\text{dB}$ ) and 5.5dBi single port gain, is designed and integrated successfully in a specific cylindrical stepped conductor. Two different pattern transform algorithms corresponding to 3 excited modes for the four-port antenna are developed and firstly compared with indoor experimental results. It shows that a indoor target can be detected successfully by the radar system with spatial resolution of 3 degrees, which is agreement well with the numerical simulations. [C2975]

### "Fast calculation of wide-band RCS for three-dimensional PEC objects based on preconditioned AWE technique"

The asymptotic waveform evaluation (AWE) technique combined with the method of moments (MOM) is often applied to accelerate the calculation of the wide-band radar cross section (RCS) of the target. However, the technique is still quite time-consuming for solving the inverse of impedance matrix when the objects are electrically large. In this paper, Krylov subspace iterative methods are applied to solve the matrix equation derived from electric field integral equation instead of matrix inverse. The dual threshold incomplete LU factorization preconditioner is adopted to improve the convergence behavior of the Krylov subspace iterative methods. The numerical computation shows that the results in this paper are in good agreement with the results obtained by the method of moments at each frequency, and the computational efficiency is improved greatly. [C2976]

### "Signal based parameter estimation for precise circular-scanning SAR imaging"

Images obtained from circular-scanning synthetic aperture radar (SAR) are mainly used for self-guidance system using the well-known scene matching techniques, where the geometry accuracy of the images is very important for high precision target location. Due to the existence of errors in parameters measurement from inertial navigation system (INS), for example, velocity and beam scanning azimuth angle especially, imaging is not optimal and geometry distortion correction also not absolute. In this paper, a new method of velocity error and scanning azimuth angle error compensation is proposed based on echo data. Doppler navigation instrument can be used to measure velocity based on Doppler shift, so Doppler measuring velocity technique is adopted in the

compensation of velocity and scanning azimuth angle error. The experimental result of a circular-scanning SAR system is given to demonstrate the validity of the proposed methodology. [C2977]

### "Target automatic recognition based on ISAR image with wavelet transform and MBLBP"

A novel feature extraction algorithm of Inverse Synthetic Aperture Radar (ISAR) image based on wavelet transform (WT) and multi-scale block local binary pattern (MB-LBP) is proposed in this paper. Firstly, the mathematical morphology method is adopted to enhance ISAR image. Secondly, 2D wavelet transform is used to get the low frequency sub-band image from the enhancement ISAR image. Then, ISAR image is divided into small regions from which block local binary pattern (BLBP) with different weight histograms are extracted and concatenated into a feature vector to be used as an efficient ISAR descriptor. At last the classification is performed by using a nearest neighbor classifier with Chi square as a dissimilarity measure in the computed feature space. The experimental results on three kinds of aircraft targets show that the method performs very well. [C2978]

### "Influence of vibration between shipboards on ship-sea integrational electromagnetic scattering in high frequency"

The vibration between shipboards on ship-sea integrational electromagnetic Scattering is presented. The numerical results of the integrational target have been obtained using MLFMM in High Frequency, computing the RCS as a function of the elevation angle and vibration angle. It has been observed that as for two different polarizations, the RCS of the integrational target have raised a dozen of dBsm as compare to non-vibration case, depending on the elevation angle and vibration angle. The RCS for each of those situations can be shown in the results section. [C2979]

### "Range Instantaneous Doppler ISAR imaging based on FRFT"

Very high resolution inverse synthetic aperture radar (ISAR) imaging of maneuvering targets is a complicated task. Due to the phase error caused by target's non-cooperative motion, we can't use conventional Fourier transform in ISAR imaging reconstruction. Therefore, the method of Range Instantaneous Doppler (RID) technique based on Fractional Fourier Transform (FRFT) is presented. First, we define a model of the ISAR received signal that is valid for maneuvering targets. In order to eliminate phase error caused by translational motion components, the strong scatter signal that backscattering from the target is used for phase compensation, which can be extracted from the echoes using FRFT. Finally, RID is proposed to reconstruct ISAR image. After time-frequency transform named SPWVD, we get the instantaneous Doppler frequency. Even without exact motion compensation, a clear image of the target, such as aircraft, is obtained, which avoids the insufficiency of conventional Fourier-based image algorithm. The theoretical analysis is validated by presenting and discussing the simulation results. [C2980]

### "Motion compensation for spaceborne/airborne hybrid bistatic SAR"

This paper concerns the compensation of known trajectory deviations in spaceborne/airborne bistatic SAR (SA-BSAR). And the motion compensation technique is effectively incorporated with the high-precision frequency domain imaging processing for SA-BSAR. Simulation results validate the proposed motion compensation method. [C2981]

### "A Migrating Target Indicator for wideband radar"

The standard way to suppress clutter in narrowband radar is to use Moving Target Indicator (MTI) cancellation techniques. High Range Resolution (HRR) radars are becoming more and more important because they can detect and track targets more accurately. As for such radars the bandwidth is increased, the resolution is decreased and leads to target range migration over the coherent pulse interval (CPI). Due to this range walk, standard low resolution MTI processing is not adapted anymore to HRR MTI radar data. We propose here to extend the principle of the MTI processing to the wideband case. We refer to this method as the Migrating Target Indicator (MiTI), since it eliminates the non-migrating targets from the received signals. [C2982]

### "Signal and image processing applications in radar ocean observations"

Signal processing is quite intensive when dealing with radar sensors. In this paper, the ability of spaceborne radars for imaging ocean surface features is explained and some of the very actual results are shown through several illustrations. The aim of such means to watch the earth is to provide useful information on a global basis regardless of the weather conditions (especially clouds) and in daylight as well as at nighttime. In this context, the main mean of observation is, without any doubt the SAR or Synthetic Aperture Radar [1]. From a signal

processing perspective, radar data and images are a very interesting domain of research. Indeed, they present non-gaussian, non-stationary and often non-linear characteristics, thus raising the challenge of their interpretation. We will first focus on the SAR signal processing and the mechanisms allowing a radar image of the ocean to be formed. Then we will detail some of the special characteristics when using SAR processing. Indeed this processing is done at the ground receiving station and present several very interesting challenges in terms of statistical behavior of the data and signal processing. The following section will deal with signal and image processing techniques aimed at achieving very high resolution spectral analysis, especially in 2D. Finally, we will present several of the main features that are detected and we will give some of the inferred parameters that can be measured and used by the oceanographic community. We will also, describe some of the environmental issues associated. [C2983]

#### "Generalization of Automatic Censored Mean Level Detector (ACMLD) for MIMO radars"

Constant False Alarm Rate (CFAR) processors are useful for detecting radar targets in background for which all parameters in the statistical distribution are not known and may be nonstationary. Many CFAR techniques have been proposed for conventional radars in nonhomogeneous background. One of the most robust CFAR detectors in multiple target situations is Automatic Censored Mean Level Detector (ACMLD) which does not require any prior knowledge about the number of interfering targets. In this paper, ACMLD algorithm is generalized for Multiple Input-Multiple Output (MIMO) radar. An exact expression for the false alarm probability of the proposed algorithm (M-ACMLD) is presented. Then, the performance analysis of M-ACMLD is studied in both homogeneous environment and multiple target situations. [C2984]

#### "CFAR detectors in presence of jammer noise"

Cell Averaging (CA)-CFAR detector is an optimum detector under the assumption of Rayleigh distributed homogenous noise background, but in presence of clipped jamming noise, it does not have the best performance. In this paper, we compare CA, GO, SO, OS, OSGO and OSSO conventional CFAR detectors to obtain superior CFAR detector in clipped jamming noise. Simulation results show that the OS-CFAR detector not only provides low loss CFAR performance in exponential background but also performs better than that of CA in clipping jammer noise situations. On other hand, by using OS detector instead of CA detector in radar, it saddles about 3dB more loss to jammer noise generator. [C2985]

#### "Front matter"

The following topics are dealt with: power electronics; digital circuits; data converters; video and image processing; wired communication; digital signal processing; analogue circuit; pipelined ADCs; RFID; RF and antenna; MEMS and sensors; biomedical circuits and systems; CMOS power regulator; GPS signal; telephone remote control system; VLSI interconnects; continuous-time delta-sigma modulator; optical transmission; FPGA; X-band polarimetric radar; wireless-LAN transceiver; nanoMOSFET; single-electron transistor hybrid circuit; and implantable medical devices. [C2986]

#### "A wireless microwave sensor for remote monitoring of heart and respiration activity"

The aim of this paper is to present a new microwave contactless sensor for heartbeat and respiration activities. The system is operating on 9 GHz. It's composed of two parts: a hardware one based on Doppler radar with a Digital Multimeter, and a software one based on the acquisition of the signals and the separation of the 2 informations of heartbeat and respiratory signals using simple filtering method with Labview. [C2987]

#### "An automatic feature extraction technique for GPR data processing in electromagnetic inverse scattering problems"

This work presents an automatic feature extraction technique for the analysis of GPR data. Despite the rapidly increasing demand for such technology, the interpretation of radargrams is still a specific task which only expert users can accomplish. As a radar probing system, in fact, the GPR is able to measure the backscattered EM waves from buried targets and the travel time of these signals, information which cannot be directly exploited, but that needs to be used in inverse scattering problems for the evaluation of the dielectric properties and spatial positions of subsurface targets. Starting from a practical example of GPR employment-the reconstruction of pavement's vertical cross section-the evaluation of the two above-mentioned features is carried out through an energy-based method, which ensures high performances and robustness to signal interference. [C2988]

#### "Model based adaptive detection algorithm with low secondary data support"

In this paper the problem of adaptive target detection in structured Gaussian clutter is considered. The clutter is

modeled as an auto-regressive process with known order but unknown parameters. To solve this problem, we have modified a well known adaptive detector (Kelly's GLRT) in four different forms. In this detector an estimation of covariance matrix is needed. In order to estimate the covariance matrix, we estimate the AR parameters based on secondary data and use the results in covariance matrix estimation. Then, we use the estimated matrix in the detector structure. In order to estimate the AR parameters using more than one set of data, we have extended four classical AR parameter estimation techniques to use more data sets. The performance of the proposed detectors have been evaluated using Monte-Carlo simulations and compared with each other. [C2989]

### "Sparse component analysis for linear mixed models"

When seeking for a sparse solution of a linear model, a common technique is the search of a solution with minimum  $\ell_1$  norm. In this paper, we present a new approach for the case of sparse linear mixed models. We combine the EM algorithm for solving the inverse problem with a decision test that guarantees sparseness by eliminating the statistically null components of the solution. We address its performance by means of simulations and illustrate its use with real radar data demonstrating its potential applications. [C2990]

### "A recursive model for partially correlated $\chi^2$ targets"

This work considers the problem of  $\chi^2$  target detection in normal (Gaussian) noise. The single pulse power, and target RCS, are  $\chi^2$  distributed with an arbitrary form factor  $k$ . The correlation between pulses is determined by target dynamics, according to a simple rule of thumb. The sequence of target pulses is constructed using a recursive model of Markov chain, and the value of the correlation coefficient is derived. An approximation of 'strict sense  $\chi^2$ ' is assumed for the probability density function (p.d.f) of the sum of the integrated pulses. The form factor  $K$  of this density is calculated in terms of the correlation coefficient, number of integrated pulses and the form factor for the single pulse p.d.f- $k$ . By determination of the normalized threshold for the given  $P_{fa}$  (probability of false alarm), the probability of detection- $P_d$  can be obtained. One way to do these calculations is using the "universal detection equation" suggested by D.K Barton (7.2005). The model can be used in radar system performance analysis and in simulations. The advantage of these methods is the elimination of the use of tables and graphs, and enabling direct computations such as in multiple situation simulations. It can be done using commercially available advanced mathematical software. [C2991]

### "Covariance-informed detection in compound-Gaussian clutter without secondary data"

We consider the problem of detecting a signal of interest in the presence of compound-Gaussian clutter, without resorting to secondary data in order to infer the clutter covariance matrix. Towards this end, we assume that both the texture  $\tau$  and the speckle covariance matrix  $R$  are random variables with some a priori distributions. Marginalizing with respect to these variables, the probability density function of the observed primary data is derived, leading to a closed-form expression for the generalized likelihood ratio test (GLRT) of the problem at hand. Accordingly, the GLRT assuming that  $\tau$  is deterministic is also derived. The two detectors are assessed through numerical simulations. [C2992]

### "Smoothing irregular data using polynomial filters"

To make provision for irregularly occurring updates a "variable-step" polynomial filter is derived which improves the smoothing-, and coasting capabilities of the 1-step predictor and the current-estimate polynomial filters. Similar to the original filters, the variable-step polynomial filter comprises an auto-initialising expanding memory filter which later switches to a fading memory filter. Results are compared by running the proposed and original filter versions in parallel. [C2993]

### "Oil spill detection in sar images using wavelets and morphology"

Oil spills at sea surface can be found at nearby vessels due to clearing tanks while sailing or by accidents. Problem of oil spill detection is considered in the paper. The basis source for the detection is radar image. The proposed method combines wavelets and morphology. Preliminary research shows that any type of morphology structural element can be used for the purpose as long as it is not too big kernel. [C2994]

### "Copyright page"

The following topics are dealt with: magnetic resonance imaging; signal processing; data processing pipeline; MIMO radar; underwater acoustic communication; covariance matrix and wireless networks. [C2995]

### **"Development of radar simulator software using AIS data for ship data"**

A radar simulator for ships is a device for effective education concerning safety in ship navigation. In existing radar simulators, it is necessary to simulate surrounding ship data, and much effort is required to input such data. Therefore, this study aims to address this problem using AIS (Automatic Identification System) data. The proposed radar simulator system simultaneously achieves the following functions: (1) the creation and display of simulated radar images based on AIS data and (2) the display and overlay of AIS information on radar screens. As a result, it is possible to train individuals in ship maneuvering using actual ship traffic of a specific ocean area as the environment in the surroundings of one's own ship. Moreover, this proposed radar simulator system works on a general PC. Thus, it is possible to have two or more people simultaneously participate in training using a network with two or more PCs. In this paper, the outline of the proposed system and simulation results are described. [C2996]

### **"High-resolution airborne SAR interferometry mapping application in Huashan mountain"**

Interferometric synthetic aperture radar (SAR) data offer the opportunity to map the western area of China, acquired from the first Chinese multi-modes airborne SAR mapping system. DEM could be obtained through airborne interferometric pairs. Furthermore, the quality of the InSAR DEM may vary significantly depending on the local topography. Aims of the approach are to smooth the noisy InSAR data, to merge the different directions DEM from the complementary interferometric pairs, to eliminate effectively spurious terrain surface points, to generate an improved 3-D visualization of the InSAR DEM scene and finally to meet DEM product accuracy requirement based on the different topography condition with a scale of 1:50,000. [C2997]

### **"Robust environment perception based on occupancy grid maps for autonomous vehicle"**

For a purposes of reduction of driving workload, traffic accidents, and so on, autonomous vehicle systems, which can drive even though no human driver rides on, have been developed all over the world. Recently, it is considered that a part of such techniques play an important roll to energy saving. To navigate the autonomous vehicle in a complex environment, it is necessary to extract static objects precisely and robustly. Moreover, about dynamic objects, it is not enough to consider its existing position, and it is considered that estimating its motion and predicting its future position are strongly demanded. In this paper, for a solution of such problems, we propose an environment perception method using a LIDAR based on Occupancy Grid Maps. [C2998]

### **"DInSAR for land subsidence monitoring using high resolution COSMO-SKYMED SAR Data: Preliminary results compared with ASAR"**

DInSAR can map ground deformation phenomena over tens-of-kilometers-wide area with centimeter-scale accuracy level, and has been considered as a powerful tool. Because of the data availability, previous DInSAR applications were mainly base on ERS, JERS, ENVISAT ASAR, and RADARSAT-1 data with resolution coarser than 10m. Nowadays, several kinds of high resolution SAR data are available for DInSAR and there are high expectations for the application of these data. In this paper, COSMO-SkyMed SAR data and grid digital elevation model ASTER GDEM (30m resolution) are used as research data. COSMO-SkyMed SAR data are preliminary processed by DInSAR technique for land subsidence mapping of Tianjin and Beijing area. Meanwhile, the DInSAR results from COSMO-SkyMed and ASAR data are preliminary compared. COSMO images are more suitable to extract high-precision ground deformation information than ASAR images in civil application given precise orbit data. While COSMO data are suitable for deformation monitoring in a relatively small and important area, ASAR data are fit for regional survey. [C2999]

### **"Privacy protection against ubiquitous marketing"**

Privacy has been recognized as an important topic in the marketing for long time. Our society is growing and adopting a more ubiquitous information-filled world with previously isolated systems evolving and being adapted to operate in completely interconnected networks. This full access to real-time public and personal data is a logical evolutionary step forward. However, the security of the individual's confidential information and our right to privacy is at stake. Many questions need to be addressed regarding the scope and volume of personal information. Seemingly, there is a tradeoff between exploiting the tremendous benefits of having shared information available to enhance the people's life and giving away one's personal privacy either directly or indirectly. The most common use of user data is in marketing, for which profiles, as collected in traditional eCommerce, are supported by data-mining the explicit self-descriptions, the behavior, and the ratings of users. For example, from credit card companies that rate based upon where you shop, to pay-per-click advertisements based upon Google searches, behavioral targeting has become an ubiquitous, if effective marketing tool. This issue has become a hot button topic for many publishers, advertisers, and privacy protection groups. Critics are concerned whether or not behavioral tracking agencies are effectively disclosing how the targeting works, and

whether or not they are offering consumers the ability to escape their radar by opting out of tracking. Despite numerous discussions on the regulation of behavioral marketing, no solution has been found that satisfies all parties. It can be said that privacy is a problem in ubiquitous marketing using consumer's situation awareness today. However, it is possible to overcome the privacy problem if careful consideration is done to the consumer. So, we should know that when does the consumer feel insecurity? How does the consumer think about the privacy problem? This-- paper examines the consumer's consideration to ubiquitous marketing. [C3000]

#### **"A method for InSAR baseline refinement and its application"**

Interferometric baseline plays a very important role in InSAR data processing, and it will directly affect the accuracy of interferometric result. In this article, three classical baseline estimation methods were described. By comparing and combining three methods, a new baseline estimation method and its flow were listed. RADARSAT-2 satellite image data and grid digital elevation model ASTER GDEM (30m resolution) in Kailuan area are used as sample data. By analyzing the differential interferometric results generated with different baseline estimation methods, it can be concluded that the new method used by this article is correct and feasible. [C3001]

#### **"Seat vibrotactile warning interface for forward vehicle collision avoidance"**

A collision warning system utilizing haptic interface is expected to be more effective than an auditory as well as visual warning types. In order to reduce the number of the traffic accidents and their injuries, this paper proposes a forward vehicle collision warning system by using seat vibrotactile interface. At first, an investigation of the frequency for using as collision warning is shown. Comparing the time response to each type of warning system, the effectiveness of seat vibrotactile warning interface is examined. Based on the examination, a forward vehicle collision warning system using seat vibrotactile is designed and installed in the experimental vehicle. Finally, the effectiveness of the proposed system is examined by test drives. [C3002]

#### **"Nondestructive measurement of diameter of reinforcing bars in concrete using an electromagnetic wave radar under the effect of cross bars"**

A method was proposed previously to measure the diameter of the deformed reinforcing bars in concrete structures nondestructively using an electromagnetic wave radar. The method estimated the periodicity of the knots of the inspected bar from the received reflections from the deformed bar and utilized the standard relationship between the knot's pitch and the diameter of the bar to measure the diameter indirectly. The effectiveness of the method was verified using test specimens where the bars were placed parallel to each other. However, in practical case, where other reinforcing bars cross the inspected bar perpendicularly, the stronger reflections from the cross bars influence the reflection from the inspected bar. The paper thus proposes a general method which eliminates such unwanted influences from the cross bars and measures the diameter accurately even in practical environment. [C3003]

#### **"Intelligent collision risk assessment based on Neural Network Ensemble"**

In this paper, we propose the collision risk assessment system. When pedestrian is detected by radar or another sensor, system could know the pedestrian's position and velocity. Using this information, system can compute the collision risk. If system does not concerned about the simulation time, Monte Carlo Simulation is simple and powerful method. But in dynamic circumstance, the position and velocity of pedestrian is changed rapidly. So I propose to apply Neural Network Ensemble in this problem. Neural Network train the network using training data, this process take a long time. But by using trained network, system can compute the collision risk quickly. However, wide range of input data can cause huge memory use, and lengthy simulation time. So we propose apply Neural Network Ensemble to this problem. Neural Network Ensemble separate the input data and training each network with different data set. This method will reduce the computation load with small error. [C3004]

#### **"Application of integrated geological prediction in expressway tunnel"**

Because of the complicated geological conditions of tunnel surrounding rocks, it is of necessity to operate geological prediction during tunnel construction. Geology analysis, seismic wave method (TSP was adopted) and GPR (ground penetrating radar) are used to make prediction in the construction of Gaojiabao Tunnel. The utilization of several prediction methods that can be seen as an integrated prediction system can avoid one-sided conclusion obtained by single method. Moreover, each conclusion can be checked and made up mutually. The application result shows that the prediction conclusions are relatively accurate, which can meet the needs of safe construction. [C3005]

### "Deformation analysis of Wenchuan earthquake based on D-InSAR with image mode"

It is considerably destructive for Wenchuan earthquake. The derived deformation field is an effective way to retrieve the geophysical parameters and study the seismic mechanism. Numerous geodetic methods can be exploited for the earthquake deformation monitoring. In spite of the high accuracy and consistent temporal scale, the results of GPS measurements are discrete. Continuous deformation field can be derived from Interferometric Synthetic Aperture Radar (InSAR). For image mode (IM) has full resolution, we will use conventional InSAR to get deformation field of Wenchuan earthquake. First, the geolocation of Longmen Mountain areas was introduced. The process of IM interferometry was analyzed in detail. At last, the deformation field was derived with the extent of 100km<sup>4</sup>100km. The results revealed that it was not the largest deformation region at the earthquake focus. The closer you get to the fault zone, the larger deformation gradient of the heading wall it become. At the same time, IM Interferometry can not reveal deformation field because IM is too narrow to obtain the entire deformation field. With the application to IM interferometry in Wenchuan earthquake, it is significant for earth science research such as earthquakes and crustal motion. [C3006]

### "SAR image target recognition based on NMF feature extraction and Bayesian decision fusion"

In this paper, a new approach of synthetic aperture radar (SAR) image target recognition based on non-negative matrix factorization (NMF) feature extraction and Bayesian decision fusion is presented for recognizing ground vehicles in MSTAR database. First, feature vectors are extracted from image chips by NMF algorithm. Support vector machine (SVM) is used to classify the feature vectors. After multiple views of the same vehicle collected at different aspects are classified by SVM, the outputs are fused by Bayesian decision fusion algorithm and then the final classification decision is generated. We evaluate NMF algorithm and the Bayesian decision fusion approach. Experimental results indicate that there are significant target recognition performance benefits in the probability of correct classification when NMF algorithm is applied and three or more views are used for Bayesian decision fusion. [C3007]

### "Precise diameter measurement of reinforcing bar and steel pipe based on bi-static model using microwave radar"

In this report, a novel signal processing method for microwave radar is considered, in order to realize precise diameter measurement of the reinforcing bars and the steel pipes in the concrete structures. Particularly, a geometric analysis which is considering the bi-static antenna configuration for the microwave propagation paths is introduced, and a diameter of the buried circular target object has been tried to measure precisely. In the proposed geometric analysis, the accurate microwave propagation length, or the accurate propagation time estimation is necessary for precise diameter measurement. Then, the improved cross-correlation envelope curve method is newly proposed, and superior propagation time estimation accuracy over the sampling interval has been accomplished. Finally, an effectiveness of the proposed methods has been confirmed experimentally, by applying them to the diameter measurement of the steel pipe in the air. Their experimental results show that the proposed methods have certain advanced performances for a precise diameter measurement. [C3008]

### "Modeling and simulation of position for the Stratospheric ISAR system"

There are many advantages to put the Inverse Synthetic Aperture Radar (ISAR) system up in the stratosphere. Compared with the Ground-based ISAR system, one problem of the Stratospheric ISAR system is the platform drifting. This paper established models for the different positions of the airship and investigated the effects of drifting on imaging. The results of simulations for Stratospheric ISAR system show effectiveness of the models. [C3009]

### "Radar Multi-Targets Real-Time Communication Based on Software Radio"

According to the modern software radio principle, a programmable general-purpose platform is designed to realize radar multi-targets real-time communication. The receiver is designed based on wideband IF sampling architecture, and cascaded with two digital attenuators. C-band signal is transformed into IF signal through twice conversions. DSP, FPGA, and ARM are used for digital signal processing. Cascaded Integrator-Comb (CIC) filter and polyphase filter are utilized to accelerate processing speed and reduce system resource consumption due to the fast signal processing. Experiment results show that the digital attenuators expand the signal dynamic range 60dB. CIC filter and channelized receiver based on polyphase filter banks can save resource consumption and improve the efficiency of signal processing. [C3010]

### "Specific Emitter Identification Based on Intrinsic Time-Scale Decomposition"

Practical signals such as communication and radar signals turn out to be non-stationary and nonlinear time

series, and estimating instantaneous parameters of such signals in time domain will benefit detecting and identifying specific emitters, such as radio stations and aerospace targets. However, conventional methods such as Wavelet and Wigner-Ville distribution (WVD) methods are difficult to deal with these transient signals when the signal is not stationary. To provide more efficient approach for estimating instantaneous parameters of non-stationary and identifying specific emitter with high accuracy, a novel method based on intrinsic time-scale decomposition (ITD) for analytic signal is proposed in this paper. The simulation results are presented to demonstrate the power and effectiveness of this novel method. [C3011]

#### "Automatic Layer-Interface Detection of Pavement Based on Matched Filter"

Ground penetrating radar (GPR) is a non-destructive and non-intrusive subsurface investigation equipment which has been widely used in the field of civil engineering. As the GPR signals are easily corrupted by noise, so it's always difficult to detect the multi-layer reflection signal of the pavement. To address the problem, In this paper we present the wavelet transform modulus maximum de-noising and Matched Filter (MF) method for clutter reduction and layer-interface automatic detection respectively. The experimental results based on simulated data using FDTD show that under the Low SNR condition, the presented algorithm outperform the MF algorithm alone. [C3012]

#### "Ultra-Thin Asphalt Pavement Layer Interface Detection and Time Delay Estimation Based on MUSIC"

Ground penetrating radar (GPR) is a non-destructive and non-intrusive subsurface investigation equipment which has been widely used in the field of civil engineering. Some challenges which GPR encountered for pavement subsurface inspection are: 1) GPR signal are easily corrupted by noise; 2) commercial GPR whose resolution is depended on system bandwidth, is not suitable for ultra-thin thickness estimation. This paper focus on using super-resolution MUSIC algorithm for ultra-thin pavement layer-interface detection and time-delay estimation compared to threshold detector and match filter. The results based on the simulation data under different conditions and measured GPR data are also presented. [C3013]

#### "Research on the Configuration of Network Radar Based on Detectable Power and Detector's SNR"

Network Radar realizes the integration of radar and radar countermeasure, thus it is a new direction for the development of radar and radar countermeasure system. This essay first introduces the existing concept and research results of the configuration of Network Radar and then it probes into how to configure the transmitters and receivers based on the method of detectable power and detector's SNR, in the end this essay provides the simulations of the configuration of Network Radar. It hopes that the research results of this essay will put the development of configuration of Network Radar forward deeply. [C3014]

#### "Theory and Measurement of Delta RCS for RFID Tag on Various Materials"

Delta radar cross section (RCS) is an important parameter for the performance of passive UHF RFID tag. It determines the bit error rate (BER) at reader side when the signal which backscattered from the tag is polluted by kinds of noises. But the measurement of delta RCS can't be obtained directly and thus, indirect method must be considered. The paper introduces our measurement methodology for tag's delta RCS, including the National Instruments (NI) RF modular and the LabVIEW based signal analysis program. This paper also has analyzed two main factors which influence delta RCS seriously, and gotten some test results when tags were attached on various material objects for different transmitted power. [C3015]

#### "Linear Combination Method for UWB Vehicular Radar Pulse Design"

Ultra wideband (UWB) vehicular radar has been studied and developed to achieve a safe driving and to promote business in an intelligent transport system. In the paper, we propose a UWB radar pulse design method that makes use of a linear multi-pulse combination of wavelet pulses which satisfy the Federal Communications Commission (FCC) regulation. Simulation results show that the UWB pulse obtained by the method have the advantages of better spectrum utility ratio and complying with the FCC spectrum mask. [C3016]

#### "A Novel Method for Recognising Radar Emitter"

A novel method for recognising radar emitter is proposed in this paper. The resemblance coefficient (CR), pulse repetition interval (PRI) mean and variance are used as the factors for recognising radar emitter which is based on the feature of these parameters. Then, the radial basis probabilistic neural networks (RBPNN) recognition is designed. Simulation experiment shows that this novel method can improve the recognition rate while it can also

improve the recognition velocity. [C3017]

### "WiTracker: An Indoor Positioning System Based on Wireless LANs"

With the rapid development of wireless local area networks, indoor positioning technology based on received signal strength in wireless networks are becoming more and more attractive. In this paper, we firstly introduced the implementation of an indoor positioning system, named WiTracker. Then three improvement mechanisms, called signal strength filter, user location filter and path tracking assistance, were proposed to improve the positioning accuracy of the WiTracker system. Thirdly, we analyzed the comprehensive performance of the WiTracker system and compared it with the Radar system. Experimental results demonstrated that the proposed WiTracker system can improve the 89% accuracy in 3 meters of Radar system to 93% in a typical office building testbed. Finally, two key influence factors to positioning accuracy were further discussed and analyzed, including number of access points, and spacing between sampling points. [C3018]

### "Diagonal Loading for STAP and Its Performance Analysis"

For the moving target detection with space-time adaptive processing (STAP), the non-homogeneity will cause the covariance matrix estimation error, which substantially results in the STAP performance degradation. Diagonal loading has long been used as a means to improve the robustness of the spatial filter against mismatches in both the desired spatial signature and the spatial correlation matrix. In this paper, we consider the application of diagonal loading to improve the detection performance for STAP, especially for the covariance matrix mismatch (statistical mismatch) in STAP, namely, there is a mismatch between the actual covariance matrix of interest and the presumed one. For the diagonal loading, the key problem is the choice of the loading level, and the method for selecting the loading level is given, and the particular performance analysis indicates that the diagonal loading can improve the detection probability and the output signal-to-noise ratio. Numerical simulations attest the validity of the analysis. [C3019]

### "An Efficient Indoor Location Algorithm Based on RFID Technology"

Virtual reference elimination algorithm is a method to investigate the location accuracy of location identification based on dynamic active RFID calibration being restricted by the number of reference tags. However, the Received Signal Strength Indicator (RSSI) values of virtual reference tags, achieved from the linear interpolation formula in VIRE, are not enough precise according to the distance-loss equation. Severe redundant calculation was induced in the case of all the tracking tags positioned intensively. The proposed location algorithm suggests a subregion selection mechanism to reduce the redundant calculation, brings forward a nonlinear interpolation algorithm to calculate the RSSI values of virtual reference tags. A trajectory revision method is used to improve the location precision as well. Simulation results demonstrate that the location accuracy of optimized algorithm is better than that of VIRE. [C3020]

### "Simulation and Analysis of the Effects of Tropospheric Scattering Channel on Signal Waveforms"

Tropospheric scattering channel is a random channel. When the signal transmitted through the troposphere, the multi-path fading could cause signal waveform distortion. In this paper, based on a valid tropospheric scattering channel model, respectively, from the time domain and frequency domain the reasons why the signal waveform was distortion were analyzed. Radar pulse as the transmit signal, and simulate the received signal waveform in different antenna beam width angle. The results show that the signal waveform is impacted in different degrees at the different antenna beam width angle. [C3021]

### "A Novel Random Sampling Method for Radar Image Compression"

In this paper, we propose a process of the radar image data by Random sampling. The sampling rate is far lower than Nyquist-Shannon sampling theorem, which shows that image data can be reconstructed from an extremely small set of measurements than what is generally considered necessary. Compressive Sampling is considered for signals and images that are sparse in a wavelet basis. A low complexity compression method for high resolution image based on block partition in wavelet region is proposed. The image is partitioned into blocks in wavelet domain and then compressed separately with CS. The bit rates for each block is allocated according to the texture complexity of the block. The proposed method eliminates the "block effect" caused by traditional block partition in pixel domain, and solves the problem caused by traditional block partition that the areas with simple texture are good in reconstruction quality while those with complicated texture are too poor to be used because of the uneven distribution of texture complexity. The experimental results show that the compression performance of the proposed method is quite similar to the results obtained by global compression. This compression method is particularly suitable for the high resolution remote sensing image which sparse in a wavelet domain. [C3022]

### "Designing of a Telematic Network to Provide Real-Time Supervision and Control for Tactical Units"

In this paper we present the design and implementation of a telematic network to provide real-time location based services for tactical units which interconnects soldiers, weapons systems, fire control units, sensors, reconnaissance and surveillance radars, as well as unmanned aerial vehicles, with company-level command and control centers to the national center at the command level and the Defense Ministry headquarters, allowing real-time transmission of voice, image and geographical data. The design is based on a telematic network in which each vehicle receives positioning information through a GPS system. It is transmitted by radio to a base station where the signal is processed. It will also be able to give orders to avoid accidents, confusion and loss of soldiers in hostile areas. A description of the proposed system is presented. Flow charts for later coding in the programming language are shown. The way of how the transmitted signal is processed and then displayed to the user is illustrated. The evaluation of the results was carried out in Venezuela with equipment purchased by the Army and the efficiency of the proposed system is verified. [C3023]

### "Data analysis of wind profiler radar(WPR) under three kinds of synoptic processes in spring on Donghai island of Zhanjiang"

Observations from the WPR located in Zhanjing are used to analysis the characteristics of wind field and virtual temperature in boundary layer under three kinds of synoptic processes during 5th-12thApril, 2010. The results show that: (1) The horizontal wind velocity first increased and then decreased with altitude in low level of spring fair weather over Zhanjing, with maxima range of 7-16 m/s, and the velocity also first increased and then decreased, with maxima less than 20 m/s in the middle level, the wind velocity was increased with altitude in high level. The horizontal wind direction was easterly in low level and southwesterly in high level, and the direction veered with altitude accompanied by warm advection. It appeared varied velocity of downdraft except for the weak updraft at the altitude of 2500-4000m. (2) During the spring fog process, the wind velocity fluctuated around 5 m/s with easterly direction in the low level and increased with altitude above 1100m which up to 19 m/s with southeasterly direction, but the velocity turned decreasing apparently around 5500m, with wind direction veering with altitude accompanied by warm advection. (3) There were two downdraft areas during precipitation, the first one was under the height of 1000m, and the second one was at the mid-level of 3000m. Updraft appeared before the onset of precipitation, and the low level was dominated by downdraft airflow after the beginning of rainfall. At the beginning of rainfall, the horizontal wind velocity shook at mid- and low-level with wider fluctuation margin of 3-9 m/s. The wind velocity increased with altitude accompanied by single warm advection and the direction was easterly below the height of 1000m, and the wind direction became more volatile with height above 1000m with alternated appeared warm and cold advection. [C3024]

### "Integrating observation systems: An example from the Great Barrier Reef"

The Australian Integrated Marine Observing System (IMOS) project has deployed a set of focused observational equipment in the southern part of the Great Barrier Reef. This represents an good case study in what it actually means to deliver an integrated set of observations, how integration can be achieved and what the real benefits of true data integration are. [C3025]

### "Sonar waveform design for optimum target detection: The impact of object burial state"

The design of transmit waveforms in sonar and radar that optimize the probability of detection of a known target is an area of active interest. Previous research has demonstrated the benefits of optimal transmit waveforms for enhanced target detection, versus the transmission of more conventional waveforms such as broadband LFM pulses. For maximum benefit, the scattering function or frequency response of the target to be detected must be known, along with the spectral or statistical properties of the environment. In this paper, we examine the impact of a mismatch between the expected frequency response of the target, for which the optimal transmit waveform was designed, and the actual frequency response of the target. In particular, we design the optimal sonar transmit waveform based on the free-field response of the target, and then examine the effects on detection performance of burial of the target in sediment. Simulations of the sonar backscatter from a steel sphere in the water column and at various stages of burial demonstrate that the impact of mismatch becomes increasingly detrimental as the target becomes increasingly buried. For fully buried targets, the impact is such that transmitting a simple broadband LFM pulse can yield improved detection relative to "optimal" waveform design wherein there is a mismatch between the expected (free-field) and actual (buried) frequency response of the target. [C3026]

### "The Integrated Marine Observing System-delivering data-streams to support marine research and

## applications"

The Integrated Marine Observing System (IMOS) is funded by the Australian Government through the National Collaborative Research Infrastructure Strategy (NCRIS) and the Education Investment Fund (EIF) to deliver data-streams from the Oceans around Australia. IMOS aims to meet the needs of the research community, address issues of national importance and contribute to international ocean observing programs. The strategic focus of IMOS is on the role of the oceans in the climate system, and the impact of major boundary currents on the continental shelf, ecosystems and biodiversity. [C3027]

## "Coherent change detection with complex logarithm transformation on SAR imagery"

A satellite-borne SAR (synthetic aperture radar) is quite promising technique for high-resolution geosurface measurement. Recently, the feature extraction method based on the CCD (coherent change detection) has been developed, which detects a small surface change on the geosurface by using the phase relationship between the plural complex SAR images of the same region in different observations. Aiming at fast and accurate detection of the surface change, the logarithm transformation method, has been proposed. This method can determine the appropriate threshold for the change detection, while enhancing the detection probability and suppressing the false alarm rate. However, it does not employ phase information of the estimated coherence function, and its detection probability deteriorates, especially in the case when target has small surface changes. To overcome this problem, a novel transformation index is proposed considering the phase difference of the coherence function. The results from the experiment modeling of geosurface measurement verify the effectiveness of the proposed method, even in the lower SNR (signal to noise ratio) situations. [C3028]

## "Comparison of ship detectors for polarimetric SAR imagery"

This paper examines the benefits of using fully polarimetric SAR imagery for ship detection. There are three related aspects to the work. First, RadarSat-2 quad-pol stripmap imagery is used to compare the performance of various ship detection algorithms/methods. The comparison is based on the use of ROC curves. Second, circular spotlight SAR imagery is used to examine how detector performance varies with the azimuth angle. Owing to the small number of available ship samples, this analysis has limitations. Third, again using the circular spotlight SAR imagery, the variation, with respect to azimuth angle, of the elements of the polarimetric covariance matrix of both the ship and the ocean are analysed. The results are as follows. Using the stripmap imagery, it is found that exploiting both polarimetry and spatial correlations greatly improves detection performance. Using the circular spotlight imagery, it is found that detection performance is variable with respect to azimuth angle and trends are hard to discern. Moreover, the performance of the Pauli double bounce detector is generally poor. It is conjectured that ship pitching motion degrades the polarimetric backscatter response in the circular spotlight imagery. Finally, the covariance matrix analysis confirms known trends for the ocean backscatter. The implication of these trends is that the polarimetric covariance matrix is sensitive to changes in azimuth angle and hence detectors based on them are also. The data indicate the extent to which this is the case. [C3029]

## "Further analysis of the modulation of high frequency radar spectra due to sea-induced antenna platform motion"

The scattering of high frequency electromagnetic waves from the ocean surface is considered for the case of the radiation source being a vertical pulsed antenna mounted on a floating platform while the receiving antenna is fixed on the shore. This represents a small extension to an earlier analysis by Walsh in which both the transmitting (TX) and receiving (RX) antennas were co-located on a floating platform and the effect of the sway was accounted for in the ocean cross section. It is known that additional features appear in the Doppler spectrum when the RX and TX antennas are permitted to sway slowly, and here a similar result is shown when only the TX antenna moves. It is seen in this case that the magnitude of the additional spectral features is reduced as compared to the case when both antennas are moving. As a motivation for continuing analytical work, a preliminary field result is depicted. [C3030]

## "An improvement to the pulse compression scheme"

The pulse-compression is a technique mainly used in sonar, radar and echography to augment the range resolution as well as the signal to noise ratio. This is achieved using a matched-filtering of the received signal with the bandpass transmitted signal. Taking into account the main assumptions of the matched filter theory, the use of the bandpass transmitted pulse as matched filter's impulse response is only available if the useful signal is well known and if the noise is white, which is not the case in practice. For this reason, we propose to improve the classical pulse-compression technique using the stochastic matched filter, which ensures a maximization of the signal to noise ratio, when the useful signal is a realization of a random process and the disturbing signal a colored noise. Results obtained on synthetic and real data are proposed and discussed. [C3031]

### "Mechanisms and system design of satellite interferometric Synthetic Aperture Radar altimeter"

Satellite radar altimeter plays an important role in microwave remote sensing, but its performance and applications on non-ocean surfaces are constrained by its poor resolution. The along-track resolution of altimeters can be improved by the synthetic aperture technology, while the cross-track resolution can be improved by the interferometric technology. Although these two technologies are well-established in side-looking radars, relevant studies on nadir-looking radar are rather inadequate. This paper reviewed the backgrounds of the synthetic aperture altimeter and interferometric altimeter. Then the mechanisms of the Interferometric Synthetic Aperture Altimeter (INSAA) are analyzed, and a set of typical INSAA system parameters are designed, especially on the phase-wrapping problem and baseline-length issue. [C3032]

### "InSAR Kalman Filter phase unwrapping algorithm based on topographic factors"

Phase unwrapping is the key step in Digital Elevation Model extraction and the measurement of surface deformation of Interferometric Synthetic Aperture Radar (InSAR). When in steep terrain or larger slope, the unwrapping result is bad and causes error transmission using the existing Kalman Filter phase unwrapping algorithm. Considering this situation, this paper presents an improved Kalman Filter phase unwrapping algorithm based on topographic factors for InSAR. It can be implemented through the introduction of the input control variable associated with topographic factors to the state-space model of Kalman Filter. Owing to the fact that the interference fringes directly reflect the change of the terrain and local fringe frequency is closely related with the local terrain slope, the local fringe frequency estimation can be used as the input control variable. In the local frequency estimation, using two-dimensional Chirp-Z transform, better estimate of the results may be quickly get. In this paper, using simulated data and real InSAR data to do the experiment, it can gain more reliable result compared with the conventional Kalman filter phase unwrapping algorithm. It is verified that the proposed algorithm can effectively deal with the situation of steep terrain and larger slope. [C3033]

### "Offshore petroleum exploration from space: A developing capability at Geoscience Australia"

Natural seepage can generate hydrocarbon slicks on the sea surface that may provide petroleum explorers with direct evidence of oil and gas below the sea bed. Remote sensing has the potential to be used as a tool for detecting such sea surface slicks, thereby identifying areas in both producing and frontier basins that are prospective for hydrocarbons. We are developing a two-pronged, remote sensing-based approach for seepage slick studies in the Australian Marine Jurisdiction: 1) building a semiautomated processing and classification system in order to scan large numbers of Synthetic Aperture Radar scenes for potential natural slick targets, and; 2) investigating the potential of optical remote sensing as a diagnostic tool for further, targeted study. Using objected-oriented classification algorithms in a bulk processing environment, large Synthetic Aperture Radar data sets were able to be efficiently screened for potential natural oil slick targets. This processing system offers a range of outputs, including classification statistics for each scene studied, as well as geo-referenced shapefiles ready for analysis in Geographic Information System software, where it can be combined with ancillary data sets for contextual analysis. Our research into the potential for optical remote sensing to enable further diagnostic study of identified, potential targets has shown that there are several commercially available, space borne sensors able to detect the types of oils found throughout the Australian Marine Jurisdiction, but that oil type is critical for this application. Further to this, we have developed an approach for performing a feasibility study of oil type versus sensor sensitivity prior to image data acquisition. [C3034]

### "The use of HF radar surface currents for computing Lagrangian trajectories: Benefits and issues"

Surface coastal currents mapped by a pair of high frequency ground-wave radars (HFR) have been used to predict Lagrangian trajectories in the proximity of Heron Island (Capricorn Bunker Group, Great Barrier Reef, Australia), and to compare with the current data measured by an Acoustic Doppler Current Profiler (ADCP) at three mooring stations. Overall the HFR and ADCP absolute current speeds showed a difference less than  $\pm 0.15$  m s<sup>-1</sup> for 68% of the observations. A good agreement between HFR (at a depth of 1.5 m) and ADCP (at a depth of 5.5 m) data were observed for the u-component (cross-shelf) which presented a stronger tidal signal, while a poor comparison was found for the v-component (north-south) more influenced by the south-easterly and northerly winds. The HFR allowed inclusion of not only the temporal, but also the spatial current variability in the tracking computation. This proved to be crucial because the Lagrangian trajectories were very sensitive to the starting position and time in the studied area, where the currents exhibit a large spatial variation imposed by tides, winds, large scale circulation and topography. One challenge in applying HFR data for Lagrangian tracking consists of estimating the missing values and including the effects of small scale fluctuations. [C3035]

### "A low power and high gain double-balanced active mixer with integrated transformer-based Baluns"

### **"dedicated to 77 GHz automotive radar applications"**

In this paper, we present a low power and high gain mixer dedicated to 77 GHz automotive radar applications. The architecture is based on a double-balanced active Gilbert cell with integrated transformer-based Baluns. These Baluns allow converting the single-ended input signals to differential with an amplitude and phase imbalance of 0.3 dB and 179°, respectively. Interconnections between devices, capacitor accesses and Tee-junctions are modeled using HFSS simulator in order to improve the simulation accuracy. The proposed mixer consumes 105 mW and achieves 16.4 dB of conversion gain and 13.2 dB of noise figure. [C3036]

### **"Forereaching motion generation of mobile robots for pedestrian face identification"**

This paper describes the generation of forereaching motion using mobile robots for pedestrian face identification. The motion generation system estimates the positions and velocity of the pedestrians and generates a path that enables the robot to forereach the target pedestrian while avoiding the other pedestrians. In this paper, the pedestrian motion estimation method, forereaching path planning method, and experiment results are described. [C3037]

### **"HF radar two-station baseline bisector comparisons of radial components"**

One simple way to evaluate errors in the radial components of surface currents is to compare the values measured from two separate radars along the baseline joining them. This is best done at the midpoint of the baseline where the areas sampled by the radars are equal. This cannot be done if the baseline is close to the coast or over land. Here we compare radial components along the perpendicular bisector of the baseline and show that the RMS difference approaches the error as the point of observation approaches the midpoint. The application of this method to SeaSonde data showed rms differences decreasing until the observations were about 25 km off shore, and then increasing. We suspect that this increase near the coast is due to a known edge effect in the processing of radials that are derived from calibrated antenna patterns. If we exclude the near-coast data points then the rms differences extrapolate to a value of about 0.10 m s<sup>-1</sup> at the midpoint of the baseline. [C3038]

### **"LFMCW SAR waveform generation with frequency nonlinearity suppression"**

Linearly frequency modulated (LFM) signals are desired in many electronic systems. For example, linearly frequency modulated continuous wave (LFMCW) radar has the good performance of lightweight, cost-effective, and high-resolution imaging. However, the presence of frequency nonlinearity in the transmitted signal will result in contrast and range-resolution degradation. In this paper, the impact of frequency nonlinearities on LFMCW synthetic aperture radar (SAR) system is addressed, and one parallel direct digital synthesizer (DDS)-driven phase locked loop (PLL) frequency synthesizer to synthesize wideband LFM signals is designed, and an adaptive system nonlinearity compensation technique is employed. In this way, an example wideband LFM synthesizer with good performance frequency linearity is designed. [C3039]

### **"Route planning for unmanned aerial vehicle based on threat probability and mission time restriction"**

In this paper, a route planning approach for unmanned aerial vehicle (UAV) with mission time restriction is investigated. According to the types and the characteristic of threats in the battlefield environment, we analyse the relation between threat extent and threat probability, build the model of threats, improve A\* algorithm through design the cost valuation function of A\* algorithm and use the variable step length strategy, it improve the search efficiency, when the route planned in safety area can't satisfy UAV mission time require, the method that suitable adding threat probability to satisfy mission time restriction was adopted. The simulation results show that the approach was feasible, effective and can plan route that satisfy the mission time requirements of UAV. [C3040]

### **"Adaptive Information Matrix Filtering fusion with nonlinear classifier"**

An adaptive filtering approach is present for fusing the tracks of multi-sensor surveillance systems. The approach is an algorithm of hierarchical estimation fusion which consists of several local nodes and a global node. A linear Kalman filter is employed by each local node to produce the track estimate of the same target. The outputs of all local nodes are transmitted to the global node. In this node, an adaptive filter, which consists of the dual-band Information Matrix Filter (IMF) and a nonlinear classifier, is utilized to combine the local estimates to generate a global estimate appropriately. The feature vectors are yielded by dual-band IMF. The classifier, which is designed by using the radial basis function network in Gaussian form, is used to divide the feature space into regions that correspond to decide the output of either high-level-band IMF or low-level-band IMF against the uncertainties of target dynamics. The proposed filter has better tracking performance than each

individual IMF. Simulation results are included to demonstrate the effectiveness of proposed filter. [C3041]

### **"Maximum likelihood estimation of target RCS in tracking"**

In this paper, a maximum likelihood (ML) approach is presented for estimating the average radar cross section (RCS), and a numerical solution to the approach is proposed based on a generalized expectation maximization (GEM) algorithm. Estimation accuracy of the approach is compared to that of a previously reported procedure. [C3042]

### **"Research on DBF SAR system in near space"**

In this paper, a SAR system with a method of Digital Beamforming (DBF) was offered, which can realize both wide swath and high resolution at the same time. This research is based on the Displaced Phase Centers Multiple system, which adopt the DBF method at the receive, and is combined with the properties and demands of near space, and through the optimization of the design and overall consideration of the antenna size, pulse repetition frequency (PRF) and the ambiguities etc, the analyzed results demonstrate that it is possible to get wide swath and high resolution, what's more, such a system combined with the advantage of the near space will create a great superiority, and is of great reference value of the near space development and applications. [C3043]

### **"Monitoring manners research on the river ice in the Yellow River"**

According to the current need of controlling ice disaster, three types automatic monitoring ice system are put forward, i.e. ice depth auto measurement system; ice depth probing system; unpiloted aircraft monitoring system. They can continuously and automatically monitor many parameters including ice thickness, water level under ice, air temperature, ice temperature, water temperature and get the ice images, drift ice velocity and the density of drift ice. The process of ice in Yellow River can be obtained by the continuous monitoring with remote images monitoring, radar detecting and unpiloted aircraft monitoring after selecting proper monitoring point. As a result, these monitoring manners provide theoretical support and technical parameters for improving ice disaster emergency monitoring techniques and conditions forecast. At the same time, the monitoring information offers more detailed support to decision maker. [C3044]

### **"Micro-doppler extraction of vibrating target based on dual-channel ATI technique in SAR"**

Aiming at extracting the time-varying micro-Doppler feature of the ground vibrating target within ground clutter environment, the method of micro-Doppler extraction based on dual-channel ATI technique is presented. The ATI technique is utilized to suppress the ground clutter, and preserve the interferometric signal of the vibrating target in the raw data domain, which is presented as a straight line along the azimuth direction. According to this feature, we can find out which range cell the signal locates at, and then by taking the time derivative of its phase, the micro-Doppler modulation can be obtained. Compared to the single-channel situation, there is no need to compensate for the Doppler shift caused by the radar's translation in advance, and we can obtain the micro-Doppler feature induced by the vibration in any direction, which will help to reduce the computation burden and improve the target detectability. Simulated results verify the validity of the proposed method. [C3045]

### **"A progressive approach for building extraction by fusing LIDAR data and co-registered bands"**

In this paper, a progressive approach is presented for building extraction from LIDAR combined with its co-registered bands. Carefully tuned Gabor wavelet filters are applied to LIDAR data for object detection on the earth, and to localize targeted objects in order to minimize hilly terrain effects. Object classification is then carried out in local areas where objects exist. The Dempster-Shafer (DS) theory of evidence is used to conduct initial classification by fusing LIDAR and its co-registered data sets; and a fuzzy Markov random field (FMRF) model takes the output from the DS theory of evidence, and is performed the further object classification to extract buildings. Finally the level set approach is employed for building boundary extraction. The testing experiments under this research have shown the potential of this approach in accurately extracting buildings from airborne LIDAR and its co-registered bands. [C3046]

### **"Simultaneous detection and tracking of multiple objects in noisy and cluttered environment using maximum likelihood estimation framework"**

We discuss a versatile framework for multiple target detection and tracking based on maximum likelihood estimation with expectation maximization and a cognitive theory called dynamic logic. In this contribution extend the framework to detection of moving objects in video sequences. The paper presents the theory and an example of detection and tracking using a real world video sequence. [C3047]

### "Target tracking in state dependent wake clutter"

Tracking methods attempt to follow the movement of a target of interest while suppressing irrelevant clutter. A particularly troublesome source of clutter is wakes that appear behind the target. This problem arises in sonar tracking of human divers, in the tracking of boats using surveillance radars, and also in radar tracking of ballistic missiles. Previous research has integrated a solution to this problem in the popular Probabilistic Data Association filter (PDAF). This paper proposes a new solution to this problem in the same framework. While previous research has used an approach described as probabilistic editing, the new solution solves the wake problem in a Bayesian framework by means of marginalization. Monte-Carlo simulations show that the new solution provides significantly increased robustness as compared to both the standard PDAF and the probabilistic editing approach. As the new solution has improved theoretical underpinnings, we hope that it can be useful for further research on tracking in the presence of wake clutter. [C3048]

### "Wind field retrieval over the ocean using X-band polarization SAR data"

An X-band wind field algorithm (XMOD) based on a linear approach is discussed in our previous work to describe the relationship between normalized radar cross section (NRCS), wind speed, wind direction and incidence angle. To apply the XMOD to TerraSAR-X data acquired in HH polarization, the two C-band polarization models are analyzed and tuned to X-band TerraSAR-X data. To demonstrate the applicability of the two models, 10m height wind speeds were computed with XMOD from several VV/HH TerraSAR-X images and validated by QuikScat and DWD model results. In addition, the wind speeds were retrieved and compared to each other from the HH and VV polarization TerraSAR-X images of the same scene at the same time. [C3049]

### "Study the feasibility of airborne LiDAR on areal earth's crust deformation surveying"

Depicting people haven't find out one efficacious method to rapidly survey the areal outburst geological disaster at present. Through analysing the characteristic and the status quo of the airborne LiDAR, the paper consider that airborne LiDAR can do it. In order to verify the feasibility of airborne LiDAR on areal earth's crust deformation surveying. First, the paper analyse the error cause and should adopte quality control measures. Then, adopte net-RTK to survey many of points three dimensions coordinate in five different terrain regions (flat, river, town, hill, mountainous region). Second, Use DEM by airborne LiDAR points cloud on 3000 m altitude to interpolate vertical coordinate on same position. Third, compute the different value between datum and processing statistics and analysis to the different values. Last, The paper draw a conclusion that airborne LiDAR on 3000 m altitude can use areal earth's crust deformation. [C3050]

### "Altitude estimation method using assumed altitude reliability based on multipath propagation model"

The problem of multipath propagation in the tracking low-altitude targets with a radar is addressed. It is well known that multipath fading causes bias errors to the target altitude over the sea. Since multipath propagation depends on the frequency of the radar waveform, the actual target altitude and range, estimation of the bias errors is difficult problem. In this paper, we propose an altitude estimation method using multipath propagation model. Our method uses the reliability of each assumed altitude hypothesis based on multipath propagation model to estimate the real altitude of targets. Through computer simulation trials, the validity of our method is confirmed. [C3051]

### "An improved CFAR detector for non-homogeneous clutter environment"

An improved CFAR detector for non-homogeneous clutter environment is proposed. At LFM CW radar receiver, after moving target detection (MTD) and linear-law envelop detector, CFAR detector is usually adopted to detect radar targets, the threshold of CFAR detector should be adaptive to the local background noise/clutter environment. Interfering targets often exist in the leading and lagging windows of the test cell which results in an increased detection threshold and a degraded probability of detection (PD). In the improved CFAR detector, an order statistic VI CFAR detector (OSVI-CFAR) is proposed to adaptively remove the interfering targets from the reference windows and increase the PD. Simulation and experiment results are given to prove the feasibility of the OSVI-CFAR detector. [C3052]

### "A SiGe-based Ku-band digital beamforming array for high speed on-the-move comm/radar system"

A digital beamforming (DBF) prototype that uses compact and low cost Balanced Antipodal Vivaldi Antenna (BAVA) array and SiGe based-receiver is presented. An example is given for a Ku-band DBF system that

demonstrates simultaneous reception of two or more full motion videos in a portable device. [C3053]

#### "Phased array digital beamforming hardware development at Applied Radar"

This paper describes technology development efforts in support of phased-array digital beamforming at Applied Radar, Inc. The development efforts are aimed at increasing the bandwidth and dynamic range and enabling real-time throughput of multi-channel array data. This digital beamforming approach enables improved calibration, increased coverage through multiple receive beams, and adaptive processing and nulling. We describe enabling component technology including multi-channel FPGA-based digital hardware and a multi-channel wideband receiver. We also discuss a multi-channel wideband receiver system that was recently developed for electronic sensing and a wideband digital receiver/exciter (DREX) for radar applications. [C3054]

#### "Calibration of panelized polarimetric phased array radar antennas: A case study"

Demand for improvements in the performance and capabilities of new polarimetric radar systems beyond those of their predominantly mechanically-rotated predecessors has led to an effort to realize large, dual-polarized phased array antennas. These arrays have changing polarization characteristics with scan angle, requiring calibration and compensation. This paper provides a qualitative discussion of the challenge in meeting polarimetric weather radar requirements, such as a low bias in differential reflectivity (ZDR) and integrated cross polarization ratio (ICPR). A case study is presented using low-cost, aperture-coupled, stacked-patch antennas, a representative example of what may be used in large polarimetric phased array applications, to predict quantitatively the performance that can be achieved through suitable calibration and size constraints. [C3055]

#### "AOA estimation of two narrowband signals using interferometry"

Conventional interferometric techniques used in electronic support (ES) systems are often limited to estimating the angle-of-arrival (AOA) of one narrowband radar signal at any given time. This paper proposes a simple, low-cost extension that enables these systems to estimate the AOA of two simultaneous narrowband radar signals using only two receivers. [C3056]

#### "Innovative aperiodic arrays for SAR spaceborne applications"

In this paper an innovative procedure for the synthesis of linear non periodic phased arrays for SAR applications is presented. The main objective consists in minimizing the number of elements while optimizing the efficiency of the amplifiers. The procedure is implemented in three steps. Preliminary results are presented demonstrating that a reduction in the number of elements in the order of 20-30% with respect to existing conventional antennas may be achieved without sacrificing the performances. [C3057]

#### "Monopulse compromise arrays-A review"

Monopulse array antennas can be synthesized through a sub-array architecture aimed at generating an optimal sum and compromise difference patterns. A strategy based on an excitation matching procedure is here reviewed. Representative numerical results are shown to assess the effectiveness of the approach. [C3058]

#### "A tray based Rotman lens array with beamforming in two dimensions for millimeter-wave radar"

A tray based Rotman lens array is presented, which consists of several low-profile Rotman lenses with beam control circuitry, miniature dual-polarized horn antenna arrays, and tray selection circuitry for elevation beamforming. The array achieves broad bandwidth from 34 to 40 GHz, and beamforming in two dimensions is realized. In azimuth, switched beamforming is implemented with the Rotman lens beam control circuitry. In elevation, adaptive beamforming using MUSIC (multiple signal classification) is implemented with the individual Rotman lens trays. A proof of concept beamforming experiment was conducted, where the locations of targets within a three dimensional space were detected with 2.5 cm range resolution. [C3059]

#### "UAVSAR Active Electronically-Scanned Array"

The Uninhabited Airborne Vehicle Synthetic Aperture Radar (UAVSAR) is an L-band (1.2-1.3 GHz) repeat pass, interferometric synthetic aperture radar (InSAR) used for Earth science applications. Using complex radar images collected during separate passes on time scales of hours to years, changes in surface topography can be measured. Due to variations in aircraft attitude between passes, antenna beam steering is required to replicate the radar look angle from pass-to-pass. This paper describes an Active Electronically Scanned Array (AESA) that provides beam steering capability in the antenna azimuth plane. The array contains 24 transmit/receive modules generating approximately 2800 W of radiated power and is capable of pulse-to-pulse

beam steering and polarization agility. Designed for high reliability as well as serviceability, all array electronics are contained in single 178cmx62cmx12cm air-cooled panel suitable for operation up to 60,000 ft altitude. [C3060]

### "Precise calibration techniques for complex SAR systems based on active phased array antennas"

In recent years, the antenna technology for spaceborne synthetic aperture radar (SAR) systems has developed from passive slotted waveguide arrays (e.g. ERS-1/2 or X-SAR) to active phased arrays (e.g. ASAR/ENVISAT or TerraSAR-X), offering electronic beam steering capabilities required for acquisitions in different swath geometries and for operation in ScanSAR and Spotlight modes. Furthermore, with an increasing number of operational applications and services, the requirements on radiometric and geometric calibration become increasingly demanding. Hence, product quality is of crucial importance and the success or failure of a mission depends essentially on the method of calibrating the SAR system in an efficient way. In example of TerraSAR-X the paper describes a precise and efficient calibration method applicable for complex spaceborne SAR systems based on an active phased array antenna. [C3061]

### "Spread Spectrum Digital Beamforming (SSDBF) radar"

Spread Spectrum Digital Beamforming (SSDBF) overcomes the CSWAP and the scalability in bandwidth-and-frequency limitations of Conventional Digital Beam Forming (CDBF) by eliminating the requirement of "one digital transceiver per element" while enabling fully capable digital beamforming with minimum hardware (and consequently minimum volume and heat dissipation) per element. SSDBF enables low-cost/low-profile/low-power digital beam forming phased arrays that scales in frequency (L through Ka and higher), bandwidth (100's MHz) and subarray size (100's elements per subarray) with a single down-converter, single digital receiver and single Nyquist-rate ADC for the entire subarray. It achieves this by replacing the MMIC T/R module at each element with much simpler bi-phase re-modulating hardware, and by re-modulating and aggregating the return signal incident at each element such that it can perfectly recover the complex baseband-equivalent of the RF signal of each element without mutual interference and with negligible noise performance degradation. The bi-phase re-modulator at each element can be extremely small and low power and amenable to implementations as simple as a single RF switch mounted directly at the antenna element with associated ON/OFF switch control logic built on the back. Thus SSDBF truly enables flat, thin, lightweight conformal phased arrays and has the potential of reducing phased array costs by, possibly, multiple orders of magnitude relative to CDBF state-of-the-art. The SSDBF parameters and waveforms are flexible, programmable and can be tailored and adapted, practically, to support any radar or communications applications. In a project for DARPA, Applied Radar is developing an X-band SSDBF-based radar prototype in which the SSDBF features and performance have been demonstrated. In this paper, we describe the SSDBF method for a radar application including simulation, indoor testbed and open-range test results. [C3062]

### "A family of G-band active electronically scanned arrays for radar applications"

The present paper describes the family of G-band Active Electronically Scanned Arrays (AESA) designed and produced by SELEX-Sistemi Integrati. The development of certain types of key components has allowed to obtain, with the same effort, AESA with different performances according to the customer needs. The overall architecture of the AESA is described. [C3063]

### "SE-IT joint M-AESA program: Overview and status"

The Multi-function Phased Array (M-AESA) program is a joint SE-IT initiative for the development of a capability driven multifunction phased array system concept. This paper will present the progress the M-AESA research and development program has made over the last three years and it follows the paper "New concepts for MRFS evolutionary trends. The M-AESA program: A joint IT-SE capability driven approach" by V. Carulli et al. presented at the Radar Conference 2008 in Rome [1]. The program, based on a number of different national initiatives, benefits from different cultural approaches and perspectives, and aims to lead an initiative in Europe for such a new family of RF systems. An overview and status of this unique R&D partnership will be discussed with a mission of evaluating new technology and system architecture for developing the next generation phased array antenna system capable of exploiting the most relevant operational functions (Radar, EW, Comm) according to the operational scenarios. However, a number of technical, operational and cost issues are still remaining to be addressed before M-AESA can become a reality. [C3064]

### "Toward common radar & EW multifunction active arrays"

Military Air platforms are fitted with Fire Control or Surveillance Radars, usually operating in X-band, Electronic Warfare Systems (EWS), and some radio links. Each of these systems is dedicated to a particular task and the cooperation is reduced to a minimal exchange of information between them mainly for avoiding mutual

disturbances. Major system performance enhancements are to be expected thanks to close co-operations of one sensor to each others and thanks to the sharing of resources, especially in the field of multifunction AESA antenna sharing. The future co-operations can be ordered in four levels. The levels one to three lead progressively to a multi-functions sensor. The last one is the deployment, on a single or multiple platforms, of compact multi-functions sensors on a network basis. Another area of co-operation is the realization of R.F. functions such as "ad-hoc" communication functions using the Radar or the EWS multifunction R.F. and antennas. [C3065]

#### "Acoustic tracking of aircraft using a circular microphone array sensor"

Runway Incursion Avoidance Systems (RIAS) are vital parts in the prevention of runway accidents at airports. Such systems depend on the accurate positioning of aircraft and ground vehicles. Today, RADAR is the predominant method, but a RADAR based system might be both impractical and too expensive for small airports. Additionally, the redundancy of several independent systems is sought after even at large airports. We investigate the application of a low-cost circular microphone array solution for acoustic detection and tracking of aircraft. The shape of the array yields 360° coverage with equal characteristics in all directions. An algorithm based on sweeps performed with the Capon adaptive beamformer followed by peak detection and thresholding is implemented for real time use. The performance of the system is tested at Evenes airport in Norway. [C3066]

#### "Adaptive space-time beamforming technique for passive radar system with ultra low signal to interference ratio"

In recent years, the passive radar, using the noncooperative illuminators of opportunity, has attracted increasing attention. We discuss beamforming technique with application to the passive radar system. For realization issue, adaptive beamforming technique can be used to detect and estimate the signal-of-interest at the output of a sensor array by means of the adaptive spatial filter to suppress interference. Specially, the adaptive beamformer based on constrained least mean squares algorithm has been derived which is capable of adjusting an array of sensors in real time to detect the signal-of-interest and eliminate interference. We will exploit the space-time processing algorithm for the passive radar system, in order to increase the degrees of freedom without limiting the system output SINR. For more efficient and practical implementation, the proposed space-time beamformer can be realized by the recursively adaptive algorithm with multiple constraints. Finally, the proposed space-time beamformer can be operated in multiple linear constraint mode to combat the angle mismatch problem. From simulation result, it is shown that the multiple constraint space-time beamformer provides better OSINR performance with resistance to strong interferences. [C3067]

#### "High precision DOA estimation of SSR transponder signals"

In this work, localization by means of DOA (Direction of Arrival) estimation is investigated. A newly developed low-cost planar linear array and improved receiver hardware is calibrated and evaluated by the use of a dedicated measurement aircraft, not based on ADS-B (Automated Dependent Surveillance-Broadcast) airborne position telegrams. It will be shown how this DOA sensor closely approaches theoretic precision limits. [C3068]

#### "MIMO radars or is it smart antennas?"

Radars were originally designed as detectors of targets. The goal was to transmit a signal with the maximum available power and then observe whether the received signal contained a portion of the transmitted signal. A matched filter was then designed using the transmitted waveform to detect the received signal and based on some statistical hypothesis testing a decision was made on whether a target is present or absent. However, when multiple targets are to be examined or one wants to search for a low observable near a large target, the conventional detection based radar processing is not adequate. A need for finding small targets in the presence of clutter and jammer evolved into an estimation theory problem rather than detection. It is illustrated that use of a phased array in a SIMO mode can perform quite well as one does not have to worry about the inhomogeneity of the clutter associated with multiple transmissions in a MIMO system as the processing becomes quite complicated. Also, the compensation of mutual coupling becomes difficult in a practical deployment on a moving platform. It is important to note that one can still exploit the advantages of super-resolution processing using estimation theory keeping the advantages of a single high power transmitting antenna in a phased array deployment. This paper illustrates such a methodology which has been in the published literature for at least a decade and compares it with the recent MIMO developments. Examples are presented related to a single snapshot based least squares methodology that can cancel interferer in the main beam using a phased array radar but performing a deterministic processing using the same number of degrees of freedom as a multisnapshot case for coherent processing. [C3069]

### "Denoising of single-look SAR images based on variance stabilization and nonlocal filters"

Synthetic-aperture radar (SAR) imaging has become an efficient tool for obtaining and retrieving useful information about surfaces of Earth and other planets. However, the formed images suffer from speckle noise, especially if single-look observation mode is used. Then, filtering is often applied to improve image quality and provide better estimation of radar cross-section and other parameters of sensed scenes. Recently, a novel class of image filters has proved to be very successful in the removal of additive white Gaussian noise from natural images; these filters are based on nonlocal image modeling, i.e. they exploit the mutual self-similarity of image patches at different locations in the image. These filters have been shown in several benchmarks to significantly outperform all previous techniques. In this paper, we evaluate the performance of nonlocal filters applied to the denoising of single-look SAR images corrupted by speckle with a Rayleigh distribution, taking advantage of exact forward and inverse variance-stabilizing transformations. Numerical simulations demonstrate the success of this approach against several known despeckling methods. [C3070]

### "On the design of integrated HF radar systems for Homeland Security applications"

In this paper, HCAC's research and development efforts on the development of integrated and low cost HF radar for coastal surveillance and other Homeland Security applications are summarized. The proposed design incorporates electrically small antenna for rapid deployment, supports operation on floating platforms by using enhanced DSP algorithms to mitigate clutter, incorporates improved propagation modeling to more accurately select optimum frequency channels based on atmospheric conditions and overcome the errors due to terrain effects, utilizes Genetic Programming for automatic target recognition and classification, and provides for passive radar operation utilizing existing broadcast transmitters to enable covert operation. [C3071]

### "Iterative focusing algorithm to estimate moving target"

In this paper, the authors have presented iterative focusing algorithm (IFA). Under the condition of the same number of bins, IFA demonstrates imaging performance superior to that obtained using DAS because of the area focusing. IFA with DAS algorithm significantly improves the amount of computation than the conventional IAA algorithm. Furthermore, by focusing the scanning area, bin size is reduced, and the estimation accuracy is improved significantly. IAF with IAA algorithm performs better than IAF with DAS algorithm. Note that IAF with IAA algorithm takes huge amount of computation. If the authors allow little ambiguity, the IFA with DAS algorithm is effective for both target imaging and computation. [C3072]

### "Adaptive filtering and target detection for ultrasonic backscattered signal"

In radar, sonar, medical ultrasound, and ultrasonic nondestructive evaluation, environmental noise makes target detection challenging. Therefore, clutter rejection and noise cancellation are necessary for the system to correctly identify targets. In this study, an adaptive filtering algorithm is used to reject clutter and detect small targets in noisy ultrasonic backscattered signals. Simulation and experimental results show that adaptive filter can efficiently reduce the clutter and improve the detection capability. [C3073]

### "High range resolution moving target indication at long stand-off ranges using minimal sampling rates in linear FMCW radar"

Combinations of high range resolution, long standoff ranges and the requirement for moving target indication in LFMW radars tend to increase the required signal sampling rate. A simple method of calculating a suitable sub-sampling rate to down-convert the signal by exactly aliasing the required information is described, providing a means of dramatically reducing the sampling rate. The technique is demonstrated in numerical simulations and with a mm-wave radar. [C3074]

### "High resolution terahertz imaging (T-ray) with a horn antenna"

We suggest a simple method overcoming the limitation of spatial resolution for wavelength by using a horn antenna. And, we verify detection limitation by THz imaging for a foreign object in flour. [C3075]

### "Combined passive and active millimeter-wave imaging system for concealed objects detection"

In this paper, a comparison between both imaging techniques is performed with the aim of integrating both in a single imaging system. It is expected that the combination of the coherent and incoherent radiation in active and passive operation will offer improved detection and identification of concealed objects. An interferometric radiometer and an active mills-cross have been studied as near field imaging systems. The main parameters have been simulated to foresee their performance as image scanning systems. Moreover, a T-shape active

imaging system has been built and measurements have been done in order to test and assess the performance of this imaging geometry. [C3076]

#### **"Measurement-based delay-and-sum signal processing for linear antenna arrays"**

The design of a delay-and-sum beamformer based on measured data is presented in this paper. Traditionally the weighting of a delay-and-sum beamformer is designed based on an idealized signal model, with specifications on the beam pattern in terms of the beam width and the sidelobe level (SLL). The goal is a trade-off between resolution and the ability to detect targets with a certain dynamic range. In this work we propose an approach to the optimization of a delay-and-sum beamformer with the same goal in mind however not based on the ideal signal model, but based on measured data. Being a measurement-based method even effects of non-idealities that are not part of the ideal signal model such as mutual coupling can be suppressed. The proposed approach is validated in simulations for a 77-GHz 36-elements non-uniform frequency-modulated continuous-wave radar array. [C3077]

#### **"Experimental validation of high-permittivity ceramic double-ridged horn antennas for biomedical ultra-wideband diagnostics"**

Low-power ultra-wideband (UWB) radar sensors are attracting more and more attention, e.g., for biomedical diagnostics. In contrast to established techniques like X-ray tomography or invasive approaches, UWB radar offers the potential for remote access and, based on suitable waveforms, ultra-low power signal intensities. This paper presents a complete characterization of a miniature ceramic double-ridged horn antenna. The input matching, radiation pattern, and impulse response reveal a performance promising for biomedical diagnostics. A further improvement and miniaturization will become accessible by optimized manufacturing processes and feed impedance, respectively. Preliminary volunteer measurements showed the suitability of the antennas for the envisaged applications and justify our approach. [C3078]

#### **"Improved range resolution for FMCW HF surface wave radar"**

A modified signal processing for FMCW waveform has been proposed that yields an improved range resolution without increasing the transmitted signal bandwidth. The chirp duration is reduced by an appropriate factor while the interval of the beat signal sequence considered for the range transform is kept constant. This modification implies a range transform over several chirp sweeps and an interleaving technique for the Doppler transform. Range resolution is improved without affecting the maximum unambiguous Doppler. This is achieved on the expense of a reduction of the maximum unambiguous range. Actually, this is not a restriction for HF SWR systems where the maximum range is limited by surface wave attenuation. However, a minimum practical range bin size is given either by the size of the targets considered or by the acceptable size of range side lobe level coming along with increasing range resolution. With this approach first and second order sea clutter is reduced which is of significant interest for ship detection. [C3079]

#### **"Low-profile dual-polarized UHF array antenna"**

A low-profile dual-polarized UHF array antenna has been developed for wide field-of-view dual sector coverage in the 250 to 450 MHz frequency range for communications or radar applications. The antenna utilizes a pair of parasitically-tuned dipole arrays for horizontal polarization and a pair of parasitically-tuned monopole arrays for vertical polarization, and both arrays are mounted on a common ground plane. The thickness of the antenna is 18.2 cm. Numerical electromagnetic simulations were used to analyze and optimize the antenna parameters prior to fabrication. Measurements of the dual-polarized prototype in an anechoic chamber demonstrate the antenna's return loss and dual-polarized radiation gain pattern performance. [C3080]

#### **"Array antenna pattern synthesis using measured active element patterns and Gram-Schmidt Orthogonalization"**

In this study, a practical and generalized method for array pattern synthesis for any given array is presented. The method is based upon measurement of active element patterns and then processing of these patterns by Gram-Schmidt Orthogonalization procedure. As the mutual coupling effects are taken fully into account by element pattern measurement, the synthesized pattern is in excellent agreement with the real behavior of the array. Usage of orthogonalization guarantees the Least Squares Error for the synthesized pattern. Combining the technique in with the proposed method, it is also possible to make Phase-Only Synthesis for a given array. The method was applied to 10 rows of X-band slotted waveguides each consisting of 44 slots. The antenna pattern was measured at a planar near field range, and practically negligible difference was observed between the predicted and measured patterns. [C3081]

### "Efficient beam scanning, energy allocation, and time allocation for search and detection"

Recently-developed unique and innovative concepts for efficient radar search and detection are reviewed. These results provide answers to the two fundamental search questions: (1) Where should the radar beam point during the next increment of search effort (energy and time)? (2) How much radar effort should be expended during the next increment of search effort? These results provide the most efficient allocation of radar search effort in both space and time which maximizes target detection performance and minimizes radar search energy and time. Typical savings of several dB of radar power-aperture product and/or expected (average) detection time are obtained. These new techniques are practical and can be used in the next generation of radars with agile beams and variable-energy search waveforms. Furthermore, the problem formulation and solution are very general, so these search and detection techniques developed for radar can also be applied to other both active (transmitting and receiving) and passive (receive only) electronic sensors: optical, IR, UV, sonar, seismic, passive RF, astronomy, etc. [C3082]

### "Bandwidth assignment for target tracking in coherent distributed aperture radar networks"

Multiple target tracking using networks of coherently integrated radar apertures is a current research topic that promises improved tracking accuracy and more efficient system implementations. The design of such tracking systems is complicated by the multiple subsystem functions involved in overall system performance. The separate isolated design of these functions results in suboptimal system performance. In this paper we consider the overall multiple radar system optimization by means of aperture waveform bandwidth allocation. In general, a greater aggregate bandwidth assigned to a target results in a more accurate target track. However, since multiple targets are simultaneously tracked, the data network transmission capacity limits the overall throughput resulting in a resource assignment problem. The assignment problem is specifically to assign available multi-radar bandwidth in a manner that maximizes the number of targets that achieve a terminal tracking error that is less than the maximum error allowed. We introduce a multistage control framework to demonstrate the performance of a proportional assignment procedure for countering a saturation attack. Conclusions for designing suitable distributed radar systems are given. [C3083]

### "The DESDynI synthetic aperture radar array-fed reflector antenna"

DESDynI is a mission being developed by NASA with radar and lidar instruments for Earth-orbit remote sensing. This paper focuses on the design of a large-aperture antenna for the radar instrument. The antenna comprises a deployable reflector antenna and an active switched array of patch elements fed by transmit / receive modules. The antenna and radar architecture facilitates a new mode of synthetic aperture radar imaging called 'SweepSAR'. A system-level description of the antenna is provided, along with predictions of antenna performance. [C3084]

### "Polarimetric phased array weather radar: Concepts for polarimetric calibration"

The National Severe Storms Laboratory (NOAA-NSSL) and the Advanced Radar Research Center at the University of Oklahoma (OU-ARRC) are presently involved in the design, development and construction of a cylindrical polarimetric phased array radar (CPPAR) to demonstrate polarimetric capabilities for weather sensing within the Multi-function Phased Array Radar (MPAR) project. The bias in radar meteorological polarimetric variables is dependent on a number of parameters like cross-to-copolar gain ratio, integrated cross-polarization level, cross-to-copolar phase, copolar beam-width mismatch and beam pointing angle mismatch [1-2]. In the first part we present a preliminary system design for CPPAR, in the second part we present a procedure for polarimetric calibration using a target of opportunity, namely rain. Polarimetric calibration such as this one is extremely important for polarimetric phased arrays, since calibration needs be done on a beam by beam basis. [C3085]

### "Analyzing SAR ambiguities in the u-v plane"

Phased array designers routinely analyze beam patterns in the u-v plane, to ensure that aliasing locations (called grating lobes) remain outside the visible beam region. A related spatial aliasing problem occurs in synthetic aperture radar (SAR) systems, where points that can fold onto other locations in an image (called ambiguities) must be kept out of the radar main beam. A well-known SAR criterion specifies the minimum area of a rectangular antenna for ambiguity-free operation. This paper employs a phased array-inspired approach to solving the SAR problem for general antennas, by overlaying SAR ambiguities onto the antenna beam pattern in the u-v plane. A theorem from Number Theory then provides the maximum beam area that does not illuminate ambiguous points, under general conditions. This maximum beam area criterion extends the classic minimum antenna area expression to non-rectangular antennas in unconventional orientations, while providing intuition and

visualization familiar from phased array design. [C3086]

#### "Analysis of a novel MIMO system for security applications"

Recent years have shown how the performances of the standard radar systems can be significantly improved by using a multiple-input multiple output (MIMO) approach. MIMO technique is an already well studied method for communications applications thanks to the benefits that it offers in multipath fading environments. This paper is aimed to present the design of a new MIMO based, short range, surveillance radar for local area security purpose. One of the main addressed features to the system under consideration is the capability to provide full 360° azimuth coverage within its working area. The following analysis will be focused on the system structure description and on the first simulated results. [C3087]

#### "Transmit/Receive Module technology and related multifunction active radars in Selex-Sistemi Integrati"

The paper deals with the SELEX-SI Transmit/Receive Module (TRM) technology and related radar applications. Since the end of '90s SELEX-SI started its activities on the active technology, establishing a 20 years Road Map including GaAs and GaN components and evolving through the increase of effective generated power and efficiency, and through the decrease of Noise Figure for sensors applications. The Road Map is comprehensive of a large frequency band interval, with specific attention to C and X band. As far as it concerns the G band radar sensor application of the active technology, this paper describes Selex-SI Active EMPAR (in the future named C-HOUND) and KRONOS radars. KRONOS and Active EMPAR are multifunctional, multi-role G-Band radars based on Active Electronically Scanned Antenna (AESA). Active EMPAR is designed as a technologic upgrade of the SELEX Sistemi Integrati well proven EMPAR Multifunctional radar system provided to the Italian and French Navies. In this paper the two radar features will be detailed in terms of implemented technical and technological solutions and related advantages in surveillance, tracking and other functionalities required for a Combat System. [C3088]

#### "Low-loss, MEMS based, broadband phase shifters"

Broadband, true time delay phase shifters based on MEMS switches provide the high instantaneous bandwidth desired for applications such as multi-frequency antenna arrays with multiple functions such as radar, communications, and ECM. MEMS based phase shifters offer significant performance advantages compared to technologies using PIN diode or MESFET switches including high linearity that does not limit the dynamic range of the receiver in a crowded signal environment. Furthermore, MEMS phase shifters offer a combination of low RF insertion loss and low switch control power consumption that is unmatched by PIN diode or MESFET technologies, giving the MEMS phase shifters a decided advantage at reducing prime power consumption in airborne or space based systems. Radant MEMS Inc., employing its high power 10 Watt MEMS switch with a demonstrated 1 trillion cycle lifetime, designed, fabricated and tested a 6-bit, 5 Watt, true time delay, 1-6 GHz, MEMS phase shifter that, with the exception of the three longest delay lines, was integrated on a single silicon die. This compact, low cost phase shifter is hermetically sealed using the same wafer capping process now employed for Radant's MEMS switches. [C3089]

#### "Development of a low-cost, man-portable, Phased Array X-Band Radar"

A compact, active scan, X-Band Phased Array Antenna has been developed and tested. This antenna is supportive of a man-portable ground surveillance Radar, and has been designed for low manufacturing cost. The design supports  $\pm 60^\circ$  azimuth scan angles, and features a "cosecant squared" elevation pattern for reduced ground clutter effects. Antenna patterns and active scanning consistent with design goals have been demonstrated. These results support the current Cobham development efforts towards a complete, low-cost, man-portable Radar system. [C3090]

#### "Antenna array diagnosis in situ: Experimental results using microwave circular holography"

This paper is presenting the experimental performance of a circular microwave holography algorithm for the troubleshooting of in-service array antennas. The experiment is conducted using an algorithm for the estimation of array element excitations from circular near field measurements. The experimental results exceed those obtained from the preliminary numerical simulations. [C3091]

#### "Phased array calibration and diagnostics utilizing a student-built planar near-field system"

A low-cost planar near-field system was designed, built, and programmed by students from the University of Rhode Island as a Capstone design project sponsored by Applied Radar, Inc. The objective of this paper is to

explore the implementation of microwave holographic metrology (MHM) for the use of calibration and diagnosis of phased array performance on this near-field system. The simplest form of MHM is to analyze the near-field data on the collected planar surface, but this is not ideal because of a loss of resolution from the spreading introduced by the measurement distance. A more attractive approach is to project a focused planar "hologram" of the radiation pattern on the surface of the aperture of the antenna under test (AUT) through manipulation of the angular spectrum. The resulting hologram allows for the observation of amplitude and phase distributions on the aperture. This paper will provide insight into the design of the back-projection algorithm and present results for faulted and calibrated phased array scenarios to verify proper functionality of the algorithm. [C3092]

#### **"Accurate antenna pattern modelling for spaceborne active phased array antennas"**

In example of measurements performed in space with TerraSAR-X, an approach for an accurate antenna characterization is described. TerraSAR-X was launched in June 2007 and is a highly flexible X-band radar satellite based on an active phased array antenna. Its primary objective is the acquisition of high quality SAR images in a multitude of possible acquisition modes. As this demand is of paramount importance, an accurate characterization of the antenna is a major task, i.e. thousands of different antenna beams being operated have to be determined precisely for compensating the impact of the antenna on SAR data products. Only then, a spaceborne SAR system based on an active phased array antenna can be successfully commissioned. This paper presents the methodology and results derived from different measurements performed for characterizing an active phased array antenna in flight. [C3093]

#### **"MIMO radar joint estimation of target location and velocity with multiple subcarrier signals"**

This paper analyzes the effect of waveform parameters on the joint target location and velocity estimation by non-coherent multiple-input multiple-output (MIMO) radar transmitting multiple subcarriers signals without energy constraint. How the number of subcarriers influence the estimation accuracy is illustrated by considering the joint Cramer-Rao bound (CRB) and the mean square error (MSE) of the maximum likelihood (ML) estimate. The non-coherent MIMO radar ambiguity function (AF) with multiple subcarriers is developed and investigated by changing the number of subcarriers, the pulse width and the frequency spacing between adjacent subcarriers. The numerical results show that more subcarriers means more accurate estimate and higher localization resolution, larger pulse width results in worse performance of target location estimation, while the frequency spacing affects target location estimation little. [C3094]

#### **"Real-time through-wall imaging using an ultrawideband multiple-input multiple-output (MIMO) phased array radar system"**

A real-time acquisition and processing architecture has been developed for an ultrawideband (UWB) S-band (2-4 GHz) multiple-input multiple-output (MIMO) phased array radar system that facilitates greater than 10 Hz imaging rates, providing a video-like radar image of what is behind a concrete wall. Video rate imaging enhances the interpretability of range vs. range through-wall and free-space radar imagery. Images are formed without a-priori information. Video framerate imaging is achieved by designing an electronically switched bi-static array using high-performance microwave components, a multi-threaded data pipeline, and efficient hardware-accelerated processing algorithms. Experiments successfully image low radar cross section (RCS) objects, fast moving objects in free-space, and a human behind a 10 cm-thick solid concrete wall. [C3095]

#### **"Scalable multifunction RF system concepts for joint operations"**

RF systems based on modular architectures have the potential of better re-use of technology, decreasing development time, and decreasing life cycle cost. Moreover, modular architectures provide scalability, allowing low cost upgrades and adaptability to different platforms. To achieve maximum benefit from modularity and scalability, the challenge is to define the front-end concept in such a way that it supports multiple functions and is applicable in multiple environments and platforms. This paper describes concepts for such modular systems that may be used for RF functions in maritime, airborne and land based systems. The first part discusses general scalability properties of various RF functions, the second part discusses example system concepts in a 'joint' scenario (land/sea/air). The focus of this paper is on X-Ku band systems: considering essential RF functions like radar and communication, and the types of platforms in maritime, land-based and airborne operations, this frequency range provides the highest potential for application in all these domains and platforms. Conceptual designs for weapon location radar, SAR/GMTI, surveillance radar and tactical data link are presented. [C3096]

#### **"A wide band low profile dual-pol "Thumbtack" array"**

A dual-pol array of 15x15 "Thumbtack" elements was built and tested for 0.5-2.0 GHz demonstration. The array

is 3 in. (7.6 cm) thick, a bout 1/8 wavelength at the low end of the band, characterized by a high impedance (~300 ohms) aperture, matching to free space's wave impedance (377 ohms) directly without a long flare as in a Vivaldi notch. The array has a square lattice of 3 in. (7.6 cm) spacing, and the "Thumbtack" element has a coincident and stationary phase center. The thin and planar structure produces very low X-pol, typically 30 dB down at bore-sight, and 15 dB at 45° of axis along the diagonal cut. The array was designed for applications that require nanosecond rise time, ultra low X-pol and non-dispersive phase response. These unique features make it possible to produce sharp images for IED detection, FOPEN SAR, see-through-the wall radars, and other EW missions. [C3097]

#### "MIMO radar for sense and avoid for UAV"

UAV are easily deployable platforms. Up to now they carry payloads (surveillance, combat) for military purposes in crisis or war time. For training, UAV are flown in special areas attributed in a limited space and a limited time slot. In the future, UAV will also be used for civilian tasks. For these reasons, UAV will have to be inserted in the general Air traffic and "Sense and Avoid" systems will be mandatory. Among the possible sensors, the radar is the most pertinent one: it is "all-weather" and provides accurate range, direction and closing speed. In this paper, a low cost solution based on the coherent "MIMO" principles is described. This solution allows the location of the radar within the UAV airframe without any moving parts, hence provides a high reliability level. The rationale of the proposed architecture is explained, then the enabling technologies and related waveforms are described. [C3098]

#### "Beampattern optimisation for sub-arrayed MIMO radar for large arrays"

The estimation of the direction of arrival (DOA) of signals in the far-field of an array has been an area of continued research. Recent advances in MIMO radar techniques have led to results whereby prior knowledge of the approximate target locations is used to generate arbitrary signals which are transmitted from an active array to improve DOA estimates. This would be a useful in a scenario such as target tracking. However, this neglects the complexities of the hardware required for larger arrays, and further, the amount of computation required on the transmit side alone. A sub-optimal method employing sub-arrays to reduce hardware requirements, and a low complexity algorithm to determine the optimal steering vectors for the arrays is presented and compared to the optimal full diversity transmit strategy. [C3099]

#### "An ultrawideband (UWB) switched-antenna-array radar imaging system"

A low-cost ultrawideband (UWB), 1.926-4.069 GHz, phased array radar system is developed that requires only one exciter and digital receiver that is time-division-multiplexed (TDM) across 8 receive elements and 13 transmit elements, synthesizing a fully populated 2.24 m long ( $\lambda/2$  element-to-element spacing) linear phased array. A 2.24 m linear phased array with a 3 GHz center frequency would require 44 antenna elements but this system requires only 21 elements and time to acquire bi-static pulses across a subset of element combinations. This radar system beamforms in the near field, where the target scene of interest is located 3-70 m down range. It utilizes digital beamforming, computed using the range migration synthetic aperture radar (SAR) algorithm. The phased array antenna is fed by transmit and receive fan-out switch matrices that are connected to a UWB LFM pulse compressed radar operating in stretch mode. The peak transmit power is 1 mW and the transmitted LFM pulses are long in time duration (2.5-10 ms), requiring the radar to transmit and receive simultaneously. It will be shown through simulation and measurement that the bi-static antenna pairs are nearly equivalent to 44 elements spaced  $\lambda/2$  across a linear array. This result is due to the fact that the phase center position errors relative to a uniform  $\lambda/2$  element spacing are negligible. This radar is capable of imaging free-space target scenes made up of objects as small as 15.24 cm tall rods and 3.2 cm tall metal nails at a 0.5 Hz rate. Applications for this radar system include short-range near-real-time imaging of unknown targets through a lossy dielectric slab and radar cross section (RCS) measurements. [C3100]

#### "Low cost Multifunction Phased Array Radar concept"

MIT Lincoln Laboratory and M/A-COM are jointly conducting a technology demonstration of affordable Multifunction Phased Array Radar (MPAR) technology for Next Generation air traffic control and national weather surveillance services. Aggressive cost and performance goals have been established for the system. The array architecture and its realization using custom Transmit and Receive Integrated Circuits and a panel-based Line Replaceable Unit (LRU) will be presented. A program plan for risk reduction and system demonstration will be outlined. [C3101]

#### "Demonstration of accurate prediction of PAVE PAWS embedded element gain"

We can now accurately theoretically predict the embedded element gain and 2-way scan loss of the PAVE

PAWS array to within 0.25 dB over 420-450 MHz band up to 60° scan and 0.4 dB up to 75° scan. When the PAVE PAWS array, which uses a bent, crossed-dipole element, was built in the 1970's tools were not available for accurate prediction. Expensive experimental trial-and-error measurements were used. The theoretical predictions were made using the Ansoft High Frequency Structure Simulator (HFSS). Accurate mutual coupling measurements made in 1977 on a 320 element PAVE PAWS test array were used for verification. [C3102]

#### "Self tapered array lattice for high efficiency transmit applications"

Applications for phased array antennas have become increasingly diverse. This is true for current state of the art radar systems (sense and avoid, imaging, weather, etc) as well as communication antennas. Many of these applications require low sidelobe performance or beam-widths tailored to a specific application. Current methods to implement amplitude taper over the array aperture involve attenuators or unequal power splitting networks. These traditional methods have negative impacts to system performance. In this paper, we present the results of the investigation of two alternate approaches for improving the EIRP and simplicity of tapered array lattices that do not make use of conventional techniques involving dissipative attenuation or unequal power dividers. These techniques are intended to improve the EIRP from a given transmit array size without compromising side-lobe suppression. A conventional approach using power dividers is presented for comparison. It is shown that the EIRP available from a transmit aperture may be increased by more than 6 dB while maintaining low side-lobe levels. [C3103]

#### "An s-band ultrawideband time reversal-based RADAR for imaging in cluttered media"

This work presents a new RADAR prototype built for the purpose of imaging targets located in a cluttered environment. The system is capable of performing Phase Conjugation experiments in the ultrawideband GHz. In addition, applying the D.O.R.T. method to the inter-element matrix allows us to selectively focus onto targets, hence reducing the clutter contribution. The system has been validated by physically backpropagating the focusing wave into the medium all over the frequency band and observing the expected focusing properties. [C3104]

#### "Concurrent multifunction transmit and receive applications with dynamic filtering"

This paper demonstrates a concept for transmitting on one set of elements of a phased array while concurrently receiving on another set at a separate frequency. Cases are analyzed using measured data from an 848 microstrip stacked patch panel array operating at 33.8GHz, and relative coupling levels from interfering elements to receive elements are characterized over various scan angles for two array configurations-side-by-side contiguous blocks and for interleaved elements at separate frequencies. It is shown that an optimum transmit frequency exists that minimizes coupled power to receiving elements in the array for a given scan angle. Additional isolation between elements is achieved with a tunable bandpass-bandstop filter cascade that, when paired with a high-linearity low-noise amplifier, reduces interference from transmitting elements to within the receiver analog-to-digital converter's (ADC) dynamic range, such that receiving elements can operate concurrently next to 25W transmitting elements. [C3105]

#### "A novel edge wall waveguide slot antenna"

In this work, a novel excitation technique for non-inclined edge wall waveguide slots is developed. The proposed method greatly facilitates the manufacturing of large edge wall slotted waveguide arrays with very low cross polarization levels at the cost of deviation from shunt slot model. Slots are characterized using the infinite array approach in two dimensions and using this characterization data, travelling wave type linear arrays are designed. A planar array is also formed using previously designed linear ones. Designed antenna arrays are simulated and the results show that the infinite array approach is suitable for the design of these types of antennas. [C3106]

#### "Detection in collision avoidance radar using active versus passive phased arrays"

This paper presents two designs for phased arrays for collision avoidance radar operating at the 76 GHz band. The two designs for the antenna use a linear waveguide horn array that is fed with a waveguide power-dividing network and is tapered to produce low side-lobe levels for low-error detection. The taper is based on a 40-dB Taylor distribution. The first design uses passive phased arrays that are stacked and bore-sighted in different directions to produce scanned beams through switching. The second design uses a single phased array with MEMS phase shifters embedded in the last stage of the waveguide power divider. The phase shifters are integrated with the help of MIC/MMIC-to-waveguide or waveguide-to-coplanar-waveguide (CPW) transitions that are housed in the waveguide sections that feed the array elements. The antenna and detection system measurement results of the passive array design are presented, along with the simulation results of the active array design. [C3107]

### "Em wave scattering by perfectly conducting disk of finite thickness"

Calculation technique for modeling of scattering characteristics for perfectly electrically conducting (PEC) disk of finite thickness is proposed. Employed algorithms are based on solving surface integral equations (IE) of the 1st and 2nd kind. The results of radar cross section (RCS) calculation for discs with various thicknesses are compared with exact results for infinitely thin disc. The backscattered radiation patterns of thin disc in E- and H-planes are presented. [C3108]

### "New Kravchenko transforms and digital UWB signal processing"

In this report the new Kravchenko transforms based on atomic distributions for digital UWB radar signal processing is proposed and proved. This approach has some advantages in comparison with Gabor transform for parameter estimation in radar. [C3109]

### "UWB noise acoustic atmospheric radar"

In this paper we discuss a new approach to create the acoustic atmospheric radar (sodar) which is based on noise sounding waveform. Such sounding waveform fits all formal requirements to UWB signals and has remarkable characteristics including extremely high range and speed resolution. It is important to remember that all these good properties exist only in the case when we have independent samples. The noise signal forms the independent samples because of its nature. The prototype of the radar is described and investigated theoretically, using computer simulation, and in natural conditions. Non-parametrical signal processing algorithm is developed based on statistical approach and digital signal processing. It has wonderful properties of invariance to the group of the noise and signal transforms and stable level of the false alarm probability can be applied for both acoustic and microwave UWB noise radars. The use of the FFT algorithm increases the speed of calculations and gives us the possibility of constructing digital random signal radars. The results of this project confirm that the random signal radar is one of the most interesting types of radar. It combines properties of UWB radar with some additional features, based on random nature of the sounding waveform. These new properties allow us to simplify signal detection algorithms and measure a distance, an azimuth and a target velocity simultaneously with high resolution and accuracy. [C3110]

### "Investigation of phase coded signals based on generalized Frank codes"

In this paper comparative analysis of spectral and correlation characteristics of phase coded signal based on Frank code is given. [C3111]

### "Copyright page"

The following topics are dealt with: GPR; radars; communication; medicine; UWB antennas; pulse generation; pulse radiation; electromagnetic compatibility; and electromagnetic metrology. [C3112]

### "Polarimetric suppression of early-time scattering for late-time target identification"

One can suppress the strong signal amplitude of the early-time scattering, relative to the late-time signal containing the natural resonances (for target identification) using various techniques. This paper discusses the use of polarization for the early-time suppression. [C3113]

### "Spectral theory analysis of UWB-oscillations in frequency synthesizers based on phase-locked loops"

In this report a general theory of phase-locked loop (PLL) for N-dimensional UWB-signals (for example radar and optical signals) is given. On the first step a discretization method for solving differential equations of the PLL systems is presented. It is shown that there are a lot of zones of synchronous in discretized PLL and a technical realization of this device (in PLL with samples). A spectral theory of analysis of oscillations in PLL with samples is given. It is shown a lot of different physical properties in PLL with samples. The effect of shape of the input signals (harmonic signals, splines and atomic functions) at the border zones of operating modes being entered into PLL with samples is examined. [C3114]

### "Scale electrodynamic modeling of ultra wideband systems"

Rules which observance is necessary at performance of scale modeling narrow-band and ultra wideband electrodynamic systems are shown. [C3115]

### "The device for remote monitoring of human's heartbeat"

This article describes creating principles of the device intended for round-the-clock human breath and heart rate monitoring. This device can be used in intensive care unit's and burns departments, maternity hospitals and also by EMERCOM employees. Heart rate detection is possible because of the Doppler effect. The Doppler frequency selection is based on the homodyne method of signal conversion. [C3116]

### "Way of an estimation trajectory instability of flight of the air targets"

In article necessity of measurement and the account for systems of construction of radar-tracking images of parameters trajectory instability flight is proved. The method of an estimation of the law of change of angular speed of turn of the air target on sequence range profiles is offered. The estimation of reliability of the received information is made at decrease in the relation a signal/noise. [C3117]

### "Estimation power and spatial characteristics of ultrawideband radar for statement of protecting handicaps"

Considered the factors that determine the conditions of radiotechnic suppress radiolines control explosive devices, an analysis of experimental studies and an estimate of parameters suppressed radiolines that allows us to determine energetically and spatial characteristics of the antenna system. On the basis of tactical considerations location ultrawideband RTS combat formations moving columns, select a maximal range of producer interference, 20 m and the spectral composition of the signal handicaps of 100 ... 3000 MHz. [C3118]

### "Sampling duration for noisy signal conversion"

A selection of the working band (sampling duration) of the sampler for optimal recording of noisy videopulse radar signals has been considered in the present work. [C3119]

### "Influence of the screen on the range properties of rarefied arrays of near-omnidirectional radiators"

The directional characteristics of arrays of isotropic radiators, Hertz dipoles and half-wave dipoles located above the screen at the arbitrary distance were theoretically investigated. To ensure minimum distortion of the form of ultra-wideband pulse signal radiated by the array, it is proposed to use the radiators of various lengths and arrange them at the different distances from the screen. [C3120]

### "The motion trajectory restoring for radar observation of living objects"

Some technologies of medical radars design are discussed in the report. Radars are intended to obtain the mechanical moving trajectory of living organism chest. Peculiarities of radar detection of targets performing seesaw motion are considered. Data obtaining and processing problems are investigated, methods of initial object motion trajectory restoring are examined by means of two quadratures use, constant component elimination and arctan-demodulation. Methods of received signal processing and computing are proposed. [C3121]

### "Design and analysis of multi-carrier multiple access systems without feedback"

In this paper we study a multiple access system without feedback supporting multiple carriers for delay critical applications with a small loss tolerance. In such a system, users transmits  $R$  times within the next  $N$  timeslots, in order to improve their success probability. In an earlier work, we considered the same problem in a single carrier system and demonstrated that the distribution of properly designed user codes significantly improved the success probability over a random selection strategy. These user codes, that determine the  $R$  slots used for transmission, corresponded to so-called  $2-(N, R, 1)$  designs. Mainly motivated by DVB-RCS satellite systems, this paper considers a system with multiple carriers with the limitation that at any time, at most one slot, and thus carrier, can be used by a single user. We introduce two static and four dynamic slot assignment schemes and under some mild assumptions provide closed form formulas for the success probability in each of these systems. For the last dynamic scheme we will show how group divisible designs are the multi-carrier equivalent of the  $2-(N, R, 1)$  designs of the single carrier system and provide a simple procedure to construct these user codes. Finally, we compare all of the proposed assignment schemes and show that the group divisible designs are superior, especially for large population sizes. Some engineering rules with respect to their usage are also provided. For two of the dynamic schemes we also compare two different strategies in case there are not enough user codes available for all users. [C3122]

### "A compact CPW resonator cell with dual-bandgap characteristics"

In this paper, a compact coplanar waveguide (CPW) resonant cell is introduced, which can exhibit dual-bandgap characteristics by only single unit. The same pattern has been adopted in the microstrip line as reported previously and here is applied to CPW. Experimental results show good agreement with numerical results. By alternating the relative position between CPW defected ground structure (DGS) and split-ring resonator (SRR), the separation between the two resonant frequencies can be controlled easily. [C3123]

### "Digital module design of a satellite rain-compatible radar altimeter"

Satellite radar altimeters play an independent role in ocean remote sensing, while the authors exploited their potential in rain measurement. This paper designs the digital system of the rain mode in an altimeter. In rain mode the altimeter receives the ocean and rain echoes simultaneously, so it can retrieve the rain layer profile without losing surface topography information. An adaptive IF-digital I/Q demodulator is designed, and all of its components are considered in turn. Afterwards the algorithm of an ocean-rain compatible processor is designed to switch the altimeter in various operate modes. [C3124]

### "Copyright page"

The following topics are dealt with: signals; systems; electronics; antenna; microwaves; millimeter-waves; circuits; radar technique; and radar application. [C3125]

### "A new method of radar target recognition based on time-frequency analysis"

In this paper, focused on three targets with simple structure, such as cone, sphere and cone, cylinder and cone, dynamic RCS echo signals is predicted with the improved Greco software. The Dynamic RCS echo signals of targets with micro-movement are preprocessed by using short time Fourier transform, and high-resolution time-frequency distribution images are obtained. A new radar target recognition method based on time-frequency distribution images is proposed. Pixel scan technique is adopted to extract the feature vector, and the nearest neighbor classifier is used for classification decision. Compared with the target recognition method based on singular value decomposition, the correction probability for recognition of the proposed method is higher. Simulation results verify the correctness and the effectiveness of the proposed method. [C3126]

### "Electromagnetic scattering by arbitrarily shaped PEC targets coated with magnetic anisotropic media using equivalent dipole-moment method"

In this article, the equivalent dipole moment (EDM) method is extended and applied to analyze the electromagnetic scattering from arbitrarily shaped three-dimensional (3D) PEC targets coated by magnetic anisotropic media. Besides the advantage of reducing the computation time, the proposed EDM method makes it unnecessary to treat the boundary condition on the surface. The numerical results indicate that the method has strong capability to calculate the RCS of three-dimensional mixed bodies consist of magnetic anisotropic media and PEC targets. [C3127]

### "A novel spiral defected ground structure and its application to the design of dual bandstop filter"

In this paper, a new type of dumbbell-shaped defected ground structure (DGS) called spiral DGS is introduced, which adopts spiral capacitance instead of direct slot capacitance. When compared with direct slot capacitance, spiral capacitance can improve coupling of capacitance, thus lower resonant frequency is obtained for the same circuit size. Simulated results show that a 3.57 GHz lower resonance is achieved, which is useful for the design of miniature devices. Based on the proposed DGS and spiral split ring resonators (SSRR), a compact dual stopband filter (DBSF) is designed and fabricated in this paper. Its dual-bandgap characteristics are verified by both simulation and measurement. [C3128]

### "Characteristics of a CPW mushroom-like resonator and its application to wideband EBG filter"

This paper proposes a novel structure called a compact coplanar waveguide (CPW) mushroom-like resonator (CCMR), which exhibits remarkable bandgap characteristics by only one single unit. The same pattern has been adopted in the compact microstrip mushroom-like resonator (CMMR) as reported previously and here is applied to CPW. When compared with CMMR, the new structure has advantages of easy fabrication and low cost due to its single-layer configuration. To investigate the CMMR deeply, the effect of structural parameters, including patch size and diameter of via, on bandgap characteristics are analyzed in detail. Also, the 1-D CCMR EBG filter is studied for various numbers of cells. Finally, the wideband CCMR EBG filter using united cells method (UCM) is designed, fabricated, and measured. The correction and validity are confirmed by the results of simulation and

experiment. [C3129]

### "Finite element analysis of three dimensional scatterers above the PEC earth"

A three-dimensional (3D) finite-element method (FEM) is introduced to study the scattering from 3D objects above the perfectly conducted earth. Numerical examples are presented to demonstrate the accuracy and efficiency of the presented method. [C3130]

### "A research of stored grain moisture detection based on RIS-K2 radar electromagnetic wave technology"

The amount of moisture in stored grain is an important factor which affects food safety. Therefore, a timely and accurate detection of the moisture content in stored grain is of great importance. Electromagnetic wave has a strong trait of penetrating, which is able to detect the moisture content of grain inside the heap in the case of non-destructive. This paper mainly takes the research of grain moisture which is based on the RIS-K2 radar electromagnetic wave technology. We carry a field test, collect and analyze the results. It shows that the RIS-K2 radar electromagnetic wave measurement of grain moisture is feasible and effective. [C3131]

### "Fused variational analysis technique for high-resolution reconstruction of remote sensing imagery"

In this study, we apply the robust error estimation theory as a basis to develop an appropriate procedure that performs the processing and enhancement of the remote sensing (RS) image contaminated by composite noise (additive and multiplicative) and degraded by the data acquisition system. The first reconstruction stage is performed using the Bayesian statistical estimators referred to as WCMAP { WCLS (Weighted Constrained Least Squares) and MAP (Maximum a Posteriori Probability) algorithms } which significantly increase the gain of image sharpness. Subsequently, we employ the isotropic diffusion and anisotropic diffusion methods for obtaining the optimal balance in reference to increasing the perceptual quality of RS images. The effectiveness of the proposed fused WCMAP method were evaluated through the comparative simulation of different RS image reconstructive. [C3132]

### "Design of high-speed digital correlator in fully polarimetric microwave radiometer"

Fully polarimetric microwave radiometer is a new type of passive microwave sensor for measuring ocean wind vector. Digital correlation technology is used in it to get all the four Stokes parameters of ocean emission in this paper. Digital correlator is the main part of fully polarimetric radiometer. In the paper, design of a novel digital correlator is presented. Two high-speed, dual A/D converters are used to sample four signals, and the sampling results are operated in FPGA-Vertex5 to make both self- and cross-correlation calculations. The test results of the correlator are given. The four channels are sampled at 360 MHz. For both 100 MHz and 150 MHz input, the correlation coefficient between the measurements and their ideal results is above 0.9999999. The whole power of digital correlator is 11.3 W. [C3133]

### "A millimeter-wave solid-state power combining circuit based on branch-waveguide directional coupler"

A new Ka-band (32-37 GHz) eight-way solid-state power combining amplifier using branch-waveguide directional coupler is proposed in this paper. By using low-loss waveguide power dividing/combining network and a monolithic microwave integrated circuit(MMIC) with a low-loss microstrip-to-waveguide transition, a high combining efficiency larger than 80% from 32 GHz to 37 GHz is achieved. With a compact structure, an easy fabrication process, and good thermal property, the power combining network could be used in millimeter-wave solid state high power combining for high efficiency in a broad-band. [C3134]

### "A new simulation model of fuse RF system"

Based on the highlight method, this paper builds up the model of the radar target especially the near field. The database of the properties of near field, which is generated by the fuse antenna, is established using FDTD method. Combining simulation of circuit with computing of near field the simulator was made for fuse system. And by means of this simulator the imitative analysis and calculation on fuse system can be more reliable and accurate. In the end the result of time-domain simulation demonstrate that the simulator can be effectively applied in the synthetic test system to the fuse of the weapon system. [C3135]

### "The usage of extremal coherent integration in the algorithms of processing of reflected signals"

The advantages of digital algorithms when processing of radar data are indicated. The directions of coherent

combining usage of returned signals in radar systems are shown. The range of new digital algorithms of the movement of air objects estimate parameters (including signals with carrier frequency tuning from impulse to impulse) is described and it is based on the list of degree of taking realizations coherence. The requirement for sound signals parameters, providing single retrieval of information, are determined. [C3136]

#### "Wireless home emergency system"

The wireless control technology, power line carrier technology, GPRS and other embedded technology are used to designs a home emergency system which receives start signal from users by wireless and uses GPRS to send help messages to specific persons, moreover starts the alarm and controls the lights to twinkle by PLC technology, so if the users are in trouble they can get help as soon as possible. The experiment result shows that this scheme can achieve the expected effect. [C3137]

#### "A wideband outdoor RCS instrumental radar with high range resolution"

Outdoor static RCS measurement is the principal means to obtain the RCS value of the full-scale targets. This paper firstly presented the imaging principles of the pulse-pulse stepped-frequency radar system. Based on the dominating characteristics of the outdoor RCS measurement, a wide-band (2-18 GHz) and two-channel RCS measurement system was designed and implemented in this paper, which could be applied to backscatter RCS measurement of the full-scale static target, and the high-resolution 2-D imaging of the scatter sources. It could provide the high-precision RCS data of target for the operational frequency range 2-18 GHz. Finally, the technical features of the instrumental radar system were also introduced in detail. This wideband RCS instrumental radar system has been successfully used in an outdoor RCS test range now. [C3138]

#### "Research on GPRS vehicle location network service system"

We can achieve vehicle location tracking on Internet by using GPRS vehicle location terminal and combining with Internet technology and GIS technology. The article gives the design structure of GPRS vehicle location network service system. The system is divided into three parts: GIS network workstations, network communications server and GPRS vehicle location terminal. Then, the article makes the brief introduction to the function of three parts of the system: GIS network workstations are responsible for sending command "Setting GPS Location Data Return Interval" to network communications server, and receiving GPS location data packet uploaded from GPRS vehicle location terminal from network communications server, making analysis of received GPS location data packet; The vehicles will be appeared as title in the specified position on the map by combining with GIS. Network communications server is responsible for receiving the command "Setting GPS Location Data Return Interval" from GIS network workstations and transmitting to the specified GPRS vehicle location terminal and receiving GPS location data packet pass backed from GPRS vehicle location terminal and distributing to the appropriate GIS network workstations simultaneously. GPRS vehicle location terminal is responsible for receiving the command "Setting GPS Location Data Return Interval" sent from network communications server and sending GPS location data collected by GPS module to network communications server. Finally, the article tests the feasibility of system design through experiment. By using the system, it will be easy and fast to make vehicle location tracking on Internet and timely access vehicle location information. [C3139]

#### "The control system for smart home based on GSM and the radio"

In order to guarantee the effective control to the appliances and ensure the safety of living environment, a control system for smart home has been designed. Based on the GSM network service and wireless communication, the system is developed with the MCU AVR mega 16 as the core. It can be divided into two working patterns: the long-distance pattern and the short- range pattern. Experiments have proved the two outstanding functions: under the long-distance pattern, the user can obtain long-distance monitoring of the living environment and get remote control to appliances through the GSM network service; under the short- range pattern, the user can observe the room environment condition through LCD and realize the short- range control to appliances using radio. [C3140]

#### "A study of automation recognition of bridge in SAR image"

According to river and bridge features in SAR (Synthetic Aperture Radar, SAR) image as well as the position relationship between bridge and river, the automatic recognition method of bridge is presented. First, the gradient of an image is calculated by gradient operator in order to get the gradient image, and river region is segmented by Fisher criterion. Then, a doubtful bridge region is extracted by morphology method, and segmented by Fisher criterion. Finally, the bridge is recognized according to the features. Experimental results show that this method can automatically and rapidly recognize bridge. [C3141]

### "A new sorting algorithm for radar emitter recognition"

The radar emitter recognition is a hotspot and difficulty for Electronic Warfare. This paper analyzed radar emitter integrated pulse data's characters and proposed a useful method for radar emitter's integrated pulse data recognition. It concluded and summarized some radar emitter recognition methods' advantages and defects, then used the characteristic values as statistic objects and calculated the weighting coefficient; at last, regarded the characters' weighting value as the sorting object and sorted the pulses. Using a train of fact data as the sample and experimented that the algorithm is effective and realizable. [C3142]

### "Rotation resistance airborne remote image real time matching algorithm"

In allusion to requirement of real time high precision matching of remote image in airborne image aided navigation system rotation resistance airborne remote image real time matching algorithm is put forward to eliminate noise and geometrical aberrance. Because of great information in remote image at first Harris corner detection algorithm is used to extract character point of remote image to increase matching speed, and modified invariant moment is done to correct image distortion caused by different time, different view angel, different sensor and so on; then robust Hausdorff distance is used to realize remote image real time matching to acquire high matching precision, then simulative experiment is done on airborne image acquired by sensor or radar and digital map stored in computer at last. Simulative experiment indicates that image matching rate of rotation resistance algorithm is better than algorithm which is not adopted modified invariant moment, and the algorithm is available and effective. [C3143]

### "Radar cross-section calculation method for antenna of P-18 radar station"

The scattered electromagnetic field calculation method for finite cylinder with resonant cross-section is considered. The method is used for calculation of radar cross-section for antenna of P-18 radar station. Also radar cross-sections for perfectly conducting antenna and antenna partially made of perfectly absorbing materials (Macdonald model) are compared. [C3144]

### "Using conformal shape, separate and dynamical apodization to improve characteristics of multibeam active phased array"

Some results of the project "Torus" are discussed. This paper is focused on 2 mutually complementary methods of improving characteristics of multibeam active phased arrays. Applications of these methods for ground based antennas, HATP and communication satellites are considered. Described methods can be also used for radars. [C3145]

### "Statistical estimation of polarimetric method potential for dangerous turbulence detection in rain"

In this paper the polarimetric approach for wind phenomena detection and study is proposed and analyzed. The polarimetric estimation of turbulence intensity is made with single unipolarized antenna radar system. The statistical estimation of proposed method is made. [C3146]

### "The study of vehicle's anti-collision early warning system based on fuzzy control"

This article mainly studies the automotive collision avoidance system based on fuzzy control. This system selects and uses millimeter-wave radar to measure the distance between two cars and the speed of a motor vehicle. First of all, create the safety distance model of the motor vehicle brake. Secondly, design the fuzzy controller for early warning. Lastly, according to the national highway safety regulation, also by analyzing the related resources theoretically, it can be testified that this system can do the trick of collision warning. [C3147]

### "Model of multi-sensor data fusion and trajectory prediction based on echo state network"

Radar receives more and more attention as an important means of access to information, and multi-sensor data fusion and track prediction become a new discipline. Compared with single radar, multi-radar system has the advantage of improving reliability of the system, enhancing the system when coverage, etc. However, this technology faces new problems when utilizing information in the complex environment. In this paper, we used the nearest data association algorithm (NNDA) to extract tracks from multifarious radar data and three spline interpolation method to make different measuring data track registration to the unity of time axis. Through the same period of fuzzy track correlation, we realized the same target track of extraction, calculated the relative radar accuracy by using the least square fitting, and applied radar tracking precision to be the integration of the weighted average method through the fusion of track-to-track reference. Finally, based on the knowledge of neural network technology, we used echo state network (ESN) to predict data, as ESN network training algorithm

is very good in effectively solving nonlinear dynamic system specifically of uncertainty model. Through simulation test, we concluded that the multi-sensor data fusion and trajectory prediction model precision accuracy is 43.18 m for uniform motion model; for a sudden turn or variable targets, precision accuracy is 122.7m; for complex moving targets, precision accuracy is 165.3m. [C3148]

#### "A study of bias error estimation method by KGBE"

Data fusion uses observations from networked multiple sensors and generates an integrated track. It achieves wide surveillance area and high accuracy, by minimizing error covariance matrix. In ideal environment, a fundamental assumption is that sensor biases are zero. However, the bias errors are not zero in real environment. As a result, the accuracy of integrated tracks deteriorate, even if the all sensors observe the same target. In this paper, we propose a new bias estimation algorithm is based on kalman filter bias estimator with grid search method. It is called the KGBE method (Kalman filter with Grid search Bias Estimator). As the result, we confirmed that the KGBE achieves higher accuracy than conventional algorithms. [C3149]

#### "Study of noise jamming based on convolution modulation to SAR"

The performance of traditional noise interference to synthetic aperture radar (SAR) is limited and to some extent it is useless. A new SAR jamming realization scheme based on convolution modulation is proposed in this essay. Theoretical analysis was presented and simulations were executed. All results prove that the proposed jamming is effective to suppress distributed targets, and much superior to traditional RF noise interference. [C3150]

#### "Detection and coordinate measurement of targets by ultra-wide band radar with antenna array"

Algorithms of digital signal processing are widely used in modern ultra-wide band (UWB) radars to solve problems of target detection and coordinate measurement. The paper deals with general algorithms of signal processing in ultra-wide band short-pulse radar with antenna array. The radar is developed for the monitoring of moving objects placed behind of radio-transparent barriers. The results of mathematical modeling are presented. [C3151]

#### "Search algorithm for local objects in GPR image"

An automatic search algorithm for local objects in GPR profile has been considered in the work. The algorithm is based on the Hough transform. The proper software tool has been developed in order to analyze the accuracy of the permittivity of ground as well as coordinates of the local object in a GPR profile. The algorithm efficiency with simulated data has been shown. The influence of the sampling-step at sounding on the algorithm accuracy has been considered. [C3152]

#### "Measurement of coordinates of the targets placed behind of radio-transparent barrier with multi-static ultra-wide band radar"

High accuracy measurement of coordinates of the targets placed behind of radio-transparent barrier (inside of closed room) using ultra-wide band (UWB) radar seems to be the perspective field of the investigation. The results of these investigations could be useful when solving problems concerned with combating terrorism, security etc. [C3153]

#### "Estimation of dielectric permittivity of medium by analysis of UWB radiolocation signals from local object"

The method of accuracy enhancement of medium permittivity estimation based on measurements of time delays of UWB signals reflected from local object and received in different points of radar scanning trace is suggested. The mathematical relations have been obtained for estimation of investigated medium permittivity and measurement errors and evaluation of algorithm accuracy gain in comparison with common methods has been made. [C3154]

#### "Practical application of UWB georadar technique for investigations of cultural heritage objects"

The UWB GPR technique is applied for investigation of covered structure of cultural heritage objects without affect their construction integrity. The obtained information is important for restorers since the most part of it is not available for conventional diagnostic methods and technical documentation is often lost. Some examples of cultural heritage objects investigations are performed. [C3155]

### "UWB Baby Monitor"

A successful case for UWB technology application to Vital Signs Monitoring Systems created by authors is presented in this paper. Baby Monitor for remote contactless monitoring of respiratory and heart rate is designed both for consumer and medical infant monitoring applications. Unlike conventional sound- and video-based baby monitors, which do not provide any useful information at infant sleep time (no sounds or static picture) the devices allow permanent parental control and effectively prevent Sudden Infant Death Syndrome (SIDS) from occurring. SIDS is reported to be leading death cause of healthy infants after one month age. [C3156]

### "Applications (GPR, radars, communication, medicine)"

{no data available} [C3157]

### "Portable system for RAC measurement based on swept frequency RCS method"

A portable device for the measurement of the reflectivity of radar absorbing coating is presented. It is based on the swept frequency RCS method. Using of this device is simple, quick and convenient than the conventional methods, as well with higher precision and more stable in performance than the other portable solutions. The design flow of this device is presented and the test results are analysed. [C3158]

### "Design of mobile robot system with remote control based on CAN-bus"

In order to realizing remote control and information collection quickly and reliably, the mobile robot with remote control is designed. In the paper, according to analysis of the overall structure, hardware circuit of the robot system is designed. Because the CAN2.0 standard only makes physical layer protocol and data link layer protocol, application layer protocol is ruled according to robot control system. In the last part of this paper, the software of master/slave computer is introduced in detail. The experiment shows that running performance of robot control system is balanced, efficient and has satisfied the practical demand. [C3159]

### "Practicability evaluation of middle atmospheric wind field based on HWM93"

Firstly, the paper describes the system model of HWM93, develops a display system of wind field in the middle atmosphere based on HWM93. The analysis and comparison was implemented between the wind field data calculated by HWM93 model, wind data observed by L-band sounding system (0-30 km) and TIDI onboard TIMED satellite (70-110 km). In the height of 0-30 km, there is a good consistency in mean zonal wind between HWM93 and L-band sounding system in December, January and February, while great difference exists below 20 km in June, July and August and good agreement is showed above 20 km in these months. The meridional wind below 30 km computed by HWM93 model is not accurate enough to reflect the actual meridional wind. In the height of 70-110 km, the mean zonal wind from HWM93 and TIDI is in good agreement above 80 km, while the mean meridional wind it has small relative difference above 80 km. The results indicate that the wind above 20 km from HWM93 model could be provided as reference and foundation for the wind information in the middle atmosphere for the regions with relatively lacking wind-measurement stations. [C3160]

### "Presentation of the field surface wave generated by an antenna at the interface of two homogeneous media"

In circumstances where the dispersion of the permittivity can be neglected, the tangential component of the surface wave is expressed through the Laplace function of two complex arguments algebraically. This reduces the computation time of the surface wave at a given point to a few milliseconds, and to determine the current in the radiating antenna, as well as the dielectric constant of the underlying surface, for the time of the order of several seconds. Obtain estimates of the surface wave field for the most typical parameters of soils. These calculations can be used to select regularizers inverse GPR for quantitative calculations of the parameters of the soil and for the qualitative interpretation of GPR data. [C3161]

### "Antenna arrays used for the cancellation of Es layer clutter"

There has Es layer clutter in the high frequency surface wave radar, and Es layer clutter have the difference arrival direction and polarized characters with the signal. Used these characters, vertically polarized antenna or horizontally polarized antenna can be added as auxiliary antenna in the high frequency surface wave radar system that uses vertically polarized antennas to suppress the Es layer clutter. The clutter-to-signal ratio in the outputs of the auxiliary antenna will affect the cancellation of the Es layer clutter in the main antennas. An antenna array consists of four vertically polarized dipoles and an antenna array consists of three horizontally polarized antennas are proposed in this paper. Used the superdirective synthetically method, the mainlobe of the

auxiliary antenna arrays are put on the direction of the Es layer clutter arrival direction, and a low sidelobe are put on the direction of the signal arrival direction. Then the auxiliary antenna arrays will have a big gain on Es layer clutter and a little gain on signal. So the cancellation of the Es layer clutter in the main antennas which use the auxiliary antenna arrays will be more effective. [C3162]

#### **"Design and implementation on wireless power meter system based on GSM network"**

This paper designs a wireless power meter system based on GSM network; the main communication way is GPRS and secondary SMS. The user can choose the different transfer modules based on different demands and can choose the Local network, dial network, ISDN, ADSL to connect into network. It accomplishes the hardware and software design in GSM network collector and the meter system software. [C3163]

#### **"Development of spaceborne radar simulator by NICT and JAXA using JMA cloud-resolving model"**

This study demonstrated preliminary results in diagnosis of the numerical model with reference to the TRMM/PR, examples of the GPM/DPR synthetic data, and application of the synthetic data to the algorithm development in the nonuniform beamfilling correction method. These were performed using a satellite radar simulation algorithm by the National Institute of Information and Communications Technology (NICT) and the Japan Aerospace Exploration Agency (JAXA) named as the Integrated Satellite Observation Simulator for Radar (ISOSIM-Radar) and a cloud-resolving model by the Japan Meteorological Agency (JMA-NHM). [C3164]

#### **"Reciprocal spectrum algorithm for radar imaging with frequency sampling waveform"**

A radar imaging algorithm named reciprocal spectrum algorithm (RSA) is proposed in this paper to get higher resolution in azimuth direction with frequency sampling waveform. Theoretical analysis and simulation results show that the algorithm can give better performance than the tradition range Doppler algorithm (RDA) at the cost of peak value reduction at the object points in radar image. [C3165]

#### **"Scientific and engineering overview of the NASA Dual-Frequency Dual-Polarized Doppler Radar (D3R) system for GPM Ground Validation"**

As an integral part of Global Precipitation Measurement (GPM) mission, Ground Validation (GV) program proposes to establish an independent global cross-validation process to characterize errors and quantify uncertainties in the precipitation measurements of the GPM program. A ground-based Dual-Frequency Dual-Polarized Doppler Radar (D3R) that will provide measurements at the two broadly separated frequencies (Ku- and Ka-band) is currently being developed to enable GPM ground validation, enhance understanding of the microphysical interpretation of precipitation and facilitate improvement of retrieval algorithms. The first generation D3R design will comprise of two separate co-aligned single-frequency antenna units mounted on a common pedestal with dual-frequency dual-polarized solid-state transmitter. This paper describes the salient features of this radar, the system concept and its engineering design challenges. [C3166]

#### **"Fetch limited sea scattering spectral model for HF-OTH skywave radar"**

Sea Normalized RCS, and Doppler spectra have been revised for HF-OTH Clutter Modelling. The Hasselmann model is firstly introduced to predict the sea directional spectrum of fetch-limited sea and results have been compared with the Pierson-Moskovitz model used for large scale ocean remote sensing. Results show that the closed fetch-limited sea has lower NRCS compared with ocean for similar wind intensity and direction. For this reasons RCS and Doppler spectra must be predicted taking into account of the fetch dimension. In future work we will generalize this interesting approach to fetch-limited wind, time-limited pulse, in order to show the waveform effect on Doppler spectrum. [C3167]

#### **"Utilization of airborne multi-aspect InSAR data for the generation of urban ortho-images"**

This paper addresses the generation of "true" RADAR ortho-images from highest resolution multi-aspect InSAR data. Due to the side-looking SAR imaging geometry, the well-known layover and shadowing effects prevent the production of truly rectified ortho-imagery from one image alone. Here, an approach for the reconstruction of Digital Surface Models of densely built inner city areas is proposed. Since in SAR interferometry each dataset pixel contains not only the interferometric phase needed for 3D reconstruction but also the corresponding amplitude or intensity value, respectively, the procedure can also be seen in the context of true ortho-rectification. [C3168]

#### **"Polarimetric sar image visualization and interpretation with covariance matrix invariants"**

In this study we give short overview of polarimetric SAR image visualization with colors. By studying the color models and polarization visualization models we propose basic principles which should be followed when presenting polarimetric information in color. We show that for different polarimetric parameters, different color models should be used, and give guidelines for color model selection. We present also two visualization schemes which are suitable for interpretation and browsing of large polarimetric SAR images. [C3169]

#### "Fully polarimetric ALOS PALSAR data applications for snow and ice studies"

In this study, the capability assessment of fully polarimetric L-band ALOS PALSAR data has been carried out for snow discrimination from other targets. Eigenvalue based polarization fraction value has been determined for assessing the capability of PALSAR data for snow discrimination. Radar snow index has been developed using polarization fraction and normalized third eigenvalue of coherency matrix. It has been found that radar snow index is more robust and simple to implement than supervised classification. [C3170]

#### "A Matchstick Model of microwave backscatter from a forest: A change of regime"

In this paper we present a forest scattering scenario consisting of solely vertical stems. Stems are the primary volume stores of forests; this model therefore simplifies the forest make-up to represent these major scatterers. This model representation is known as the "Matchstick Model" and is used as a comparison to backscatter data resulting from the combination of macro-ecology with a numerical scattering model (RT2). The "Matchstick Model" provides SAR scattering trends based on equations for the Optical and Rayleigh scattering regimes and presents forest scattering as a combination of the two. Conclusions state that saturation is a consequence of basal area and thinning limitations and ultimately that backscatter is not directly proportional to stand volume, even in the simple case of a single layer of stems. [C3171]

#### "Multichannel Coherent Radar Depth Sounder for NASA Operation Ice Bridge"

The Multichannel Coherent Radar Depth Sounder (MCoRDS) system was developed by the Center for Remote Sensing of Ice Sheets (CReSIS) to map the thickness of ice sheets. This radar system was used in Antarctica as one of the primary sensors for NASA's Operation Ice Bridge (OIB) during the fall of 2009. Compared to its predecessors, MCoRDS features several new capabilities which enabled it to successfully capture ice thickness measurements over multiple glaciers on an aerial platform. This paper will focus on the capabilities of MCoRDS and also provide a sample of the processed radar results. [C3172]

#### "Estimation of building density using Terrasar-X-Data"

This study presents an approach towards the estimation of building density by utilizing the intensity data of the German space borne very high resolution SAR system TerraSAR-X. By using reference data we segmented a SAR scene of the city of Munich, Germany, on the scale of city blocks. Then we computed first order statistics and texture measures according to Haralick on the image objects. We used a random forests regression algorithm to establish the relationship between these features and the building density taken from reference data. The result is a promising coefficient of determination of 0.63. [C3173]

#### "Oblique polarimetric SAR processor based on signal and interference subspace models"

We develop a new SAR processor based on oblique projection. We take into account the scattering properties of the target and the interferences by using subspace models. To detect the target and to reject the interferences, we process images with the oblique projection of the received signal into the target subspace along the interference one. This new SAR processor is applied to realistic simulated data for FoPen (Foliage Penetration) application. [C3174]

#### "Surface reference normalized radar cross section over land for the improvement of the TRMM PR algorithm"

The Tropical Rainfall Measuring Mission (TRMM) precipitation radar (PR) standard algorithm 2A21 produces the surface normalized radar cross section (NRCS) values under no rain conditions as functions of the incidence angle and surface physical parameters which affect surface scattering. These NRCS values are used as the reference values to calculate the path integrated attenuation (PIA) values in the surface reference technique (SRT) to perform the rain attenuation correction. This paper shows the relation between the land surface NRCS values and the three land surface physical parameters which are NDVI (Normalized Differential Vegetation Index), the surface roughness, and the soil moisture over the land for each of the incidence angles and tries to improve the methods to calculate surface reference NRCS values over the land. [C3175]

### "Applications of polarimetric decomposition technology in a dried up lake evolution"

This paper presents fundamental reason to Lop Nur "Ear" feature based on polarimetric decomposition technology. Lop Nur is located at the east Tarim Basin in China, and in history, all the major rivers running in Tarim Basin converged to this lowest place. Lop Nur belongs to arid region, and satisfies penetration conditions for SAR signals. Through comparison between decomposed volume scattering contribution and sub-surface salinity, it is found that subsurface properties (such as salinity) is the fundamental reason to "Ear" feature. And dynamic mechanism of geomorphology builds the relationship between surface and subsurface evolution processes, and indirectly unifies previous points on the reasons to formation of Lop Nur "Ear". Polarimetric technology is anticipated to be used to retrieve more information and to help extend applications in environment of arid region. [C3176]

### "Electromagnetic simulations of borehole radar for metal ore detection"

We perform finite difference time domain (FDTD) numerical simulation for metal ore detection by borehole radar. The ore-body model is adopted from a practical Ni-Cu-Pt ore body which is a magmatic deposit located in Sudbury, Canada. We design three boreholes along a cross-section perpendicular to the geological strike of the formation which is composed with overburden, ore zone, iron formation, peridotite, granite-gneiss, and sediments. We analyzed the simulated borehole radar profiles and found that some interfaces could be detected and some could not, also the ore zone is very absorptive to the wave. [C3177]

### "ESA Earth Observation educational tools contribution to the creation of awareness for World Heritage site conservation"

EO from space is a key tool to assess the effects of anthropogenic activities to our planet (e.g. deforestation, urban growth). It can provide measurements supporting the process of sustainable development, or observations allowing the detection of changes in the surface of our planet related to climate change. UNESCO and ESA have launched a call to all national and international space agencies, space research institutions and universities to make use of space technologies in order to assist developing countries in the monitoring of the World Heritage sites. ESA and UNESCO are also covering associated educational aspects by using all the results of the projects under implementation as educational material to support UNESCO's 'UN decade for education and sustainable development', within a common and joint strategy of education, targeting schools, universities and young professionals. This includes creating new tools for the creation of awareness and savoir-faire in the use of space technology for the conservation and preservation of the environment and for a sustainable development. Material derived from satellite images provided to decision makers is also being used to support teachers and school children from the surroundings of the World Heritage sites where the space partners of the 'Open Initiative' are working. In the frame of its educational activities for Earth Observation, ESA is creating particular modules oriented to UNESCO sites. All this material comes out of the different activities being implemented by partners of the ESA-UNESCO 'Open Initiative', in complete integration with the EDUSPACE programme of ESA, a platform and web-based tool for Earth Observation Education, in eight different languages, available for free to worldwide secondary schools teachers and students, aiming to provide schools with tools for teaching and learning. It offers an entry point to Earth Observation satellite data and software applications for training. The website is-- host to a multitude of didactical material inclusive high-resolution local and lower resolution global remote sensing satellite data in order to show students how to study the planet as a whole from space as well as the possibility of zooming into specific areas and natural features to investigate their behaviour over space and time. An image processing tool called LEOWorks (Learning Earth Observation), including a GIS, soon in open source, is made available for data analysis and image interpretation. New dedicated content, like case studies and projects dedicated to the monitoring of UNESCO archaeological sites and to sustainable development are presently under development. [C3178]

### "Physical optics-based method to compute the radar signature of complex objects over a sea surface"

In this paper, a model based on asymptotic methods is proposed in order to compute the scattered field from a complex maritime scene. The basic idea is to combine the geometrical optics and the physical optics technique. The sea surface is generated by using the Elfouhaily directional wave spectrum to obtain a realistic scene. Both the target and the sea surface are meshed with triangular patches in order to compute the scattered field. Simulated results are presented to validate this model through a simple configuration by comparisons with the method of moment. Then more complex scenes for different sea states and different kind of targets (PEC or inhomogeneous) are investigated. [C3179]

### "Nasa's Laser Risk Reduction Program: A risk reduction approach for technology development"

The benefits of Earth Science (ES) laser instrumentation have been proven by decades of earth-science observations. Lasers allow remote sensing of earth-system variables such as sea elevation, atmospheric composition, wind profiles, cloud cover, ice mass, and vegetation canopy. Further, orbiting platforms provide a unique vantage point that allows laser measurements on a global scale. NASA implemented the Laser Risk Reduction Program (LRRP) to identify and address capability-gap areas where new devices or processes could yield high-reliability mission-ready parts, and to develop components needed to advance the state-of-the-art of laser-based instrumentation. This paper discusses LRRP's approach and the evolution of the program's developments from inception to their planned infusion into NASA's missions. It is the first part of a three-paper presentation (Program goals and organization; 1<sup>st</sup> developments and results at the Goddard Space Flight Center (GSFC); and 2<sup>nd</sup> developments and results at Langley Research Center (LaRC)) that summarizes LRRP's goals, formulation approach, management organization, and final results. [C3180]

### "A comparison of two CA-CFAR loss calculation methods in spatially correlated K-Distributed sea clutter"

Radar target detection of targets in sea clutter modelled by compound K-distribution is examined from a statistical viewpoint by Monte Carlo simulations. The target detection is processed by Cell Averaging Constant False Alarm Rate (CA-CFAR) processor and the performance evaluations are quantified by CFAR loss. Curves for CFAR loss versus the spatial correlation and spikiness of sea clutter, number of cells of CA-CFAR processor and the number of non-coherently integrated pulses are presented. [C3181]

### "Exact discrete minimization for TV+L0 image decomposition models"

Penalized maximum likelihood denoising approaches seek a solution that fulfills a compromise between data fidelity and agreement with a prior model. Penalization terms are generally chosen to enforce smoothness of the solution and to reject noise. The design of a proper penalization term is a difficult task as it has to capture image variability. Image decomposition into two components of different nature, each given a different penalty, is a way to enrich the modeling. We consider the decomposition of an image into a component with bounded variations and a sparse component. The corresponding penalization is the sum of the total variation of the first component and the L0 pseudo-norm of the second component. The minimization problem is highly non-convex, but can still be globally minimized by a minimum s-t-cut computation on a graph. The decomposition model is applied to synthetic aperture radar image denoising. [C3182]

### "Coupling polarimetric L-Band insar and airborne lidar to characterize the geomorphological deformations in the piton de la fournaise volcano"

Until recently the coarse resolution of topographic mapping acted as a break on understanding the forces and processes that shape the Earth's surface. However, active surface deformation is an important indicator for the earth crustal dynamics since it is directly linked to earthquakes, volcanic eruptions and landslides. Both airborne laser scanning systems (LiDAR) and spaceborne interferometric synthetic aperture radars (InSAR) have provided valuable information for many case studies requiring high-resolution characterization of ground movement in relatively large areas to assess the threat and impact of natural hazards especially for volcanic eruptions. The Piton de la Fournaise volcano (Reunion Island, France) is one of the most active basaltic shield volcanoes in the world. It has reached an anomalous activity level in the past years with a major eruption occurring in April 2007. In this paper, we explore the statistical, spatial and temporal behavior of the L-Band backscattering coefficient at both HH and HV polarizations over different type of terrains in the Fournaise lava field as a function of the LiDAR intensity data. The correlation will be used in setting empirical models to correct for the L-Band phase distortion on ash and rough surfaces in volcanic terrains. [C3183]

### "Robust estimation of pasture biomass using dual-polarisation TerraSAR-X imagery"

The efficient management of pasture is a key driver of profitability for New Zealand's pastoral dairy and meat industries. In this paper, we report results from a study that tests the viability of using short-wavelength imaging radar to estimate pasture biomass. We use images from the TerraSAR-X satellite, comparing the HH & HV and VV&HV dual-polarisation combinations. Several linear models have been tested for field-measured pasture biomass. The best model is a linear regression using backscatter from the HH&HV combination, resulting in a residual standard error of 317 kg/ha. This standard error is 61% less than the standard error for the VV&HV combination (511 kg/ha), which clearly suggests adopting the HH&HV model. A model for prediction of the pasture biomass rank percentile is somewhat less convincing than the model for the pasture biomass itself. Finally, a repeated measures analysis for the HH&HV pair, suggests invariance of the regression for pasture biomass over time, except for a possible outlier date 01 September 2008. [C3184]

### "TanDEM-X commissioning phase status"

After the recent launch of the TanDEM-X satellite, the twin of TerraSAR-X, its demanding commissioning phase has started. On the one hand, it has to ensure the same monostatic operation performance as TerraSAR-X. On the other hand, the bistatic aspects have to be verified, which are essential for the acquisition of the global digital elevation model (DEM). This has to be done in a limited time period in order to keep the required nominal operation duration. This paper shows the summary of the commissioning phase activities and its running status.

[C3185]

### "Copyright"

The following topics are dealt with: SEAGRASS HABITATS; HIGH RESOLUTION DIFFERENTIAL SAR TOMOGRAPHY; FOREST COVER CHANGES; HYPERSPECTRAL IMAGERY CLASSIFICATION; REMOTE SENSING; GEOSPATIAL IMAGE ANALYSIS ALGORITHMS; SOIL MOISTURE; LAND USE CLASSIFICATION; WATER QUALITY; LAKE; RADIATIVE TRANSFER; CALIBRATION; VOLCANIC DEFORMATION; SEA SURFACE TEMPERATURE FRONT; and FLOOD MONITORING. [C3186]

### "Physical-based models of speckle for high resolution SAR images"

In this paper we present a physical model for the description of the speckle in Synthetic Aperture Radar (SAR) images. The proposed model highlights the analytical dependence of the speckle characteristics on the surface roughness and the sensor parameters. The illuminated surface is represented using the fractal geometry. In addition, a SAR raw signal simulator able to generate SAR images whose speckle characteristics are coherent with the observed surface properties is presented. [C3187]

### "Remote sensing image synthesis"

For remote sensing data, the testing analysis tools is difficult since the ground-truth data are not available in many cases. To address this issue, a novel method for image synthesis is presented for use as a evaluation test-bed. Given the scale-dependent, non-stationary nature of remotely sensed data, a new modeling approach that combines a resolution-oriented hierarchical method with a regional label-oriented binary tree structure is introduced to synthesize such complex data. In this paper, we are proposing on first synthesizing a label field, which contains the complex structural characteristics, then synthesizing the texture based on the generated label field for a more accurate modeling. Experimental results using operational RADARSAT SAR sea-ice image data show that the proposed method is capable of modeling complex, nonstationary scale structures, thus making it well-suitable to produce reliable, realistic remote sensing imagery. [C3188]

### "Synchronous retrieval of forest canopy cover by airborne LiDAR and optical remote sensing"

Forest canopy cover is retrieved Synchronous by the airborne LiDAR data and SPOT-5 HRG data, using the method of linear spectrum decomposition model combined with Li-Strahler geometric-optical model. First, the airborne LiDAR data is used to retrieve forest parameters and then the proportion of pixel not covered by crown or shadow Kgof each pixel in the sample was calculated using Li-Strahler geometric-optical model, while the linear spectrum decomposition model is used to extract the proportion of pixel not covered by crown or shadow Kgof each pixel in the whole imagery. [C3189]

### "A new global Snow Extent product based on ATSR-2 and AATSR"

The ESA project GlobSnow develops products and services for snow extent and snow water equivalent. The time series of Snow Extent (SE) products will cover the whole seasonally snow-covered Earth for the years 1995-2010 based on the optical sensors ERS-2 ATSR-2 and Envisat AATSR data. A laboratory processing chain has been developed for testing and improving algorithms in an iterative process. The final version of the laboratory processing chain will function as a reference system for the implementation of an operational system for production of the full time series of products as well as near-real-time products produced on a daily basis. The first version of the SE product set spanning 15 years of the Northern Hemisphere is expected to be ready by the end of 2010 and will be made freely available. [C3190]

### "Next generation of multi beam rotating antenna on SWIM scatterometer"

In the frame of the development of the instrument SWIM (Surface Waves Investigation and Monitoring) on the CFOSAT program (Chinese French Oceanographic Satellite) funded by CNES, Thales Alenia Space is currently developing a new multi beam rotating antenna in Ku Band. This single reflector offset antenna includes a rotating

feed comprising 6 beams. The SWIM instrument is the first ever space radar concept that is mainly dedicated to the measurement of ocean waves directional spectra and surface wind velocities through multi-azimuth and multi-incidence observations. Orbiting on a 500 km sun-synchronous orbit, its multiple Ku-band (13,575 GHz) beams illuminating from nadir to 10° incidence and scanning the whole azimuth angles (0-360°) provide with a 180 km wide swath and a quasi global coverage of the planet between the latitude of -80 and 80°. Such a wide range of observations requiring high range resolution (about 20 m on the ground) have led to design an instrument whose architecture and technology goes beyond what has been done on altimeter and scatterometer systems. At antenna subsystem level, multi-azimuth and multi-incidence observations requirements have led to design an ambitious antenna subsystem that rotates at 6 rotations per minute while transmitting RF signals towards 6 different beams in Transmit and Receive Modes. Thales Alenia Space started in January 2009 under CNES contract phase B studies on the design of this multi beam rotating antenna in order to contribute to the System Preliminary Design Review held successfully in January 2010. B Phase complementary activities are currently under progress to prepare the C/D Phase planned to start beginning of 2011. This paper aims at giving an overview of the SWIM antenna preliminary design and performances. [C3191]

#### **"Calibration accuracy enhancement in the field experiment with a ground-based scatterometer"**

An improved field-measurement technique for enhancing the calibration accuracy of a ground-based scatterometer is proposed in this paper. The automatic two-dimensional (2-D) measurement of a calibration target, so-called '2-D target scanning technique (2DTST)', gives a precise alignment between a point calibration target and an antenna bore-sight. Averaging of the calibration-target measurements increases further the accuracy and reliability of the automatic alignment. The measurement results show that the correlation among the measurements is larger than 0.95 and the error-rate is below 5% at a frequency range from 9.4 GHz to 9.9 GHz. The evaluation of the calibration accuracy using the STCT (Single Target Calibration Technique) shows that 2DTST in the field experiment can secure the precise calibration accuracy within 0.5 dB for magnitude correction and 4° for phase correction. [C3192]

#### **"Evaluation of vegetation effect on the retrieval of snow parameters from backscattering measurements: A contribution to CoReH2O mission"**

In preparation of the satellite mission CoReH2O, one of the three missions selected for scientific and technical feasibility studies within the Earth Explorer Programme of the European Space Agency, experimental and theoretical studies started in order to investigate backscatter properties of snow covered terrain and improve the methods for retrieval of snow physical properties from SAR data. The aim of this paper is to investigate the impact of vegetation in the retrieval of snow parameters from backscattering measurements. First a radiative transfer model, able to simulating scattering from a vegetated snow-covered terrain was developed and implemented. Lastly, a sensitivity analysis on snow and vegetation parameters was conducted for coniferous forest. Results confirm that with increasing biomass the sensitivity to SWE strongly decreases. Moreover when biomass is in the 0-150 m<sup>3</sup>/ha range a procedure to correct the vegetation effect in the SWE retrieval algorithm is suggested. [C3193]

#### **"Tropospheric correction for InSAR using interpolated ECMWF data and GPS Zenith Total Delay from the Southern California Integrated GPS Network"**

A tropospheric correction method for Interferometric Synthetic Aperture Radar (InSAR) was developed using profiles from the European Centre for Medium-Range Weather Forecasts (ECMWF) and Zenith Total Delay (ZTD) from the Global Positioning System (GPS). The ECMWF data were interpolated into a finer grid with the Stretched Boundary Layer Model (SBLM) using a Digital Elevation Model (DEM) with a horizontal resolution of 1 arcsecond. The output were converted into ZTD and combined with the GPS ZTD in order to achieve tropospheric correction maps utilizing both the high spatial resolution of the SBLM and the high accuracy of the GPS. These maps were evaluated for three InSAR images, with short temporal baselines (implying no surface deformation), from Envisat during 2006 on an area stretching northeast from the Los Angeles basin towards Death Valley. The RMS in the InSAR images was greatly reduced, up to 32%, when using the tropospheric corrections. Two of the residuals showed a constant gradient over the area, suggesting a remaining orbit error. This error was reduced by reprocessing the troposphere corrected InSAR images with the result of an overall RMS reduction of 15-68%. [C3194]

#### **"Spaceborne-airborne bistatic radar for UAS navigation purposes: Preliminary analysis and strawman system identification"**

The study of a novel navigation system for Unmanned Airborne System (UAS) based on bistatic Synthetic Aperture Radar (SAR) is presented. The innovative bistatic configuration builds on spaceborne radar transmitters

and airborne receivers, the latter mounted in a forward-looking geometry. Such approach, impossible or extremely demanding with a monostatic approach, allows one to achieve dual information with two different radar working modes: imaging capability can be in fact coupled with the possibility of moving target indication. The study is particularly suited on one of the most common UAS platforms: a close range, medium takeoff weight, with an endurance of roughly 7 hours and cruise speed of about 50m/s, whose requirements have been identified. The finalization of the study is achieved by the definition of a strawman system concept with different approaches. Four options are identified, with different performance and system complications/challenges. The study herein reported was carried out under ESA contract 22449/09/F/MOS. [C3195]

#### **"Improving hydrological forecasting using multi-source remote sensing data together with in situ measurements"**

This paper describes the development of information systems and techniques for improving hydrological forecasting by applying satellite observations, weather radars, and in situ measurements from automatic monitoring stations. In the methodology developed and demonstrated, the observation data are accompanied with a detailed soil and land cover information. The information system is concerned with the following physical characteristics relevant to river discharges and flooding: snow water equivalent (SWE), cumulative amount of precipitation, fraction of snow covered area during the melting period (FSC), soil moisture, and soil frost. Feasibility of the multi-source information system is demonstrated in a pilot experiment for Finnish Lapland, using the hydrological forecasting system of the Finnish Environment Institute (SYKE) as an example of a typical operational distributed model. [C3196]

#### **"Ground penetrating radar for tunnel detection"**

Ground penetrating radar (GPR) systems have important civil and military applications and can be used for surveying subsurface structures such as bunkers, tunnels and buried pipes. However, GPR systems for detecting deep tunnels still face many challenges, and their performance often depends on soil types, specific targets and subsurface geological features. This paper discusses challenges in tunnel detection and provides a useful and efficient procedure to develop system requirements and predict detection performance. [C3197]

#### **"GPR evaluation test for humanitarian demining in Cambodia"**

ALIS is a dual sensor for humanitarian demining, which is a combination of electromagnetic Induction sensor (EMI) and Ground Penetrating Radar (GPR), developed by Tohoku University, Japan. ALIS is equipped with a sensor tracking system using a CCD camera with image processing, which enables signal processing for subsurface imaging. Two sets of ALIS have been deployed in mine fields in Cambodia since 2009 and more than 50 buried landmines have been detected. We found that the Synthetic Aperture Radar processing (SAR processing) is effective not only imaging the buried objects, but also for reduction of clutter of soil. [C3198]

#### **"Nowcasting rainfall fields estimated from specific differential phase"**

This paper presents a preliminary evaluation of short-term prediction (nowcasting) of rainfall fields estimated from specific differential phase fields derived from Collaborative Adaptive Sensing of the Atmosphere X-band radar data. A Fourier-space, linear system-based nowcasting method used these rainfall fields as input to generate rainfall forecasts up to 20 min. The results show the extent to which specific differential phase-derived rainfall fields can be predicted and the utility of such predictions to be approximately 15 min. [C3199]

#### **"A novel three-step focusing algorithm for TOPSAR image formation"**

This paper conducted thorough research to the theory of space-borne TOPSAR data processing. The time-frequency characteristic of TOPSAR mode signal was analyzed and discussed in detail by mathematic derivation combined with the TOPSAR factor. Based on the analysis, an efficient and precise three-step image formation algorithm was presented for TOPSAR image formation without data division, and the operation in every step was theoretically proved effective. The de-rotation operation in the first step and deramp operation in the third step are adopted to finish the stretch in both frequency and time domains respectively, by which the azimuth folding effects in the time and frequency domains are overcome. [C3200]

#### **"IMage formation algorithm for bistatic forward-looking SAR"**

The conventional monostatic SAR shows a limitation of achieving a high azimuth (angular) resolution if a forward-looking geometry is used. Bistatic SAR offers a possibility of the forward-looking formation image, e.g. one platform operates as a separated illuminator while another works in a forward-looking mode. In this special bistatic configuration, the forward-looking beam will introduce two problems. The first one is the significant

Doppler shift, which will produce the range-azimuth coupling. The second one is that the targets located at symmetrically about the flight path of the forward-looking platform have the same antenna-to-target range which would cause the range migration ambiguity of the receiver. This paper will develop a mathematical model to describe the Doppler characteristic of bistatic forward-looking SAR (BFLSAR). Based on this model, the previous bistatic point reference spectrum (BPTRS) can be applied. Using the BPTRS, a modified range-Doppler algorithm is proposed to handle the two problems and focus BFLSAR data in the azimuth-invariant configuration. Finally, simulation experiment is used to validate the proposed model and processing approach.

[C3201]

### "Retrieval of soil moisture under vegetation using Polarimetric Scattering Cubes"

Soil moisture inversion from polarimetric SAR data has attracted significant attention for the past twenty years. Comparing with the simple case of bare surface, it is extremely complicated for vegetated terrain to invert soil moisture because of a larger number of scattering mechanisms that contributes to the observation. In this paper, we show how polarimetric decomposition technique, which decomposes SAR observations into preferred scattering mechanisms, can be used for the inversion. The result leads us to give up the use of polarimetric decomposition because of an unknown attenuation ratio caused by the canopy. Then a new inversion algorithm using Polarimetric Scattering Cubes (PSC) is introduced with simulation results to show a sensitivity to physical parameter such as vegetation distribution. Finally, we also discuss how the technique should be implemented for the real SAR data. [C3202]

### "Remote sensing atmospheric CO<sub>2</sub> column abundance using an airborne pulsed laser sounder at 13 km altitude"

Accurate global measurements of tropospheric Carbon Dioxide abundance to the "parts per million" (ppm) level is required to better quantify processes that regulate CO<sub>2</sub> exchange between atmosphere, land and ocean. To measure CO<sub>2</sub> globally NASA has planned the ASCENDS mission, Active Sensing of CO<sub>2</sub> Emissions over Nights, Days and Seasons. We report on an airborne laser-based remote sensing instrument we have developed at NASA-GSFC as a candidate for the ASCENDS mission. Preliminary analyses of data from initial flight testing to 13 km altitude indicates a CO<sub>2</sub> mixing ratio of 396 ppm from CO<sub>2</sub> column abundance where in situ sensors determine 390 ppm mixing ratio. [C3203]

### "Monitoring thickness change of the Dongkemadi Glacier on Qinghai-Tibetan Plateau using SRTM DEM and map-based topographic data"

In this paper we measured the long-term thickness change of the Dongkemadi Glacier (DG) on Tanggula Mountain, Qinghai-Tibetan Plateau, using the Shuttle Radar Topography Mission (SRTM) C-band data (2000) and a digital elevation model (DEM) generated from topographic map (1969). First we check the accuracy of SRTM DEM by comparison at 16 random independent points in surrounding non-glacier area below 5500m a.s.l., then we focus on an analysis of the glacier's surface thickness change features and a validation of the results using GPS survey data (2007) and DEM (1969) in Xiao Dongkemadi Glacier (XDG). The result shows XDG decreased by an average of 6.15m, or 0.20 m a<sup>-1</sup> between 1969 and 2000. We estimate the error of annual thickness change rate to be on the order of 5% compared to the result of field measurement while Da Dongkemadi Glacier (DDG) decreased by an average of 20.74m or 0.67m a<sup>-1</sup> (1969-2000). [C3204]

### "TropiSAR: Exploring the temporal behavior of P-Band SAR data"

The TropiSAR campaign has been conducted in August 2009 in French Guiana with the ONERA airborne system SETHI. The main objective of this campaign was to collect data to support the Phase A of the Earth Explorer candidate mission, Biomass. Several specific questions need to be addressed to answer the recommendations of the ESAC group and the data collection strategy has been constructed accordingly. The first part of the paper lists these specific questions. We then describe the selected test sites, followed by a summary on the radar instrument and the radar configuration (geometry and waveform). The data acquisition plan is provided and the temporal behaviour of the P-Band data is explored. [C3205]

### "AMSR and DFS synergy"

The Japan Aerospace Exploration Agency (JAXA), National Oceanic and Atmospheric Agency (NOAA), and Jet Propulsion Laboratory (JPL) are now proposing to launch the second satellite of the Global Change Observation Mission-W (GCOM-W2) carrying the Advanced Microwave Scanning Radiometer-3 (AMSR-3) together with Dual Frequency Scatterometer (DFS). This paper reviews sensor and science synergy of microwave scatterometers and radiometers. [C3206]

### "Logistic regression for detecting changes between databases and remote sensing images"

This paper studies database updating using optical and synthetic aperture radar images. Logistic regression is used to model the conditional probability of presence/absence of buildings given features extracted from the images. The logistic regression parameters are estimated using the maximum likelihood method. Binary hypothesis tests are then constructed from these estimates to detect changes between the optical/radar images and the existing database. The estimation and detection algorithms are evaluated using simulated and real data sets. [C3207]

### "DVB-T passive radar for vehicles detection in urban environment"

Passive radar systems exploit non-cooperative transmitter to detect targets in areas of interest. Some of the main advantages of such systems with respect to conventional radars include low cost architectures, low energy requirements and potentially null probability of intercept. In this paper a low-cost solution for vehicles detection making use of passive radar concept is presented. A Software Defined Radio (SDR) solution and commercial antennas have been used to realize a DVB-T passive radar demonstrator. An analysis of the DVB-T signal is firstly presented together with a study of its capability as radar waveform. Afterwards an experimental setup is presented and analysed and finally some results of targets detection are shown. [C3208]

### "Monitoring sea-ice and dry snow with GNSS reflections"

GPS reflected signals have become a source of opportunity for remote sensing of the Earth's surface. In this work, we present several capabilities of this technique in two different polar environments: Greenland and Antarctica. The first part is dedicated to the retrieval of sea-ice properties, giving emphasis to the study of the coherent phase for altimetric and roughness estimations, and polarimetric measurements for the determination of the ice salinity variation. The results show good agreement with a tide model and daily ice charts. On the second part, some preliminary results and analysis strategies to retrieve dry snow signatures are presented. [C3209]

### "RADARSAT-2 continuing system operations and performance"

This paper provides a status report for RADARSAT-2 system operations and performance now that two years of Routine Phase operations have been completed. Experience from the second year of operations is reviewed. System status, performance, and trends are described along with performance and achievements of the RADARSAT-2 operations functional groups. Normal operations now includes increased attention to orbital collision risk avoidance, and the RADARSAT-2 risk mitigation experience is summarized. In addition to meeting and maintaining specified performance requirements for the Routine Phase, the operations team has implemented a number of improvements to both the system and operations to provide enhanced performance. These include reduced tasking latency, enhanced beam modes, and further improved image quality. The improvements are described as part of the evolution of the mission capabilities along with some further planned enhancements. [C3210]

### "Enhanced Cloud algorithm from collocated CALIPSO, CloudSat and MODIS global boundary layer lapse rate studies"

Coincident profile information from CALIPSO's lidar and CloudSat's radar offers a unique opportunity to map the vertical structure of clouds over the globe with accuracies never before realized. At Langley NASA, both CALIPSO and CloudSat are collocated with each MODIS 1-km pixel to create a new data set named C3M (Figure 1). A year (July 2006-June 2007) of C3M data is used to derive global lapse rate maps, as an enhancement to NASA Langley's CERES Cloud Property Retrieval System (CCPRS). The lapse rates are derived for boundary layer clouds using the the cloud-top temperature from Aqua MODIS level 1 data, skin temperature over ocean and surface temperature over land from the GMAO GEOS-4, and cloud-top height from CALIPSO. The derived global lapse rate maps are used to process a month of CERES-MODIS data to calculate cloud top heights, which are compared with CALIPSO cloud top height. The comparisons shows good agreement between CERES-MODIS and CALIPSO. [C3211]

### "Investigations into high resolution mapping of precipitation features utilizing the TRMM precipitation Radar"

Precipitation measurements from the Tropical Rainfall Measuring Mission (TRMM) satellite's Precipitation Radar (PR) have been used to create high-resolution grids of precipitation features at a resolution of 0.05degrees. This grid size is on the order of a nominal PR instantaneous field of view (ifov) of 4.9km at nadir. Currently 12 years of data has been collected from the TRMM mission, resulting in sufficient sampling to begin these high-resolution

studies. Precipitation fields at this resolution show detailed, local climatological features and comparisons with topographic data sets allow for the identification of potential problem areas in the retrieval algorithms. [C3212]

### "Tree height retrieval methods using POLInSAR coherence optimization"

This paper investigates to what extent interferometric coherence optimization in radar polarimetry improves the performance of forest height inversion method using POLInSAR measured data. Based on repeat pass E-SAR data and the corresponding ground measured forest stand heights, several available forest height inversion methods are validated and compared together with coherence optimization algorithms such as the iteration for the maximization of the magnitude difference (BF-mag) coherence optimization algorithm and phase diversity (PD) coherence optimization algorithm. The results show that coherence phase optimization can improve the performance of the tree height retrieval method based on coherence phase information, but can not improve the performance of the retrieval method based on coherence amplitude information alone. Furthermore, an integrated inversion method, which combines coherence phase with coherence amplitude information and includes corresponding polarization coherence optimization and compensation of non-volume scattering decorrelation, is proposed and discussed. [C3213]

### "A comparison of estimated mixing height by multiple remote sensing instruments and its influence on air quality in urban regions"

Urban areas suffer from high pollutant loadings due to their proximity to emission sources as well as transported aerosols. Therefore it is essential to have an accurate technique for measuring the pollutants and evaluate their effect. Since the atmosphere mixing height (MH) defines the total volume available for the pollutant transport and dispersion, it is important that air-quality models can provide realistic estimates. This paper studies multiple instruments for MH determination and their potential for validating air-quality model forecasts such as WRF. In addition, use of automated PBL height retrieval using wavelet analysis is briefly described and long term statistical comparisons of MH and WRF mixing height are obtained. [C3214]

### "High-resolution 3-D radar imaging using pseudo-random noise coded waveform"

In this paper, high-resolution 3-D radar imaging using a 3-step image formation procedure based on the Huggens-Fresnel's principle is analyzed and discussed. To achieve high spatial resolution, large antenna array is required. The array can be implemented with a synthesized antenna array, or a sparse antenna array. To achieve high range resolution, pseudo-random noise (PN) coded signal waveform is used. The ability of generating high-resolution 3-D imaging is verified by computer simulation. Numerical simulation shows the reconstructed 3-D radar image of an object. PN coded signal waveforms also has the advantage of noise immunity. Applications of the high resolution 3-D radar imaging can be in ground penetration radars, microwave medical imaging, and down-looking SARs. [C3215]

### "Interpretation of buildings in high resolution sar images based on electromagnetic method"

High resolution SAR (Synthetic Aperture Radar) will provide an innovative tool for urban area applications. Nevertheless, interpretation of SAR image in urban area is far from solved by the increase of spatial resolution. It is usually difficult to establish a determined relationship between scattering centers in high resolution SAR images and the basic units of building targets. In order to thoroughly understand the backscattering behaviour of building targets in high resolution SAR images, a method of high resolution SAR imaging simulation based on electromagnetic model is proposed in this paper, which mainly includes 3-D model establishment for the building target, triangular facets partition, RCS prediction for each facet, and SAR imaging through coherent superposition of echo from each triangular facet. Through comparison of the simulated and the original SAR image, building scatter mechanisms in high resolution SAR images can be well interpreted. [C3216]

### "Observation of a boat and its wake with a Dual-Beam along-track interferometric sar"

The Dual-Beam Interferometer is an airborne instrument that combines two along-track interferometric synthetic aperture radars observing the surface below at different squints. This configuration allows retrieving vector velocities of surface flows in a single aircraft pass. The system was designed by the University of Massachusetts and saw several deployments in the early 2000s. An imagery of a boat with a rather pronounced wake system captured during one of these flights is the subject of this paper. The velocity of the vessel is estimated based on the "train off the tracks" displacement in one of the looks. This estimate, which will be affected by uncertainty in target position due to smearing, is then used to remove unknown phase biases in the interferometric channels. Retrieved velocity variations are examined along cuts traversing the wake, with the focus on its narrow "turbulent" part. We find that the reconstructed velocities 150 m behind the boat are intuitively satisfying, but we are unable to fully account for the cross-wake component of velocity at 400 m behind the vessel. [C3217]

### "Wall-to-wall mapping of forest extent and change in Tasmania using ALOS PALSAR data"

Consistent estimation of carbon stocks at national level requires the integration of wall-to-wall, time-series satellite and in situ data of forest area, type and change. In this paper we demonstrate a consistent approach to the generation of wall-to-wall time-series mosaics using ALOS PALSAR data acquired over 2007 to 2009 for Tasmania, Australia. The project is part of a series of National Demonstrators initiated by the Group on Earth Observations (GEO) Forest Carbon Tracking (FCT) task that emphasize the contribution and operational use of satellite measurements for forest monitoring and national carbon accounting. Interoperability between optical and Synthetic Aperture Radar (SAR) derived forest measurements will also be demonstrated. The project will deliver a series of forest monitoring products and technical documentation, which will be made available as a guide to GEO member countries with a desire to develop their own national carbon accounting systems. [C3218]

### "Bistatic SAR tomography: Processing and experimental results"

This paper presents across-track tomography applied to a bistatic geometry with fixed receivers. This kind of geometry can overcome some of the classical monostatic tomography limitations such as temporal decorrelation and irregular baseline distribution. The Remote Sensing Laboratory (RSLab) of the Universitat Politècnica de Catalunya (UPC) has implemented a SAR Bistatic Receiver for INTERferometric Applications, SABRINA, with 4-channels. SABRINA has been used to carry out a bistatic tomographic experiment. The acquired data has been processed with different tomographic methods and their performances compared. [C3219]

### "An improved fast Viterbi algorithm for track-before-detect"

This paper addresses the problem of moving dim target detection in radar systems using track-before-detect approaches (TBD), which are implemented by a fast Viterbi algorithm (FVA). Traditional Viterbi algorithms (VA) traverse all the resolution cells including many noise cells in every frame, whereas FVA improves the searching method by combining with a Constant False Alarm Rate (CFAR) approach to expel many noise cells, and provides the same performance with much less computational cost. What's more, it avoids target extend with no post-processing due to a novel maximization operation, and consequently reduces the complexity of the proposed algorithm. Simulation results prove the performance of the new algorithm. [C3220]

### "A novel method of SAR terrain target scattering signal simulation"

Synthetic Aperture Radar (SAR) raw signal simulation is crucial for SAR system design and processing algorithms. This paper proposes the simulation method of SAR scattering signal of big area terrain target. At first, the SAR imaging principle is analyzed. Then, the space-borne SAR scenario model is constructed. The echoes of point target are calculated, which is impulse response of the SAR signal acquisition system. In tradition, the Radar Cross Section (RCS) simulation parameters of terrain target calculation is based on the scattering model expressions of a random roughness surface and the electromagnetic wave shadow theory. The approach of this communication utilizes the practical SAR SLC (Single Look Complex) or MGD (Multi-Look Ground-range Detected) image as terrain target backscattering coefficient, instead of the traditional method aforementioned. Then, 2D-FFT method is utilized to improve simulation efficiency significantly. The results of simulation prove the validity of the approach. [C3221]

### "An EMD-based denoising method for lidar signal"

Lidar echo signal is a typical non-steady-state, non-stationary signal, and difficult to be dealt with by the traditional filtering methods. As a new signal processing theory proposed in recent years, Empirical Mode Decomposition method can adaptively divide the lidar echo signal into different intrinsic mode function (IMF) components according to different time scale, and noise mainly concentrates in the high-frequency component. However, when filtered with simply removing high frequency component, the useful signal will be possible to be reduced. In this paper, a new method which combines Empirical Mode Decomposition (EMD) with Savitzky-Golay filter is proposed. With experiments, it is indicated that our approach not only removes the noise component effectively but also maintains the useful signal, then will improve the accuracy in the next phase of data processing. [C3222]

### "MST phase unwrapping based on new weighted map"

Phase unwrapping can be cast as a minimization problem under the  $L_p$ -norm framework. In this framework, it is a critical step that derives weighted function from prior information. This letter presents a new weighted map which is calculated by local phase signal to noise ratio(SNR) based on linear phase hypothesis. The proposed weighted map can reduce slope effect of coefficient and fuse the consideration of intensity. Lastly, the tests

performed on real data confirm the validity of our method. [C3223]

### "SAR raw echo simulation of ground scene"

Synthetic Aperture Radar (SAR) raw echo simulation methods are studied in this paper. A simulation method is proposed based on fractal theory, facet model and clutter scattering characteristic model. Digital Elevation Model (DEM) of a natural terrain is used in computer simulation. The SAR raw echo simulation is realized in the frequency domain. The simulation results demonstrate that the method is effective, and the stochastic property and special geometric distortion phenomena of natural ground scene in the SAR image are reflected. [C3224]

### "Simulation of Faraday rotation on longer wavelength spaceborne polarimetric InSAR"

The effects of Faraday rotation (FR) on longer wavelength (i.e. L or P-Band) spaceborne linearly full-polarized interferometry synthetic aperture radar (Pol-InSAR) processing are addressed. A model for linearly full-polarimetric InSAR data subject to Faraday rotation is investigated. Due to Faraday rotation, the received signal in each channel will be contaminated by backscattering signals from other polarimetric channels, which consequently reduce the coherence of the two single look complex SAR images received by the same channel for PolInSAR processing. The numerical simulation results are presented, which indicates that Faraday Rotation has significant impact on the coherence of the interferograms, especially for the spaceborne longer wavelength Pol-InSAR system. [C3225]

### "Subimage fusion for high-resolution ISAR imaging"

With the improvement of resolution in the inverse synthetic aperture radar (ISAR) imaging, the effect of the rotational motion of the target is much larger than ever before. In this letter, we propose a novel subimage fusion method to compensate for the large rotational motion in high-resolution ISAR imaging. By dividing the large rotational motion into several small ones, the subimage formation can be realized easily with current ISAR imaging algorithms. At the same time, with the increasing of the number of the subimages, the change of the aspect angle during the coherent processing interval can be very large, and high resolution can be achieved. Moreover, because the whole processing is achieved with Fast Fourier Transforms and vector-multiplication operations, the proposed approach is computationally efficient and has no interpolation operation. Numerical examples are provided to demonstrate the performance of the proposed approach. [C3226]

### "Segmentation of Polarimetric SAR images using graph partitioning active contours"

In this paper, a novel segmentation method for Polarimetric Synthetic Aperture Radar (PolSAR) images is proposed. Image segmentation is formulated as a graph partitioning problem which is addressed by curve evolution. Graph partitioning active contours (GPAC) [1], which is flexible and can be classified as a region-based active contour framework, is applied to PolSAR images. In order to apply GPAC to PolSAR image segmentation, the pairwise dissimilarity between two arbitrary pixels in the image should be measured appropriately. The selection of dissimilarity measures is discussed. Synthetic and real PolSAR images are both used in the experiments to verify the proposed approach. A quantitative evaluation and comparisons of segmentation results, including iteration times of curve evolution, segmentation accuracies in term of pixel and object count, are provided. The proposed scheme has shown to be promising for PolSAR image segmentation. [C3227]

### "Prospects of new real-time radar applications for environmental remote sensing"

Remote sensing used to assess geophysical parameters on Earth is increasingly exploited and necessary for sustainable human life on Earth. A goal of using satellites to monitor changes and characteristics of Earth's surfaces is to further understanding of the planet and its systems, as well as understanding of how humans interact with and change the environment. Mostly underexploited, biomass detection via active radar remote sensing could provide a more thorough and in depth analysis of Earth. Upcoming NASA Earth monitoring satellites cover a wide range of science products and applications, but little influence is put on the possibility of harnessing data from biomass reaction to radar pulse. In addition to the benefit of radar remote sensing in observing large areas at once, an added ability of transmitting detected frequencies in nearreal-time has potential to provide countless advantages. Direct Broadcast increases possibilities and practical uses for collected data. [C3228]

### "Simulation studies on data fusion algorithms for forest structure from lidar and SAR data"

The NASA's DESDynI mission will provide global systematic lidar point-sampling data and areal coverage of L-band SAR data with polarimetric capabilities for 3-D structural studies of vegetation. The combined use of lidar's

direct sampling measurements and radar's global areal mapping capabilities creates a real opportunity to map global ecosystem structures and functions that link to carbon dynamics. However, the relationship of the lidar point-sample data and corresponding areal SAR data is yet to be established. In this study the data fusion algorithms for the estimation of parameters of forest structure from Lidar and SAR Data is investigated. The results show that SAR intensity data is sensitive to forest biomass which is less than 15kg/m<sup>2</sup>(or 150 ton/ha) and insensitive to the maximum forest height. Lidar data can be used to provide the information of forest height and the introduction of the information of forest height is helpful in the estimation of forest biomass. [C3229]

#### "Application of monopulse techniques in angle-measuring of single-beam mechanical scanning radar"

Due to large computation cost and low accuracy of traditional angel measurement in single-beam mechanical scanning radar, a new application of monopulse techniques is proposed. First of all, this paper introduces the principle of monopulse and analyzes the difference in accuracy between monopulse and the traditional methods. Based on that, engineering implementation is then discussed. Finally, experimental data obtained in detection mode for inverse synthetic aperture radar (ISAR) is processed by this method, and results demonstrate effectiveness of the proposed method. [C3230]

#### "Analysis of Faraday rotation on spaceborne CTLR compact polarimetric SAR image reconstruction"

The CTLR (circular transmit and linear receive) compact polarimetric (CP) synthetic aperture radar (SAR) system transmits only right or left circular polarized signal and receives H and V linear polarized signal. CP SAR mode has significant advantage of doubled swath width compared to the traditional full-polarimetry (FP) mode. In this paper, the effective FP data are reconstructed using Souyris' iteration algorithm from the covariance matrix of the CTLR mode CP SAR data. Then the performance of the algorithm is analyzed. Moreover, the ionospheric effect of Faraday rotation (FR) on longer wavelength (i.e. P-band) spaceborne CP SAR was introduced in the simulation. After simulating the impacts of FR on SAR image reconstruction, an information-theoretical evaluation method was proposed for analyzing the quality of SAR image reconstruction. The mutual information between the original FP data and the reconstructed FP data (namely, from the CTLR CP SAR image) as a function of FR was illustrated, for quantitatively evaluating FR on longer wavelength (e.g. P-band) spaceborne CTLR CP SAR image reconstruction. [C3231]

#### "A measurement method for Doppler frequency rate-of-change with coherent pulse train"

The information of target's acceleration is reflected in the Doppler frequency rate-of-change of the received radar signal. Limited in target's velocity, the information of Doppler frequency rate-of-change is very subtle. This information is quite difficult to measure precisely since it is very subtle and the pulse duration is very short. Therefore, a precise method is proposed to measure this information based on Morlet wavelet transform. Morlet wavelet transform has low signal-to-noise ratio (SNR) threshold. According as auto correlating the wavelet transform coefficient of radar signal, the Doppler Frequency rate-of-change is enhanced and phase ambiguity is unwrapped. By exploiting the coherent property of pulse train, the observation time is extended equivalently and so the measurement precision is improved greatly. The simulation study shows that this method has low SNR threshold and obtain the parameter measurement fast and accurately. [C3232]

#### "Compressive sensing SAR imaging with real data"

As an active and coherent microwave high resolution imaging system, Synthetic Aperture Radar (SAR) has the capability to image in all weather and day-or-night conditions. Recent advent of theory of Compressive Sensing (CS) has introduced a novel concept that an unknown sparse signal can be recovered exactly with an overwhelming probability even with highly sub-Nyquist-rate samples. In this paper, a new scheme for the test bed of CS based SAR imaging is proposed. Experimental results on some real raw SAR data reveal that there are some practical limitations on the use of CS based SAR imaging, especially for complex imaging scenes and the systems with low Signal-to-Noise Ratio (SNR). [C3233]

#### "Estimation of significant wave height from X-band marine radar images"

Radar images include abundant information about ocean waves. Sea state parameters and surface currents can be obtained by analyzing time series of radar images of the sea surface. Due to the non-linearity of the imaging mechanism of ocean waves, significant wave height ( $H_s$ ) can not be determined directly from radar images. Applying a method to infer the  $H_s$  from synthetic aperture radar (SAR) images, the  $H_s$  can be estimated from marine radar images. Comparing the  $H_s$  obtained by this method with buoy data, the results show that it is

feasible to obtain reliable data of the Hs from marine radar images. [C3234]

### "Fish-pond change detection based on short term time series of RADARSAT images and object-oriented method"

As an important type of wetlands, fish-pond provides a number of important ecosystem services. It was easily affected by human activities such as the change of cultivation structure. Tracking the fast change of fish-pond can obtain the information that the environment is impacted by human activities to what extent. In this study, we proposed a change detection procedure in order to delineate fast change fish-pond using high resolution, short term time series of SAR imagery. The procedure includes (1) SAR images preprocessing, (2) object extraction, (3) multi-temporal change characteristics analysis of fish-pond, (4) change objects classification, and (5) a final change results analysis. In this study, object-oriented method was adopted to extract and analyze the texture characteristics of fish-pond in the high spatial resolution of SAR data. Objects were generated with suitable scale parameters by means of multi-temporal segmentation approach according to the image features (including backscatter, difference and ratio of three temporal RADARSAT images, shape characters), and the changed objects were extracted through analyzing the shape index and contextual information generated by Definiens software. Six change types of fish-pond were achieved. The results indicate that high resolution SAR data can provide better information for fish-pond change detection in the study area, and the procedure proposed in this study can efficiently obtain the fast change objects with high accuracy between three short term time series SAR images, which are useful for the further classification. [C3235]

### "A 3D microwave imaging method for earth observation"

Microwave imaging techniques which can provide all-weather, day-and-night imaging capability have important applications to many fields. It is an active area to explore new microwave imaging ideas, systems and techniques. In our previous work, we proposed a new microwave imaging method for earth observation. In this method, the transmitter and receiver are located in different platforms, and only a monochromatic microwave is required to illuminate the earth surface. Numerical simulation results show that this method can produce microwave images with high spatial and radiation resolutions. In this paper, as an extension of our previous work, we study some important properties of this method, which lead to a very promising potential application in 3-dimensional (3D) imaging for earth observation. [C3236]

### "Airborne LiDAR strip adjustment based on LSM"

An airborne LiDAR system is an integration of GPS, INS, and laser scanner. Because of errors of these instruments or sub-optimalities of the GPS/INS integration, points of neighbouring laser scanner strips will usually show vertical and horizontal discrepancies. Currently the more common way for the reducing or ultimately eliminating discrepancies found in strip overlap areas is strip adjustment. Based on Microsoft Visual Studio 2008 C++ platform, a data-driven method of seven parameters conformal transformation for airborne LiDAR strip adjustment is realized in our paper, the algorithm improved Robert (2004) least squares surface matching algorithm, by introducing the Gauss-Markoff model, Acquired the unbiased minimum variance estimation for the unknown parameters. Real data sets are used to validate the method. We study the matching precision of different reference surface from two strips, the need for using Gauss-Markoff model and the matching accuracy. Experimental results show that after correction the point clouds show much better alignment and the vertical matching error is less than 0.05m. [C3237]

### "High resolution radar imaging using bandwidth extrapolation"

The resolution of a synthetic aperture radar (SAR) image, in range and azimuth, is limited by the transmitted signal bandwidth and the synthetic aperture length, respectively. Bandwidth extrapolation algorithm is one of the various superresolution techniques for improving the resolution. The frequency AR model is used in the paper to expand the effective bandwidth of the signal based on the bandwidth extrapolation together with linear prediction algorithm. The performance estimation function, namely the prediction error as a scaling power-law function of the linear error prediction filter length, is derived through analyzing large numbers of computer simulation experiments. It is of considerable importance to determine the linear error prediction filter length for optimizing the bandwidth extrapolation parameters. It is demonstrated by the theoretical analysis and simulation results that the bandwidth extrapolation method is feasible and effective for expanding the bandwidth to obtain higher resolution SAR image by applying the method to the range and azimuth directions, respectively. [C3238]

### "Analysis and modification to the method of bistatic clutter range dependence mitigation"

Clutter range dependence mitigation is very important for bistatic space-time adaptive processing (STAP) radar. The paper focuses on the technique of clutter spectrum registration-based nonuniform frequency sampling (RB-

NFS). Analysis indicates RB-NFS method brings inadequate clutter rejection and the dependence on STAP training sample number. Modifications to RB-NFS method are proposed to solve the problems. Simulations prove the correctness of analysis of RB-NFS. STAP with modified RB-NFS is hardly affected by the number of training samples and can achieve approximately optimal performance even with only two training samples. [C3239]

#### **"Power-level surveillance for an FMCW-based local positioning system"**

Local positioning systems which are based on the bistatic frequency modulated continuous wave (FMCW) radar principle generally evaluate the time of flight (TOF) of signals. However, the FMCW principle also provides the power level (PL) of the received signal, which is often neglected since various unknown parameters must be considered. In this contribution, we present a method which exploits this additional source of information by predicting its value accurately based on the knowledge of the antenna characteristics, hardware parameters, and the estimated position of the measurement transponder (MT). This information can then be used to determine the quality of each PL measurement and to discard data which are obviously corrupted. [C3240]

#### **"Wetland cover information extraction research based on the multi-polar radar images and multi-spectrum optical images fusion"**

The research takes Radarsat-2 multi-polarization radar images and ALOS multi-spectrum optical images for example, through the information filtering and extraction methods such as information quantity statistics and correlation matrix, we obtain the cognition of the spectral characteristics and detection performance of each polarization mode radar image, and select the optimal data for fusion and classification experiment. Using Brovey, PCA, HPF and Wavelet transformation methods to fuse, and adopting non-supervision, supervision and object-oriented method to carry out classification experiment, we explore the application of radar and optical remote sensing image fusion technology in the wetland area covers information extraction, which verifies the effectiveness and feasibility using radar and multi-spectral image fusion technology in the wetland cover information extraction. [C3241]

#### **"A new method of three-dimensional visualization of satellite cloud image"**

To solve the problems on 3D visualization of satellite data, such as the inaccuracy of cloud mask, ignorance of visual affect of gray, transparency and orientation, this paper brings forward a series of methods. Through radiation background to detect cloud mask and cloud top inversion etc, can obtain high precision application data, moreover, advances the revised model on aspects of gray, transparency and orientation. modeling by the methods advanced above, 3D satellite data could gain a better effect. [C3242]

#### **"SAR interference signal feature vector extraction and simulation based on wavelet packet analysis"**

This paper studies the use of wavelet analysis method to realize the non-coherent narrow-band SAR radar signal interference suppression. Based on the full study of Irregular wavelet tree in interference detection and filtering, an adaptive filter using wavelet packet decomposition to extract the interference signal feature vector has been proposed. Simulation experiments based on this method have been carried out, by using SNR improvement, interference rejection ratio, signal distortion and other evaluation criteria to evaluate the results of interference suppression, the results show that the effect of wavelet packet filtering interference suppression is good. [C3243]

#### **"Research on extracting the tree height based on LiDAR data"**

In this paper, extraction of the forest tree height based on LiDAR (Light Detection and Ranging) data was studied. A simple algorithm was proposed to compensate the result computed by the DEMs of first return and last return. The satellite image download from the GoogleEarth was used to facilitate the analysis. The algorithm was tested with these data, and had been proved to be effective. Although the data we used was not suit for extracting tree height, LiDAR has great potential in this field. [C3244]

#### **"A novel SAR fusion image segmentation method based on Markov Random Field"**

Markov Random Field (MRF) method is a popular technology in SAR image segmentation nowadays. It considers the statistical characteristics of SAR image and achieves optimal image segmentation result. In this paper, a novel SAR fusion image segmentation method based on MRF model is proposed. Firstly, the mechanism of MRF segmentation on single SAR image is studied. Secondly, the Maximum a Posterior (MAP) formula for SAR fusion image segmentation is deduced by supposing the two SAR images for fusion are statistically independent. Then the energy function of SAR fusion image segmentation is presented and the

processing steps are given. At the end, computer simulation indicates that the performance of this new approach is much better than that of single SAR image segmentation based on MRF. [C3245]

### "Synthesis of four-level Z-complementary sequences"

Sequences over the alphabet  $\{1, -1, 2, -2\}$  are called four-level sequences. Including the conventional complementary sets as special cases, the aperiodic four-level Z-complementary sets (FLZCS) with zero correlation zone (denoted by Z) are introduced, and the elementary transformations on four-level sequences and elementary operations on FLZCS are given. In particular, comparing four-level Z-complementary pairs with binary and quadriphase Z-complementary ones, the results show that the maximum zero correlation zone (denoted by  $Z_{\max}$ ) of four-level and quadriphase Z-complementary pairs is generally much longer than that of binary Z-complementary ones, and that  $Z_{\max}$  of four-level Z-complementary pairs is pretty close to that of quadriphase Z-complementary ones. It is verified that most synthesizing methods of quadriphase Z-complementary sets and their mates are also applicable to FLZCS, in addition to which, other synthesizing methods of FLZCS and their mates are provided here. [C3246]

### "A novel method of resolving velocity ambiguity in the pulse doppler radar"

In this paper, a novel method of resolving velocity ambiguity in the pulse Doppler (PD) radar is proposed. By using multi-carrier-frequency waveform and Chinese Remainder Theorem (CRT), this method is able to overcome the velocity ambiguity. Furthermore, a modified algorithm with better robustness is deduced and its performances are analyzed in detail. Specific conclusions are verified with some simulation results. [C3247]

### "In-situ broadband soil measurements: Dielectric and magnetic properties"

This paper presents an in-situ method for measuring both electric and magnetic properties of Hawaiian volcanic soil for GPR applications in a broad frequency range from 50 MHz to 1GHz. For the in-situ probe, we combined two monopole antennas with parasitic elements into one piece to achieve reflection (S11) and transmission (S21) measurements simultaneously. Finally, the in-situ probe has a shape of a multi-conductor TEM transmission line, which consists of five conducting rods, two ground plates and two coaxial feed connectors. In a typical measurement the in-situ probe is connected to a two ports vector network analyzer and system calibration is then performed to characterize the sample free device. The calibration is based on measurements of the S-parameters for sample free and sample loaded devices. A unique post processing algorithm has been developed to extract accurate constitutive parameters ( $\epsilon^*$ ,  $\mu^*$ ) from the scattering parameters (S11, S21) of the soil probe, which will be discussed in this paper. The prototype in-situ soil probe and post processing algorithm were also tested by both numerical simulation and actual soils in volcanic red soil. The simulation results showed around 1 % of error over the operational frequencies between 100 MHz and 800 MHz. Actual measurement results conducted by the in-situ probe and developed algorithms were in very good agreement with those obtained by a laboratory method. Simulation and actual measurement data will be presented in this paper. [C3248]

### "Building detection and height retrieval in urban areas in the framework of high resolution optical and SAR data fusion"

In this paper, we propose a symmetrized version of a semiautomatic processing chain, able to provide the simple 3D reconstruction of buildings in urban scenes, from high-resolution optical and SAR imagery. The new elaborated chain gives an equivalent part to the optical and SAR components, in order to fully exploit complementary information provided by proper building features in both images. First, the initial processing chain is reminded and completely illustrated on a studied scene on real data. Then, three points of improvements by process symmetrization are discussed: an augmentation of the detection rate in the footprint extraction step, an increase of the reliability attached to the estimated building heights and a joint improvement of the steps of building validation and qualification. It is shown that the appropriate combination of optical and SAR features, inside some processing steps, could give better results of reconstruction. [C3249]

### "Infrared satellite precipitation estimate using waveletbased cloud classification and radar calibration"

We have developed a methodology to enhance an infrared-based high resolution rainfall retrieval algorithm by intelligently calibrating the rainfall estimates using space-based observations. Our approach involves the following four steps: 1) segmentation of infrared cloud images into patches; 2) feature extraction using a wavelet-based method; 3) clustering and classification of cloud patches; and 4) dynamic application of brightness temperature ( $T_b$ ) and rain rate relationships, derived using satellite observations. The results show that using wavelet features along with other features increase the performance of rainfall estimate in terms of quantitative

rain/no rain area estimates. In addition, using lightning data as a feature improves the estimates as well. [C3250]

### "Potentials of a compact polarimetric SAR system"

The goal of this study is to show the potential of a compact-pol SAR system for vegetation applications. Compact-pol concept has been suggested to minimize the system design while maximize the information and is declined as the  $\pi/4$ ,  $\pi/2$  and hybrid modes. In this paper, the applications such as classification, Faraday rotation and soil moisture estimates are first reminded, then, biomass estimation from CP data is presented and a calibration procedure using external targets is proposed. Finally, the interferometry concept is added to assess the capabilities of a compact-pol system to retrieve vegetation height. [C3251]

### "Metallic objects and oil spill detection with multi-polarization SAR"

In this study, two innovative physically-based approaches have been developed to detect man-made metallic objects and oil slicks in polarimetric SAR data. They are based on the different sea surface scattering mechanisms expected with and without oil slicks and metallic objects. Experiments, accomplished over Single Look Complex (SLC) Level 1.1 quad-pol L-band ALOS PALSAR SAR data, demonstrate the effectiveness of the two approaches for oil slick and metallic target detection purposes and witness the capability of ALOS PALSAR data for such applications. [C3252]

### "Modeling lidar scene sparsity using compressive sensing"

One of the major problems associated with LIDAR sensing is that significant amounts of data must be collected to obtain detailed topographical information about a region. Current efforts to solve this problem have focused on designing compression algorithms which operate on the collected data. These, however, require the collection of large amounts of data only to discard most of it in some transformed domain. Instead, compressive sensing has demonstrated that highly accurate signal reconstructions are achievable even when sampling below the Nyquist rate. Such sensing is clearly desirable for LIDAR range data compression if it can be achieved. One notes, however, that compressive sensing requires a priori knowledge of the sparsifying basis of the signal which is a major problem for LIDAR since that basis depends not only on the underlying scene complexity but also on the laser spot size and target distance. For these reasons, the goal of this research is to take the first steps in establishing a relationship between typical LIDAR scenes of varying complexity and the sparsity of the scene compressively sampled. [C3253]

### "The snowscat ground-based polarimetric scatterometer: Calibration and initial measurements from Davos Switzerland"

The COld REgions Hydrology High-resolution Observatory (CoReH20) Mission proposes a dual frequency radar operating at 9.6 and 17 GHz utilizing VV and VH polarization [1]. By combining X and Ku-Band with both co and cross-polarization diversity it is possible to estimate the Snow Water Equivalent of dry snow. To support this proposed mission, ESA has sponsored the development of a ground-based coherent polarimetric scatterometer operating over the 9-18 GHz frequency range. ESA is supporting campaigns to acquire and process data using SnowScat for validation of Snow Water Equivalent (SWE) retrieval algorithms. [C3254]

### "Performance status of the wave scatterometer SWIM"

SWIM is a Ku-band radar designed for wave directional spectrum estimation. This radar operates at six incidence angles (from  $0^\circ$  to  $10^\circ$ ) with a complete azimuth scanning covering a swath of 180 km. The phase B (addressing preliminary design) of SWIM is currently under finalization. In, the preliminary design and associated performance analysis have been published taking into account the first results of Phase B design. This paper is focused on the last performance assessment of this phase B for all the measurements performed by the SWIM instrument. [C3255]

### "One micron laser technology advancements at GSFC"

In recent years, lasers have proven themselves to be invaluable to a variety of remote sensing applications. LIDAR techniques have been used to measure atmospheric aerosols and a variety of trace species, profile winds, and develop high resolution topographical maps. Often it would be of great advantage to make these measurements from an orbiting satellite. Unfortunately, the space environment is a challenging one for the high power lasers that would enable many LIDAR missions. Optical mounts must maintain precision alignment during and after launch. Outgassing materials in the vacuum of space lead to contamination of laser optics. Electronic components and optical materials must survive the space environment, including a vacuum atmosphere, thermal cycling, and radiation exposure. Laser designs must be lightweight, compact, and energy efficient. Many LIDAR

applications require frequency conversion systems that have never been designed or tested for use in space. For the last seven or eight years the National Aeronautical and Space Administration (NASA) has undertaken a program specifically directed at addressing the durability and long term reliability issues that face space-borne lasers (The Laser Risk Reduction Program-LRRP). [C3256]

### "On-ground tests and measurements of the Passive Advanced Unit Synthetic Aperture (PAU-SA)"

This paper presents the current state of the Passive Advanced Unit Synthetic Aperture's instrument (PAU-SA), its installation in the transportation truck, and the preliminary tests that have been performed to verify the instrument's status. [C3257]

### "3D imaging of ice sheets"

We developed and deployed, in July 2005, a wideband 8-channel synthetic aperture radar (SAR) at Summit Camp, Greenland (72.5783° N and 38.4596° W). The radar was designed to map internal layers, measure topography, and generate backscatter maps-all in a single pass. Information on ice thickness, bed topography and basal conditions is essential to the refinement of glaciological models of ice sheets, which are used to predict ice-sheet behavior (especially mass balance) and to select deep ice-core sites. This work focuses on the use of fine-resolution 3D imaging algorithms for combining all 8-channels to form cross-track image slices through the ice. As compared with traditional 2D depth sounding, these 3D images allow for the characterization of bed topography with very fine resolution. They also allow for the generation of strip-map SAR images with absolute geocoding without ground control points (these are unavailable at the bottom of the ice), and the ability to analyze the ice-sheet volume in 3D. Topography, backscattering, and 3D ice volume results are illustrated here. [C3258]

### "Atmospheric phase screen-estimation for PSInSAR applied to TerraSAR-X high resolution spotlight-data"

The PSInSAR technique, invented by Ferretti et. al. ten years ago, meanwhile has proven it's capability for very precise measurement of surface deformations. To achieve this, the influence of the atmospheric phase screen (APS) has to be removed. We investigated the APS for two series of TerraSAR-X high resolution spotlight data of a scene in Bavaria. Our approach was to consider the APS as composed of a phase ramp, a part stratified with height and a turbulent component. We estimated the turbulent component via kriging. The variograms show for short distances a regime which is not visible for lower resolutions. In this paper we discuss the choice of appropriate variogram models with respect to our data. [C3259]

### "Doppler effect and compensation in a Rotating Fanbeam Spaceborne Scatterometer"

Spaceborne Rotating Fanbeam Scatterometer, RFSCAT, has a wider continuous swath that can provide a large number of independent samples of Sigma0 for wind speed and direction retrieving. But the large swath and footprint result in a wideband Doppler frequency shift. For a low earth orbiting satellite, the maxim Doppler bandwidth between forward and backward echoes will be about 500 KHz. Even in a single echo of RFSCAT, the Doppler bandwidth is about 90 KHz, while in a pencil beam scatterometer the Doppler bandwidth is almost a single tone. A method of Doppler frequency compensation both on center frequency of transmitted pulses and signal processing section of the echoes are carried out and evaluated. [C3260]

### "Fractal based filtering of SAR images"

In this paper an innovative fractal based filtering for the analysis of SAR images of natural surfaces is presented. Its definition is based on a complete direct imaging model developed by the authors. The application of this innovative algorithm to SAR images makes it possible to obtain a complete map of the fractal dimension of the observed scene. Significant results obtained on actual SAR data are shown in the last section of the paper. [C3261]

### "Exploitation of the additive component of the polarimetric noise model for speckle filtering"

Ratio filters for speckle noise reduction in SAR imagery are recursive filters where the image structure is iteratively recovered from an initial oversmoothed image. We show that the MBPolSAR filter could be interpreted as a ratio filter applied to the off-diagonal terms of the covariance/coherency matrix. From this observation, we propose a new polarimetric ratio filter allowing us to recover the image structure from all the terms of the covariance matrix. In addition, we briefly look at how the additive noise component could also be exploited for the image structure extraction. Filtering results on both simulated and real PolSAR images are shown. [C3262]

### "SAR performance monitoring for TerraSAR-X mission"

The TerraSAR-X satellite features an advanced X-Band SAR based on the active phased array technology which allows flexible operation of Spotlight, Stripmap, and ScanSAR mode for various combinations and elevation angles. It combines the ability to acquire high resolution images for detailed analysis as well as wide swath images for overview applications. The SAR performance of the system is analysed with respect to geometric and radiometric parameters. Long-term monitoring of system parameters like instrument characteristics or SAR image quality confirms the continuous stability of the system. By launching a twin satellite TanDEM-X for global DEM acquisition, the TerraSAR-X mission is now supported by two satellites. The approach presented in the following shows how to keep the SAR performance for both satellites, TerraSAR-X and TanDEM-X. [C3263]

### "Using airborne & space lidars for large-area inventory"

NASA plans to launch two space lidar missions over the next decade, and at least one proposal for a space lidar is being considered by the European Space Agency. All designs call for single-beam or multi-beam profiling systems. These space ranging systems, like the ICESat/GLAS lidar that collected over 1.91 billion waveforms between January 2003 and October 2009, must necessarily be used as sampling tools to characterize vegetation cover and to estimate forest volume, biomass, and carbon globally. Recent investigations conducted by these authors have centered on developing, testing, and refining statistical approaches that can incorporate airborne and space lidar acquisitions to inventory large areas. [C3264]

### "Case studies of automatic change detection using AVNIR-2 onboard ALOS"

This paper suggests a new automatic change detection approach using image-object-based contextual inference. The approach first detects changed areas, and then infers what happened there. The inference process uses knowledge based on a change detection process performed by humans. It enables flexible and intuitive description of the change detection process. In this paper, we describe the results of case studies on automatic change detection using the Advanced Visible and Near Infrared Radiometer type-2 (AVNIR-2) onboard the Advanced Land Observing Satellite (ALOS, nicknamed "Daichi"). [C3265]

### "Progress in the validation of dual-wavelength aerosol retrieval models via airborne high spectral resolution lidar data"

The Constrained Ratio Aerosol Model-fit (CRAM) technique is a method for making aerosol retrievals from dual-wavelength elastic scatter lidars which attempts to constrain the retrievals so as to be consistent with a number of aerosol models thought to characterize a variety of aerosol types observed around the world. The NASA Langley Research Center Airborne HSRL is an airborne high spectral resolution lidar capable of direct measurements of aerosol extinction and backscatter at 532 nm and having the capability for elastic backscatter measurements at 1064 nm. Aerosol measurements by HSRL during the TEXas Air Quality Survey/ Gulf of Mexico Atmospheric Composition and Climate Study (TEXAQS/GoMACCS) campaign are used to validate existing aerosol models critical to the application of CRAM, in particular to data from the Cloud-Aerosol Lidar with Orthogonal Polarization (CALIOP) lidar instrument on board the Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observations (CALIPSO) satellite. [C3266]

### "Focal plane approximation for near field interferometric radiometer imaging"

Applying synthetic aperture interferometric radiometer (SAIR) in near field imaging has been receiving great interest in the recent years. Because the traditional far-field Fourier imaging theory is not valid in near-field condition, developing the proper near-field imaging techniques is the major desirable objective of near field SAIR applications. This work is devoted to establish an effective near field imaging method still with traditional far-field plane antenna array. The discrete numerical inversion method with focal plane approximation is developed. The regularization method is also introduced to deal with the ill condition and measurement errors. [C3267]

### "Oil-slick observation using single look complex TerraSAR-X dual-polarized data"

In this study single look complex (SSC) TerraSAR-X dual-polarized data are firstly exploited for sea oil slick observation purposes. An electromagnetic model which, based on the Co-polarised Phase Difference between the HH and VV channels (CPD), allows describing the X-band sea surface scattering with and without surface slicks is proposed. Following this rationale, the polarimetric approach is firstly developed and applied to X-band Synthetic Aperture Radar (SAR) data in which both certified oil slicks and look-alikes are present. Experimental results demonstrate, for the first time, that X-band dual-polarimetric SAR data are suitable for sea oil slicks observation purposes and witness the paramount importance of the TerraSAR-X dual-polarimetric mode for such application. [C3268]

### "Observational studies of atmospheric aerosols in the lower troposphere using multiple sensors"

Atmospheric aerosols play a large role in the Earth's radiation budget, but their specific radiative forcing effects vary wildly depending upon species, altitude and geographic location. A suite of instruments has been developed and deployed at Montana State University in Bozeman for the purpose of conducting altitude-resolved atmospheric aerosol studies. [C3269]

### "The preliminary temporal analysis of ground deformations in the area of Dabrowski Coal Basin (south Poland)"

In this work the preliminary temporal analysis of ground deformations in the area of Dabrowski Coal Basin was performed. In this region the intensive coal exploitation has been performed for about 200 years. The studied region covers the mining areas of seven coal mines. Moreover this area is crossed by many faults. In the described work the analysis concerned only the small, long lasting deformations that were detected using PSInSAR technique. The aim of this work was to analyze the changes in the deformations' trend between years 1992 and 2003 for each PS point. In order to perform this task the special algorithm was developed. It allows detecting maximum one (the most significant) trend change in the considered period of time. Performed analysis revealed that in the study area the changes of trend deformations occurred for about 40% of PS points. The spatial and temporal distribution of PS points with trend changes showed some regularity. This regularity may indicate the influence of coal exploitation on the values of small, long period deformations that were previously explained only by neotectonics movements. [C3270]

### "TerraSAR-X observations over the antarctic ice sheet"

An incoherent correlation approach is used to derive ice motion fields for outlet glaciers through the Transantarctic Mountains, Antarctica. High-resolution repeat-pass, left-looking-mode TerraSAR-X data from 2009 were analyzed. Detailed ice velocity patterns on the Nimrod glacier basin and Starshot glacier are presented. [C3271]

### "The BIOMASS mission-An ESA Earth Explorer candidate to measure the BIOMASS of the earth's forests"

The European Space Agency (ESA) released a Call for Proposals for the next Earth Explorer Core Mission in March 2005, with the aim to select the 7th Earth Explorer (EE-7) mission for launch in the next decade. Twenty-four proposals were received and subject to scientific and technical assessment. Six candidate missions were selected and further investigated in the preliminary feasibility studies (Phase 0). One of these missions is BIOMASS, which has recently been selected to proceed to Phase-A. BIOMASS is a response to the urgent need for greatly improved mapping of global biomass and the lack of any current space systems capable of addressing this need. [C3272]

### "Temporal snowpack density mapping using C-band multi-polarization ASAR data"

Radar remote sensing has great potential to determine the extent and properties of snow cover. Availability of spaceborne sensor dual-polarization C-band data of ENVISAT- ASAR can enhance the accuracy in measurement of snow physical parameters as compared to single polarization data measurement. This study shows the capability of C-band SAR data for estimating dry snow density over snow covered rugged terrain in Himalayan region. The snow density is an important parameter for the snow hydrology and avalanche forecasting related studies. An algorithm has been developed for estimating snow density, based on snow volume scattering and snow-ground scattering components. The radar backscattering coefficients of both HH and VV polarization and incidence angle are used as inputs in the algorithm to provide the snow dielectric constant which can be used to derive snow density using Looyenga's, semi empirical formula. Comparison was made between snow density estimated from algorithm using ENVISAT-ASAR HH and HH polarization data and the measured field value. The mean absolute error between estimated and measured snow density was found to be 24.38 kg/m<sup>3</sup>. [C3273]

### "A new polarization ratio model from C-Band RADARSAT-2 fine Quad-Pol imagery"

We propose two new analytical polarization ratio (PR) models based on the RADARSAT-2 Quad-Polarization (HH+VV+HV+VH) observations over the ocean. One is a function of incidence angle only and the other has additional dependence on wind speed. Comparisons are presented with theoretical and empirical PR models from the literature. The new PR model with wind speed and incidence angle dependence is shown to compare best with observed RADARSAT-2 data. An assessment of the PR model with only incidence angle dependence

is given using CMOD algorithms and HH-polarized images. Results suggest that this PR model can accurately convert normalized radar cross sections (NRCS) in HH polarization to VV polarization and retrieve wind speeds from RADARSAT-1 or RADARSAT-2 HH polarization images. [C3274]

### "Lidar education at Georgia Tech"

The Georgia Tech Research Institute's atmospheric laser radar (lidar) team became involved in education projects starting in 2001, when we developed an eye safe lidar with undergraduate women at Agnes Scott College in Decatur, Georgia. We have initiated several other projects since that time, including short courses, an academic course at Georgia Tech, a lidar textbook, and a lidar system designed specifically for education. The lidar education program at GTRI is reviewed here with comments about future plans and prospects. [C3275]

### "Three dimensional reconstruction of urban areas using jointly phase and amplitude multichannel images"

The aim of this paper is the three dimensional reconstruction of urban areas using Very High Resolution (VHR) images. The proposed innovative approach for the three dimensional reconstruction is based on the joint exploitation of both amplitude and interferometric phase images of a multichannel SAR system. The information provided by the amplitude data is added to the 3D reconstruction chain, considering that in urban areas edges of amplitude image are likely also present in the interferometric phase one and conversely. Differently from other works present in literature, the proposed technique exploits the amplitude image, not only to improve the phase regularization, but also to improve the phase unwrapping step. The results will show the effectiveness of the method. [C3276]

### "IMaging geodesy with TerraSAR-X"

We report on a method and experiments to achieve about 3 centimeters pixel location accuracy of TerraSAR-X SAR images. The method is based on atmospheric refraction corrections, Earth tide compensation and image correlation or the use of corner reflectors. Our method does not exploit the SAR phase and is therefore not subject to phase unwrapping problems or unknown phase offsets. [C3277]

### "Development of the LiDAR data processing system for the rapid generation of the terrestrial information"

This paper present an improved application system which can generate the 2.5D or 3D terrestrial information like DSM, DEM rapidly using LiDAR data. To process and manipulate input LiDAR data, various function modules are contained in the developed system. It allows users to display LIDAR data using TINS and even allows users to analyze the data using a profile viewer. In addition, the system also allows users to save the processed data with LAS file format, ASCII format. [C3278]

### "The Hurricane Imaging Radiometer wide swath simulation and wind speed retrievals"

The knowledge of peak winds in hurricanes is critical to classification of hurricane intensity; therefore, there is a strong interest in the operational remote sensing of ocean surface winds for monitoring tropical storms and hurricanes, especially those which threaten landfall. Presently, the airborne Stepped Frequency Microwave Radiometer (SFMR) is the state-of-the-art remote sensor for providing this information in real-time, during hurricane surveillance flights. However, for the future, NASA and NOAA are collaborating in the development of the Hurricane Imaging Radiometer (HIRAD), which is a prototype of the next-generation high-flying airborne instrument for monitoring hurricanes. This paper describes a realistic end-to-end simulation of HIRAD hurricane measurements while flying on an unmanned Global Hawk aircraft. The objective of this research is to develop baseline retrieval algorithms and provide a wind speed measurement accuracy assessment for the upcoming NASA hurricane field program, Genesis and Rapid Intensification Processes (GRIP), to be conducted in 2010. [C3279]

### "Forest change detection from L-band satellite SAR images using iterative histogram matching and thresholding together with data fusion"

In this study, we assess the efficiency of using L-band satellite SAR for forest change monitoring, by applying a combination of change detection techniques to SAR backscatter intensity images acquired over Swedish forest. We use a bi-temporal change detection approach based on image rationing. Histogram based techniques are used both for radiometric normalization and thresholding. For a final classification step, we evaluate a data fusion based change detection method that exploits the spatial and spectral information from one or multiple SAR channels. Pre-applied filters are also evaluated as alternatives to tackle low resolution and speckle. HH and HV

polarized Fine Beam Dual images, acquired 34 degrees off nadir (FBD34) by the Advanced Land Observing Satellite Phased Array type L-band Synthetic Aperture Radar (ALOS PALSAR), are used to find clear-cuts in Swedish boreal forest. Our results show that clear-cuts can be clearly extracted from L-band SAR data. [C3280]

### "Ground penetrating radar measurements: Applications to synthetic data generation and target characterization"

Ground penetrating radar (GPR) is widely studied for detection of landmines and mine-like targets; GPR is particularly useful for detecting minimum metal mines which are harder to detect using traditional metal detection devices alone. In order to expand the phenomenology for GPR, careful measurements of homogeneous and heterogeneous soils with and without targets (landmine simulants and metal objects) are performed in a controlled environment. These measurements will aid in the development of models for soil response beyond the initial air-ground interface. Such explicit models for soil will increase the effectiveness of algorithms designed to discriminate between returns from targets and from naturally occurring geologic materials and interfaces. Furthermore, careful measurement of soil characteristics will enable comparison and refinement of models of soil with embedded targets developed in electromagnetic simulations (using finite-difference time-domain codes (FDTD), e.g.). [C3281]

### "On radar sounding applications for Enceladean ice"

Due to the nature of observations taken by planetary spacecraft, many surface and atmospheric studies have been performed at the icy moons of the outer planets, which have left the many seemingly complex interior processes in these bodies left unexplored and unexplained. It is notably difficult to access the interior regions in which planetary formation and dynamics take place. This paper presents the possibility that radar measurements could contribute to the understanding of interior structure, particularly that of Enceladus, the small but notably dynamic icy moon of Saturn. The application of such radar may lead to discoveries concerning formation mechanisms and surface processes. Additionally, radar sounding will contribute measurements that aid in diagnosing the dynamics system at work in the subsurface-perhaps most notably, the source reservoir and/or dynamics of the observed water plume at the moon's south pole, in addition the moon's role as a whole in the Saturnian system. [C3282]

### "A physically-based approach to observe man-made metallic objects in dual-polarized SAR data"

An electromagnetic model to observe man-made metallic objects in dual-polarized SAR data has been developed. The model predicts that man-made metallic objects and sea surface, being characterized by completely different symmetry properties, call for a different and well-distinguishable HH-HV correlation. Following this rationale, a simple and very computer-time effective filtering technique has been developed to observe man-made metallic objects in full-resolution dual-polarized SAR data. Experiments accomplished over Single Look Complex (SLC) Fine Quad Polarization RADARSAT-2 SAR data confirm the effectiveness of the proposed approach. [C3283]

### "Quantifying the results of wind and rain on ifsar tree height estimation"

The horizontal and vertical (3D) structure of Earth's forested ecosystems are of great significance to their ecological functioning and societal uses. An IfSAR approach is one methodology whereby a forest's structure and height in particular can be successfully estimated. Critical to the successful estimation is a high correlation between multiple SAR images. Regardless of a forest's location on the Earth, wind and precipitation can significantly alter a forest's appearance to a SAR system operating in either the L or C bands and so too decrease this necessary correlation. In order to investigate and quantize the decorrelation induced by factors such as wind and rain, we have developed a model for the repeat-pass interferometric SAR response of a forest including the application of a wind field and / or a rain storm. The simulation consists of multiple interconnected parts including the generation of fractal tree geometries, a wind simulator to apply variable wind forces to the generated trees, an electromagnetic model to allow us to calculate a Single Look Complex value for the SAR return of the combined target, an image forming technique based on antenna array theory, and an image processing algorithm. Results present polarimetric coherence as a function of platform look angle, wind speed, and moisture content. An important feature of this research is the usage of a physically based realistic wind model that is based on measurements of wind effects on trees as well as realistic models of fluid flow and simple harmonic branch segment resonators. Allowing branches to bend and move out of the plane of the incident wind field enables our model to capture numerous features of a physical tree blowing in the wind. This realistic model is necessary for a realistic simulation of the effects that wind has on a given InSAR imaging system as expressed in this study by the interferometric coherence. [C3284]

### "Preliminary result of polarization property analysis using fully polarimetric GB-SAR images"

Korea Institute of Geoscience and Mineral Resources (KIGAM) and Kangwon National University (KNU) ground-based synthetic aperture radar (GB-SAR) team has been developed a fully polarimetric and interferometric GB-SAR system over past several years. The objective of this paper is to investigate an application of the obtained fully polarimetric GB-SAR images and an effective polarimetric analysis method to extract polarization properties from different terrain targets as a preliminary study. We utilized an unsupervised classification method for analyzing of a fully polarimetric GB-SAR image, in particular, Cloude and Pottier's method and a combined  $H/A/\alpha_{\perp}$  and the complex Wishart classifier method based on the  $H/A/\alpha_{\perp}$  polarimetric decomposition theorem.

[C3285]

### "AN SVM classifier with HMM-based kernel for landmine detection using ground penetrating radar"

We propose a landmine detection algorithm using ground penetrating radar data that is based on an SVM classifier. The kernel function for the SVM is constructed using discrete hidden Markov modeling (HMM). Typically, the kernel matrix could be obtained by defining an adequate similarity measure in the feature space. However, this approach is inappropriate as it is not trivial to define a meaningful distance metric for sequence comparison. Our proposed approach is based on HMM modeling and has two main steps. First, one HMM is fit to each of the  $N$  individual sequences. For each fitted model, we evaluate the log-likelihood of each sequence. This will result in an  $N \times N$  log-likelihood similarity matrix that will be adapted to serve as the kernel of the SVM classifier. In the second step, we train an SVM classifier to learn a decision boundary between the positive and negative samples. [C3286]

### "A multimodal Matching Pursuits Dissimilarity Measure applied to landmine/clutter discrimination"

The Matching Pursuits Dissimilarity Measure (MPDM) is an effective way to compare signals that are sparsely approximated using a Matching Pursuits method. The CAMP algorithm uses an MPDM distance measure in Competitive Agglomeration clustering to model and classify signals. The MPDM approach can only compare signals originating from a single source. Many landmine detection systems use multiple sensors to make simultaneous measurements of the same region of interest. In this paper we propose a Multimodal MPDM that can be used with CAMP to fuse signals from multiple sensors. We demonstrate the effectiveness of the Multimodal MPDM over the single sensor MPDM in improving discrimination of landmines from clutter objects.

[C3287]

### "The external calibration study for EarthCARE/CPR"

The Cloud Profiling Radar (CPR) is one of key sensors on EarthCARE for joint project between Europe and Japan. The CPR is developed by National Institute of Information and Communications Technology (NICT) in Japan and Japanese Aerospace Exploration Agency (JAXA). The CPR uses W-band frequency and large antenna diameter in order to obtain enough sensitivity. In other words, beam footprint becomes small but antenna scanning cannot be performed. Two external calibration methods are considered. The first method is external calibration using active radar calibrator (ARC). It is foreseen the difficulty to place exact location on sub-satellite track. The second method is external calibration using naturally distributed target, such as sea surface. We describe about test experiment for first method and statistical analysis using satellite data for second method as the feasibility study. [C3288]

### "Accelerating InSAR raw data simulation on GPU using CUDA"

This paper describes a scalable parallel method for interferometric synthetic aperture radar (InSAR) raw data simulation on graphic processing unit (GPU) with common unified device architecture (CUDA). The advantages of the new method rely on the three contributions: GPU hardware provides lots of stream processors for threads calculating, CUDA software environment runs thousands of threads working in parallel for assigned task, raw data simulation adopts the fine-grained task parallelism. Compared with OpenMP, MPI and grid computing, the method not only improves the computational efficiency greatly, but also save the resources such as hardware, electric power and room space. The results show that the method not only ensures accuracy, but also be able to obtain the speedup about 30 times. [C3289]

### "Estimation of pasture biomass and soil-moisture using dual-polarimetric X and L band SAR-accuracy assessment with field data"

This paper presents the results of a study conducted to relate X and L band polarimetric SAR backscatter to pasture soil moisture and biomass as part of an environmental monitoring program. Extensive field data was collected concurrently with satellite SAR data acquisition-including dry/wet above ground biomass, soil moisture,

surface roughness profiles and EM-38 electromagnetic sensor data. This data is used for both electromagnetically modeling the surface to work out the theoretical backscatter as well as empirical fitting regression models to the recorded SAR data and validation of existing inversion models. [C3290]

### "Diverse methods to monitoring volcanic deformation based on SAR interferometry"

In this paper, different methods for the detection of the deformation signal with SAR data based on persistent scatterer interferometry (PSI) are described. Two test sites have been selected. For experimental purposes, two corner reflectors (CRs) were installed in the Fogo volcano. The location, phase as well as intensity of corner reflectors were analyzed with 11 TerraSAR-X stripmap (TSX-SM) data. For algorithmic development and validation, four stacks of TerraSAR-X high resolution spotlight (TSX-HSL) data from the Stromboli volcano have been acquired and used for PSI processing. The PSI results of deformation and topography update are fused by using point matching method with Iterative Closest Point (ICP). This research is a part of the German volcano monitoring project Exupery, Work Package 2: 'Space based observation techniques'. [C3291]

### "Breaking wave measurements with sar depolarized returns"

The wind generates a distribution of small slope waves and sporadic steep breaking events. Such double structure of the sea surface is expected to have a strong impact on the radar scattering from the ocean surface. The signature of the double structure is in the wind speed dependence of radar returns: linear for scattering from gentle waves and cubic for breaking contribution. The composite-surface Bragg resonance (CB) theory describes the former very well. Detection of the breaking contribution remains difficult. Here we show that the depolarized (de-pol) radar return exhibits the typical double structure, its wind speed dependence increases with wind speed from linear to cubic. The increased sensitivity of the de-pol returns in high winds is ideal for hurricane wind retrieval. The strong breaking connection offers an opportunity to measure wave breaking and the associated energy dissipation and area of foam coverage from space, their quantification is important in air-sea interaction and electromagnetic and electro-optical remote sensing. [C3292]

### "Operation icebridge: Using instrumented aircraft to bridge the observational gap between icesat and icesat-2"

Operation IceBridge, a six-year NASA mission, is the largest airborne survey of Earth's polar ice ever flown. Data collected during IceBridge will help scientists bridge the gap in polar observations between NASA's Ice, Cloud and Land Elevation Satellite (ICESat), in orbit from 2003 to 2009, and ICESat-2, planned for launch in late 2015, making IceBridge critical for ensuring a continuous series of observations. Operation IceBridge is using airborne instruments to map Arctic and Antarctic areas once a year, building on two decades of repeat airborne measurements of rapidly changing areas in the Arctic. Operation IceBridge is also producing critical data that cannot be measured from space such as ice thickness measurements. The first Operation IceBridge flights were conducted in boreal spring 2009 over Greenland and the boreal fall 2009 over Antarctica. Other smaller airborne surveys around the world are also part of NASA's Operation IceBridge campaign. [C3293]

### "Surf zone surface displacement measurements using interferometric microwave radar"

Vertically polarized backscattered power, Doppler velocity, and interferometric height were measured in the nearshore ocean region using a high-resolution imaging microwave radar. The interferometric surface displacement measurements are compared with normalized radar cross sections (NRCS) and Doppler velocities, and with in situ pressure sensor estimates of wave height. The rms uncertainty in the interferometric surface displacement is computed from the data. The interferometric surface displacement measurements are intuitively satisfying in that positive displacements are generally associated with pixels that have larger NRCS values. Interferometric surface displacements compare well with heights derived from in situ pressure sensors, and we provide some possible explanations for the differences. [C3294]

### "Supporting precision agriculture with dual-polarimetric TerraSAR-X-yield prediction and identification of in-field variations to generate fertilizer prescription maps"

This paper presents studies carried out over 2 growing season in South Australia to evaluate the suitability of TerraSAR-X dual-polarimetric imagery for crop growth monitoring and yield prediction. End of season crops were observed in 2008 and significant correlation with yield was noted. Mid-season crops were observed in 2009 and due to the lower biomass no significant in field trends were observed in the SAR when compared with concurrently acquired ground NDVI sensor and multispectral optical data. Separability between different crop types is evident in both studies, but crop biomass has to be significant for any in-field variations to be apparent. [C3295]

### "Estimation of building damage ratio due to earthquakes and tsunamis using satellite SAR imagery"

In order to expand the existing C-band SAR based damage estimation model into L-band SAR, this paper introduces a likelihood function to estimate severe damage ratio by earthquakes on the basis of dataset from JERS-1/SAR (L-band SAR) images observed the 1995 Kobe earthquake and its detailed ground truth data. The model is applied to JERS-1/SAR images taken over the tsunami affected areas by the 1993 Hokkaido Nansei-oki, Japan earthquake. [C3296]

### "Topography effects on forest radar scattering, consequences on biomass retrieval"

Ground topography under vegetated area is liable to bring significant changes on radar backscattering and thereby on the associated standard retrieval algorithms dedicated to forest biomass. Within the framework of the ESA BIOMASS mission, this paper evinces the evolution of P-band polarimetric intensities with a tilted underlying ground. For that purpose, electromagnetic simulations have been achieved using our model MIPERS which theoretical specificities accounting for the topographic effects are herein described. Its originality lies mainly in the 3D characterization of the ground and the volume, as well as the coupling effects between both. This description is followed by a sensitivity analysis in order to further-on quantify the possible consequences on biomass retrieval, conducted with the two standard approaches, namely the P-HV intensity technique and the Pol-InSAR one assuming the RVoG model. This investigation have been also undertaken for a better understanding of experimental data, particularly with the BioSAR and the TropiSAR airborne campaigns over boreal and tropical forests. [C3297]

### "Use of the merged dual-frequency radar altimeter backscatter data over China land surface"

It is a special way to investigate continental surfaces using radar altimeter, besides scatterometers and Synthetic Aperture Radar among the active microwave remote sensing sensors for the altimeter works at the nadir point of satellite and at dual-frequency, which can measure the backscatters from different layers instantaneously. The aim of this paper is to merge multi-radar altimeter dual-frequency backscatter measurements over land surface to achieve better spatial and temporal resolution. The  $0.5^{\circ} \times 0.5^{\circ}$  merged altimetry backscatter maps between  $66^{\circ}$  N to  $66^{\circ}$  S over land surface every 6 days are generated in Ku, C, and S band for the period from January 2002 to June 2009. Temporal profiles of backscatters are examined for main land types (desert, forest, savanna) to validate the dataset and to analyze radar response to land surface variability through 8 years. [C3298]

### "Longtime monitoring of mine subsidence in Northern Moravia, Czech republic using different insar techniques"

In the undermined Northern Moravia region, the land is subsiding even more than a metre per year causing damages to many human-made objects. Such a fast subsidence is almost not possible to estimate using multitemporal radar interferometry techniques that were applied to ERS-2 data of 1996-2001. Classic differential radar interferometry approaches were successfully applied allowing to visually interpret the evolution of subsidence in the area using Envisat and ERS-1/2 images from years 1996-2009. Results of the radar interferometry usage have been compared with the levelling data. Because of several factors, most of the interferograms are decorrelated. These factors are depicted and several solution scenarios are pointed out. To overcome such limitations as a relatively strong vegetation cover in the area and to detect such a fast subsidence in small areas, the ALOS PALSAR images in fine resolution mode has been successfully used. [C3299]

### "Optimal sensor positioning for ISAR imaging"

ISAR imaging is a powerful signal processing that allows obtaining images of non-cooperative targets. Such images are often used as input to classification and recognition systems since they contain useful two-dimensional features. Nevertheless, the interpretation of ISAR images remains problematic since the image plane cannot be defined by the user but it depends on the target's own motions and on the relative position of it with respect to the radar. In this scenario, the only degree of freedom that is controlled by the user is the position of the sensor. In this paper, the problem of selecting an optimal position of the sensor to maximise the probability of obtaining a desired image projection plane is addressed. Moreover, mathematical tools are derived that may assist the user in deciding where to place an ISAR sensor given a priori knowledge of the scenario. [C3300]

### "KaRIn-the Ka-band radar interferometer on SWOT: Measurement principle, processing and data specificities"

The principal instrument of the SWOT (Surface Water and Ocean Topography) altimetry mission is KaRIn, a Ka-band interferometric SAR system operating on near-nadir swaths on both sides of the satellite track. This article briefly describes the measurement principle, the processing steps and the specificities of the interferometric SAR data of KaRIn as compared to conventional spaceborne SAR systems. [C3301]

### "Spatial latency reduction in GPR processing using stochastic sampling"

Ground penetrating radar (GPR) is a promising technique for buried threat detection which provides a complimentary phenomenology to electro-magnetic induction (EMI) based sensing. However, many successful GPR-based buried threat detection algorithms require data collected both before and after an object of interest is encountered to make a declaration (typically this data is used to perform background normalization, or to adequately characterize the object's shape). Samples taken past an object of interest, but before a decision is made, constitute an algorithm's "spatial latency". For vehicular mounted antennae arrays, where vehicle stopping distance is a function of vehicle dynamics, driver responsiveness, and algorithmic spatial latency, reducing an algorithm's spatial latency can increase overall system safety and help keep operators out of harm's way. In this work we propose a stochastic sampling algorithm that can help reduce spatial latency for a wide range of GPR-based buried threat detection algorithms. [C3302]

### "Use of wavelets decomposition to reduce outside transmissions during measurement of RCS"

If the RCS of a target is measured in measurement facility which is not a Faraday cage, this RCS might be corrupted by eventual outside transmissions which fill the same spectral band than measurement. In this situation, outside radiations are going to pollute the value of the measured RCS and as a consequence their level must be reduced in order to be able to get correct values of RCS. This article deals with a mathematical method which allows limiting the influence of interferences on the measured values of RCS thanks to the use of wavelets. [C3303]

### "An overview of recent advances in Polarimetric SAR information extraction: Algorithms and applications"

Recent advances in Polarimetric SAR information extractions are reviewed. Papers published in IEEE Transactions on Geoscience and Remote Sensing and IGARSS proceedings over the last five years were included. We found that PolSAR technology has reached a certain degree of maturity. The availability of high-resolution multi-frequency PolSAR data from space borne and airborne SAR systems will stimulate significant PolSAR applications. [C3304]

### "CASA dual-doppler system"

Conventional radar networks are limited at warning against low-altitude wind hazards such as tornadoes and micro-bursts due to the combined effects of their long range, far spacing, and Earth's curvature. The Collaborative Adaptive Sensing of the Atmosphere (CASA) Engineering Research Center aims to solve these limitations through dual-Doppler systems operating in densely-spaced short range radar networks. The CASA test bed radar network incorporate the Distributed Collaborative Adaptive Sensing (DCAS) model in order to optimize scanning and retrieval for fast Doppler wind field products. Under the DCAS environment, fast coordinated sector scans are made by each radar based on weather detection and competitive end-user needs. The retrieval subsystem then makes the best pair selection for dual-Doppler synthesis based on optimal beam-crossing angles for target areas. Together, they create a fast, accurate, and robust dual-Doppler system suitable for weather emergency warnings. [C3305]

### "PS-InSAR time series analysis for measuring surface deformation before the L'Aquila earthquake"

L'Aquila area has a high topography and complex geological structures, and is covered with thick vegetation and snow in areas of high topography. To monitor the characteristics of crustal deformation in this region before the 2009 L'Aquila earthquake, we apply StaMPS software to analyse 20 descending ASAR images acquired between September 2003 and March 2007 and 39 ascending ASAR images acquired between February 2003 and March 2009. In this paper, two mean LOS deformation velocity maps are acquired for this area, which reveal the same deformation pattern. Several deformation gradient in this area can be clearly identified, furthermore, we discover that most faults in this region may strike approximately NW-SE and dip  $< 90^\circ$  to SW. We also draw the conclusion that descending SAR images are superior to ascending ones in monitoring crustal deformation with InSAR in this region. [C3306]

### "A study on different PS-like methods for subsidence in Tianjin, China"

In this paper, the methods, primary PS-like method and Stanford Method for PS (StaMPS) are both studied and used to monitor the subsidence in Tianjin area. PS (Permanent Scatter) technique is possible to avoid many of the limitations of conventional DInSAR by analyzing just certain pixels which behave like point scatters and retain good correlations. Several PS-like methods have been developed and practiced by many researchers. StaMPS is a relatively new PS-like method, which uses spatial correlation of interferogram phase to find a network of stable pixels in almost all terrain without prior knowledge of temporal variations in the deformation. 17 ENVISAT SLC data for Tianjin area are used, covering from April 2003 to March 2006. The SLC scene acquired on Nov-05-2004 is chose as the master. And the results of the two methods are compared. By using the primary PS-like method and StaMPS, the subsidence field in Tianjin area has been mapped. As to PS selection, the primary PS-like method needs less input parameters and easier to understand than StaMPS. For deformation value calculation, StaMPS is good at evaluating non-linear subsidence history. [C3307]

#### "A fuzzy-logic-based approach for flood detection from Cosmo-SkyMed data"

The Cosmo-SkyMed mission offers a unique opportunity to obtain radar images useful for flood mapping, being characterized by high revisit time, thanks to the four satellites that form its constellation. In the context of a study aiming at evaluating the usefulness of Earth Observation data for managing flood events, particularly focused on Cosmo-SkyMed, an algorithm to map flooded areas from synthetic aperture radar imagery has been developed. It employs also ancillary data as a land cover map and a digital elevation model. The approach is based on the fuzzy logic because such a theory allows us to exploit the theoretical knowledge about the radar return from inundated areas and to account for simple hydraulic considerations and contextual information. [C3308]

#### "Extracting structural land cover components using small-footprint waveform lidar data"

Previous work has shown the ability of waveform LiDAR sensors to accurately describe various land cover types [1] and biomass estimates made in the field [2]. What is lacking, however, is a way to describe the different structural components that are embedded in the digitized backscattered energy from the LiDAR pulse. This study aims to extract structural components from waveform LiDAR data in terms of woody, herbaceous, and bare ground components from data collected over a savanna environment in and around Kruger National Park (KNP), South Africa. These components are comprised of metrics extracted from the waveforms and validated using biomass measurements made in field plots. Different size windows around plot centers, 3 4 3 pixels and 9 4 9 pixels (resulting in 1.5m and 4.5 m footprint, respectively), were used to examine scale effects of larger footprints. It was found that composite waveforms resembling plot sizes (9 4 9) most often are able to describe more than 80% of the woody biomass variability across the entire study site, and individually for two of the three land uses within the area. However, the herbaceous component of the waveform did not correlate well with the field measurements, while the bare ground component was verified visually in a side-by-side comparison with optical imagery. [C3309]

#### "Assessment of compact polarimetry over different tropical environment and dataset"

This paper presents different radar polarimetric modes over different study sites in Tropical environment: Full polarimetry (FP), Dual Polarimetry (DP) and Compact Polarimetry (CP). By using SVM classification, we show the capabilities of each polarimetric mode linked to the scattering model assumption of the fully polarimetric reconstruction for CP mode proposed by Souyris et al.. We are focused on 3 study sites which have different landscape: Tubuai in French Polynesia (AIRSAR data), the Fazenda Saio Nicolau in Brazil and Cayenne in French Guyana (PALSAR data). It shown that the reflection symmetry assumption may not be verified due to spatial heterogeneity or due to the definition of the study classes. Even if the choice of the DP modes is strongly dependant of the study site, the CP mode have shown equivalent or better overall accuracy than the other DP modes, particularly when the study area are very homogeneous. [C3310]

#### "Vision-based detection and tracking of aerial targets for UAV collision avoidance"

Machine vision represents a particularly attractive solution for sensing and detecting potential collision-course targets due to the relatively low cost, size, weight, and power requirements of the sensors involved (as opposed to radar). This paper describes the development and evaluation of a vision-based collision detection algorithm suitable for fixed-wing aerial robotics. The system was evaluated using highly realistic vision data of the moments leading up to a collision. Based on the collected data, our detection approaches were able to detect targets at distances ranging from 400m to about 900m. These distances (with some assumptions about closing speeds and aircraft trajectories) translate to an advanced warning of between 8-10 seconds ahead of impact, which approaches the 12.5 second response time recommended for human pilots. We make use of the enormous potential of graphic processing units to achieve processing rates of 30Hz (for images of size 1024-by-768). Currently, integration in the final platform is under way. [C3311]

### **"Assessment of tree and crown heights of a maritime pine forest at plot level using a fullwaveform UltraViolet Lidar prototype"**

This study aims to determine the potential of a new lidar prototype with an ultraviolet laser and a medium footprint for retrieving forest parameters. The lidar is embedded on an ultra-light aircraft. The choice of the Landes forest in southwestern France as study area was made regarding the flat topography of the area and the stand height consistency. We chose three plots from different stands (different height characteristics) and compared the lidar derived metrics to field measurements. To derive metrics from lidar data, we summed the lidar waveforms within a plot and calculated derived reflectance profiles to correct the lidar signal from the occlusion effect. We then retrieve plot mean total and mean crown base heights measurement from reflectance profiles. We obtain a good consistency of the lidar measurements compared to field measurements, even if we noticed the existence of a 5 to 10% bias probably linked to the lidar sampling strategy. [C3312]

### **"GNSS illuminator based high range resolution algorithm in space-surface bistatic SAR"**

Space-surface bistatic synthetic aperture radar (SS-BSAR) has gained more and more researcher's interests. In this paper, we focus on improving range resolutions of GNSS illuminator based SS-BSAR with the method of spectrum synthesis of ultra-wide-band (UWB). Narrow bandwidth signals, such as GPS P code, can be spliced into a wider signal. Simulation results show that it can effectively increase signal processing bandwidth, improve range resolution and target recognition capabilities. [C3313]

### **"Remote sensing applications for petroleum resource exploration in offshore basins of China"**

In this paper, a new approach for detecting and analyzing sea surface slicks caused by hydrocarbon seepage of offshore petroleum accumulations has been developed. This approach uses remote sensing radar technology and geophysical exploration techniques and has been developed based on hydrocarbon seepage theory. In this study, Synthetic Aperture Radar (SAR) data were used as the main data source. These data were integrated with gravity data inversed from satellite altimeter data, geophysical abnormal data from airborne magnetic data, and geological data of oil-and gas-bearing basins. Using the geographical information system, the oil and gas accumulating areas were outlined by the prospect models. This approach for the exploration and evaluation for offshore petroleum accumulations has been applied to two study areas in offshore petroleum basins in China: the Bohai Sea and Pearl River Mouth basins. By comparing the drilling outcomes and relative materials, our results show that the application of this integrated method is very effective. [C3314]

### **"Scansar signal processing and image quality enhancement with fitted-geometry doppler surface"**

In this paper, an efficient and relatively high quality ScanSAR processor is implemented based on SPECAN algorithm. The role of the accurate Doppler parameter estimation is described with regard to the processed SAR images. A method of extracting the essential Doppler parameters with high precision is introduced and its performance is verified. For this purpose, we have adopted a Doppler surface fitted-geometry method and demonstrated how it can contribute to the improved Doppler parameter estimation. [C3315]

### **"Taxi: A versatile processing chain for experimental TanDEM-X product evaluation"**

TanDEM-X is a high-resolution interferometric radar mission with the main goal of providing a global digital elevation model (DEM) of the Earth surface by means of single-pass X-band SAR interferometry. It is, moreover, the first genuinely bistatic spaceborne SAR mission, and, independently of its usual quasi-monostatic configuration, includes many of the peculiarities of bistatic SAR. An experimental, versatile, and flexible interferometric chain has been developed at DLR Microwaves and Radar Institute for the scientific exploitation of TanDEM-X data acquired in non-standard configurations. The paper describes the structure of the processing chain and focusses on some essential aspects of its bistatic part. Some experimental results performed with TerraSAR-X demonstrate the flexibility of the implemented processor. [C3316]

### **"Retrieval of raindrop shape-size relation using dual polarization radar measurements"**

Dual polarization radar measurements of rainfall parameters are based on the assumption of a mean shape-size relationship of raindrops. This paper focuses on retrieving and interpreting the mean raindrop shape-size relation from polarimetric radar observations. A procedure to retrieve the drop shape-size relation that governs the polarimetric radar observations of reflectivity ( $Z_h$ ) differential reflectivity ( $Z_{dr}$ ) and specific differential propagation phase ( $K_{dp}$ ) is presented. The mean drop shape-size relations retrieved from measurements collected by the NCAR SPOL radar during three campaigns are analyzed to explore whether the natural raindrop shape-size relation can be described by a unique model. [C3317]

### "A Ku-band rotating fan-beam scatterometer: Design and performance simulations"

This paper introduces the design and simulation results of a Ku-band rotating fan-beam radar scatterometer for ocean surface wind vector measurement. It will be flown on a small satellite dedicated to provide data for investigation of the ocean wave and ocean surface wind vector interactions, along with another payload for measurement of directional ocean wave spectra by a real-aperture radar with multiple scanned pencil beams. Key issues about the design of a Ku-band rotating fan-beam radar scatterometer, and results of performance simulations are provided as well. The performance of the system is simulated by the absolute and relative specifications. For the absolute specifications, retrieval performances for both wind speed and wind direction are evaluated, with the maximum likelihood method being employed. For the relative specifications, the figures of merit (FOM) is simulated, for comparison with other Ku-band scatterometers and optimization of system parameters. Simulation results of both the  $\sigma^\circ$  precision and wind retrieval accuracies for different wind speed from 4m/s to 24m/s will be provided, which shows that SCAT can satisfy the performance requirements within most part of the swath. [C3318]

### "A broad band lidar for precise atmospheric CO<sub>2</sub> column absorption measurement from space"

Accurate global measurement of carbon dioxide column with the aim of discovering and quantifying unknown sources and sinks has been a high priority for the last decade. In order to uncover the "missing sink" that is responsible for the large discrepancies in the budget the critical precision for a measurement from space needs to be on the order of 1ppm. To better understand the CO<sub>2</sub> budget and to evaluate its impact on global warming the National Research Council (NRC) in its recent decadal survey report (NACP) to NASA recommended a laser based total CO<sub>2</sub> mapping mission in the near future. That's the goal of Active Sensing of CO<sub>2</sub> Emissions over Nights, Days, and Seasons (ASCENDS) mission-to significantly enhance the understanding of the role of CO<sub>2</sub> in the global carbon cycle. Our current goal is to develop an ultra precise, inexpensive new lidar system for column measurements of CO<sub>2</sub> changes in the lower atmosphere that uses a Fabry-Perot interferometer based system as the detector portion of the instrument and replaces the narrow band laser commonly used in lidars with a high power broadband source. This approach reduces the number of individual lasers used in the system and considerably reduces the risk of failure. It also tremendously reduces the requirement for wavelength stability in the source putting this responsibility instead on the Fabry-Perot subsystem. [C3319]

### "Evaluation of two region based classifications in Tapajys National Forest using the ALOS/PALSAR polarimetric and interferometric coherences"

The use of phase information present in complex multi polarized images may increase the classification results. Thus, the coherence is one attribute that may be extracted from these images and used to distinguish some land cover classes. Therefore, its discriminatory capability for land use and land cover classification is analyzed. The analysis is based on the classification results of a region classifier, which needs a segmented image as one input. The influence of this kind of image input is also evaluated using of two segmentation algorithms, the SegSAR and the SPRING region growing. Two ALOS/PALSAR images acquired over Tapajos National Forest in the Brazilian Amazon were classified. The classifications were quantified by the overall accuracy, the kappa values and its variance. The classification improvement using the coherence information with intensity images was noticed for every image set. [C3320]

### "How does dew affect L-band backscatter? analysis of pals data at the Iowa validation site and implications for smap"

NASA's Soil Moisture Active Passive satellite mission will use both an L-band radiometer and radar to produce global-scale measurements of soil moisture. L-band backscatter is also sensitive to the water content of vegetation. We found that a moderate dew increased the L-band backscatter of a soybean canopy by 1 dB. Dew thus has the potential to add error to satellite observations of soil moisture. [C3321]

### "Four-component scattering power decomposition with rotation of coherency matrix"

In this presentation, a new decomposition scheme of first using a rotation of the coherency matrix followed by the four-component decomposition is presented. It is shown using airborne Pi-SAR data sets that oriented urban areas are clearly distinguished from volume scattering as double bounce objects by the rotation of coherency matrix. [C3322]

### "Integrating space-time processing into time-domain backprojection process for detection and imaging moving objects"

This paper discusses a possibility to integrate space-time processing into the time-domain backprojection process. This combination allows detection as well as imaging moving objects. Two space-time techniques, Displaced Phase Center Antenna (DPCA) and Space-Time Adaptive Processing (STAP), are considered for this integration. Simulated results based on the LORA parameters demonstrate the efficiency of detection and imaging moving objects. [C3323]

### "Use of 2D FDTD simulation and the determination of the GPR travel path angle for oblique B-scans of 2D geometries"

Scattering from a subsurface point object, such as a reinforcing steel bar embedded concrete or a tunnel buried in sand, results in a B-scan contour that is essentially hyperbolic as the Ground Penetrating Radar (GPR) passes over the object. The shape of the hyperbola can be used to determine the angle at which the GPR traveled over the point object. This information is very useful in determining the orientation and size of an object such as reinforcing steel, buried utilities, and subsurface tunnels. A 2D Finite Difference Time-Domain (FDTD) method can be used to simulate the GPR B-scan when the geometry is invariant in the third dimension and the sensors are appropriately located. The shape of the hyperbola extracted from 3D simulation, analogous to field-collected data, can be compared to a library of hyperbolas extracted from 2D simulations and used to determine the angle of the GPR travel path from the cross-sectional plane. [C3324]

### "The Slope Imaging Multi-polarization Photon-counting Lidar: Development and performance results"

The Slope Imaging Multi-polarization Photon-counting Lidar is an airborne instrument developed to demonstrate laser altimetry measurement methods that will enable more efficient observations of topography and surface properties from space. The instrument was developed through the NASA Earth Science Technology Office Instrument Incubator Program with a focus on cryosphere remote sensing. The SIMPL transmitter is an 11 KHz, 1064 nm, plane-polarized micropulse laser transmitter that is frequency doubled to 532 nm and split into four push-broom beams. The receiver employs single-photon, polarimetric ranging at 532 and 1064 nm using Single Photon Counting Modules in order to achieve simultaneous sampling of surface elevation, slope, roughness and depolarizing scattering properties, the latter used to differentiate surface types. Data acquired over ice-covered Lake Erie in February, 2009 are documenting SIMPL's measurement performance and capabilities, demonstrating differentiation of open water and several ice cover types. ICESat-2 will employ several of the technologies advanced by SIMPL, including micropulse, single photon ranging in a multi-beam, push-broom configuration operating at 532 nm. [C3325]

### "Electromagnetic infrastructure monitoring: The exploitation of GPR data and neural networks for multi-layered geometries"

In this paper, an inversion ANN-based algorithm for the estimation of geophysical properties (i.e. thickness and permittivity) of subsurface layers in stratified geometries is presented. The basic procedure for the analysis of GPR scans of single subsurface layers placed over a uniform background recently proposed by the authors has been here extended and inserted into a general framework where each stratum is recursively processed. [C3326]

### "Towards Bayesian estimator selection for QuikSCAT wind and rain estimation"

The QuikSCAT scatterometer infers wind vectors over the ocean using measurements of the surface backscatter. During rain events the QuikSCAT observations are subject to rain contamination. Three separate estimators have been developed: wind-only, simultaneous wind and rain, and rain-only, which account for rain contamination in varying degrees. This paper introduces a Bayes estimator selection technique to adaptively choose a best estimator from among the three types of estimators at each measurement location. Bayes estimator selection is introduced from a general perspective after which it is applied specifically to QuikSCAT wind and rain estimation. Bayes estimator selection is demonstrated in a case study to illustrate improvements in wind and rain estimation which can be obtained. [C3327]

### "Segmentation of lakes from the local background on the surface of Titan using Cassini SAR images"

Synthetic Aperture Radar (SAR) images of Titan, the largest satellite of Saturn, reveal quasi-circular to complex features which are interpreted to be liquid hydrocarbon lakes. One of the major problems hampering the derivation of meaningful texture information from SAR imagery is the speckle noise. It overlays real structures and causes gray value variations even in homogeneous parts of the image. A filtering technique is applied to

obtain the restored SAR images. Our method is based on probabilistic methods and regards an image as a random element drawn from a prespecified set of possible images. The TSPR (Total Sum Preserving Regularization) filter used here is based on a membrane model Markov random field approximation with a Gaussian conditional probability density function optimized by a synchronous local iterative method. The despeckle filter can be used as intermediate stage for the extraction of meaningful regions that correspond to structural units in the scene or distinguish objects of interest like lakes. [C3328]

#### "Experimental validation of the Corbella's visibility function using HUT-2D and MIRAS"

The Corbella's revision of the fundamental equation of the interferometric aperture synthesis radiometry is verified using airborne and spaceborne data. This experimental verification uses the measurements of the airborne instrument HUT-2D from the Aalto University (Helsinki), and the unique spaceborne microwave imaging radiometer by aperture synthesis (MIRAS) from the ESA's Soil Moisture and Ocean Salinity (SMOS) mission. The data acquired with those sensors support the Corbella's revision of the visibility function. The revised function predicts that visibilities depend on the contrast between the target's brightness temperature and the backward noise of the receivers emitted through the antennas. [C3329]

#### "Using airborne lidar to retrieve crop structural parameters"

Airborne LIDAR (Light Detection and Ranging) is an active remote sensing technique that measures the properties of scattered light to determine the range and intensity information of a distant target. Many studies have been reported on estimating a suite of forest characteristics such as fractional vegetation cover, leaf area index and canopy height using LIDAR data. The three characteristics of crop canopy also play key roles in vegetation radiative transfer models and yield estimation. But crops are so small and low that more than 95% pulses have ground hit, it is difficult to separate the crop and soil completely, so the methods used in forest may not be suitable for crops. In this paper, based on theoretical analysis, we propose a new method, trying to derive gap fraction of crop field using the airborne LIDAR intensity of ground hits, so we can manage to retrieve the fractional vegetation cover, LAI and the height of crop canopy. We choose corn field as study object, field validation shows that our method can accurately retrieve the three structural parameters of corn field. This study documents the great potential of LIDAR remote sensing for accurately characterizing crop canopies. [C3330]

#### "A revised geophysical model function for the advanced scatterometer (ASCAT) at NOAA/NESDIS"

The current ASCAT winds retrieval is based on the CMOD5.n geophysical model function (GMF) with the ASCAT wind data processor developed at the Royal Netherlands Meteorological Institute (KNMI). Recent validation of ASCAT wind retrieval reveals that high wind retrievals were underestimated as being compared to the operational QuikSCAT scatterometer. The goal in this paper is to improve ASCAT wind retrievals at high winds. In this paper we map the radar backscatter ( $\sigma_0$ ) as a function of extreme wind conditions as measured by an airborne scatterometer and adjusted the isotropic term in CMOD5.n to follow the aircraft GMF trend. The geophysical model QuikSCAT wind inputs are improved for  $\sigma_0$  that calculated from QuikSCAT wind inputs are improved for  $\sigma_0$  approximately  $> -15$  dB and in very good agreement with the ASCAT  $\sigma_0$  measurement. The wind retrieval validations show wind speed rms error is improved at approximately wind speed  $> 12$  m/s and example mean wind composite from two winter seasons shows significant in detection of storm-force winds. [C3331]

#### "Monitoring of collapsed built-up areas with high resolution SAR images"

A new concept for change detection algorithm for urban areas affected by earthquake is here presented. It is characterized as applicable to just one post-event amplitude Synthetic Aperture Radars (SAR) image and employs the inversion of sound scattering models already introduced in literature by the same authors. Aim of the algorithm is to try obtaining fast mapping of damaged areas and provide a first, even rough, evaluation of damage reported. In particular in this paper the overall block diagram chain and the algorithm rationale behind that framework are introduced and discussed in details. Some preliminary results are presented and the performance analyzed. New possible applications based on similar rationale are also commented. [C3332]

#### "Estimation of sea ice thickness in the Arctic Sea using polarimetric parameters of C- and X-band space-borne SAR data"

In this study, we derived the relationship between target depolarization factor and physical parameters of sea ice in order to estimate the thickness using dual-polarization C- and X-band space-borne Synthetic Aperture Radar (SAR) data. The target depolarization factor, the cross-polarized ratio of C-band SAR data, which can explain the target depolarization effect, were strongly related to changes in surface roughness of thick First-Year Ice (FYI) and Multi-Year Ice (MYI), and were almost insensitive to variations in the surface dielectric constant of thick FYI and MYI and the incidence angle of C-band SAR data. This relationship showed a high correlation

between target depolarization factor of C-band SAR data, the cross-polarized ratio, and thick FYI and MYI thickness. We validated the estimated method using RADARSAT-2 and TerraSAR-X data and ground-truth data acquired in the Arctic Sea off the northern coast of Greenland. [C3333]

### "SAR tomographic focusing by Compressive Sampling: Experiments on real data"

In this paper a 3-D SAR imaging technique based on Compressive Sampling is experimented on ERS 1-2 data. The technique is based on the sparsity property of the image to be focused along the elevation direction (i.e. only few scatterers with different elevation are present in the same range-azimuth resolution cell), exploits a reduced number of unevenly spaced acquisitions and allows an increased elevation resolution. Numerical results on real data are compared with those obtained by using Truncated Singular Value Decomposition (TSVD) techniques. [C3334]

### "Extracting trees and structure parameters via integration of LIDAR data and ground imagery"

Detailed tree information, such as tree counts, tree heights, crown base heights, diameter at breast height (DBH), and tree biomass, is critical for the effective management and quantitative analysis of trees in urban area. Automatic detection of trees, and their parameters using light detection and ranging (LiDAR) data has been widely employed. However, at the single-tree level along road in urban area, LiDAR data deposited the disadvantages such as space points, no texture information, so that the detailed tree parameters mentioned above cannot successfully be obtain at enough accuracy. This paper presented an integration of LiDAR data and ground mobile truck data. This development is driven by the fact that the information obtained from ground-mobile truck images can be substantially complemented by the data from LiDAR. [C3335]

### "Ocean wave field measurements using X-band Doppler radars at low grazing angles"

Ocean wave field observations using two types of Doppler radar systems are compared with time series measurements of the surface elevation at the USACE Field Research Facility (FRF) in Duck, NC. [C3336]

### "A polarimetric two-scale model for soil moisture retrieval"

A polarimetric two-scale surface scattering model employed to retrieve the surface parameters of bare soils from polarimetric SAR data is proposed. The scattering surface is considered as composed of slightly rough randomly tilted facets, for which the Small Perturbation Method holds. The facet random tilt causes a random variation of the local incidence angle, and a random rotation of the local incidence plane around the line of sight, which in turn causes a random rotation of the facet scattering matrix. Unlike other similar already existing approaches, our method considers both these effects. The proposed scattering model is then used to retrieve bare soil moisture and (large-scale) roughness from the co-polarized and cross-polarized ratios. The performances of the resulting retrieval algorithm is finally assessed by comparing obtained results to "in situ" measurements. To this aim, data from Little Washita campaign available in literature is employed. [C3337]

### "Microphysical retrievals of dual polarization and dual frequency ground radar for GPM ground validation"

A dual-frequency precipitation radar (DPR) will be deployed aboard GPM (Global Precipitation Measurement) core satellite in order to enhance our knowledge of precipitation microphysics. A ground based dual-frequency (Ku and Ka band) and dual-polarization radar D3R is being built to perform cross validation with GPM-DPR which helps provide insight into the physical basis of the retrieval algorithm. This paper is the follow up study of the author's previous paper where a new drop size distribution (DSD) retrieval algorithm was proposed. In this paper, the algorithm evaluation is extended to the complete region including rain, melting ice and ice based on simulation data. A possible method to classify the hydrometeor identification for dual-frequency and dual-polarization ground radar is also proposed which might be applied to D3R. [C3338]

### "Coherent MIMO radar for GMTI"

In addition to imaging, coherent MIMO radars have a strong potential for detecting moving objects and estimating their parameters. This paper investigates different MIMO schemes based on spatial, waveform, and frequency diversity for their GMTI capability. The fully configurable MIMO radar MIRACLE X is taken as the baseline design for comparing the different approaches. [C3339]

### "Trail following with omnidirectional vision"

We describe a system which follows "trails" for autonomous outdoor robot navigation. Through a combination of

visual cues provided by stereo omnidirectional color cameras and ladar-based structural information, the algorithm is able to detect and track rough paths despite widely varying tread material, border vegetation, and illumination conditions. The approaching trail region is simply modeled as a circular arc of constant width. Using an adaptive measure of color and brightness contrast between a hypothetical region and flanking areas, the tracker performs a robust randomized search for the most likely trail region and robot pose relative to it with no a priori appearance model. Stereo visual odometry improves tracker dynamics on uneven terrain and permits local obstacle map maintenance. A motion planner is also described which takes the trail shape estimate and local map to plan smooth trajectories around in-trail and near-trail hazards. Our system's performance is analyzed on several long sequences with diverse appearance and structural characteristics using ground-truth segmentations.

[C3340]

#### "Icesat lidar and global digital elevation models: applications to desdyni"

Geodetic control is extremely important in the production and quality control of topographic data sets, enabling elevation results to be referenced to an absolute vertical datum. Global topographic data with improved geodetic accuracy achieved using global Ground Control Point (GCP) databases enable more accurate characterization of land topography and its change related to solid Earth processes, natural hazards and climate change. The multiple-beam lidar instrument that will be part of the NASA Deformation, Ecosystem Structure and Dynamics of Ice (DESDynI) mission will provide a comprehensive, global data set that can be used for geodetic control purposes. Here we illustrate that potential using data acquired by NASA's Ice, Cloud and land Elevation Satellite (ICESat) that has acquired single-beam, globally distributed laser altimeter profiles ( $\pm 86^\circ$ ) since February of 2003. The profiles provide a consistently referenced elevation data set with unprecedented accuracy and quantified measurement errors that can be used to generate GCPs with sub-decimeter vertical accuracy and better than 10 m horizontal accuracy. Like the planned capability for DESDynI, ICESat records a waveform that is the elevation distribution of energy reflected within the laser footprint from vegetation, where present, and the ground where illuminated through gaps in any vegetation cover. The waveform enables assessment of Digital Elevation Models (DEMs) with respect to the highest, centroid, and lowest elevations observed by ICESat and in some cases with respect to the ground identified beneath vegetation cover. Using the ICESat altimetry data we are developing a comprehensive database of consistent, global, geodetic ground control that will enhance the quality of a variety of regional to global DEMs. Here we illustrate the accuracy assessment of the Shuttle Radar Topography Mission (SRTM) DEM produced for Australia, documenting spatially varying elevation biases of several meters in magnitude. [C3341]

#### "A distributed LiDAR processing model based on OWS and BPEL"

Traditional LiDAR post process is centralized. In centralized process model, data, process module and workflow can only be accessed within specific platform. This results in interoperability problem ranging from data sharing to functionality and workflow reuse. To tackle this problem, this paper proposes distributed process model for LiDAR post process. The distributed process model consists of interoperability solution on three aspects: data, process module and workflow. According to experiment, distributed LiDAR process model overcomes problems mentioned above. The process model and interoperability solution proposed in this paper can serve as reference to other geo-processing application. [C3342]

#### "The RADARSAT-1 imaging performance, 14 years after launch, and independent report on RADARSAT-2 image quality"

This paper summarizes the calibration monitoring activities of the Canadian Space Agency (CSA) executed under the RADARSAT Program. The performance history of the RADARSAT-1 SAR since its commissioning in 1996 is reviewed, along with the calibration systems and methodologies used, in the context of the mission's thirteen-year calibration history. Independent image quality measurements for the privately-owned RADARSAT-2, launched in 2008, are also presented. It is shown that the calibration parameters of the RADARSAT-1 SAR have consistently been maintained within the mission's design goals and specifications, mostly thanks to payload stability and timely recalibrations performed using the calibration ground equipment. For RADARSAT-2, CSA's measurements report outstanding image quality levels. [C3343]

#### "Extraction of coastal wavefield properties from X-band radar"

The dynamic wave field in a high-energy coastal environment is investigated using frequency direction wave spectra obtained by nautical X-band radar imagery. Nautical radars are generally used for navigation and ship traffic control. Under various conditions (wind speed  $> 3\text{m/s}$ , significant wave height  $> 0.5\text{m}$ ), signatures of the sea surface (sea clutter) become visible in the near range (less than 3 nautical miles) of nautical radar images. Swell and wind sea waves become visible in nautical radar images as they modulate the sea clutter signal. Since

standard X-band nautical radar systems scan the sea surface with high temporal and spatial resolution, they are able to monitor the sea surface in both time and space. The combination of the temporal and spatial wave information allows the determination of unambiguous directional wave spectra. Here, wave data collected from February-October 2005 at the US Army Corps of Engineers Field Research Facility (USACE-FRF) in Duck, North Carolina is presented. For the radar wave measurements the Wave and surface current Monitoring System WaMoS II was connected to a Furuno FR-7112 X-Band radar with a 6 feet open antenna and an update rate of 2.5s (24 rpm). The radar covers a range from 240m to 2160m from the antenna with a spatial resolution of 7.5m. The wave analysis was carried out over an area of 3.7 km<sup>2</sup> located in relative homogeneous bottom topography, off the near shore breaker bar system, in a water depth of 8m -10m. The WaMoS II wave measurements were compared to those obtained from a pressure gauge array located in the same area. Earlier WaMoS II validations provide a general indicator of the quality of the measurement performance as they were carried out for standard integral wave properties over all existing wave systems such as mean or peak wave parameters. Here the XWaves ocean wave field analysis toolbox is used to compare data sets by means of a wave spectral partitioning analysis. This approach provides a more detailed validation especially for bi- and multi modal sea states, allows for a comparison of the heights, periods and directions of individual wind sea and swell components, and tracking the evolution of specific wave systems. Such analysis methods have been successfully applied in a variety of wave model validations. The data comparison was carried out for different sea state and wind conditions. Preliminary results of the data comparison show that the WaMoS II system captures the temporal evolution of the individual wind sea and swell wave components entering the surf zone. A statistical error analysis of the isolated wind sea and swell wave systems provides a quantitative assessment of WaMoS II performance in a coastal setting. [C3344]

#### "Inferring the impact of radar incidence angle on soil moisture retrieval skill using data assimilation"

The impact of measurement incidence angle ( $\theta$ ) on the accuracy of radar-based surface soil moisture ( $\Theta_s$ ) retrievals is largely unknown due to discrepancies in theoretical backscatter models as well as limitations in the availability of sufficiently extensive ground-based  $\Theta_s$  observations for validation. Here, we apply a data assimilation-based evaluation technique for remotely-sensed  $\Theta_s$  retrievals that does not require ground-based soil moisture observations to examine the sensitivity of skill in surface  $\Theta_s$  retrievals to variations in  $\theta$ . Application of the evaluation approach to the TU-Wien European Remote Sensing (ERS) scatterometer  $\Theta_s$  data set over regional-scale (~10002 km<sup>2</sup>) domains in the Southern Great Plains (SGP) and Southeastern (SE) regions of the United States indicate a relative reduction in correlation-based skill of 23% to 30% for  $\Theta_s$  retrievals obtained from far-field ( $\theta > 50^\circ$ ) ERS observations relative to  $\Theta_s$  estimates obtained at  $\theta < 26^\circ$ . Such relatively modest sensitivity to  $\theta$  is consistent with  $\Theta_s$  retrieval noise predictions made using the TU-Wien ERS Water Retrieval Package 5 (WARP5) backscatter model. However, over moderate vegetation cover in the SE domain, the coupling of a bare soil backscatter model with a "vegetation water cloud" canopy model is shown to overestimate the impact of  $\theta$  on  $\Theta_s$  retrieval skill. [C3345]

#### "Performance and application of different image matching algorithms for investigating glacier and ice-shelf flow, permafrost creep and landslides"

This study focuses on evaluating image correlation methods for deriving surface velocity fields of glaciers, ice shelves, rock glaciers and landslides from both repeat optical and synthetic aperture radar (SAR) images. Firstly we show that low resolution MODIS images (250 m spatial resolution) can in fact be used for determining displacements on Antarctic ice shelves. In this particular case, orientation correlation operated in the frequency domain and using only the phase part of the signal performs better than normalized cross-correlation operated in the spatial domain. Secondly we demonstrate that for determining subpixel displacement when using normalized cross-correlation, image intensity interpolation before the matching process outperforms interpolation of the correlation peak after the matching. We also study methods for adaptively varying the matching template size in order to create the most reliable and accurate matches. The last part of the work shows some application studies of glacier flow from optical and SAR images, rock glacier creep and land sliding. [C3346]

#### "Mapping and change detection for boreal wetlands of North America based on JERS and PALSAR data"

We have been developing high-resolution thematic maps of wetlands throughout the North American boreal regions. We assemble a wetlands map for each region based on data collected during the late 1990s, then construct a second map based on data collected during the late 2000s. Comparison of the two maps then makes it possible to assess changes that have occurred over the course of the intervening decade.. [C3347]

#### "A scattering similarity based classification scheme for land applications of polarimetric SAR"

### **image"**

In this paper, a new classification scheme, which extracts the main scattering mechanism with target scattering similarities, is proposed. This approach not only leads to improved understanding of scattering mechanisms, but also has good performance in discriminating different scattering type of land cover. The NASA/JPL AIRSAR data is used for validating its effectiveness. [C3348]

### **"The detection performance of Neyman-Pearson detector for MIMO radar in K-distributed sea clutter"**

Use of multiple transmit and receive antennas have become a popular research area in radar community after the success of the same concept in communication. It is shown by Fishler et al. in that multi-input multi-output (MIMO) radar has considerable advantages compared to traditional radar and phased array radar systems. In this paper, detection performance of MIMO radar using Neyman-Pearson detector is investigated in K-distributed sea clutter for a practical scenario. Also, spikiness of K-distributed MIMO radar clutter is discussed with respect to the number of nodes. [C3349]

### **"Comparisons of rain rate and reflectivity between TRMM precipitation radar and Gosan S-band radar"**

As a part of GPM joint Ground Validation (GV) projects with the US and international partnership, one of the Korea Meteorological Administration (KMA) S-band radar at Gosan, Jeju Island, South Korea has been selected in the Validation Network (VN). It performs the match-up of TRMM Precipitation Radar (PR) data with ground-based radar (GR) during August 2006 to May 2008 for the rain events on criteria of at least 25 % overlap of the PR swath and 25 % or more of the points in the overlap area indicating rain certain in the PR data. 60 events with these criteria during the period have been selected to compare the reflectivity only over 18 dBZ from both radars. Overall comparisons between GR and PR reflectivity roughly 1.37 dBZ low bias over 163,586 points. The results came out good quality and recently asked the TRMM Precipitation Processing System (PPS) to add the site to the daily TRMM site overpass coincidence table (CT) product. Rain rate comparisons between GR and PR show PR over estimate the rain rate in these events. [C3350]

### **"Spatial spectrum of bistatic SAR with one fixed station"**

Bistatic synthetic aperture radar (BSAR) with one fixed station (OF-BSAR) can be used in wide area surveillance, interferometry and etc. This paper analyzed the spatial spectrum of OF-BSAR. Analytical expressions of the spatial spectrum was given. Using this result, we can determine the resolution performance of OF-BSAR. [C3351]

### **"ISAR imaging of an aircraft target USING ISDB-T digital TV based passive bistatic radar"**

Passive bistatic radars (PBRs) exploit existing transmitters such as TV broadcasts as the source of illumination. PBR is consisted of two receivers, with one antenna pointed at the source and the other at the target, and the target range is determined by correlating the signal scattered by the target with the signal directly arrived at the receiver. Since PBR does not transmit any waveform, it consumes lower power, and no frequency allocation is required. We have conducted a field experiment exploiting terrestrial digital TV broadcast to assess the feasibility of ISAR (Inverse Synthetic Aperture Radar) observation based on PBR. The wide and flat spectrum of the OFDM signal and the small gap between the channels enables us to obtain high range resolution of up to several meters by exploiting multiple physical channels. Therefore, moderate resolution ISAR imaging is expected to be possible. In this paper, PBR based ISAR algorithm is briefly explained, and the first example of observed PBR based ISAR image of an aircraft target is shown. [C3352]

### **"Full wave analysis of VHF-UHF forest bistatic scattering mechanisms an investigation on the influence of electromagnetic coupling"**

A 3D coherent scattering model simulating the interaction of electromagnetic waves with forests has been developed. It is obtained by means of a full wave approach, based on an integral representation of the electric field. A method of moments is used to solve the integral equation and compute the scattered fields related to the various scattering mechanisms as well as the contribution of tree-trunks and branches. This model is used here to evaluate the impact of electromagnetic coupling effects between a group of scatterers (which can be the branches and the trunk of a single tree, multiple tree-trunks, or multiple trees) for monostatic and/or bistatic radar configurations. To validate our model, we compare our simulation results with anechoic chamber measurements. [C3353]

### "Estimation of the degree of polarization in compact polarimetry"

The degree of polarization (DoP) has long been recognized as one of the most important parameters characterizing partially polarized electromagnetic waves. This parameter can be effectively used to describe the information content of polarimetric images collected by synthetic aperture radar (SAR) systems. Estimation of DoP is standardly performed using four measurements. In SAR compact polarimetry (CP), however, only two measurements are available. In this paper, we develop maximum likelihood estimators of the DoP, in SAR CP modes, based on only two intensity images. We evaluate and compare the performance of these estimators for different CP modes on RADARSAT-2 polarimetric data, over various terrain types such as urban, vegetation, and ocean. [C3354]

### "ALGAE: A fast algebraic estimation of interferogram phase offsets in space varying geometries"

This work deals with the estimation of terrain topography from multi-pass Synthetic Aperture Radar (SAR) interferometry (InSAR), focusing on the case where the variation of the system geometry within the imaged swath is relevant, as in airborne multi-pass interferometric campaigns. The space varying nature of the system geometry gives rise to a major issue in multi-pass InSAR analyses, in that it prevents from compensating for the presence of interferogram phase offsets by simply phase locking the data stack to a reference point, therefore hindering the retrieval of terrain topography. To cope with this issue properly we propose a novel approach that exploits the algebraic properties of the problem. Such an approach allows to cast the problem in terms of identification of a null space component for terrain topography, after which both topography and the interferogram phase offsets are quickly obtained without exploiting calibration points. [C3355]

### "Remote sensing research in undergraduate education: An international fieldwork perspective"

Institutions of higher education in the U.S. are increasing their use of project-based courses and experiential learning using projects or service in other countries. Project-based instruction provides students with an opportunity to make connections between the classroom and the world around them. Research suggests that fieldwork strongly enhances curriculum instruction and provides additional learning value to students. The goal of this grant was to increase the international content of existing curriculum by providing to students advanced skills in sampling design, geospatial statistics, and remote sensing for mapping and monitoring of crops and natural areas including semi-arid mountains, sub-tropical mountains, and tropical rain forests. This experience for the students has opened their eyes to new cultures and environments, allowed them to apply their classrooms skills in a real-world context and importantly to see how what they are learning is readily usable outside the classroom. [C3356]

### "Land cover classification based on single-polarized VHR SAR images using texture information derived via speckle analysis"

Speckle is a SAR specific noise effect caused by constructive and destructive interference from multiple scattering within the resolution cell of the imaging radar system that superposes the true radiometric and textural information of SAR images as a grainy 'salt-and-pepper' pattern. Fully developed speckle basically follows circular Gaussian image statistics. However, this assumption is not applicable for very high resolution SAR systems and for data showing sceneries with a significant amount of directional backscatter-e.g. urban areas. In those cases the multiple scattering processes within a resolution cell show-subject to the true structuring of the imaged area-rather a directional behavior than a random distribution. Consequently, the speckle is no longer fully developed. In our study we demonstrate how information on the local development of speckle can be used to differentiate between basic land cover types such as water, open land-meaning farmland, grassland and bare soil -, woodland and urban area in single-polarized, single-date VHR SAR images. The research is based on the analysis of a TerraSAR-X scene of Munich, Germany. [C3357]

### "Investigations on TOPS interferometry with TerraSAR-X"

This paper presents results on SAR interferometry with the so-called TOPSmode. The rationale to retrieve accurate interferometric products with such a mode is expounded, emphasizing the critical step of coregistering the pairs. Due to the particularities of the TOPS mode, a high Doppler-centroid is present at burst edges, demanding very high azimuth coregistration performance. A coregistration accuracy of one tenth of a pixel, as it is usually recommended with interferometric applications, will result in a large undesired azimuth phase ramp in the TOPS mode, above all at X-band. This paper presents two approaches based on the spectral diversity technique to estimate this offset with the required accuracy. Experimental results with repeat-pass TerraSAR-X data are shown to validate the proposed approach. [C3358]

### "Polarimetric scattering analysis for accurate observation of stricken man-made targets using a rotated coherency matrix"

This paper investigates polarimetric scattering features generated from man-made targets for accurately observing stricken residential area by making full use of quad. polarimetric SAR data set. First, we propose a simple improvement of the scattering power decomposition method by introducing a unitary rotation of the coherency matrix. It is found from the results of the POLSAR image analysis for a mountainous region including some stricken residential areas that by carrying out the rotation procedure, double-bounce scattering contribution can be enhanced even when the targets are oriented and/or set on small inclined ground plane. This peculiar scattering feature is utilized as a useful marker for precisely detecting man-made targets. To verify the generating and enhancing mechanism of the double-bounce scattering, we also carry out the Finite-Difference Time-Domain (FDTD) polarimetric scattering analysis for a simplified man-made target model. The dependency of the polarimetric scattering feature on the variation of squint angle is investigated. It is confirmed from the FDTD analysis for oblique squint angular range that by applying the rotation procedure before the scattering power decomposition, the double-bounce scattering contribution tends to be enhanced, and the volume scattering becomes small. [C3359]

### "Compressed sensing on ambiguity function domain for high resolution detection"

In this paper, by using compressed sensing techniques, a new approach to achieve robust high resolution detection in sparse multipath channels is presented. Currently used sparse reconstruction techniques are not immediately applicable in wireless channel modeling and radar signal processing. Here, we make use of the cross-ambiguity function (CAF) and transformed the reconstruction problem from time to delay-Doppler domain for efficient exploitation of the delay-Doppler diversity of the multi-path components. Simulation results quantify the performance gain and robustness obtained by this new CAF based compressed sensing approach. [C3360]

### "Target detection in missile warning receivers via speeded-up robust features approach"

Missile warning receivers are electronic support systems which are widely used for the protection of fixed and rotary wing aircraft against infrared guided missiles. Proposed methodology for the detection of missile threats in missile warning receivers depends upon the estimation of background from consecutive image frames. By removing the estimated background from the images, foreground objects (missile plume images) are detected. In this study, "Speeded-Up Robust Features (SURF)" methodology based on feature correspondence is used for the estimation of background motion. [C3361]

### "The microasar experiment on CASIE-09"

During the summer of 2009, the Characterization of Arctic Sea Ice Experiment 2009 (CASIE-09) operated a small, unmanned aircraft system (UAS) over the Arctic Ocean for a number of long-distance flights from Svalbard Island. In addition to other instruments, the UAS carried a small C-band synthetic aperture radar (SAR) known as MicroASAR to image sea ice roughness at 1 m resolution. This paper briefly describes the SAR, its role in CASIE-09, and presents sample SAR image results. [C3362]

### "Development of an Off-The-Grid X-band radar for weather applications"

The Student Led Test Bed (STB) is part of the NSF Engineering Research Center CASA and is currently focused in developing low-cost and low infrastructure radar networks to fill lower atmosphere gaps not covered by current technology. The first radar node, which is part of a small region radar network, will significantly improve the time and spatial resolution of the radar data measured for the lower atmosphere. This paper describes the development of an Off-The-Grid (OTG) X-band radar node that requires minimum infrastructure for its deployment and can operate using solar energy and wireless communication links. The OTG radar was developed for meteorological applications modifying a commercially available marine radar. Hardware modifications for meteorological purposes were performed as well as the design and implementation of a photovoltaic system to power the radar using solar energy. The system was moved to the Colorado State University (CSU)-CHILL National Weather Radar facility for a cross-calibration and system evaluation. Satisfactory results were obtained where it was demonstrated that the OTG radar can provide precipitation measurements with improved spatial and temporal resolution, both necessary to have better lower troposphere measurements. This OTG node is the first prototype of a low infrastructure X-band weather radar network to aid forecasts in the western region of Puerto Rico. [C3363]

### "Model level fusion of edge histogram descriptors and gabor wavelets for landmine detection with ground penetrating radar"

We propose a discriminative method for combining heterogeneous sets of features for the continuous hidden Markov model classifier. We use a model level fusion approach and apply it to the problem of landmine detection using ground penetrating radar (GPR). We hypothesize that each signature (mine or non-mine) can be characterized better by multiple synchronous sequences that can capture different and complementary features. Our work is motivated by the fact that mines and clutter objects can have different characteristics depending on the mine type, soil and weather conditions, and burial depth. Thus, different sets of specialized feature extraction mechanisms, may be needed to achieve high detection and low false alarm rates. In order to fuse the different modalities, a multi-stream continuous HMM that includes a stream relevance weighting component is developed. In particular, we modify the probability density function that characterizes the standard continuous HMM to include state and component dependent stream relevance weights. We generalize the Minimum Classification Error (MCE) objective function to include stream relevance weights and derive the necessary conditions to update all model parameters simultaneously. Results on a large collection of GPR alarms show that the proposed model level fusion outperforms the baseline HMM when each feature is used independently and when both features are combined with equal weights. [C3364]

#### "Processing of MEMPHIS millimeter wave multi-baseline InSAR data"

This paper presents a processing method for multi-baseline interferometric data acquired with the MEMPHIS airborne sensor. The processing method ingests the SAR raw data from each receiver and extends up to the generation of digital elevation models (DEMs). Critical steps include the correction of the azimuth phase undulations, the multi-baseline processing and the phase-to-DEM conversion. Methods for resolving the various hurdles were adapted to the MEMPHIS sensor and are presented here. The results obtained for a data take over a test site near Zurich, Switzerland are shown; these results are in a good agreement with comparable LIDAR products. [C3365]

#### "Monitoring slow moving landslides in the Berkeley Hills with TerraSAR-X data"

Large, slow moving landslides in the Berkeley Hills cause many damage and pose a potential threat to public safety due to the close proximity of the Hayward Fault. We have been using Differential SAR interferometry (DInSAR) and time-series analysis of SAR data to resolve the rates of the landslide motion. In this paper, we aim to interpret the new satellite TerraSAR-X data in this small landslides area. We have acquired both Stripmap data and Spotlight data. Standard InSAR method as well as Persistent Scatterer InSAR is utilized in the processing. [C3366]

#### "An improved content-adaptive mesh-generation method for image representation"

A new content-adaptive mesh-generation method for image representation, based on the greedy point-removal scheme of Demaret and Iske, is proposed. The proposed method is shown to be capable of producing meshes of higher quality than those generated by the scheme of Demaret and Iske, while requiring substantially less computation and memory. Furthermore, with the proposed method, one can easily tradeoff between mesh quality and computational/memory complexity as needed. Since a mesh-generation scheme proposed by Yang et al. is a key component of the proposed method, some factors affecting the performance of this scheme are also explored. [C3367]

#### "Theoretical and practical design considerations for a small, multi-band SAR: The SlimSAR"

The SlimSAR is a small, low-cost, Synthetic Aperture Radar (SAR) system and represents a new advancement in high-performance SAR. ARTEMIS employed a unique design methodology that exploits previous developments in designing the SlimSAR to be small, light, and flexible while consuming very little power. The system contains an L-Band core and uses block-converters to operate in a number of other bands. It also has the capability to operate in either deramp or direct-sampling mode and can collect data in two polarizations simultaneously. The flexible control software allows us to change the radar parameters in flight. Multi-frequency SAR provides day and night imaging through smoke, dust, rain, and clouds with the advantages of additional capabilities at different frequencies (i.e. dry ground and foliage penetration at low frequencies, and high-resolution change detection at high frequencies). [C3368]

#### "Advanced digital beamforming concepts for future SAR systems"

This paper reviews advanced multi-channel SAR system concepts for the imaging of wide swaths with high resolution. Several novel system architectures employing both direct radiating arrays and reflector antennas fed by a digital array are introduced and compared to each other with regard to their imaging performance. In addition, innovative SAR imaging modes are proposed which enable the mapping of ultra-wide swaths with high azimuth resolution. The new techniques and technologies have the potential to enhance the imaging performance

of future SAR systems by one order of magnitude if compared to state of the art SAR sensors like TerraSAR-X, ALOS, Radarsat-2 or Sentinel-1. [C3369]

### "Graph-based segmentation for colored 3D laser point clouds"

We present an efficient graph-theoretic algorithm for segmenting a colored laser point cloud derived from a laser scanner and camera. Segmentation of raw sensor data is a crucial first step for many high level tasks such as object recognition, obstacle avoidance and terrain classification. Our method enables combination of color information from a wide field of view camera with a 3D LIDAR point cloud from an actuated planar laser scanner. We extend previous work on robust camera-only graph-based segmentation to the case where spatial features, such as surface normals, are available. Our combined method produces segmentation results superior to those derived from either cameras or laser-scanners alone. We verify our approach on both indoor and outdoor scenes. [C3370]

### "Preliminary model for wind estimation from Cosmo/SkyMed X band SAR data"

In the paper we present a preliminary model for wind estimation from SAR data in X band. The data set we have used is composed of more than 300 Cosmo/SkyMed SAR images and the wind data obtained from the SeaWinds instrument on QuikSCAT. We have derived 18 parameters to express  $\sigma$  as function of wind intensity, direction and Radar look angle. The preliminary validation results are encouraging although our data set needs to be extended in order to increase those conditions poorly represented. [C3371]

### "Use of PALSAR polarimetric data for tropical forest stratification and comparison of simulated dual and compact polarimetric modes"

This paper presents a case study addressing the comparison between different SAR polarimetric mode for tropical forest stratification: Full polarimetry (FP), Dual Polarimetry (DP) and Compact Polarimetry (CP). These 2 latter modes are simulated using FP data acquired by the L band PALSAR sensor over 2 study sites. Cayenne in French Guyana and the Fazenda Saio Nicolau in Brazil. The classification approach used to evaluate each mode based on Support Vector Machine (SVM) algorithm shows the good capabilities of the FP mode to discriminate different kinds of vegetation. The choice of one DP mode that gives twice bigger swath than FP mode depends on the study classes. In this tropical environment the hh/hv existing mode seems to be a good choice and CP mode show a good alternative to all the actual DP modes. [C3372]

### "Development of ALOS/PALSAR data on-demand processing and providing system on GEO Grid"

GEO Grid has been proposed by AIST in order to contribute to earth science. GEO Grid mainly provides satellite and field observation data related to earth science through data search service, data processing service and data providing service. Recently, we have developed ALOS PALSAR data on-demand processing and providing system as one of GEO Grid data providing system. The system allows users to easily search and quickly receive PALSAR products without careful considerations and advanced skills. There are two important points in the system. One is seamless connection between AIST and an external archive system. The other is that the system can provided calibrated PALSAR products according to observations using Corner Reflectors. As a future plan, OGC-CSW is applied to this system for data search service. [C3373]

### "Geo-location error correction for Synthetic Aperture Radar image"

Spaceborne SAR (Synthetic Aperture Radar) image inherently contains geo-location errors which are caused by SAR image acquisition geometry, imaging mode, characteristics of reflectivity and image formation process. Since the geo-location error caused by SAR image acquisition geometry is inevitable, these errors are should be considered and corrected during the image formation process. In this paper, a geo-location error correction method is presented to analyze and correct the azimuth skew and ground range non-linearity error, and orientation error. This scheme does not require the aids of GCP and DEM, and instead directly extract the key correction parameters from the SAR raw data. Using RADARSAT-1 image, a simulation is performed to evaluate the proposed geo-location algorithm. To analyze the effect of proposed correction method, the corrected SAR images are compared with the reference image by RMSE values. [C3374]

### "Using AMSR-E land product to monitor the drought process in China"

This paper presents a method (drought index) to monitor the drought process in China. The method based on the relationship between drought and soil moisture change. Although the absolute value of soil moisture from AMSR-E land product is not accurate enough, but we can use the soil moisture change information in the temporal scale. The soil moisture product of AMSR-E from 2002 to present is used to build up the drought index.

In each EASE-GRID grid, the smallest soil moisture value and the largest soil moisture value in the 8 years are defined to dry/wet edge points and the drought index of them are 0/100. With the two edge points, we can get drought index in each grid, each day. Using the former method, we represent 4 typical drought processes in China. Result show that the drought index from AMSR-E soil moisture product can brought out the development and distribution of drought process roughly. [C3375]

#### "A system trade model for the monitoring of coastal vessels using HF surface wave radar and ship automatic identification systems (AIS)"

Coastal nations have an interest in maritime domain awareness for applications in national security, coastal conservancy, fishery and stewardship of the exclusive economic zones (EEZs) along their coastlines. Using our previously developed HF radar and AIS ship detection models we find signal to noise ratio (SNR) as a function of range, including ducted propagation for the AIS radio signals. We use these SNR estimates to find probability of detection  $P_d$  and then explore multiple systems and stations at variable spacings along the coast. Our example HF radar has significant power and aperture, similar to the Pisces radar. The AIS model is for high power (12.5 W) AIS and a significantly elevated receiver ( $\approx 250$  ft asl). A combined system of HF radar and AIS shows good capability ( $P_d > 0.9$ ) to ranges of  $\approx 125$  km for small ships and to 200 km for large ships. Considering a system of sites separated by 100 km we find that a  $P_{dof} > 0.9$  can be maintained to a distance off shore of 130 km even for small, 120 ton, ships. [C3376]

#### "Synthetic aperture radar image analysis as a tool for validation of baroclinic internal wave 3D modeling in Algeciras Bay (Strait of Gibraltar)"

This paper presents the main results obtained from the application of synthetic aperture radar (SAR) sea surface image analysis to the validation of the baroclinic internal wave 3D modeling in the Strait of Gibraltar and Algeciras Bay. Appropriate SAR images, showing the occurrence of short-wavelength oscillations in the sea surface in this area, were selected and compared with the modeled spatial fields of the M2 free-surface elevation at the corresponding tidal stages, sometimes corrected for the consideration of neap or spring episodes. A good agreement between SAR images and model fields was found. The analysis of SAR images has showed to be a powerful tool for the study of the internal wave phenomena in the Strait of Gibraltar and Algeciras Bay, providing a holistic way for the validation of 3D model experiments in that matter. [C3377]

#### "Effect of quantization on MIMO radar performance"

Multi-input multi-output (MIMO) radar systems have taken considerable attention among radar community in recent years. As stated in some publications MIMO radars have serious performance advantages compared to single-input single-output (SISO) radars. Although MIMO radars perform well theoretically, they have some practical problems. One of these problems is the data transmission rate required by MIMO radars. Quantization directly affects the amount of data to be transmitted. In this paper effects of quantization on MIMO radar performance is covered. [C3378]

#### "Adapting the sir algorithm to ASCAT"

Scatterometers have been launched primarily to measure ocean winds. The value of scatterometer data is increased by application of the SIR (Scatterometer Image Reconstruction) algorithm. The SIR algorithm enhances the effective resolution of the scatterometer data to support its use for other studies. SIR has been used successfully on several scatterometers, including QuikSCAT. In this paper, we describe how the SIR algorithm is adapted to ASCAT data. Using SZF data from ASCAT leads to the best resolution enhancement. SIR requires an estimate of the spatial extent for each measurement. We detail our method to estimate an approximate spatial response function for each ASCAT measurement. Finally, SIR parameters are tuned for use with ASCAT. [C3379]

#### "Airborne Doppler Wind Lidar investigations of western Pacific typhoon genesis and evolution"

The first ever extensive study of tropical cyclones using Doppler Wind Lidars (DWL) was conducted in 2008 within the THORPEX Pacific Asian Regional Campaign. More than 100 hours of DWL profiles were obtained with an average spacing of 3 km. These wind profiles along with dropsonde temperature, moisture and wind profiles are being used to study the genesis and evolution of tropical cyclones. Initial investigations are focused upon the impact the DWL profiles have on numerical weather prediction. [C3380]

#### "Advanced classification of UXO using fully polarimetric GPR and frequency-polarization features"

The classification of buried UXO has been a difficult task due to the large amount of false alarms resulted from

troublesome clutter objects. This paper closely examined scattering characteristics of such clutter objects by using numerical simulations. From the numerical study, we found that some clutter objects, which mainly causes the false alarms, produce multiple resonances at different frequencies and different polarizations. Based on these observations, we developed new classification algorithms which utilize the frequency-polarization dependent responses of complex targets in order to discriminate UXO-like objects from such trouble some clutters. The developed algorithms were tested by experiments in a test plot. In the test, the new classification algorithms clearly discriminated such clutters from UXO-like targets. In this paper, we present the simulation results for scattering characteristics of complex clutters and the new classification algorithm based on frequency-polarization dependent responses will be discussed. Finally, results from experimental verification will be presented. [C3381]

#### "Wide area assessment-Development and case study"

Munitions response is a high priority issue for the Department of Defense (DOD). Over 3,600 munitions response sites (MRS) are in DOD's inventory of sites with potential military munitions and explosives of concern (MEC) contamination, including unexploded ordnance (UXO) and discarded military munitions (DMM). Because many of these sites are large in size (greater than 10,000 acres), the investigation and remediation of these sites could cost billions of dollars. To address this issue, a wide area assessment (WAA) process was developed to quickly and cost effectively assess 100% of a site to reduce the footprint to only those areas with known MEC contamination (i.e. MRS). In this paper, we present a discussion of the origins of the WAA concept, a case study of its first large scale application, descriptions of the component technologies, and conclude with recommendations. [C3382]

#### "Track initiation using multiple bistatic range and range rate measurements with multidimensional assignment algorithm"

Track initiation using multiple bistatic range and range rate measurements with multidimensional assignment algorithm was investigated in this work. The assignment algorithm was tested on a problem involving three targets moving in close proximity inside a two dimensional radar network of six bistatic radar pairs. The accuracy and consistency of initiated tracks as well as measurement association performance of the assignment algorithm was demonstrated through Monte Carlo simulations. [C3383]

#### "Tandem-L: And innovative interferometric and polarimetric SAR mission to monitor earth system dynamics with high resolution"

Tandem-L is a proposal for an innovative interferometric and polarimetric radar mission that enables the systematic monitoring of dynamic processes on the Earth surface. Important mission objectives are global forest height and biomass inventories, large scale measurements of millimetric displacements due to tectonic shifts, and systematic observations of glacier movements. The innovative mission concept and the high data acquisition capacity of Tandem-L provide a unique data source to observe, analyze and quantify the dynamics of a wide range of mutually interacting processes in the bio-, litho-, hydro- and cryosphere. By this, Tandem-L will be an essential step to advance our understanding of the Earth system and its intricate dynamics. [C3384]

#### "A concept for high performance reflector-based Synthetic Aperture Radar"

The success of current spaceborne Synthetic Aperture Radar (SAR) is boosting the performance requirement of next generation systems. In order to cope with the evolution of SAR the design of the new systems will need to meet higher requirements for spatial and radiometric resolution together with an increased availability. This tendency is recognized nearly independently of the application area and manifests itself through several study programs initiated by space agencies aiming at the design of future SAR systems. In this context the use of large reflectors combined with digital feed arrays for SAR is considered a possible alternative to planar array antennas. This paper suggests an X-band spaceborne SAR system utilizing a deployable reflector together with a digital feed array, analyzes its performance and highlights its advantages compared to other systems based on direct radiating arrays. [C3385]

#### "Leaf area index (LAI) estimation based on vehicle-based laser scanning"

This paper proposes a novel approach for leaf area index (LAI) estimation based on vehicle-based laser scanning (VLS), which occurs as a state-of-the-art mapping technique. The method is advanced from the traditional terrestrial laser scanning (TLS), which has been primarily validated capable of predicting LAI. The associated schematic is to explore the correlations between VLS and TLS collections of the same trees. If positive, LAI can be retrieved with the related TLS data as reference. In this study, the consistency between the

multi-echoes per pulse received by VLS and the single-echo per pulse recorded by TLS is further tackled, and LAI, thus, can be derived more accurately. The experiments based on the real-measured VLS and TLS data have validated the applicability of VLS for estimating LAI. [C3386]

#### "Dual-polarization performance of the phase-tilt antenna array in a casa dense network radar"

In this paper the evaluation of dual-polarized scanning performance of a large planar array antenna for a solid state radar for weather is discussed. The antenna array is designed to operate at 9.36 GHz  $\pm$ 50 MHz, and the transmission and reception mode is configured to work alternatively. The antenna array architecture based on a series-fed array configuration of Dual-Polarized Aperture Coupled Patch Antennas (DP-ACPA) was designed and implemented to achieve the required radar polarimetric performance at low cost. Measured patterns of the array in the elevation and azimuth plane are used to evaluate the two principal polarimetric radar parameters (Zdr and LDR) over the scanning range in azimuth plane. It is shown that the biases in the differential reflectivity due the cross-polarization of this antenna configuration are negligible in comparison with the biases produced for the mismatch antenna patterns (H and V). [C3387]

#### "Design and Implementation of High Resolution Radar Video Transfer System"

The characteristic of radar video is analyzed in detail. The design and implementation of high resolution radar video transfer system are described. And the experiment is performed. The experimental results have revealed that the high efficient compression coding of radar video is achieved and the high resolution of echo signal is assured. The system has good practicability. [C3388]

#### "Motion Compensation for Spotlight-Mode SAR Data"

To the question that motion errors restrict improving of spotlight SAR resolution, this paper puts forward a kind of processing method that is wavenumber domain algorithm with two-step motion compensation of spotlight-mode SAR data combining phase gradient autofocus algorithm (PGA), which removes the influence of range motion error and opposite rotate error to spotlight SAR imaging and improves the quality of spotlight SAR images. Simulation results indicate this method has remarkable effect to improve the resolution of spotlight SAR. [C3389]

#### "Subsidence Monitoring by Permanent Scatterers in InSAR: A Case Study of Yancheng City in Jiangsu"

The thesis adopts time series analysis of the SAR images in 10 phases up to 4-year span of Yancheng city area in Jiangsu province, by selecting the SAR image acquired on September 3, 2005 as the main image and the rest of the SAR images as vice images, interferometric processings are carried out and 9 interferograms consisting of the terrain and the deformation information are extracted. By dealing with the 9 difference interferograms with PS technology, terrain feature spatial distribution characteristics with stable electromagnetic reflecting characteristics are successfully ascertained. After temporal and spatial analysis of the 9 unwrapping interferograms, DEM error, atmospheric delay error in the main image and the vice image are obtained, thus the PS-point nonlinear distortion of the ground is extracted. Then by integrating analysis of ground deformation direction, reference datum, floor deformation positiveness and negativeness three aspects, the surface subsidence distributed situation in time and space of Yancheng city area are discovered. [C3390]

#### "Development and Application of Mobile Water Level Monitoring Based on Multi-sensor Integration"

According to the current status of water level monitoring of inland river, this paper presents and designs a multi-sensor integrated dynamic system for mobile water level measurement, which is based on CORS(continuous operational reference system) GPS(global positioning system), GPRS(general packet radio service), PDA(personal digital assistant) technology as well as a post processing platform. The system design, signal quality control and data processing are researched in detail. This system has been used for an actual experiment. The results show that this system has high stability, reliability and flexibility. It is a very-well supplement for the present water level monitoring based on water-level stations. [C3391]

#### "The Detection of Range Extended Target Based on Adaptive Searching and Twofold Sliding Windows"

The detection of range extended target in UWB radar has been the research focus in the field of signal detection. The paper gives a detection method based on twofold sliding windows, and the theoretical value of the detection threshold using adaptive searching algorithm is derived. The simulation confirms that the detection of range extended target based on adaptive searching and twofold sliding windows shows good performance. [C3392]

### "Target Recognition Based on the Self-Correlation Function of HRRP"

The theoretical result shows that the self-correlation function not only has the time-shift invariant feature, but also largely reduces the computational work. To overcome the sensitivity of High-Resolution Range Profile(HRRP), this paper has extracted the self-correlation function of HRRP as a feature for target recognition. Templates and test data are created by using the measured data of sea targets. The results of comparison among the self-correlation function feature, the original range profiles and the amplitude spectrum feature show that the self-correlation function feature has higher recognition efficiency and better anti-noise performance.

[C3393]

### "Speckle Reduction for SAR Images Based on Adaptive Gaussian Mixture Models"

A new algorithm for suppressing speckle in synthetic aperture radar (SAR) images was proposed based on the local statistical property of wavelet coefficients. This method modeled the distribution of wavelet coefficients as an adaptive Gaussian mixture model. This model took into account geometrical structures of the coefficients within one scale and it was adaptive to the wavelet subbands corresponding to three orientations in the image. Based on this model in a Bayesian framework, a spatially adaptive Bayesian shrinkage function was obtained and each modified coefficient was decided separately. Experimental results demonstrate the proposed method improves the performance of speckle reduction and preserves the details of the image. [C3394]

### "A Study of Suppressing Strong Clutter in Radar Signal Based ICA"

It is great difficult to handle the clutter in Radar signal processing. To reduce the influence of clutter, the paper firstly attempts to use FastICA algorithm by separating the target signal and clutter to suppress the strong clutter. The pretreatment of increasing the dimension and dividing the frequency is used before Fast ICA algorithm because of the special radar complex signals. In the same matched filter conditions, Fast ICA algorithm is proved effectively through the increased peak side lobe ratio (PSLR) and signal clutter ratio (SCR). [C3395]

### "Extraction of Radar Target Length Based on High Resolution Range Profile"

In the identification of radar target based on high resolution range profile (HRRP), the target length is an important feature. It can be used not only for the rough sort to decrease the time of identification, but also for the interception of real target echo information from the raw data to reduce noise redundancy. In this paper, an adaptive difference operator for target length feature extraction from HRRP is proposed. It is used to deal with three airplane-measured data. Experimental results and analysis are provided to show that the proposed method can effectively acquire the radial projection length of the target with high precision even in case of lower Signal-to-Noise Ratio (SNR). [C3396]

### "Design of Universal Radar Signal Processor Architecture Based on Crosspoint Switch"

The traditional radar signal processor have a poor performance in scalability and universality. To solve this problem, this paper proposes a new kind of radar signal processing system architecture based on crosspoint switch. A radar signal processor is usually composed of multiple circuit boards .The crosspoint switch is able to make circuit boards connection dynamically. The connections of channels between boards can be one channel to another, one channel to several channels or several channels to one channel. A single signal processing circuit board also has the characteristics of scalability and universality. Eight general digital signal processing chips(ADSP-TS201) form a cubelike network which can be constructed a variety of parallel signal processing systems. Data transmission rate between boards can reach 18.75Gbit/s(3.125\*6). The internal processing speed of each signal processing board reaches 4.8G(600M\*8) times per second. It meets the needs of high speed real-time computing. [C3397]

### "Paddy Rice Identification Using Polarimetric SAR Data in Southern China"

Rice is one of the largest food grains in the world, providing food for more than one third of globe population. The radar remote sensing has been proved as an effective tool for rice mapping. With the emergence of spaceborne polarimetric SAR satellite, researches on polarization backscattering behavior and identification methods of paddy rice are of great significance and attract attention of remote sensing communities. Zhazuo Area located in Guizhou Province of southwest China was selected as the test site of this study. The RADARSAT-2 polarimetric data acquired at four dates were used to analyze the polarization backscattering behaviors and temporal variation characteristics of rice, and identification method for rice based on optimal polarization combination was established. This study shows that HH with HH/HV is the best polarization combination for rice identification under the adoption of linear polarization combination. [C3398]

### "DOA Estimation for Strong and Weak Signals in the Presence of Array Gain and Phase Mismatch"

A new method for estimating direction of arrival (DOA) of the strong and weak signals is proposed in the presence of array gain and phase mismatch. Firstly, the array gain and phase mismatch is estimated using the norm of the error vector between the practical steering vector and the theoretical vector of the strong signal, and then the data covariance matrix is calibrated. Secondly, the new seek vectors are obtained by the eigenbeamforming normalization with the eigenvalues and eigenvectors of the calibrated covariance matrix. Finally, the directions of arrival of all the signals are estimated according to the spatial spectrum like MUSIC with the new seek steering vector. The proposed method has the simpler computation and the more accuracy compared with RELAX and JJM. The effectiveness and the superiority are demonstrated via the simulation results. [C3399]

### "Monitoring Ground Subsidence in New Orleans with Persistent Scatterers Interferometry"

Ground subsidence and flooding are well publicized problems in the area of New Orleans, USA. Interferometric Synthetic Aperture Radar (InSAR) has been applied by various research groups to study the ground subsidence in the area as an international effort supported by the Canadian Space Agency (CSA), National Aeronautics and Space Administration (NASA) and United States Geological Survey (USGS). This paper presents some of the work carried out at the Hong Kong Polytechnic University in contribution to this effort. 23 Radarsat-1 images acquired over a 2.5-year period from December 2004 to March 2007 are used in the PS-InSAR processing. Over 23,000 PS points are identified in the area based on both the amplitude and the coherence variations in the sequence of images. A network of PS points is then formed and used in the PS solution. The LAMBDA method is used to facilitate the determination of the phase integer ambiguities. The average subsidence rate along the direction of the radar illumination determined is 2.1 mm per annum. [C3400]

### "Joint DOD and DOA Estimation Using Real Polynomial Rooting in Bistatic MIMO Radar"

An algorithm for joint direction-of-departures (DODs) and direction-of-arrivals (DOAs) estimation using real polynomial rooting in bistatic multiple-input multiple-output (MIMO) radar is presented. Compared with the conventional spectral Capon method, the proposed approach estimates the angles by the alternating maximization (AM) algorithm and one-dimensional real polynomial rooting instead of two-dimensional angle search to reduce the computational burden. The novel real root-Capon method can perform well even without the prior knowledge of the initial values of unknown parameters which is a prerequisite to AM algorithm. Furthermore, the DODs and DOAs of targets can be paired automatically. Numerical examples validate the effectiveness of the algorithm. [C3401]

### "Passive Tracking and Locating Radar Based on Double GSM Base Stations"

Passive radar is a kind of that without its own transmitter and receive the thermal emission energy of an object or its source of microwave energy reflected from the radar to detect targets. The widely distributed GSM base station signals have GMSK frequency modulation characteristics, these signals can be used as a passive radar radiation source for its ambiguity function diagram with axes at a distance and no ambiguity in Doppler shift and the high side-lobe and so on. Multi-base stations passive radar positioning system is one of the important research area. According to the urban low-altitude air defense warning system development, this paper do some researches on line and plane intersection algorithm for passive location and tracking, based on dual-GSM base stations. Meanwhile, probe into the passive tracking technics by utilizing the State-Dependent Riccati Equation Filter tracking algorithm under the dual GSM base stations. Experiments shows that the algorithms have better positioning accuracy, high efficiency and practical value. [C3402]

### "Electrical impedance tomography reconstruction using a monotonicity approach based on a priori knowledge"

Electrical Impedance Tomography (EIT) has been proposed as an alternative modality for breast imaging. Current EIT reconstruction algorithms are based in optimization procedures that aim to minimize the difference between the recorded data and a set of candidate scenarios. However, these methods produce images with diffused edges, as sharp structures are penalized by current regularization techniques. In this paper, a novel edge preserving EIT reconstruction method is proposed. This technique uses a priori information obtained from Breast Microwave Radar images to estimate the location of the dense breast regions. Then, the monotonicity of the impedance matrix of the collected data is used to reconstruct a profile of the tissue distribution in the breast region. The proposed method yielded promising results when applied to numeric phantoms generated from Magnetic Resonance Imaging datasets. [C3403]

### "Experimental demonstration of noncontact pulse wave velocity monitoring using multiple Doppler radar sensors"

In this paper, two Doppler radars are used to monitor the pulse movements at the heart and the calf in order to measure the pulse wave velocity (PWV) wirelessly. Both simulation and experiment have been performed to demonstrate the feasibility of the proposed noncontact PWV monitoring. A three-stage calibration procedure, including DC offset calibration, circuit delay calibration and antenna radiation pattern calibration, has been developed for reliable long-term PWV monitoring. The measurement results have been verified by wired contact measurement with pulse transducers. [C3404]

### "Phase unwrapping using region-based Markov Random Field model"

Phase unwrapping is a classical problem in Magnetic Resonance Imaging (MRI), Interferometric Synthetic Aperture Radar and Sonar (InSAR/InSAS), fringe pattern analysis, and spectroscopy. Although many methods have been proposed to address this problem, robust and effective phase unwrapping remains a challenge. This paper presents a novel phase unwrapping method using a region-based Markov Random Field (MRF) model. Specifically, the phase image is segmented into regions within which the phase is not wrapped. Then, the phase image is unwrapped between different regions using an improved Highest Confidence First (HCF) algorithm to optimize the MRF model. The proposed method has desirable theoretical properties as well as an efficient implementation. Simulations and experimental results on MRI images show that the proposed method provides similar or improved phase unwrapping than Phase Unwrapping MAX-flow/min-cut (PUMA) method and ZpM method. [C3405]

### "Low power and high gain double-balanced mixer dedicated to 77 GHz automotive radar applications"

In this paper, we present a mixer implemented in a 130 nm BiCMOS technology dedicated to 77 GHz automotive radar applications. The architecture is based on a double-balanced Gilbert cell with integrated transformer-based Baluns. Interconnections between devices, capacitor accesses and Tee-junctions are modeled using EM software in order to improve the simulation accuracy. The measurement results of the circuit exhibit a conversion gain and a SSB noise figure of 18.5 dB and 13.8 dB respectively over a 74 to 81 GHz band. Supplied under 2.5 V the power consumption is 80 mW and the ICP1 is -13 dBm. The transformer-based Balun allows a good input matching at the RF input port over a 16 GHz range from 72 to 88 GHz. [C3406]

### "The missile SAR echo signal simulation technology research"

SAR simulation technology is of great significance for the development of synthetic aperture radar. The paper firstly proposes the constituted principles of missile SAR echo simulation system, discusses and establishes mathematical model of the Missile SAR echo signal, and describes the target Scattering model and the geometric model on the distributed targets and described the target Scattering model and the geometric model on the distributed targets, and finally provides a theoretical basis for further study the simulation of missile-borne SAR echo system. [C3407]

### "A 45-67GHz UWB transmitter with >8dBm output power for indoor radar applications"

A transmitter IC for indoor presence and position detection based on radar is presented. The IC supports carrier frequencies between 45-67GHz, which includes the 60GHz ISM band. Wide RF bandwidth is achieved by applying low to moderate quality factor networks in the signal path. A bi-phase modulator multiplies the carrier with a pseudo-random data sequence of up to 4Gb/s for UWB signal generation. The 0.79mm<sup>2</sup>IC produces >8dBm saturated output power and >25dB small-signal gain for frequencies from 35-67GHz. At 60GHz, the saturated (differential) output power is 10.7dBm. The IC dissipates 462mW from a 3.5V supply voltage and is implemented in a 0.13μm SiGe BiCMOS IC process. [C3408]

### "A 117mW 77GHz receiver in 65nm CMOS with ladder structured tunable VCO"

A low power 77GHz receiver, suitable to be used in a FM-CW Automotive Radar has been designed using a 1P6M 65nm RFCMOS process. It has been implemented using a direct conversion architecture. The 77GHz signal generation block generates a FM-CW signal that pre-drives the external PA with a power level of -4.5dBm and also works as a Local Oscillator (LO) signal in the downconversion mixer. The ladder structured CPW differential transmission line used in the VCO core presents an inductance value of 83pH and a quality factor of 30 at 77GHz. By cutting the different ladders of the inductor, together with the implemented varactors, a tuning range of 15.8% is measured for the VCO, which is suitable to cover process variations. The front-end exhibits a

maximum voltage gain of 15 dB over the baseband and presents a LNA noise figure of 7dB at 77GHz. The VCO measured phase noise is -109dBc/Hz at 10MHz. The achieved power consumption of the complete receiver is only 117mW from a 1.5V voltage supply, 43.5mW coming from the receiver block and 73.5mW from the signal generation block. [C3409]

#### "A Novel Long-Distance Measurement Method Based on Secondary Radar"

In this paper we present a novel method for high precision long-distance measurement based on secondary radar. In this method, we employ two transceivers unit to work in an acknowledged mode as secondary radar system to achieve the round-trip time-of-flight (RTTOF), and introduce a system group delay (SGD) to estimate the time of the measurement signal through the system circuit. The real RTTOF related to the measured distance is acquired by deducting the SGD in the RTTOF. The prototype operates within the 433MHz ISM-Band. The results show the method has a good preference in long distance measurement at 1 km and the measurement principle is robust towards multi-path effect and target identification. [C3410]

#### "Multitarget Tracking Before Detection via Probability Hypothesis Density Filter"

Tracking-before-detection (TBD) is well suitable for radar detection and target tracking of low-observable objects because it makes full use of the raw sensor data without using the threshold and takes advantage of the gains of time integration. The main difficulty in the TBD is that the measurement is a highly nonlinear function of the target state and the associations of measurements are hard to be built when multiple targets are presented. Probability hypothesis density (PHD) filter is regarded as an efficient solution to multitarget tracking problems. To deal with multitarget TBD problem, a classical PHD filter, with "standard" multitarget measurement model, is proposed in this paper. The advantage of proposed filter is analyzed compared with traditional multitarget particle filter. Numerical simulations show our approach has better performance in estimated accuracy and precision of position, velocity and number of targets than multitarget particle filter. [C3411]

#### "Hybrid Method of DOA Estimation for Low-Angle Target Tracking"

In the presence of sea-surface multipath, it is difficult to estimate the direction--of--arrival (DOA) of target for the low-angle tracking problem due to the interference between the direct path and the specular path. We can apply the method of array signal processing to reduce the multipath effect. In this paper, a series of measures are adopted to eliminate the correlation, so one can distinguish the real angle of elevation from the specular, and promote the accuracy and performance of angle measuring, by using MUSIC algorithm. Stimulation results are provided to verify the feasibility of the methods in this paper. [C3412]

#### "Research on the Method of Airborne SAR Direct Geocoding Based on Correction of Systematic Error"

In this paper, a algorithm of airborne SAR Direct Geocoding based on correction of airborne SAR systematic error including slant range measurement error and time delay is put forward to improve the positioning precise, and POS/PPP technique is used to obtain radar phase center position data taking into account work efficiency. Many factors result in airborne SAR positioning accuracy, but main of them are slant range measurement error and time delay, if they couldn't be corrected precisely, the positioning accuracy won't be satisfactory. So this paper calculates the errors through some control points with P-band airborne SAR image of 2.5 meters resolution in mountain area of China (Xian, ShanXi), then we select eleven check points to make statistics. As a result, the horizontal accuracy is 12.6 meters, so the new algorithm on airborne SAR presented in this paper is efficient and practicable for airborne SAR Direct Geocoding in mountain area. [C3413]

#### "A new paradigm for telehealth implementation"

Recently, efforts have been made to treat patients at home as much as possible. In many cases, the reason for the patient staying in hospital is not that he/she actually needs active medical care. Often, the principal reason for a lengthy stay in hospital is simply continual observation. This paper explains our experience and strategy to support the treatment of patients in their own home through the remote monitoring of physiological signals. The benefits of such remote monitoring are wide-ranging; the patient can continue to live their normal life, their risk of infection is reduced, costs are significantly decreased for the hospital, and clinician time is utilised more effectively. [C3414]

#### "Clip-on wireless wearable microwave sensor for ambulatory cardiac monitoring"

We present a new type of non-contact sensor for use in ambulatory cardiac monitoring. The sensor operation is based on a microwave Doppler technique; however, instead of detecting the heart activity from a distance, the

sensor is placed on the patient's chest over the clothing. The microwave sensor directly measures heart movement rather than electrical activity, and is thus complementary to ECG. The primary advantages of the microwave sensor includes small size, light weight, low power, low-cost, and the ability to operate through clothing. We present a sample sensor design that incorporates a 2.4 GHz Doppler circuit, integrated microstrip patch antenna, and microcontroller with 12-bit ADC data sampling. The prototype sensor also includes a wireless data link for sending data to a remote PC or mobile phone. Sample data is shown for several subjects and compared to data from a commercial portable ECG device. Data collected from the microwave sensor exhibits a significant amount of features, indicating possible use as a tool for monitoring heart mechanics and detection of abnormalities such as fibrillation and akinesia. [C3415]

### "A Survey of System Platforms for Mobile Payment"

With the evolution and significant growth in wireless technology and the development of mobile commerce, businesses can achieve superior performance through the implementation of platforms for mobile payment. However, there are several platforms for mobile payment to choose from which makes the selection of an appropriate platform for specific applications a challenging task. In response to this challenge, the most common mobile payment platforms recorded in the literature have been reviewed. This paper presents the result of this review describing the advantages and disadvantages of each system and offers ranking of the technologies considered. MCDM method is used for assessing and comparing different platforms from technical and business points of view. The results indicate that SIM-based application with binary SMS offers the best solution compared to other alternatives. [C3416]

### "Design and development of autonomous driving vehicle"

In this paper, a new type of autonomous vehicle is developed. This vehicle consists of three sets of control systems to regulate the direction, brake and fuels. The sensing system is a combination of laser radar and camera. The localization system is constructed with GPS device and electronically compass. Currently, three tasks, including lane detection and following, object detection, and obstacle avoidance, has been implemented on this platform. We reported some experimental results. [C3417]

### "Research on the image mismatching points eliminating and the integrated arithmetic in the INS/SAR integrated navigation"

The error of the inertia navigation system can be modulated critically by using the real-time SAR image through image matching and positioning. The mismatching points are inevitable in the SAR aided navigation. In the integrated navigation, the measurement outliers will affect the filter seriously. In order to eliminate the effect of the mismatching points, combining the discontinuous working characteristics of the SAR image matching navigation, the paper proposes the image mismatching points eliminating arithmetic and the integrated navigation arithmetic. We found the mathematical models of the INS/SAR integrated navigation system which has the discontinuous working characteristics. And basing on the Kalman filtering information we design the arithmetic to eliminate and displace the image mismatching points. The simulation indicates the arithmetic proposed in this paper can eliminate and displace the image mismatching points availably and consequently improves the accuracy of the integrated navigation greatly. [C3418]

### "Close range coverage ship radar with distance high resolution"

Close range coverage ship radar with high (1.5 m) resolution at range was developed and implemented for navigation of boats as well as for lay-up and mooring of super-size vessels. Examples of the radar-tracking images obtained during natural tests of "River" radar manufactured as a small lot by Micran Co. (Tomsk, Russia) are given. [C3419]

### "Distribution analysis of multi-source decoying system against ARM"

Based on the theory of active decoying system against anti-radiation missile (ARM), decoying error formula was presented, decoying process of multi-source against ARM was analyzed and decoying effectiveness evaluation model was also established. In view of three-source and four-source decoying system, three simplified distributions' models (two for three-source decoying system and one for four-source decoying system) were proposed. According to given attack angle of ARM, the influence of distributions' omnidirectional change on radar and baits' protected probabilities was analyzed. Besides, illustrated by the case of four-source distribution, the effect of bait-to-radar power ratio on radar's protected probability was discussed. Simulation results have great significance in researching the operational effectiveness of multi-source decoying system against ARM. [C3420]

### "Study on strapdown decoupling technology for rolling missile using RF interferometer seeker"

Because strapdown seeker is fixed on the missile body, the guidance signal for proportion navigation law can not be directly got. And the outputs of strapdown seeker are not appropriate to be directly used in the control system of the missile, for it couples with the missile body angular motion, Aim at a strapdown seeker using RF interferometer for guidance, this article presents a decoupling method that a dynamic gyro is used to decouple from the body angular motion of the missile, The dynamic gyro is used for tracking line of sight, and at the same time line of sight rate and gimbal angle outputs are available for autopilot command application. The guidance signal for proportion navigation law is derivation from outer gimbal's precessing current of the dynamic gyro. First, the angle-measure principle of phase interferometer is analyzed in the paper; second, the decoupling principle from body angular motion is advanced in the paper. It is proved that the guidance signal, namely line of sight rate in inertial space can follow the input signals well, and the effect of body angular motion can be effectively isolated. [C3421]

### "The attitude tracking maneuvers of spaceborne spotlight SAR"

The spotlight mode of spaceborne SAR platforms often have to point its payload to immobile target on the ground which means the satellite attitude have to follow a specific trajectory in a fixed time span. In this paper, the attitude angle, angular velocities and angular accelerate are derived. A PD control law with feedforward is developed to achieve the purpose. The approach is verified using numerical simulation with external disturbance and uncertain model. [C3422]

### "An improved signal subspace decomposition method in low SNR case"

The SNR (Signal-to-Noise Ratio) of the targets in HF radar is usually not high enough and the array data length is short. Therefore, the Toeplitz construction method is applied to achieve better azimuth resolution and higher azimuth estimation accuracy than the classic covariance matrix construction method of the spatial spectrum estimation technique. However, its signal subspace and noise subspace could not be separated clearly by the conventional subspace decomposition method. In this paper, an improved signal subspace decomposition method based on the cross-correlation coefficients analysis of the eigenvectors is presented. This method uses an adaptive three sigma rule to select the eigenvectors corresponding to the smaller eigenvalues as the signal subspace. Thus, the signal subspace is divided more clearly. Then, combined with the Multiple Signal Classification (MUSIC) algorithm, the estimate performance for the coherent targets is improved. [C3423]

### "W-band pulsed radar receiver in low cost CMOS"

A CMOS heterodyne receiver integrating a phase-locked loop that includes a bulk of transmitter functions for W-band pulsed radar is realized using low leakage transistors of a low cost 65-nm bulk CMOS process with 5 thin and 1 thick metal layers used to manufacture cell phone RFIC's. The peak conversion gain of receiver is 7 dB and the minimum NF is 10.8 dB between 78 and 88 GHz in measurement. The entire receiver front-end consumes ~190 mW. [C3424]

### "A 43.5mW 77GHz receiver front-end in 65nm CMOS suitable for FM-CW Automotive Radar"

A low power mmW receiver front-end, suitable for a FM-CW Automotive Radar has been implemented using a 1P6M 65nm RFCMOS process. It has been designed using a direct conversion architecture. The input and interstage impedance matching networks have been implemented using Multi-layer Coplanar Wave guide (MCPW) based inductors. MCPW lines can realize small inductance values with high quality factor at mmW frequencies, improving gain, noise figure and power consumption performance of the receiver. It is shown that by adjusting the ground spacing and conductor width of the MCPW, an optimized 52pH inductor can achieve a quality factor of 37 at 77GHz. The fabricated front-end exhibits a maximum voltage gain of 15dB over the baseband and presents a LNA noise figure of 7dB which makes it suitable for next generation of collision avoidance systems. The achieved power consumption of the receiver front-end is only 43.5mW from a 1.5V voltage supply. [C3425]

### "A 77 GHz power amplifier using transformer-based power combiner in 90 nm CMOS"

A 77 GHz fully-integrated power amplifier (PA) with 50  $\Omega$  input and output matching has been realized in a general purpose 90 nm CMOS technology. In order to improve the output power and reduce the signal loss, a transformer and a short stub topology are employed respectively. The power amplifier achieves a saturated output power ( $P_{out,sat}$ ) of +13.2 dBm and 1dB compressed output power ( $P_{out,1dB}$ ) of +11.2 dBm with a peak power-added efficiency (PAE) of 10.4% while operated with a 1.2 V supply. [C3426]

### "Target maneuver detection using high resolution Doppler profile"

A novel maneuver detector for radar targets is described. The high resolution Doppler profile is used to detect abrupt variation in attitude as the target maneuvers, which can be extracted within the coherent processing interval. A brief introduction of the detection principle is presented, along with feasibility study results from a back propagation neural network implementation. [C3427]

### "Robust adaptive ground moving target indication technique applied to distributed spaceborne SAR system"

Through formation flying, distributed SAR satellites system can increase the number of spatial degree-of-freedom (DOFs) and provide flexible multi-baselines for SAR-GMTI (ground moving target indication), while improving the system performance. This letter proposes a robust optimum adaptive clutter suppression technique for SAR-GMTI applied to the distributed spaceborne synthetic aperture radar (SAR) systems. Some realistic problems related to the implementation of the processor are investigated, which include decorrelations from multiplicative speckle noise and moving target steering vector mismatch. Diagonal Loading (DL) techniques is resorted to improve the estimation of clutter statistics in the presence of multiplicative speckle noise. A prior information, like road network information, is integrated into the optimum adaptive processor to reduce moving target steering vector mismatch. Simulation experiments and performance analysis demonstrate the effectiveness and robustness of the proposed processor. [C3428]

### "The robust adaptive signal processing in correlated noise"

A new approach is considered for solving the problem of spatiotemporal signal processing in adaptive antenna arrays in conditions intensive correlated noise processes. The method of synthesis of robust algorithms is based on the game-theoretical principle of searching a minimum of the root-mean-square error that characterizes quality of received estimations of the existential spectra. The signal processing algorithms, constructed on this principle, relate to the class of minimax algorithms being invariant with respect to the prior uncertainty concerning noise distributions. [C3429]

### "A survey on feature extraction of SAR Images"

The feature extraction is one of the key steps for SAR ATR. It can greatly reduce the amount of information processing by SAR ATR, improve the identification efficiency, reduce the time of recognition and lower resources utilization by means of the feature extraction. In the beginning, the feature extraction methods are classified by target type and then various categories methods are summarized. Finally, some unsolved problems of feature extraction are probed. [C3430]

### "Implementation of real-time video streaming with fuzzy logic controller"

The increasing demand of video streaming recently causes a trouble on network congestion due to a huge data rate transmission. One concept to reduce such a problem is to dynamically adjust the rate of video streaming according to an available bandwidth. This paper introduces a fuzzy logic controller to control a real-time video streaming by adjusting either a frame rate or a video quality. In this paper, two experimental environments, LAN or GPRS connections, are investigated. The results show that a fuzzy logic controller is able to control a frame rate and a quality of video streaming according to an available bandwidth automatically. [C3431]

### "A Study on Removal of Radial Interference Echo with Weather Radar"

Electromagnetic disturbance (EMI) is an unpredictable event which often cause abnormal radar echo. EMI enables invariant radial interference echo (features such as sun-strobes) existing in certain directions in radar echo charts at many radar stations, the interference echo and the precipitation echo overlap in many regions. The paper key research has analyzed removal of interference echo which laps over precipitation echo, and an algorithm has been proposed. The radial interference echo could be distinguished from precipitation echo by analyzing their differences. According to the wave principle of superposition and the weather radar signal processing principle, the effective precipitation echo power was obtained by processing the echo power, thus disturbance was eliminated. The analyses results show that most of interference echo were detected and removed by the algorithm, especially in the overlap regions. It can eliminate radial interference echo and retain precipitation echo well at the same time. [C3432]

### "Eigen-Decomposition Method for RFI Suppression Applied to SAR Data"

This paper proposes a novel eigen-decomposition method for narrowband radio frequency interference

suppression for SAR. This method decomposes the eigenvectors of the RFI contaminated signal into interference subspace and signal-plus-noise subspace. The orthogonality of the two subspaces is used to suppress the RFI signals. Compared with the existing algorithms in previous literatures, the proposed method is more computationally efficient with satisfactory suppression results. Further more, this algorithm will neither estimate nor need the prior knowledge of the parameters of the interference signals. The point-target simulation is used to show the working principle of the proposed algorithm. Experimental results based on SAR real data are also shown to verify the proposed algorithm. [C3433]

#### "The Research on RIC-ISAR Image of Ship Target Based on High-Order Match-Phase Transform"

Due to the constantly changing motion of a ship target, high order phase terms which cannot be neglected and results in bad azimuth focusing are generated. In this condition the RD algorithm is not a very effective way for ISAR imaging. In fact, the azimuth position of target scattering point can also be illustrated by the instantaneous chirp rate of received signal not just by the Doppler frequency. In this paper, a new approach is proposed, which is based on Product High-Order Matched-Phase Transform (PHMT) to estimate the value of the changing rate of chirp rate, chirp rate, central frequency and amplitude, thus the high quality range-instantaneous chirp rate (RIC) ISAR image of the object can be obtained. At last, the simulation results prove the effectiveness of the method proposed. [C3434]

#### "A Methodology for Trees' Detection Using LiDAR Data in Urban Areas"

In this paper, we present an approach to detecting and locating trees using LiDAR point data. The motivation for this issue comes from urban planning and management, in which LiDAR data is used to obtain information of the cities. As for the echo characteristic of the LiDAR data is sensitive for the trees, we propose a three-step method for tree detection consisting of data- preprocessing, tree-points extraction and connectivity detection and merging, which make full use of the echo information for the LiDAR points to get the location of the trees in the urban areas. [C3435]

#### "FMCW Radar Imaging with Multi-channel Antenna Array via Sparse Recovery Technique"

A radar system composed of a single transmitter, M receiving channels is studied. Radar echo signals are acquired to estimate the angle, range and velocity in a multiple moving target scenario. The developed algorithm is based on sparse recovery technique by exploiting the sparseness of the targets in angle-range domain. It is shown in simulations for automotive scenario that the proposed algorithm yield better performance in terms of both imaging accuracy and multiple-target resolution compared with the methods of conventional beamforming and minimum variance (Capon) beamforming. [C3436]

#### "SAR Imaging of Moving Targets via Compressive Sensing"

An algorithm based on compressive sensing (CS) is proposed for synthetic aperture radar (SAR) imaging of moving targets. The received echo is decomposed into the sum of many basis sub-signals that are generated by discretizing the target spatial domain and velocity domain and synthesizing the SAR received data for every discretized spatial position and velocity candidate. In this way, the SAR imaging problem is converted into sub-signal selection problem. Thus, in the case that moving targets are sparsely distributed in the observed scene, their positions and velocities can be reconstructed by using the CS technique. It is shown that, compared with traditional algorithms, the target image produced by the proposed algorithm has higher resolution and lower side-lobe. Moreover, multiple targets with different speeds can be imaged simultaneously, so the proposed algorithm has higher efficiency. [C3437]

#### "Design of the Simulation and Assessment Software of Missile-Borne SAR Imaging System"

It is a key step to study and design the missile-borne SAR (Synthetic Aperture Radar) by the computer simulation. In this paper, we present a simulation and assessment software of the missile-borne SAR imaging system, which calculates the flight path of the missile, generates the echo data of the target, outputs the imaging result and its quality assessment. After dividing functional modules, we exhibit each function of the modules respectively. Moreover, three important problems are analyzed: the computation load of the echo data generation, the approach to generating layover and shadow of the 3D target, and the imaging algorithm and geometric correction formula. The simulation example shows the feasibility and effectiveness of the proposed software. [C3438]

#### "The Sky-Scanner System for Air Traffic Management: Test Sessions and Statistical Analysis"

Air Traffic Management (ATM) is traditionally performed by means of radar systems, but new detection and

ranging systems based on LIDAR (Ligth Detection And Ranging systems) are emerging as a critical design trend and yielding to new generation ATM paradigms. The main goal of the designers of the system under discussion was to develop a novel laser tracking technology (SKY-Scanner System) that could allow the detection and tracking of aircrafts up to at least 6 nautical miles. Moreover, the purpose was also the definition of techniques, protocols, numerical prediction tools and devices specifically designed for the analysis of the laser system performances in Air Traffic Control applications. The ultimate purpose was to define a new generation ATM paradigm that is based on radar and laser tracking data fusion, as well as on ground to air laser communications. This paper reports the test session that has been run on a prototype of the laser range finder, in order to find accuracy and possible dependence of measurement errors on temperature, humidity, distance and position of the target. The results show that high humidity and temperature can affect the accuracy of the measurements. [C3439]

#### "Research on scheme and algorithm of high-precision fault-tolerant integrated navigation for HALE UAV"

To meet the need of high-precision navigation for HALE (high-altitude long-endurance) UAV (unmanned aerial vehicle), multi-sensor fault-tolerant autonomous navigation system was researched. For the shortcoming that the GPS signal is easily interfered by electromagnetic techniques, combining sundry integrated navigation patterns such as the INS/CNS integrated navigation, the INS/SAR (Synthetic Aperture Radar) integrated navigation, and other autonomous navigation system, the fault-tolerant federated filter scheme is proposed in this paper. This scheme can effectively take advantage of multi-sensor information redundancy. When the GPS system failure occurred, the system can effectively detect and isolate the corresponding failure subsystem, and at this time the INS/CNS integrated navigation system plays a leading role in the navigation system to maintain a certain degree of navigation accuracy. By importing the SAR-aided navigation system in the terminal, the system can achieve high-precision navigation positioning. The integrated navigation system can detect failure in rapid speed, so it has a high application value in practical engineering. The simulation results by covariance analysis show that the proposed navigation scheme is feasible, and this navigation scheme has important theoretical reference value to improve accuracy and reliability of integrated navigation system for the HALE UAV. [C3440]

#### "Broad beam high-frequency bistatic cross sections of the ocean surface"

For a bistatic high-frequency radar with a broad beamwidth receiving antenna, over the range-limited clutter cell, the deviations of bistatic angle and wind direction would bring about broadened bistatic cross sections of the ocean surface in contrast to a narrow beam bistatic hf radar. Based on Eric Gill's narrow beam HF cross sections of the ocean surface, broad beam HF bistatic cross sections of the ocean surface were presented and the results were obtained by numerical simulation. The results showed that the broad beam bistatic cross sections of the ocean surface were the superposition of narrow beam and were broadened at the same time. [C3441]

#### "Surface Acoustic Wave Resonators as Passive Buried Sensors"

Acoustic wave devices are well known passive transducers for probing through a wireless link a physical quantity. Amongst the two main classes of designs-resonators and delay lines-the former have the advantage of providing informations in a narrow band signal and are hence compatible with an interrogation strategy compliant with radiofrequency (RF) emission regulations, while the latter are probed by a short RF pulse with larger instantaneous energy and shorter response time. We here demonstrate the measurement of temperature using the two configurations, and more specifically for sensors buried in soil. While we demonstrate long term stability and ruggedness of packaged resonators, and signal to noise ratio compatible with the envisioned application, the interrogation range is insufficient for most purposes and we focus towards the use of delay lines. Indeed, the interrogation method of the latter is similar to that used by Ground Penetrating RADAR (GPR) which displays interrogation ranges in the meter to tens of meters in the lower RF range, depending on soil water content, permittivity and conductivity. Thus, we demonstrate here both the temperature measurement capability of a delay buried delay line and the limit of detection of its signal. [C3442]

#### "Performance Analysis of Frequency Sweep Nonlinearities in LFM Radars"

The frequency sweep nonlinearity distortion of LFM signals is one of the most important factors that affect the performance of LFM radars. In this paper, the mathematical models for periodic frequency deviation distortion and non-periodic frequency deviation distortion of LFM signals are made. And the effects of these two types of FM nonlinearity of LFM signals on the matched-filtering pulse-compression performance of LFM radars are investigated profoundly. The computer simulation experiments are performed by using MATLAB language. Also the results are acquired and prove the correctness of preceding theoretical analyses. All the conclusions

obtained theoretically and experimentally, provide lots of indispensable theoretical basis and important experiential reference for the linearity correction of LFM signals, the design of wideband (WB) or ultra wideband (UWB) LFM radars, and the performance evaluation and performance optimization of LFM radars. [C3443]

#### "Quantifying Human Indoor Activity Using a Software Radio-Based Radar"

Human activity quantification consists of computing a numerical or qualitative metric that indicates the amount of movement a person engaged in a given time interval. Such a metric has important applications in elderly care, wellness and healthcare given the strong empirical relation between a person's health and his or her activity level. This paper proposes and evaluates methods to quantify the level of human activity in an indoor environment using a continuous wave radar. An experimental evaluation is carried out using a flexible and low-cost software defined radar platform. Results showed a good correlation between the proposed metrics and the motion sequence performed by the subject suggesting that accurate activity quantification in indoor environments can be achieved using a few simple off-body sensors. [C3444]

#### "Estimating Indoor Walking Velocity Profile Using a Software Radio-Based Radar"

Radar is an attractive technology for long term monitoring of human movement as it operates remotely, can be placed behind walls and is able to monitor a large area depending on its operating parameters. A radar signal reflected off a moving person carries rich information on his or her activity pattern in the form of a set of Doppler frequency components produced by the specific combination of limbs and torso movements. Deploying radars in indoor environments poses however challenges for the interpretation of signals reflected off a moving object due to multipath propagation. Two strategies for the estimation of human walking velocity profile in indoor environments are suggested and discussed. The accuracy of the strategies are evaluated and compared in a field experiment using a flexible and low-cost software defined radar platform. The results obtained indicate that both methods are able to estimate the velocity profile of the person's translational movement with less than 10% error. [C3445]

#### "Analysis of the quantization and saturation error for Space-borne SAR raw data compression algorithm in data domain"

The quantization and saturation error always exist in Space-borne SAR raw data compression process. The explicit formula on quantization and saturation error was not found in previous literatures, though much study has been executed. The analytical formulas of the error of quantization and saturation induced by Block Adaptive Quantization (BAQ) and Interception of High (IH) algorithms are deduced in this paper. The relationship between the standard deviation of input echo signal (SDIS) and the Signal-to-noise ratio (SNR) of these two algorithms is also given. Finally, the simulation test based on simulated SAR raw data and real data is executed to verify the work in this paper. The result of simulation test shows validity of our work which can provide a good criterion for choosing SAR raw data compression ratio parameter in engineering practice. [C3446]

#### "Research on the simplified algorithm of unobstructed areas radar calculation"

Based on the current methods of the radar's unobstructed areas calculation, this paper presents a simplified calculation, which is called the gradually reduced unobstructed areas calculation.. The projection of unobstructed areas that this method produced is intuitive, and the detection of invasive aircraft is simple, which is applicable to the calculation of a smaller range of the radar's scan. Though the verification of MATLAB, the processing speed and space using have been greatly improved. In other words, it improves not only time efficiency but also space efficiency. [C3447]

#### "The study on helicopter route planning"

Route planning is a very important part in simulation system. Under a simulated circumstance, the simulation can be improved if we can plan a reasonable flight path. This paper studies the helicopter route planning in hilly terrain. The whole route planning is divided into two levels. Firstly, the reference trajectory was planned, then replan parts of them, according to the changes in the environment (such as the emergence of new threats), and the others still in their track. Finally, on the platform of MATLAB, simulated the algorithm and the algorithm validity can be verified. [C3448]

#### "Threshold variation based analysis and implementation of an optimized AGC circuitry for digital IF receiver"

In digital receiver designs, An Automatic Gain Control (AGC) block is used to scale the power of input signal so as to meet high dynamic range requirement. This paper proposed a new method called Threshold Variation (TV)

analysis that best suits framed based Pulsed Doppler (PD) radar Step AGC design. The minimal dB control step, system threshold and the stability of Envelop Detector Filter (EDF) could be attained from TV analysis. By utilizing a Cascaded Integrator Comb (CIC) Filter and the  $\alpha|Max|+\beta|Min|$  magnitude approximation, an optimized AGC circuitry is implemented in FPGA. Our practice has proved that the circuitry has appealing performance in a digital Receiver. [C3449]

#### "Application of particle swarm optimization with stochastic inertia weight and adaptive mutation in target localization"

Target localization based on time difference of arrival (TDOA) measurements has important applications in sonar, radar and sensor networks. This paper simply introduced the target localization principle of moving emitter and the position location algorithm. Further more presented an improved particle swarm optimization with stochastic inertia weight and adaptive mutation, and adopts it to solve the target localization problem according to the batch of continuous TDOA measurements. The experimental results show that the new algorithm has higher localization accuracy, better algorithm stability and faster convergence rate. [C3450]

#### "Development of a high performance Wireless Mesh Network for video streaming"

Wireless Mesh Network (WMN) is a fast developing intelligent community network to provide multimedia services to the residents. With the latest development of technologies in broadcasting and smart mobile devices, to view videos on these handheld devices via WMN will become an essential lifestyle in the future. However, current WMN faces challenges to deliver videos to multiple users because of the constrained wireless medium. This paper addresses the challenges of video streaming in WMNs by providing a high performance design architecture to allow smooth delivery of videos. This includes the load balanced routing via multiple gateways and over multi-paths, efficient usage of the bandwidth by multicast routing, effective congestion control for video streaming and scalable video streaming to deliver videos to various devices at the same time. Practical implementation demonstrated the effectiveness of the current design and development. [C3451]

#### "A low-power wireless remote sensor node design based on GPRS"

For the limitation of transmission distance and power volume of sensor node, a low-power remote data acquisition node which implements long-distance data transmission by combining General Packet Radio Service network with wireless sensor network is designed to acquire data periodically and upload data to remote server through General Packet Radio Service network. This paper expatiates hardware design principles of the node, power management model and software protocol design of the test system. Test results show that nodes can reliably acquire and upload data, the average work current of sensor node is 34mA, the peak current of cluster-head is 260mA when cluster-head uploads data to server, and sleep mode current are both less than 35uA. Performance indicators of node can fulfill the needs of remote monitoring applications in industrial field. [C3452]

#### "The design of a GPRS-Based Intelligent Access Control System for Base Station"

This article describes the method for the design of a GPRS-Based Intelligent Access Control System for Base Station. The structure theory of the GPRS access control system is described in details in this paper. It gives topology structure between the devices in the base station, which are through up by RS485 fieldbus. In this paper, the SMS and caller identification methods and the IC card identification methods are analyzed, and it points out the advantages of the SMS and caller identification methods. Meanwhile, it gives a brief description of the function of the intelligent access control system management software. [C3453]

#### "Application research on intelligent pattern recognition methods in hail identification of weather radar"

Firstly, advantages of the learning ability of intelligent pattern recognition models, which have been used in hail identification of weather radar based on echo parameters, is discussed. Then, structures and working principles of hail identification models which based on fuzzy neural network and support vector machines (SVM) are described respectively. Finally, effect validation of hail identification has been finished by using echo samples from Chengdu and Kuitun to train the hail identification models. The experimental results show that hail identification models based on intelligent pattern recognition have the better effect than which based on the statistical pattern recognition. Besides, in the case of limited training samples, the identification model based on SVM has stronger adaptability than which based on fuzzy neural network. [C3454]

#### "Study on Defocus compensation using variable pulse repetition time stepped-frequency waveform"

In this paper, a new technology for compensating the defocus due to the velocities of multiple moving targets is

presented. By using this technology, the blur produced by defocus can be compensated when the velocities are unknown. And a method is proposed to solve the range-Doppler coupling caused by the multiple targets. The effectiveness of the algorithm is illustrated with simulation results. [C3455]

#### **"Research on intelligent monitoring and protection system of distributive multi-tower cranes"**

During construction phase of large buildings, it is of great significance to maintain safety protection on multi-tower cranes operating. Based on distributive and multi-intelligent agents design concept, and adopting ARM embedded technology, wireless network transmission, an intelligent monitor and protection system for the multi-tower cranes has been established. A multi-tower crane communication network has been set up to realize status information transmission of tower crane by adopting wireless token-ring communication. "Implication Confirm" feedback is used to speed up data transmission of communication network. Remote monitoring on working status of multi-tower cranes can be realized by using GPRS network. Field tests show the tower crane intelligent monitoring and protection system meets the requirements of monitoring construction safety of multi-tower cranes operating. [C3456]

#### **"Improved regularized particle filter algorithm for SINS/SAR integrated navigation"**

This paper presents a new improved regularized particle filter algorithm for SINS/SAR (Strap-down Inertial Navigation System / Synthetic Aperture Radar) integrated navigation system. By adopting MCMC (Markov Chain Monte Carlo) move to the regularization process, a MCMC based filtering algorithm is developed through combining local resampling with MCMC move to prevent a large number of particles from being rejected. The proposed particle filtering method prevents the degeneracy of particles and guarantees that the resultant particles have a common distribution with the practical probability function, without causing extra noises on the estimates. It also reduces the estimation variance and the computational load. By using improved regularized particle filter algorithm and extended Kalman filter algorithm, simulate for the SINS/SAR integrated navigation system. Experimental results demonstrate that the improved regularized particle filter algorithm can reduce the navigation positioning errors, and filtering performance obviously exceeds the extended Kalman filter algorithm. [C3457]

#### **"Mosaic in g the ocean/terrestrial SRTM-DEM and making t he geomorphologic relief shading map"**

Ocean and terra are the largest geomorphologic units on the earth, and there are essential differences between them. Hence, while we make the geomorphologic relief shading map, it is necessary to make the ocean/terrestrial geomorphologic relief shading map respectively. Then combining the ocean and terra map, we can get a whole geomorphologic map about the study area. However, the SRTM-DEM(Shuttle Radar Topography Mission-Digital Elevation Model) we get from USGS(United States Geological Survey) is clipped by SWBD(Shorelines and Water Bodies Database) coastline, so the coastline may be not accordance with the coastline we get about the study area. To solve this problem, we had to clip the DEM and patch the void data. Only in this way can we assure the DEM is accordance with the coastline. If the DEM is larger than the coastline, we can cut the spare parts by using the tool-extract by mask. However, if the DEM is smaller than the coastline, we have to patch the void data. This paper tries to find the best interpolating method to patch the void area according to the geomorphologic units. After that, we illustrate the processes of how to make the geomorphologic relief shading map by the software-Global Mapper. [C3458]

#### **"Compilation of DEM based on lidar data"**

Lidar has provided one new method for the digital elevation model (DEM). It has the advantage of gaining the three dimensional information, the wide measuring range, the high spatial and elevation resolution. What the lidar system gains is the cloud data, which can produce the digital surface model of the scanning area directly. However, if we want to withdraw the digit terrain model, still need to classify and process the cloud data. This article introduce how to use Lidar post-processing software such as POS software, the ALS40 post-processing software as well as the Terrasan module and the LPS module deal with the cloud data together, finally produce DEM in the ERDAS software. [C3459]

#### **"Bi-station OTH radar locating and tracking using only range and Doppler measurements"**

Azimuthal measurements of the high frequency ground wave over-the-horizon (OTH) radar are either coarse or unavailable in an actual environment. It is very hard for a single station OTH radar to performance effective tracking under that condition. A bi-station OTH radar system is proposed to triangulate target tracks using range and Doppler measurements only. Multi-sensor data association and combining positioning are key issues of this system. This paper focuses on positioning and tracking filter algorithm. The locating and tracking model is established and the extended Kalman filter (EKF) is used to solve the bi-station nonlinear tracking problem. Simulation result shows that EKF can handle this well, and the bi-station OTH radar system can meet or slightly

better than the accuracy of the conventional single station OTH radar tracking system with poor bearing resolution. [C3460]

### "Design of Tap Water Pipe's Monitoring System Based on GSM/GPRS"

This paper analyzes the whole network architecture of Tap Water Pipe's Monitoring System Based on GSM/GPRS, and then analysis the hardware design and software design of the system, through the effective design of the system reached the real-time monitoring and Leakage-Detecting of underground water-pipe system, and improve the maintenance efficiency of the system. [C3461]

### "Design and optimization of radio frequency stealth signal based on SAGA"

A good stealth performance of radio frequency (RF) signals is very important for fighters in order to have high penetration capacity, survivance capacity and combat effectiveness in an electronic warfare. Some design principles of RF stealth signals are proposed in this paper. In the light of design principles, hopping-frequency signals were proved to having the good RF stealth performance. The simulated annealing genetic algorithm (SAGA) was used to design hopping codes based on the maximal sidelobe level criterion. The performance of frequency-hopping signals was verified by experimental simulations. [C3462]

### "A design of alarm system for substation perimeter based on laser fence and wireless communication"

In recent years, with the transformer substations basically unattended, a new topic for the security of power equipments and electric power lines is presented. Many alarm systems based on ac high-voltage grid, electronic pulse fence or infrared electronic fence have been installed in substations. In this paper, we propose an intelligent anti-theft alarm system based on laser fence and wireless communication network technology. Once occlusion of the laser beams occurs, it will transmit alarm information with accurate location to the control center through ZigBee network, and then send short messages to the defender's phone by GPRS. Moreover, the on-site searchlights could be remotely controlled by SMS with GPRS network. The architecture and implementation of the system is described in detail. Practical results show that our system is high-security, low-power and low false-negative compared with the conventional anti-theft systems. [C3463]

### "Research on power spectrum estimation based on periodogram and burg algorithm"

With rapid development of modern intelligent traffic management, the measuring speed radar becomes an important device. Using Doppler principle, speed can be measured by obtaining frequency deviation signal of moving target. Traditional measuring speed method uses analog filter whose measuring accuracy is low and measuring speed is slow, so it's difficult to meet the requirements of modern intelligent traffic management. Signal processing of speed radar generally use power spectrum estimation method. This paper focuses on classical period spectral estimation and modern spectral estimation based on Burg algorithm. By comparing various algorithms in computational complexity and resolution, Burg algorithm was used to signal processing finally. Experimental and simulation results indicated that digital signal processing system would meet system requirements for measurement accuracy. [C3464]

### "A refuse-recognition method for radar HRRP target recognition based on mahalanobis distance"

In the radar automatic target recognition (RATR) system using high resolution range profile (HRRP), if a test sample has not been trained in training phase, it would lead to a full miss classification in test phase. In this paper, we design a classifier based on generalized confidence, which can efficiently refuse-recognize a new target. Firstly, principal component analysis (PCA) method is used to extract feature vector from every sample. Secondly, the classifier calculates each feature vector's generalized confidence on mahalanobis distance. Consequently, the distribution of confidence is used to define a refuse-recognition threshold for each training target. In test phase, for each trained-target in the database, we suppose that the test sample belongs to current target, calculate the generalized confidence, judge whether the test sample really belongs to the target or not via comparing the confidence with the target's refuse-recognition threshold. The final class is determined by vote. The experimental results demonstrate the effectiveness of the proposed algorithms. [C3465]

### "A bus management system based on ZigBee and GSM/GPRS"

This paper introduces a system design about bus management system based on ZigBee and GSM/GPRS, which implemented the basic functions of the intelligent public transport management system, such as monitoring the time of bus arrival, departing from the bus station and reporting stations name automatically. This system can ensure punctuality of vehicles to run, improve the automation level of reporting stations and quality of public

transport service. The management system has low cost and thus it is more feasible. [C3466]

### "A design of the Intelligent electronic control seat belt retractor based on automotive active safety technology"

Designs an Intelligent electronic control seat belt retractor, with integrated controller area network (Controller Area Network, CAN) communications, millimeter-wave radar technology, micro electro-mechanical systems (MEMS) sensor technology and embedded processing technology. The millimeter-wave radar warning signal, MEMS accelerometer information, occupants status and CAN bus data, trigger the appropriate seat belt traction control strategy, implementation of reminder, collision avoidance, thus it can protect the automotive occupants safe, and reduce or prevent occupants not to be injured during a crash. Therefore, the intelligent electronic control seat belt retractor links up active safety and passive safety technology. [C3467]

### "Simulation of radar electronic warfare range of visualization applications"

At present, applications of visualization technology are expanding, and are playing an increasingly important role in various fields. In this paper, radar visual range of electronic warfare simulation has been studied based on transcendental equation method and graphic space intersection method. This paper gives the maximum radar detection range and the detection range of two-dimensional visualization in electronic warfare simulation. In the actual simulation application, a preliminary design achieves the expected target. [C3468]

### "Coastal Radar WERA, a tool for Search and Rescue and oil spill management"

The HF-Coastal Radar "WERA" is a shore based remote sensing system to monitor ocean surface currents, waves and wind direction. This very reliable long range and high resolution monitoring system based on short radio wave radar technology. Due to the outstanding accuracy WERA can provide very valuable data to be assimilated into hydrographic models. In case of accidents in a distance of up to 200 km off the coast the real-time ocean surface current data can help Search and Rescue (SAR) operators. Presently, SAR tools are based on hydro-dynamical and atmospheric models to provide hindcast and forecast situations. Even if these oceanic numerical models are efficient to produce instantaneous maps of currents, the accuracy of derived Lagrangian trajectories often is not sufficient for search and rescue purposes. To improve these numerical models by means of realtime data it is essential that the quality of the assimilated data is very high and reliable. For this reason long term comparisons with buoy data for ground truthing and statistical analysis were carried out for more than two years. The resulting data availability (98,7 %) is outstanding and the data quality is as good as buoy data. [C3469]

### "Use of earth observation data and numerical modeling in the development of marine downstream services in Estonia"

The objective of the Global Monitoring for Environment and Security (GMES) is to provide, on a sustained basis, reliable and timely services related to environmental and security issues in support of public policy makers' needs. MyOcean is the implementation project of the GMES Marine Core Service (MCS), aiming at deploying the first concerted and integrated pan-European capacity for Ocean Monitoring and Forecasting ([www.myocean.eu.org](http://www.myocean.eu.org)). MyOcean develops upgraded European capabilities for reference marine information and provides a wide range of key ocean indicators. The MCS provides information to intermediate users who combine it with other forms of information and data to provide customized downstream services for end users. The end users range from wide public to special target groups. Downstream marine services in Estonia are built on in-situ real time and near real time measurements, satellite remote sensing imagery and numerical modeling. Two-day marine forecasts for the North-Eastern Baltic Sea are produced by 3D circulation model HIROMB-EST. The downstream service portfolio consists of following items. Real time sea level observations including history and two-day forecasts on 12 locations around the Estonian coast are available in the Internet. Sea surface temperature (SST) and salinity are complimented with near real time ferry-box observations on the cross-section between Tallinn and Helsinki. During cloud free sky SST charts are produced using MODIS (Moderate Resolution Imaging Spectroradiometer) imagery for the Gulf of Finland and Gulf of Riga. Illegal oil spills are detected from SAR imagery. The drift of the slick is simulated by Seatrack-Web and potential polluters are identified combining Seatrack Web and the Automatic Identification System (AIS). The monitoring of suspended particulate matter during harbor dredging is based on MODIS and MERIS (Medium Resolution Imaging Spectrometer) data. The laboratory analyses of water samples are used for the-- calibration and validation of satellite products. The in situ measurements of vertical profiles of absorption and attenuation coefficients are used to determine the profiles of particle origin, concentration and size distribution. Operational ice extent monitoring using SAR data is rather widespread. Optical remote sensing imagery from MODIS and MERIS sensors complement SAR imagery. Ice concentration maps are produced using the histogram analysis of MODIS

250 m reflectance data. This data is used for model evaluation with the purpose to get reliable ice forecast from the HIROMMB-EST model. Spectral optical remote sensing data from MERIS helps to identify different ice types. The determination of high spatial resolution marine and coastal wind from the Advanced Synthetic Aperture Radar (ASAR) is quite a novel application in the Estonian waters. Wind field data can be retrieved from ASAR C-band data and model results using CMOD algorithm. [C3470]

### "High-performance system design of SAR real-time signal processing"

Synthetic aperture radar is a high resolution imaging radar, SAR signal processing is an important branch of signal processing, while the performance of SAR signal processing system greatly influences the resolution of SAR image. In this paper, a high-performance signal processing system which has strong computation ability, high-width connectivity and flexible expandability is presented, meanwhile, the program design of FPGA is introduced, further more, the RD algorithm implementation result with the system proposed in this paper is provided as an illustration. [C3471]

### "Sea ice monitoring in the Baltic Sea using dual-pol C and L band SAR data"

Summary form only given. Monitoring of ice dynamics and ice type classification is an important task for understanding environmental changes as well as for safe winter navigation. SAR (Synthetic Aperture Radar) is a powerful spaceborne instrument to detect ridged ice regions as the radar backscatter is strongly influenced by geometrical properties of the ice surface. Data from polarimetric (or dual-pol) SAR sensors like Radarsat-2 and ALOS/Palsar enables to determine more precisely ice types as it contains more information about the ice surface geometry than single polarization images. Use of dual polarization SAR imagery also known as compact polarimetry has shown to be useful as it has reduced the complexity, cost and data rate of SAR image while preserving most of the capabilities of fully polarimetric image. A study for sea ice monitoring and characterization was carried out in the Baltic Sea from January to March 2009. The focus of current study was on enhanced monitoring of small scale changes/processes (ice types and dynamics) in the western Estonian archipelago sea. Secondary objective was to compare the backscatter characteristics at different frequencies (C-band and L-band) and polarizations (HH, HV, W) from various ice types (ridges, fast ice, water etc.) using data from different SAR sensors. Considering the objectives of the study high resolution SAR data from the following sensors was included: RADARSAT-2 (fine mode, HH/HV), ALOS/Palsar (fine mode, HH), ERS (image mode, W) and ASAR (wide swath, HH). Also optical remote sensing data from MODIS (Moderate Resolution Imaging Spectroradiometer) sensor was used to carry out non SAR dependent ice type classification. In addition to remote sensing imagery the meteorological data (wind measurements, air temperature, precipitation etc) from three different stations near the study area was analyzed to determine the cause of backscatter variations. A sea ice classification from C-band dual-pol Radarsat-2 imagery-- was performed. The classification on SAR image was based on entropy/alpha differences that were caused by ice type variations. Analysis showed that four ice types (level ice, fast ice, ridged ice, deformed ice and water) were identifiable from dual-pol data. Also two independent analyses that were performed on optical remote sensing imagery (MODIS) supported the classification results from Radarsat-2 data. Ice types were also determined from L-band SAR data and single polarization C-band data to characterize dependence of backscatter properties on surface type (roughness). The backscatter properties of ice types detected from RADARSAT-2 (C-band, HH/HV) were compared with single-pol data from Palsar L-band (HH), ERS (W), and ASAR (HH). Results showed that while C-band data was better for monitoring small scale ice deformations, the inclusion of L-band data improved significantly the analysis in snow covered ice regions in the coastal zone. The study provides additional information for enhanced ice monitoring in small areas (e.g. harbours, coastal zone) using high resolution data at multiple bands and polarizations. [C3472]

### "Design of a correlated Lognormal distributed sequence generator based on Virtex-IV series FPGA"

Proposed is a hardware correlated Lognormal distributed sequence generator based on the Virtex-IV XC4VFX100-10 FPGA. The random number is generated by the improved Tausworthe architecture and the non-correlated Gaussian random sequence is generated by Box-Muller algorithm. The correlated Lognormal distributed sequence is generated by zero memory non-linearity transformation with the proposed digital architecture. The complex cepstrum is used in the proposed frequency filter to generate the correlated coefficient. The logarithmic and exponential functions are calculated with CORDIC IPCore. The implementation on FPGA occupies 4210 slices, 4 block RAM and 2 DSP48s. The numeral experiment show the feasibility and accuracy of the proposed method. This proposed Lognormal distributed sequence generator can be used as a key component in a hardware radar echo and clutter simulator. [C3473]

### "SAR imagery and Seatrack Web as decision making tools for illegal oil spill combating-a case"

### study"

The number of marine pollution arising from illegal oil discharges from ship tank or bilge pumping is much greater than those spectacular ship accidents. Illegal spills are mainly detected on essential navigation routes. In every country, marine surveillance agencies are responsible for oil spill combating and on identification of illegal polluters. They rely on information that has been provided on potential oil spills by responsible institution. The first information is usually provided by satellite remote sensing. The decisions about oil combating action is taken based not only on SAR imagery, but checking confirmation from aerial surveillance and using oil spill modeling, also. SAR imagery and aerial surveillance does not provide information about the type of spilled oil, which is important input information for oil spill modeling. Different types of oil have different behavior in water and may affect the decisions about which oil combating activities should be taken. The aim of this study was to show how different type of oil behaves in water according to the Seatrack Web oil drift model, which is the main modeling tool of Estonian Border Guard who is responsible in oil combating. Current study is based on illegal oil spill accident that happened in the eastern Baltic Proper on 10 April 2010. Potential oil pollution was detected on SAR image at 9:08 UTC. Consecutive SAR image was obtained at 9:40 UTC showing no significant change of the slicks area and shape in such a short time. Oil pollution was also confirmed by aerial surveillance at 11:10 UTC. Report that was based on visual observations said that it was probably a bilge water, which started to vanish due to ship traffic. The pollution was also recorded by Side Looking Aperture Radar (SLAR). Seatrack Web model (STW) was used for the forecast of oil slick drift. The input of light and medium oil was chosen. The results showed rather different results about oil drift as well as about oil fate. In case of med--ium oil 20% of oil was expected to evaporate within a couple of hours and the rest stayed in water surface. In the case of light oil 20% was evaporated, but the rest of the oil was expected to disperse in to the water column and emerge on the surface in time to time. The light oil was simulated to drift to the NWW, while medium oil to the SW. Laboratory analyses of the sample that was taken at 14:30 UTC showed that heavy fraction of the oil (hydrocarbons C16-C36) was maintained in the water until then. In conclusion, this study shows that the information about the type of spilled oil is needed as soon as possible after the oil detection to make appropriate decision on oil combating activities. [C3474]

### "Advancing coastal upwelling observations with use of SAR data: Case study from SE Baltic"

Nowadays exploitation of satellite data, mostly infrared and visible, became a regular practice for upwelling detection and analysis. At the same time these types of satellite data strongly depend on sun illumination conditions and cloud cover, with the latter being very limiting factor specifically for the Baltic Sea. In this case SAR (Synthetic Aperture Radar) imagery not affected by clouds and with high spatial resolution can significantly contribute to upwelling observations. The aims of this study are to show how SAR complements both in situ and satellite optical data, and to examine general SAR limitations to observe sea surface temperature (SST) fronts associated with coastal upwelling. [C3475]

### "Active Traffic Management applications in Greece. The case of Attica Tollway"

Active Traffic Management (ATM) has been recently gaining a lot of attention world-wide after the successful implementation in M42 in the UK. The primary goal of ATM applications is the reduction of traffic incidents and the resulting improvement of traffic conditions. Dynamic traffic management practices can have different impacts and effectiveness in different networks. This paper discusses the opportunities and challenges related to the use of ATM in Greece and presents empirical results from the first related applications in the Attica Tollway. Furthermore, a statistical analysis of data collected from the Attica Tollway application is performed, aiming at investigating the impact of speed-limit messages on traffic flow. [C3476]

### "Visual confirmation of mobile objects tracked by a multi-layer lidar"

Integrity of the information provided by a perception system is crucial for advanced driver assistance systems intended for safety applications, like obstacle avoidance systems. A method to ensure integrity is to use different kinds of perception sources. Lidars are key sensors for multiple objects detection and tracking. Stereo vision systems (SVS) can be used to improve the tracking but, in this paper, we use also SVS to confirm the real existence of potential obstacles thanks to 3D dense reconstruction in focused regions of interest. Synchronization issues between the different sensors are addressed using predictive filtering. The proposed approach is evaluated in real conditions thanks to five use cases relevant to urban situations. Results show that this visual confirmation strategy is efficient. [C3477]

### "A new method for robust far-distance road course estimation in advanced driver assistance systems"

An advanced method for road course estimation is presented. It is based on the state-of-the-art Kalman filter

lane detection and allows for a robust sensor-based estimation of road courses in great distances. Only the parameters for the road course are estimated which results in a reduced parameter space and therewith more robustness. Instead of laterally displaced single feature points tangential structures are used as measurements in the filter model. Therefore the method is translation-invariant and applicable for all continuous differentiable road course models. As shown with video and radar input examples it is also sensor-independent and particularly suitable for sensor fusion approaches. For accuracy estimations an advanced method based on inertial navigation is used which is independent of lateral movements of the host vehicle and the road model. [C3478]

### "Ground truth evaluation of the Stixel representation using laser scanners"

Modern real-time dense stereo vision provides precise depth information for nearly every pixel of an image, indicating stereo cameras as a key sensor for future vehicle safety systems. Efficient analysis of this large amount of data by different tasks running in parallel asks for a medium level representation that decouples application specific analysis from low-level vision. Recently, the so called "Stixel World" has been proposed. It models the objects in the scene, implicitly separates them from the ground plane, encodes the freespace to maneuver and thus represents the scene in a highly compact manner that supports different recognition tasks efficiently. The potential of this new representation depends on the accuracy that can be achieved. Therefore, this paper analyzes the precision of this representation using a high performance laser scanner as reference sensor. The statistical analysis confirms the high accuracy as expected from visual inspection. [C3479]

### "Signal processing methods for non-contact cardiac detection using Doppler radar"

We investigate two signal processing methods, time and frequency-based approaches, for non-contact cardiac detection. A 5.8-GHz Doppler radar sensor was used for non-contact measurement of respiration and heart rate from stationary and semi-stationary subjects at a distance of 0.5 to 1.5 meters. We report on the accuracy of the heart rate measurements obtained using the two signal processing approaches, as compared to a reference heart rate obtained using a pulse oximeter. Simultaneous Photoplethysmograph (PPG) and non-contact sensor recordings were recorded over fifteen minute periods for five healthy subjects (4M/1F, ages 29.2±4.32 yrs) One algorithm is based on extraction of heart rate using spectral analysis and a second algorithm is based on automated detection of individual peaks associated with each cardiac cycle. Peaks were also extracted manually for comparison with the automated method. The peak-detection method was less accurate than the spectral method but suggests the possibility of acquiring beat by beat data. It was found that the signal SNR affects the ability to detect heart rates. An increase in SNR could lead to more accurate rates being obtained. The results described provide an estimate of the accuracy expected when measuring heart rate using a Doppler radar sensor. Non-contact measurement of heart rate will be useful in chronic disease monitoring for conditions such as heart failure and cardiovascular disease. [C3480]

### "Estimating surrounding vehicles' pose using computer vision"

This paper presents a computer vision-based approach to tracking surrounding vehicles and estimating their trajectories, in order to detect potentially dangerous situations. Images are acquired using a camera mounted in the egovehicle. Estimations of the distance, velocity and orientation of other vehicles on the road are obtained by detecting their lights and shadow. Because 3D information is not readily available in a mono-camera system, several sets of constraints and assumptions on the geometry of both road and vehicles are proposed and tested in this paper. Kalman filters are used to track the detected vehicles. We also study the advantages of tracking the vehicles in road space (world coordinates), or tracking the position of the lights and shadows on the image. The performance of the approaches is evaluated on video recorded in urban environment. [C3481]

### "Telecommunication systems enabling real time navigation"

Traffic is one of the most important problems in industrialized countries: roads are getting more and more crowded, especially during rush hours, with heavy consequences on people's quality of life, accidents, pollution, and fuel consumption. The transmission of up-to-date traffic information to on-board navigators would allow the redistribution of traffic flows over alternative routes, thus reducing road congestions and slowdowns. In this paper we investigate the possibility to send the information on the average-speed in any road of interest to on-board navigators by means of current broadcast and unicast communication technologies. A discussion on the most convenient transmission strategy will also be given with reference to real scenarios. [C3482]

### "AngelCare mobile system: Homecare patient monitoring using Bluetooth and GPRS."

The quick progress in technology has brought new paradigms to the computing area, bringing with them many benefits to society. The paradigm of ubiquitous computing brings innovations applying computing in people's daily life without being noticed. For this, it has used the combination of several existing technologies like wireless

communications and sensors. Several of the benefits have reached the medical area, bringing new methods of surgery, appointments and examinations. This work presents telemedicine software that adds the idea of ubiquity to the medical area, innovating the relation between doctor and patient. It also brings security and confidence to a patient being monitored in homecare. [C3483]

#### **"Clutter isolation and cardiac monitoring using harmonic doppler radar with heterodyne receiver and passive RF tags"**

A harmonic radar employing the use of harmonic passive RF tags can be successfully used to isolate the human respiration from environmental clutter. This paper describes the successful use of heterodyne receiver architecture with Doppler radar to track the heart-rate of a human being using passive body-worn harmonic tags in presence of a controlled noise generator at distances up to 120 cm. The heterodyne system results have been compared with those of a conventional Doppler radar for cardiopulmonary monitoring that fails to isolate the noise from heart-rate in presence of a noise source. [C3484]

#### **"Design radar signal interface for navigation Radar/ARPA simulator using radar display"**

Using radar/ARPA simulators for seafarers training is made mandatory by International Maritime Organization (IMO) as early as 1978. This paper presents a new radar simulator using one PC, one radar signal interface and one radar display. PC generates radar echo of any sea area and simulates all kinds of radar echo effects and features. Then the radar signal interface receives the radar echo through PC USB and outputs all kinds of signals to radar display. In the interface, lots of logical circuit is implemented by CPLD, which largely simplifies the design and improves the flexibility. Seafarers can operate the radar display in simulated environment of any sea area in Radar/ARPA Operation training. It provides more flexibility and fidelity and effectively improves the training effect. The result shows that this type of radar simulator meets with the requirements of radar simulator standard completely and has been used in our full mission ship handling simulator successfully. [C3485]

#### **"2D Beamforming for Through-the-Wall Microwave Imaging applications"**

Recently, microwave imaging has received a considerable amount of interest with respect to other imaging techniques. A large number of studies rely on microwaves, as a powerful electromagnetic tool to retrieve physical and electrical properties of penetrable and impenetrable objects. The capability of microwave signals to penetrate light opaque materials and sense distant or inaccessible objects with reasonable spatial resolution makes them attractive for different industrial, civil and medical applications. Our Through-the-Wall Microwave Imaging (TWMI) radar system facilitates us to detect and localize objects behind the wall. Measurements with mono-static radar configuration are made with various sizes of metallic materials inside the room with wooden wall (of known thickness and dielectric constant) using 2D antenna positioning assembly and scattering data is recorded in frequency domain. The simple and fast algorithm for compensation of different wave velocity inside the wall is used and the measured raw data is processed with 2D SAR Beamforming algorithm in time domain to reconstruct the image of the targets behind wall. This paper provides an overview of the basic concepts, foundation prototype system of TWMI, SAR Beamforming algorithm and Comparison of Various matched filter approaches and their effects on quality of image are elaborated in detail. [C3486]

#### **"A cascade classifier applied in pedestrian detection using laser and image-based features"**

In this paper we present a multistage method applied in pedestrian detection using information from a LIDAR and a monocular-camera mounted on an electric vehicle driving in urban scenarios. The proposed method is a cascade of classifiers trained in two subsets of features, one with laser-based features and the other with a set of image-based features. A specific training approach was developed to adjust the cascade stages in order to enhance the classification performance. The proposed method differs from the conventional cascade regarding the way the selected samples are propagated through the cascade. Thus, the subsequent stages of the proposed cascade receive both negatives and positives from previous ones, relying on a decision margin process. Experiments were conducted in off-line mode, for a set of single component classifiers and for the proposed cascade technique. The results are compared in terms of classification performance metrics and ROC curves. [C3487]

#### **"Communicating Driver Intent: A Layered Architecture for Cooperative Active Safety Applications"**

The great promise of vehicle to vehicle communications includes a reduction or even elimination of collisions and fatalities on roadways, especially of those due to driver error. A major roadblock to the effectiveness of these systems is the market penetration of cooperative Driver Assistance Systems. Many proposed and existing implementations of cooperative systems are only effective if a majority of vehicles are capable of cooperating. We propose the use of a Layered Architecture for Cooperative Active Safety Applications (LACASA) that includes

driver behavior or intent prediction as a fundamental building block for cooperative assistance systems. Simulation results show how such information could improve safety even in limited-deployment scenarios, and in wide-scale deployment, unsafe maneuvers are nearly eliminated. [C3488]

#### "Design and implementation of an OS-CFAR processor based on a new rank order filtering algorithm"

A novel rank order statistic calculation algorithm for OS CFAR is presented. OS CFAR gives improved performance in a multitarget environment as compared to CA CFAR. However, the computational requirements of sorting data arrays complicate its implementation. We present an algorithm to overcome this challenge by employing a rank order statistic finding algorithm coupled with the exploitation of parallelism offered by FPGAs. In this technique previously computed results are used to successively divide the data array in order to find the new rank order value. The design is tested on MTI processed data from a TA-10K air traffic control radar and is part of a single chip FPGA based radar signal processor. It is implemented on a Virtex-4SX35 FPGA using the Xilinx XtremeDSP kit. [C3489]

#### "A quantitative assessment of the compatibility of Ultra Wideband with radiolocation services"

In this coexistence study, the effect of an Ultra Wideband (UWB) MB-OFDM signal, as defined in the ECMA-368 standard, on an S-band radar device working in the 3.1 GHz to 3.4 GHz range is investigated. An extensive series of 6460 measurements, done with 20 different radar waveforms and for various radar and UWB signal levels is analyzed, using a laboratory test bed specifically designed for this purpose. The interfered radar signal is acquired by a spectrum analyzer and then processed on a stand-alone PC. Different post-processing techniques are applied, depending on the type of the selected radar receiver structure. [C3490]

#### "Layered Media Q Estimation for GPR signal processing using the frequency shift method"

Layered media attenuation algorithm using constant Q model for ground penetrating radar (GPR) signals processing is introduced in the paper. We can use different Q value to describe different layered media. Over the bandwidth of a GPR wavelet, the attenuation of electromagnetic waves in many geological materials is approximately linear with frequency. As a result, the change in shape of a radar pulse as it propagates through these materials can be well described using one parameter, Q, related to the slope of the linear region. Under the assumption of a frequency-independent Q model, we present a method for the estimation of layered media Q from GPR data based on a technique developed for seismic attenuation tomography using the frequency shift method, Q is computed from the downshift in the dominant frequency of the GPR signal with time. And the downshift is obtained by using the generalized S-transform. Tests on synthetic vertical radar profiling (VRP) data indicate that this method can be very effective at estimating layered media Q value of GPR signals. [C3491]

#### "Implementation of high performance signal processing system to generate spaceborne SAR imagery products"

To produce different levels of spaceborne SAR imagery product, a real-time/near real-time signal processing system is discussed. Based on analysis of optimization of SAR signal processing algorithm, especially in CS imaging and normal geometric correction for level 1-2 product, the implementation of these algorithms on specific hardware is elaborated. The structure and design of the entire system provide great flexibility and high performance. Finally, some experiments and tests have been carried out to verify the feasibility of the system in high-resolution SAR signal processing. [C3492]

#### "SAR image data compression based on contrast modulation and warped wavelet Markov modeling"

SAR image compression is very important in reducing the cost of data storage and transmission in relatively slow channels. In this paper, we propose a compression scheme driven by sharpness and contrast, rich texture information included in SAR images and speckle noise reduction within the wavelet framework. Firstly, we modulate and enhance the contrast of the original data in different scales using contrast pyramid, and then we use warped wavelet transform to capture geometric features of different scales. Finally Markov models are used to quantify how well a particular arrangement of wavelets fits our notion of edge structure. Compression performance is evaluated through subjective inspection, as well as objective performance measurements. Results clearly demonstrate the superiority of this new approach when compared to conventional SPIHT and JPEG systems. [C3493]

#### "The character inversion of the mid-course missile based on the sphere-ellipse model"

This paper is for the identification from the RCS sequence of the mid-course missile. On the base of analyzing its motion and electromagnetic scattering characteristic, a new method using RCS magnitude changes with respect to the object gesture angle for extracting the mid-course object's two-dimensional length is presented. Comparing with the traditional method, the new method overcomes the disadvantage of the necessity for the maximal and minimal RCS value of the object. The experiment results tested by the simulated and anechoic chamber data of the representative missile object show the effectiveness of the method. [C3494]

#### **"A modeling method of radar seeker in the presence of electronic warfare"**

Due to the requirements of evaluating the performance of the radar seeker in the combat conditions or in the presence of electronic warfare, this paper gives a design of A Sensitive and Generalization Modeling of The Radar Seeker simulation system, and describes its Modularization, Parameterization, Interface support, Sensitivity Analysis Support design method, a pulse Doppler radar seeker based simulation system which is designed according to the method is given in details, the working flow of the simulation system and conclusions are given at last. [C3495]

#### **"Analysis and improvement for Proportional Conflict Redistribution rules"**

The Proportional Conflict Redistribution (PCR) rules based on Dezert-Smarandache theory (DSmT) is a useful method for dealing with uncertainty problems. It is more efficient in combining conflicting evidence. Therefore, it has been successfully applied in identity identification. However, there exist shortcomings in PCR rule. So in this paper we propose a new improved rule which is based on new Proportional Conflict Redistribution. The six PCR rules (PCR1-PCR6) and improved PCR rule are analyzed and compared through numerical examples, and the results show that the improved rule is effective. [C3496]

#### **"Design and realization of a radar simulation system base on CPCI bus"**

In this paper, design and implementation of a radar signal simulation system is introduced. It is based on standard CPCI bus and follow the design principle of standardized, modular and extendable in design process. This system is made up of standard hardware and the simulated waveform can be obtained from any algorithms. This system is flexible to extend based on complexity of the algorithms. [C3497]

#### **"Doppler estimation and data detection for underwater acoustic ZF-OFDM receiver"**

A new scheme for Doppler estimation and data detection for OFDM underwater acoustic communications is derived in this paper. We design the OFDM symbol as a concatenation of two sub-blocks. The first one is shorter and carries out few data with few subcarriers whereas the second one contains both informative and pilot symbols. The first sub-block serves to estimate the Doppler scaling factor while the pilots in the second sub-block are used for estimating the equivalent channel. Both estimation approaches are based on high resolution methods for solving harmonic retrieval problems in time and frequency domains respectively. Each sub-block contains a cyclic suffix, which allows having more data to be processed. The effectiveness of the proposed scheme is evaluated by means of simulation results. [C3498]

#### **"Advances in vegetation management for power line corridor monitoring using aerial remote sensing techniques"**

This paper presents a comprehensive discussion of vegetation management approaches in power line corridors based on aerial remote sensing techniques. We address three issues 1) strategies for risk management in power line corridors, 2) selection of suitable platforms and sensor suite for data collection and 3) the progress in automated data processing techniques for vegetation management. We present initial results from a series of experiments and, challenges and lessons learnt from our project. [C3499]

#### **"Over head line real-time tracking for automatic inspection or user interface enhancement"**

Power line maintenance inspection builds around real time signal processing and mobile robotics techniques. The authors show how to take advantage of hardware and software dedicated to inspection to improve the process. Hardware solutions are first developed on the ground and later transferred to airborne systems when airworthiness compliance is verified. Over-head line tracking is based on a two stage procedure: a coarse LiDAR tracking followed by a refined video tracking. Automatic tracking allows for surveys to be carried autonomously while inspectors focus on higher level issues. Real time is essential to assist the airborne inspection crew and to improve safety. Investigation of helicopter accidents directed the research towards practical tools that minimise inspection risk. Also, real time is an effective feature to build confidence in the robotics system, improve human efficiency and reciprocally, to improve the robotics with human know-how. [C3500]

### "Micro-Doppler extraction from ballistic missile radar returns using time-frequency analysis"

The spinning motion of a ballistic missile (BM) induces periodic frequency modulations on the returned radar signal. This micro-Doppler modulation frequency is a stable and unique parameter in radar target recognition. This paper first establishes the radar signal model of the spinning missile during flight, and then extracts the micro-Doppler modulation frequency through analysis of the periodic structure of the resulting spectrogram (short time Fourier Transform (STFT))-i.e., the time-frequency distribution (TFD). In order to be used for BM target recognition we implemented a data-dependent optimal window length for the STFT. We treated the resultant TFD as an image and then used the 2-D DFT/FFT for feature extraction. Experimental results illustrate the validity of the proposed method. [C3501]

### "An inverting method of moisture constant for huge grain pile based on distribution of dielectric constant"

Aiming at the detection of moisture content of grain pile, we proposed a scheme in which Ground Penetrating Radar is applied in this paper. The method proposed is that we used a permittivity-moisture model to calculate moisture content indirectly by measuring the distribution of dielectric constant in grain pile. The precise detection is discussed in this paper under the condition of extensiveness and the calculation algorithm of dielectric constant is provided by using layer inverting method based on reflection law and refraction law. In addition, we used well logging method to obtain precise detection results to infer the accurate calibration coefficient required in layer inverting method. By this way, a higher precision can be obtained by the method. At the same time, we proposed a model named permittivity-moisture from nonlinear model of dielectric constant of mixed media. The experiment results indicate that, compared to sampling method, the calculating results of moisture content from the method has less error by combining the layer inverting algorithm and permittivity-moisture model and can meet the requires of application well. Thus can provide a convenient and practical method to the detection of huge grain pile. [C3502]

### "A research of stored grain moisture content detection based on ground penetrating radar detection technology"

The amount of moisture in stored grain is an important factor which affects food safety. Therefore, a timely and accurate detection of the moisture content in stored grain is of great importance. Electromagnetic wave has a strong trait of penetrating, which is able to detect the moisture content of grain inside the heap in the case of non-destructive. This paper mainly takes the research of grain moisture permittivity and its mathematical model which is based on the ground penetrating radar electromagnetic wave technology. It introduces the radar electromagnetic wave theory, construction of granary system's forward model, and the mathematical models of grain moisture permittivity. Through analyzing the results of the continuous section-scan measurement, we get the speed of electromagnetic waves. Then combining grain moisture-dielectric model, we calculate the dielectric constant of grain moisture. Further, we can get grain moisture content through the calculated dielectric constant. Under the guidance of the theory, we carry a field test, collect and analyze the results. It shows that the radar electromagnetic wave measurement of grain moisture is feasible and effective. [C3503]

### "Development of a test-cradle for the p-i-n diode phaseshifters"

Discrete phase-shifters are widely used in modern radars with phased-array antennas. So fast and exact measurement of phase-shifter parameters is important part of their production process. In the paper a design and parameters of the test-cradle for discrete p-i-n diode X-band phase-shifters are described. [C3504]

### "Fuzzy fusion approach for hospital illness tracking"

In multi-target hospital illness tracking, for data fusion, data with noise as input must be sent to fusion center to be filtered, associated, combined and made final decision as output. In this paper, an efficient fuzzy fusion approach for hospital illness tracking is proposed. The proposed approach is developed based on the fuzzy clustering means algorithm, which differs from many other fuzzy logic data fusion algorithms. Performance evaluation and results using simulations are reported, and a comparison with other fuzzy logic approaches based on the results described in other reference is also shown. The efficiency of the new approach has been demonstrated by the fuzzy system performance evaluation. [C3505]

### "Simulation research of microwave automatic clutter-cancellation in life-detection radar"

Clutter signal can bring interference to life-detection radar and reduce accuracy of recognition. This research attempts to resolve the problem in clutter jamming by simulation experiment. The automatic clutter-cancellation

model is established according to theories and experiments are simulated on computer. The result suggests that the variation of auto-cancellation signal is not correlative with time and precision of the cancellation but amplitude and phase of the clutter signal. The result has instructive significance for the design of digital auto-cancellation circuit in life-detection radar. [C3506]

### "Study on adopting optimum binary phase serial to enhance SNR and Penetrating of Ultrasonic Images"

This paper present adopting optimum binary phase serial to enhance signal to noise ratio and Penetrating of Ultrasonic Images. It combine the advanced theory of radar, spread spectrum communication theory and technique of pulse reflection ultrasound imaging. It completely expatiates the feasibility of coded pulse compression technique applied to medical ultrasound system. Since the signal to clutter ratio (SCR) couldn't meet the requirement of medical ultrasound imaging when adopting self-correlation decoding for optimum binary phase serial, this paper presents the CSIFIR(codes spectrum inverse filter) decoding filter and practical and efficient solutions based on the least mean square. The results show the validity of theories and the efficiency of the methods. [C3507]

### "Microwave and millimeter wave nondestructive measurement in biomedical engineering"

Recent microwave and millimeter wave nondestructive measurement in biomedical engineering are reviewed. Millimeter wave reflection from the human skin was studied in the frequency range of 37-74 GHz in steps of 1 GHz. The forearm and palm data were used to model the skin with thin and thick stratum corneum (SC), respectively. To fit the reflection data, a homogeneous unilayer and three multilayer skin models were tested. A novel in vitro test of blood analysis based on the measurement of the dielectric properties at microwave frequencies is reported. The measurements were made using rectangular cavity perturbation technique at the S-band of microwave frequency with the different samples of blood obtained from healthy donors as well as from patients. The measurements are in good agreement with clinical analysis. Noncontact measurement of heart rate variability using a compact 24 GHz microwave radar is developed, without large scale equipment and placing a heavy burden on the monitored individual. This method appears to be promising for future monitoring of stress induced autonomic activation of operators and may reduce stress induced accidents. Finally the technical challenges of microwave and millimeter wave nondestructive measurement in biomedical engineering are discussed. [C3508]

### "Deterministic propagation modeling for joint radar and communication systems"

In this paper investigations on the performances of joint radar and communication systems in realistic traffic scenarios are presented. This is achieved by combining dedicated MatLab models for transmitter and receiver with a deterministic propagation simulator based on ray-tracing. Two different approaches towards a joint implementation of radar and communications with one common transmit signal are regarded. In the simulations in particular the direction of arrival estimation with the reflected signal has been investigated for different waveforms and beam-forming algorithms. [C3509]

### "Security-related active imaging of dielectric objects attached to human bodies"

In the last years, several approaches for the detection of concealed threats at the body of a person have been developed using millimetre-waves. The utilisation of millimetre-waves allows for the detection of both metallic and non-metallic objects. Setups using active illumination mainly exploit coherence between transmitted and received signal to perform beamforming or processing along a synthetic aperture. When dielectric objects should be detected, the assumptions done in these processing steps are often no longer given. The same applies for objects that are placed in front of a reflecting background like the human skin. The effects that can occur for these conditions are discussed in this paper. [C3510]

### "Polarimetric through-the-wall imaging"

A novel full polarimetric beamforming algorithm for Through-the-wall imaging (TWI) is proposed in this paper. The far field layered medium Green's functions are incorporated in the beamformer for the quad-polarizations (VV, HV, VH and HH). Due to the incorporation of the layered medium Green's function, the imaging algorithm not only takes into account the wall reflection, bending, and delay effects but also accounts for the complex EM scattering mechanism due to the presence of the wall. By employing the Green's functions, the solving of a nonlinear equation, needed to find the wave propagation path, is avoided. Similar method can also be generalized to multilayered composite walls such as a hollow-core concrete wall. Simulation results show that the proposed method can provide high quality focused images for TWI applications. [C3511]

### **"New proposal for eliminating interferences in a radar system. Lobes at 45.5° and 24°"**

In this work we present a new proposal to initialize the weights in a Backpropagation Neuronal Network using the coefficients from a FIR Low-Pass Filter, to introduce a null in the radiation pattern in a seven- element array of antennas to eliminate interferences in a radar system. A radar system needs to eliminate the directional noise in order to obtain a cleaner signal. The method used to eliminate this kind of noise (jitter) has to be adaptive because the objective is in constant movement, therefore, the adaptation time must be as fast as possible. Our work is based on the window method to reduce the secondary lobes in fixed arrays of antennas. We modify the radiation pattern by introducing a null at 45.5° which corresponds to the secondary lobe where the interference is presented. This is achieved when we create windows from several FIR Low-Pass Filters. The coefficients of these filters are used to initialize the weight vectors of a Backpropagation Neural Network which performs the adaptive process to obtain the final parameters to achieve the noise elimination. For testing our proposal we calculate the Mean Square Error (MSE), the Signal Noise Relation (SNR) and we graphed the Radiation Pattern. In addition we calculated the Cross Correlation Index, in each iteration, between the desired signal and our results. With this method we reduced the number of iterations required by the process. [C3512]

### **"A human-automation interaction approach to the evaluation of resource allocation strategies in adaptive distributed sensor networks"**

How to design and to evaluate adaptive distributed sensor networks with respect to end user decision making is an important topic in human-automation interaction. This study evaluates four resource allocation strategies (static automation, adaptive sensing, mixed-initiative control, and control incorporating end user task analytic information) in a simulated prototype weather sensor network. Performance of each sensor network resource allocation strategy was assessed with measures of sensor coverage quality over a target geographic region of interest. Coverage measures calculated from the number of radar nodes, tilts and cycles were derived for partial (radar scan touches at least part of the analysis region) and complete coverage of the region by single and multiple (two or more) radars. Single and multi-radar coverage area scores were also derived from the cumulative fraction of the analysis regions area that was scanned. Using three weather scenarios, results show that static automation significantly outperforms the other strategies in all cases using measures of single and multi-radar complete coverage and for a uniformly distributed weather event using single and multi-radar coverage scores. Otherwise the three strategies outperform static automation. As the performance of resource allocation strategies are sensitive to the weather events themselves as well as the measures used to evaluate them, the design of next generation of algorithms should consider these performance distinctions. [C3513]

### **"Collision avoidance in a recursive nested behaviour control structure for Unmanned Aerial Vehicles"**

In this paper, the collision avoidance behaviour in a recursive nested behaviour control structure for Unmanned Aerial Vehicles will be discussed. The architecture is an extension of the behaviour-based recursive control structure, which has been applied successfully to mobile robot applications. The system structure, as an abstraction of multiple cascaded control loops with feedback mechanisms, is robust against disturbances and model uncertainties. The obstacle awareness and collision avoidance are considered to be the most important issues in the field of Unmanned Aerial Vehicles (UAV), thus more attention will be paid to this topic. The collision avoidance utilizes a potential field method tailored for UAV application domain. The formulation of a repulsion forces based on radar sensor measurement is presented. The implementation of the collision avoidance system is also described. [C3514]

### **"Research on the effect of electromagnetic radiation of 220KV power transmission and transformation project on marine radar"**

Taking cross-sea and cross-river 220 KV power transmission and transformation project as the research object, and through field observation and theoretical analysis, mathematical model of power frequency electric field of EHV (extra-high voltage) overhead transmission lines is established. This paper presents the calculation method of electric field intensity around the transmission lines, and analyzes the effect of electromagnetic radiation on radar reflection and the characteristics of radar echo. Finally, according to the research results, measures and suggestions on correct operation and use of marine radar are put forward. [C3515]

### **"A tutorial for applying DMOC to solve optimization control problems"**

This paper presents a detailed procedure to apply newly-proposed DMOC (Discrete Mechanics and Optimal Control) methodology to solve optimal control problems. DMOC is based on a direct discretization of Lagrange-d'Alembert principle for a system. First, this tutorial explains the principle of DMOC, and how to formulate the

problem in DMOC. Next the steps are shown about how to install and configure nonlinear programming solver IPOPT, and how to use the modeling language AMPL. In particular, the user-defined function is involved with AMPL to solve a more complicated problem. Furthermore, a glider example is provided in this tutorial to solve optimal control problem with the user-defined 2D time-varying B-spline ocean current model. The ocean current original data was collected by HF-Radar stations located around Monterey Bay, CA in August 2000. Practically, this tutorial is shown how to use DMOC to solve optimal control problems with IPOPT and AMPL as the components. The possible users are robotic researchers, control system engineers, operations management researchers, and so on. [C3516]

#### "Automatic monitoring and speed violation ticket system"

An automatic speed violation control system is proposed to warn the driver and using SMS communication for transmitting the speed and the unique information of the vehicle to the police station when a speed violation ticket to be issued. The system notifies a driver of certain control details in real time and prevents vehicle violation in advance via warning messages when the vehicle exceeds a safe speed zone, thus eliminating the manpower needed to use radars to check the speed of the cars or examine photographs of speeding vehicles taken by fixed cameras. [C3517]

#### "A random finite set based detection and tracking using 3D LIDAR in dynamic environments"

In this paper we describe a fully integrated system for detecting and tracking pedestrians in a dynamic urban environment. The system can reliably detect and track pedestrians to a range of 100 m in highly cluttered environments. The system uses a highly accurate 3D LIDAR from Velodyne to segment the scene into regions of interest or blobs, from which the pedestrians are determined. The pedestrians are then tracked using probability hypothesis density (PHD) filter which is based on random finite set theoretic framework. In contrast to classical approaches, this random finite set framework does not require any explicit data associations. The PHD filter is implemented using a Gaussian Mixture technique. Experimental results obtained in dynamic urban settings demonstrate the efficacy and tracking performance of the proposed approach. [C3518]

#### "Hybrid SVM-GPs learning for modeling of mitogen-activated protein kinases systems with noise"

In this paper, the hybrid support vector machines (SVM) and Gaussian process (GPs) are proposed to modeling of mitogen-activated protein kinases systems with noise. In the proposed approach, there are two-stage strategies. In stage 1, the support vector machine regression (SVMR) approach is used to filter out the some larger data set in the mitogen-activated protein kinases systems data set with noise. Because of the larger noise data in the training data set are almost removed, the large noise data's effects are reduce, so the concepts of robust statistic theory are not used to reduce the large noise data's effects. The rest of the training data set after stage 1 is directly used to training the Gaussian process for regression (GPR) in stage 2. According to the simulation results, the performance of the proposed approach is superior to the least squares support vector machines for regression, and GPR when the noise is existed in the mitogen-activated protein kinases systems. [C3519]

#### "SAR Autofocus Using Wiener Deconvolution"

This paper proposes a new approach to synthetic aperture radar (SAR) autofocus. The proposed metric-based autofocus algorithm is based on the Wiener deconvolution filter, which has the advantage of the phase error compensation as well as noise suppression. The sharpness metrics are used to measure the degree of the focus of the SAR image. To compare the performance of the metric-based SAR autofocus, we also present a detailed analysis of different sharpness metrics. Then, a guide about the optimal sharpness metric in various SAR scenes is presented. The simulation results with the real data demonstrate that the proposed algorithm has better restoration capability in comparison with conventional minimum-entropy algorithm. [C3520]

#### "Angle Estimation for Bi-static MIMO Radar Based on Tri-iterative Algorithm"

The Bi-static MIMO (multiple-input multiple-output) radar signal modal is established in this paper. And the proper coefficient of the MF (matcher filter) is chosen in order to keep the noise output has the same statistical property as the noise input. To make the computational complexity lower and the convergence speed faster, the signal subspace is used as a dimension-reducing matrix. A novel cost function is proposed based on the LS (least squares), which is solved by using the Tri-Iterative Algorithm. Afterwards, a unique closed solution in each iteration which is posed a typical least square problem is derived and the receiving and the transmitting angles are estimated for bi-static MIMO radar. It is worth mentioning that the estimated angles can be paired automatically. Finally, Simulation results are presented to verify the effectiveness of the proposed method. [C3521]

### "Study on the Time-Frequency Two Dimensional CFAR Algorithm for Moving Targets on Ground in PRC-CW Radar"

PRC-CW radar is mainly used to detect moving targets on ground. Ground clutter heaves fiercely, and its distribution is complex, which makes it difficult to detect targets correctly from time domain. The characteristics of moving targets and ground clutter differ in frequency domain. And the spectrum of targets may change with time, so, this paper designs the time-frequency two dimensional constant false alarm rate(CFAR) algorithm. Based on the analyze of pulse compression and moving targets detection(MTD) of this type radar, the two-dimensional CFAR algorithm is proved to be feasible via simulation. The results of simulation show that, the algorithm can measure the velocity and range of targets correctly. The clutter and noise are also restrained effectively. [C3522]

### "Linearly Constrained Coherent Sidelobe Canceller for Ionosphere Interference Suppression for HFSWR"

In this paper, a linearly constrained coherent sidelobe canceller for high frequency surface wave radar is presented to improve the interference cancellation performance. To overcome the target-canceling problem of traditional coherent sidelobe cancellation algorithm, a linear constrain is applied to the adaptive weight vector of auxiliary array in order to keep this adaptive weight vector within a subspace that is orthogonal to the main beam, so the target echoes in the main beam are well preserved. Measured data from real high frequency surface wave radar system is used to compare the performance of the new algorithm and the traditional one, and the results show that the new algorithm is clearly superior to the traditional algorithm. [C3523]

### "A Detector of DTTB Based Passive Radar Using FRFT and Hough Transform"

Detecting weak moving targets is an important task for digital television terrestrial broadcasting (DTTB) based passive radar. The cross ambiguity function (CAF) suffers from the range and Doppler frequency migrations caused by the velocity and acceleration of the targets. The integration gain can't increase anymore. A new detector is proposed for this problem. In this detector, the fractional Fourier transform (FRFT) is used to compensate the Doppler frequency migration, and the Hough transform is utilized to accumulate the echo of the moving targets during the long integration time. The block diagram and the procedure of this detector are given. Simulation results show that the proposed method can detect weak moving targets effectively. [C3524]

### "Two Methods for Constructing the Difference Set Pairs"

In this paper, by using the nature of Cyclotomic class, presents two new methods for constructing Different Set Pairs. The methods are based on the Cyclotomic class, and different Cyclotomic class could construct Different Set Pairs of Different parameters. New tools for using Different Set Pairs to construct Perfect discrete signal are provided. [C3525]

### "Study on the Method for Radar Signal Receiver Channel Modeling"

A modeling method for radar signal receiver channel is proposed under the situation that part of the mechanism is unknown. Firstly, the traditional identification methods including Levy least square, pulse response and frequency-domain multiply are analyzed. The experiments show that those methods are hard to get the accurate model of high order radar signal receiver channel. Then, a method of time-domain convolution numerical model using frequency response data is proposed. The simulation and experiment shows that the method is implemented easily and applied widely. It improves the efficiency and precision of system simulation and can be applied to other high order system. [C3526]

### "Information selection based on fuzzy comprehensive evaluation"

Under the modern information-based operational environment, the interface receives and processes more and more information, so organizing and selecting operational information in different combat missions are becoming more significant. Based on this background conditions, this paper sets up information selection evaluation index system, confirms the evaluation index weight by using analytic hierarchy process (AHP), and applies fuzzy comprehensive evaluation method to evaluate the importance degree of all operational information in various operational tasks. Finally, according to the importance degree of information in different operational missions, operational information is displayed on interface in reasonable way. [C3527]

### "Recent theoretical and experimental advances in electromagnetic sensing of subsurface profiles"

We present an overview of recent developments in subsurface image formation using iterative profile inversion

and focusing using concepts of tomography and SAR signal processing. Electromagnetic forward and inverse scattering techniques are presented, along with the subsequent focusing techniques. Experimental and simulation results are presented. [C3528]

#### "Large scale underwater FDTD ELF simulations using Acceleware and MPI parallel processing"

Very large FDTD simulations are being developed to determine the underwater propagation of EM signals at ELF frequencies. Two different approaches are being used to handle the large computation spaces, the use of hardware and software by Acceleware, and the use of the Message Passing Interface (MPI) for parallelization. [C3529]

#### "Characterization of layered media using full-waveform inversion of proximal GPR data"

Full-waveform inversion of proximal ground penetrating radar (GPR) data is used to determine the electromagnetic properties of layered media. The radar system consists of a vector network analyzer combined with an off-ground horn antenna operating at ultra wideband. The GPR wave propagation is modeled for a multilayered medium using a recursive Green's function computed in the frequency domain. The antenna and its interactions with the layered medium are modeled using a linear system of complex transfer functions. GPR signals were acquired in laboratory above a two-layered sand medium and two concrete slabs separated by a thin air layer (simulating a fracture). Subsequent inversions permit to retrieve the electromagnetic properties and the dimensions of these thin-layered media. For humid sand, GPR-derived dielectric permittivities showed a good agreement (RMSE = 1.65) with measured volumetric water contents. Dimensions of the three-layered concrete medium could be retrieved with a millimetric accuracy. The method is promising for the non-destructive characterization of multilayered media, including thin layers, owing to the full-waveform inversion of the radar data in a large frequency bandwidth. [C3530]

#### "SIMO-based approach for subsurface sensing"

In this paper, application of near-field digital beamforming for shallow subsurface imaging is described. The main novelty of the approach is SIMO topology of the sensing (single transmit-multiple receive antennas). Dedicated antenna systems and imaging algorithms have been developed in order to take maximal advantages from the SIMO data acquisition. Verification of the approach has been done by development of a radar system for landmine detection. Field tests have demonstrated reliable detection of antipersonnel mines by scanning velocity of 10m/s. [C3531]

#### "An evaluation method of anti-jamming performance to receiver based on sample entropy"

Aiming to make a quick and right evaluation of the anti-jamming performance to receiver, an evaluation method is put forward, in which the sample entropy (SampEn) values of input and output sequences of receiver are evaluation indexes. The analysis of simulation signals' SampEn validates the rationality of SampEn substituting for Signal to Noise Ratio (SNR), because SampEn does not change with the change of signal's amplitude, and monotonically decreases as SNR increases when SNR is in certain range. The evaluation method is able to solve the problem that the SNR gain is difficult to compute, because of the uncertain relation of signal and noise and the distortion in the receiver process. The method can also avoid the huge statistical computing, which achieves the purpose that the receiver's anti-jamming performance is evaluated only by input and output sequences, without any other conditions. Lastly, an experiment validates the feasibility and effectivity of the proposed evaluation method. [C3532]

#### "Information fusion of integrated navigation based on self-adaptive filter"

In order to realize high accuracy and excellent reliability of navigation system, information fusion technology of integrated navigation based on self-adaptive filter is researched in this paper. Inertial navigation system (INS), global navigation satellite system (GNSS), synthetic aperture radar (SAR) and barometric altimeter (BA) are taken to construct INS/GNSS/SAR/BA integrated navigation system. INS is regarded as the primary navigation equipment, and other systems are aided navigation equipments. Firstly, errors of INS, GNSS, SAR and BA are modeled and chosen as system states of integrated navigation. Based on self-adaptive filter algorithm, output information of INS and GNSS are fused in INS/GNSS integrated navigation filter, and output information of INS, SAR and BA are fused in INS/SAR/BA integrated navigation filter. Then the federated filter frame is designed, and estimations of system states from INS/GNSS and INS/SAR/BA local filters are fused once more in the master filter independently. Consequently global optimal estimations of system states are given by the master filter, which are used to correct errors of INS. Simulation results show that, position accuracy of INS/GNSS/SAR/BA integrated navigation reaches  $\pm 11.6\text{m}$ , attitude accuracy reaches  $\pm 0.52'$ , velocity accuracy reaches  $\pm 0.14\text{m/s}$ , and its reliability is very excellent when noise statistics characteristics of some navigation

equipment are variational in the navigation process. [C3533]

#### "Safety issues and damage to equipment with both Smart Grid and home network connections"

Equipment getting power from the Smart Grid often has connections to the home network, a configuration which during a lightning storm is prone to safety issues and damage. Lightning can occur as direct strikes to a service, or as nearby strikes which induce currents in a service. Protection against these events is important, and existing standards deal with these. But there is a situation that existing standards have not considered, and it can result in a shock hazard and equipment failure. This potential failure is caused by Ground Potential Rise (GPR), in a site which has two or more ground references; for example AC power grounded at the service entrance at one side of a house, and a phone line grounded via a surge protector at the opposite side. The GPR produces a voltage gradient between the two ground references. This high voltage is a potential shock hazard. It can also cause a breach of basic or enhanced insulation, with damage and potential exposure to hazardous voltages resulting. This paper discusses GPRs; how to test an equipment to see if a GPR will cause a problem; and what to do if it does. [C3534]

#### "Design of sewage flow remote monitoring system over GPRS network"

In this paper, a new sewage flow remote monitoring system over General Packet Radio Service (GPRS) is presented, which monitors the sewage flow parameter remotely in real time. In the proposed system, GPRS network is adopted as the wireless sensor network, and the data between the slave computer and the remote terminal are transmitted via the GPRS and Internet networks. Finally in the remote terminal, the Winsock control of Visual Basic 6.0 is responsible for displaying, storing and analyzing the data of the sewage flow. The system is easy to implement and has a high degree of automation, by which the acquisition, transmission and processing of the sewage flow data can be achieved in wireless, networked and intelligent manners. [C3535]

#### "Improvement of image resolution in ScanSAR simulation"

For spaceborne ScanSAR system, the wide swath is the advantage whereas it induce some problems. In this thesis the importance of accurate geometry model for ScanSAR simulation is fully analyzed. A SAR geometry model based on valid coordinate systems is proposed. It provides actual phase history and echo not only for ScanSAR but also traditional SAR system. The simulation shows that it is effective and practical. [C3536]

#### "Water objects extraction from polarimetric SAR imagery based on blind source separation and morphological reconstruction"

The SOMMR nonlinear blind source separation (BSS) method is proposed for speckle noise suppression and water objects extracting from synthetic aperture radar (SAR) imagery based on self-organizing maps (SOM) neural networks and morphological reconstruction (MR). The multiplicative speckle noise and image data are separated from multipolarimetric imagery by means of SOM neural networks. Morphological reconstruction is employed to remove the residual noise. The experimental results using ENVISAT ASAR polarimetric imagery show that the proposed method can extract water objects accurately, and the speckle noise index is better than ICA and SOM method. [C3537]

#### "Infrared object tracking based on particle filter"

A novel infrared moving object tracking method based on particle filter and mean shift algorithm is presented in this paper. Based on the framework of particle filter, the mean shift algorithm is introduced as better proposal distribution to improve the sampling efficiency. Compared to conventional particle filter, the proposed method uses much fewer particles to maintain the multi-mode distribution, and overcomes the degeneration problem effectively. Experimental results on sequential images show that our method can track steadily when the object move fast or be occluded, the overall performance of the proposed method is better than traditional particle filter algorithm. [C3538]

#### "The target detection for GPR images based on curve fitting"

Due to the complexity of the medium composition, physical characteristics and the spreading of electromagnetic waves, the extraction and automatic target detection of the Ground-penetrating Radar (GPR) is extremely complicated and has become an important issue in the practical application of GPR. In this paper, a method based on curve fitting is proposed by using the hyperbolic echo characteristics. The edge lines of GPR images firstly obtained by using image preprocessing methods and hyperbolas are fitted to approximate the edges. Finally, hyperbolic echo apex positions in the GPR images are extracted and marked on their apexes. The experimental results show that all targets are detected correctly. [C3539]

### "Target detection algorithm for spatial diversity MIMO radar with space partition"

For spatial diversity multiple input multiple output (MIMO) radar, target echo signals received by its widely separated antennas may be semi-correlated and different in SNR. According to the correlation and SNRs of received target echo signals, a space partition based target detection method is proposed, which partitions the surveillance volume into two sections, one using the coherent accumulating detector and the other using the incoherent accumulating detector. The partition method is shown to achieve an improved detection performance at a low computation cost. [C3540]

### "A model based bias field correction algorithm for SAR sea ice image"

A novel algorithm using multi-exponential model is presented in this paper for correcting the intensity bias field, produced by the variation of SAR incidence angle along SAR range direction, in SAR sea ice image. In the algorithm, the image's mean values along SAR azimuth direction are calculated firstly. Then a one-dimensional correction field is modeled by a multi-exponential model. Whereafter, the one-dimensional correction field is calculated by applying entropy minimization method. After that the original image is corrected by the two-dimensional correction field derived from the one-dimensional correction field. The experiment result indicates that the proposed algorithm is effective in correcting SAR sea ice image's incidence angle bias field. Besides, the proposed algorithm has better correction result than Karvonen's method and it does not need the incidence angle information of the image pixels. [C3541]

### "CFAR and KPCA for SAR image target detection"

A SAR target detection model based on CFAR and KPCA is presented in this paper. This Detection is divided into a pre-screening and discrimination process. Within the large-scale and low-resolution SAR imagery, pre-screening adopts classic CFAR techniques, while the discrimination process adopts kernel principal component analysis to separate the target from clutter. Experimental results show that the detection performance of our algorithm appears to be superior to the classic CFAR methodology. The combination of both pre-screening and prior knowledge of targets can effectively enhance detection rate and inhibit false alarm at the same time. [C3542]

### "Improved denoising method of SAR image"

The reduction of speckle in SAR image is necessary for processing of SAR image such as feature detection and extraction. In Contourlet transform, a drawback of Laplacian pyramid (LP) is implicit oversampling and non-orthogonal decomposition, Wavelet transform is a critically sampled scheme but it only generated three direction. Taking advantage of Wavelet and Contourlet, the proposed method is complemented by Wavelet transform in conjunction with directional filter banks. First, the proposed method derived Wavelet coefficients of entry image by Wavelet transform, then reconstruction the image only by lowpass coefficients and after processing it can derive a highpass subbands. The proposed method keeps critical sampling and it is convenient for direction filter banks partitioning the highpass subbands. The results show that the proposed method can eliminate the noise, keep edge information effectively and also avoid artifacts over Wavelet and Contourlet transform. [C3543]

### "Realization of high data rate DUC based on FPGA"

This paper discusses the issues on "how to save multiplier resource" and "how to cope with high data rate", when implementing Digital Up Converter (DUC) with Field Programmable Gate Array (FPGA). A novel implementation structure of poly-phase interpolation filter is proposed, which could reduce the consumption of multiplier by half. Parallel processing is adopted in designing Numerical Controlled Oscillator (NCO), which could generate high data rate LO required. By following these methods, a DUC module is designed for certain radar IF echo simulator, which could generate digital IF signal with data rate up to 1.2Gsps. [C3544]

### "Signal analysis of downward-looking and forward-looking array FMCW SAR"

Downward-looking and Forward-looking (DL & FL) array Synthetic Aperture Radar (SAR) can image scene beneath and in front of the platform that can not be realized by side-looking (SL) SAR. According to curve sketch of equidistance and equi-Doppler, blind zone beneath the platform and ambiguity symmetrical to the track of SL SAR are analyzed, and DL & FL array Frequency Modulated Continuous Wave (FMCW) SAR signal model is established. By virtue of signal model, expansions of range course in different forms are applied in analyzing Doppler characteristic and Range Cell Migration (RCM). Parameters affecting cross-track resolution, such as array length, target position and platform height are analyzed combining with effective array aperture. Simulation results show optimization and effectiveness of the parameters, which can provide reference for parameter design

of array SAR. [C3545]

### "Adaptive-adaptive beamforming algorithm of planar array based on one-dimensional auxiliary beam"

To avoiding two-dimensional search for the incoming angle of jamming while constructing two-dimensional auxiliary beams, an adaptive-adaptive beamforming algorithm of planar array based on one-dimensional auxiliary beam is presented in this paper. Owing to only need to estimate one-dimensional spatial angle of jamming, computational complexity of searching for the incoming angle of jamming can be reduced greatly. Thus, the approach is fit for engineering implementation. Computer simulations demonstrate the validity finally. [C3546]

### "Automated road extraction from LiDAR data based on intensity and aerial photo"

A clustering method based on intensity data is used to extract road from LiDAR data in this paper. And the result is refined by using the spectrum information of aerial images. An experiment is performed with a group of LiDAR data in BeiJing. The results presented in this paper have shown that clustering method based on intensity could extract road in some extent, but many error points exist at the same time. When fusing the spectrum information of aerial images, the experiment result is improved obviously. Large amount of error points is removed, while the point cloud of road keep down. [C3547]

### "Despeckling SAR image using nonsubsampling directionlets combining with GSM model"

As speckle noise suppression is important for Synthetic aperture radar (SAR) images processing, this paper presents an approach for SAR image despeckling based on nonsubsampling directionlets. Firstly, images are partitioned into subbands using nonsubsampling directionlets. Then, the coefficients of subbands are modeled with Gaussian scale mixtures (GSM). Besides, for reducing the speckle noise, coefficients are estimated by Bayes least square estimation. Lastly, to evaluate the performance of this despeckling method, four performance evaluation parameters are used. Experimental results show that this method performs better in comparison with the spatial filter and standard wavelet transform not only in speckle suppression, but also in detail preservation. [C3548]

### "A general radar surface target echo simulator"

A general radar echo simulator system proposed in this paper is to satisfy the various needs of the radar signal processor testing. This simulator is based on the type of echo data playback device, the surface target echo data is pre-calculated and stored in the device at first, then according to the external timing PRI signal, echo data is read out to the device processor, on which target information is modulated and interpolation operation is made. After the DA Converter, the radar echo is created. The system is simple and easy to implement general. [C3549]

### "Classifying multisensor images by support vector machine in Chongming Dongtan"

Optical remote sensing (ORS) technology has been extensively used for the investigation of the environment and resources. Considering it is heavily constrained by the weather conditions, especially in the coastal zone, the round-the-clock SAR (Synthetic Aperture Radar) data are chosen to compensate for the shortcomings of optical data. In this paper, we will use the fusion image of ASAR and TM to identify five land cover types in Chongming Dongtan. And the SVM algorithm is adopted because of its capability to take numerous and heterogeneous parameters into account. Results have been shown that the fusion data of SAR and ORS is particularly suited to account for the rainy and cloudy weather in costal zone. And the SVM algorithm has attained a high level of classification performance with the overall accuracy 90.83%. [C3550]

### "The mechanism of Pt films to suppress the electron emission of grid in TWTs"

Pulsed grid-controlled traveling-wave tubes (TWTs) are widely used in the field of space and defense for navigation and directing of radars, aircrafts, satellites, and guided missiles. In order to attain even higher frequency and power requirements, gun designs for modern microwave tubes have utilized grids, which are very close to cathode. However, during the course of the TWTs work, electron emission substances such as Ba and BaO on the cathode can be evaporated and deposited on the counter electrode. Harmful electron emission from the grid, namely, grid emission, is very likely triggered, this in turn destroys the working condition of the controlled traveling-wave tube, making it necessary to suppress the electron emission properties of the grid. Pt films as an anti-emission material have been widely used, but little is known about its electron emission suppression characteristics and surface composition at high temperature when grids works. In our investigation, Pt films were deposited onto the surface of the molybdenum grids by ion-beam-assisted deposition (IBAD). The

mechanism for electron emission suppression of the molybdenum grid coated with Pt films is discussed. [C3551]

#### "94 GHz, CW, low-voltage gyrotron"

Gyrotron are the primary high-power source of millimeter waves. Although the application of electron cyclotron heating of fusion plasmas has been primarily responsible for the gyrotron's development, many other applications exist, including millimeter-wave ceramic sintering, high-density communications, and high-resolution radar within the atmospheric windows of 35, 94, and 140 GHz. One problem with high-frequency gyrotrons is the strong magnetic fields required to satisfy the fundamental electron cyclotron resonance condition. For example, a 35-kG magnet would ordinarily be needed to generate 94 GHz at the fundamental cyclotron frequency. However, by operating the gyrotron at the sth cyclotron harmonic, the required magnetic field can be decreased by a factor of s. To develop 94-GHz oscillator that is both compact and efficient is the objective of this work. [C3552]

#### "Application of artificial fish school algorithm in UCAV path planning"

The path planning method based on artificial fish school algorithm (AFSA) was proposed to solve unmanned combat aerial vehicle (UCAV) path planning problem under the 2-D radar threats environment. According to the path planning requirements, the threat detection and artificial fish coding method were designed in detail. Besides, the method of perceiving threats was applied for advancing the feasibility of the path. A comparison of the results was made by WPSO, CFPSO and AFSA, which showed that the method we proposed in this paper was effective. AFSA was much more suitable for solving this kind of problem. [C3553]

#### "Study on aluminate of cathode emission active substances"

Microwave tubes are used at the field of radar, electron counterwork and communication widely. The cathode is the heart of the microwave tube. The impregnated aluminate Ba-W cathode is used most widely. Along with the development of microwave technology, the high performance cathode is necessary with big current density, long life. The performance of cathode is decided by aluminate of cathode emission active substances. Forming method and sintering process are very important to the emission performance of aluminate. This paper studies the emission performance of aluminate forming method and sintering process. [C3554]

#### "Design and implementation of MMS system based on GPRS modem"

Currently MMS systems, most of them existed a lot of problems, such as code confusion, large limitations on Secondary Development, bundled editing and sending. Through studying on GPRS MODEM and mechanism of MMS receiving and sending, a design project for multimedia communication system based on GPRS modem is proposed in this paper. SMIL and NowSMS platform was adopted in the design, to ensure unified coding and receiving and sending interfaces. Also, the separation of editing and receiving and sending improves the efficiency of using the system. By using this method, the MMS system can be easily embedded into other systems. [C3555]

#### "The detection of long chirp signal with small frequency rate in low SNR"

The detection of a long linear frequency-modulated signal (LFM) with small frequency rate is studied in very low signal-noise ratio (SNR). By wigner-hough transform for each subsection of the signal, the LFM signal can collect a peak in each WHT plane. Making use of the character that and the peak moves continuously in multi-frame WHT plane is same as the moving target of a image sequence, a new detection technique combined WHT with image Processing is proposed. The technique is proved out by computer simulation of keeping good performance for this signal. [C3556]

#### "The database of radar echoes from various targets with spectral analysis"

In this paper we describe a database, noted as RadEch Database, containing radar echoes from various targets. The data has been collected in controlled test environments at the premises of Military Academy-Republic of Serbia. Our goal is to provide a balanced and comprehensive database to enable reproducible research results in the field of classification of ground moving targets (pattern recognition). A time-frequency analysis of radar echoes has been performed, in order to identify the main features of the various targets. The RadEch Database is freely available for download and we hope that our database provides researchers with a valuable tool to benchmark and improve the performance of classification algorithms. [C3557]

#### "An instances sampling approach based on cellular automata for ensemble learning"

As the instances that are difficult to classify draw more attention in ensemble learning, an instances sampling

method based on cellular automata is presented. The definition of the instance cellular and the neighbor region are researched, and the instance cellular kernel is designed for describing the cellular structure and cellular dynamics rules. The dynamics transfer rules of the cellular which are suit for instances sampling are investigated by combining the dynamics transfer rule of the cellular automata with the change rule of the instances distribution. The instances distribution is modified according to the transfer rule of cellular automata. An improvable ensemble algorithm is investigated by using of the sampling method base on cellular automata. The experiment results show that our ensemble method is more accurate than those obtained through the standard method. [C3558]

#### **"A novel multi-channel SAR-GMTI algorithm based on raw data"**

This paper presents a novel SAR-GMTI algorithm based on the range-compressed raw data. FrFT is introduced to the classical three-channel DPCA system to realize the moving target detection, parameter estimation and SAR imaging, acquiring an exact GMTI image of accelerative moving targets. As a pretreatment, Keystone transform is firstly applied to process the echoes receiving from each sub-aperture respectively in order to remove the range migration. Our scheme is available even under a clutter-rich and low SNR environment. The simulation results indicate the efficiency of the method. [C3559]

#### **"Super resolution processing of SAR images by Matching Pursuit method based on Genetic Algorithm"**

This paper adopts Genetic Algorithm in reducing the complexity of the Matching Pursuit method in super resolution of SAR images. Firstly, we introduce the attributed scattering model according to the target feature of SAR images. Secondly, we introduce the sparse representation of image based on Matching Pursuit. This sparse representation evolves into a nonlinear optimization problem, which has a huge computational burden. In this part, we also introduce the structure of the Fourier dictionary, from which we search for the atoms to decompose the images. Thirdly, we introduce Genetic Algorithm to solve the nonlinear optimization problem to get a faster computational speed. Then we apply Genetic Algorithm in searching the best atom from the Fourier dictionary for each step of Matching Pursuit. The reason is given why it is possible to get the faster speed via Genetic Algorithm by analyzing the character of Genetic Algorithm itself and its relationship with the problem theoretically. Finally, we program to realize this idea. The computational results of measured MSTAR data demonstrate that Genetic Algorithm match this problem well. Thus the Matching Pursuit method based on Genetic Algorithm is really effective and fast in SAR image super resolution. [C3560]

#### **"A novel ISAR jamming method based on randomly sinusoidal phase modulation"**

In order to jamming ISAR imaging effectively, a novel jamming method based on randomly sinusoidal phase modulation is presented in this paper. This method changes randomly the frequency of the signal of sinusoidal phase modulation in the slow time. How the jamming signal affects the range alignment of ISAR is analyzed in detail. The research result shows that the jamming method can destroy severely the range alignment of ISAR and realize the unfocused image barrage jamming to ISAR. Furthermore, the validity of the jamming method is justified by simulation experiment. [C3561]

#### **"Multiple Sub-Spaces particle filtering for multi-target tracking"**

A new multiple target tracking method based on Bayesian filtering and Sequential Monte Carlo approximating method is proposed in this paper. The key principle of the proposed method is to decompose the multiple target tracking problem into multiple single target tracking problems by allocating Sub-Spaces which are sub-sets of single-target state space to targets. The computational cost of the proposed method is remarkably reduced by avoiding jointly estimating posterior probability distribution used in many conventional multi-target tracking methods. And compared with Finite Set Statistics based methods, the proposed method is more general, moreover, it could supply high level applications with trajectory of moving targets which is not available in Finite Set Statistics based method. The proposed method is tested by tracking pedestrian in video sequence captured from real-world and the tracking result shows that all targets are well tracked in real-time while the number of targets is unknown and varies with time. [C3562]

#### **"Study on pedestrian detection and tracking with monocular vision"**

Pedestrian detection is a rapidly evolving topic in many computer vision applications such as intelligent vehicle, surveillance and advanced robotics. The pedestrian collision avoidance not only requires detection of pedestrian but also requires prediction by tracking to analyze its dynamics and behaviors. The objective of this paper is to provide a method realizing pedestrian detection and tracking based on monocular vision. The first part of the paper is to detect pedestrian from the image. Both the rectangle features and edge orientation features are

calculated by integral image techniques and Adaboost is used to fulfill discriminative features selection and classifiers training. The second part contains a pedestrian tracking method based on Kalman filtering. Experiments are performed to test and verify the pedestrian detection and tracking method under normal urban environments. The experiment results show that the method can detect and track pedestrian ahead of vehicle with different sizes and postures. [C3563]

#### "Wireless communications technologies for energy networks in a non-industrialized society"

It is of great importance to the organisational strategy of the energy utility as well as to the society at large the activities involving the utility and the energy consumer's communication activities. However, we discovered that such communication activities in the poor third world countries with poor infrastructures are wholly undeveloped. This article will propose a framework to define the strategy which can leverage on the wireless technologies usage in order for the usefulness, efficiency and effective utilization of energy resources which are supplied by a particular electric utility could be further enhanced. [C3564]

#### "Application of the deconvolution method in the processing of Full-waveform Lidar data"

Full-Waveform Lidar (light detection and ranging) records the entire backscatter signals of each emitted pulse, which is benefit to know the surface features. Full-waveform Lidar has strong ability in detecting the vertical structure of vegetation and terrain. The location or height information can be extracted from the received waveform. Most common extraction techniques may be invalid sometimes, such as Gaussian decomposition will be invalid when the received signal cannot be composed of pure Gaussian function combinations. In the application of processing returned signal, the method of deconvolution has the unique advantages in extracting parameters of position, amplitude range and height. It has been widely used in spectroscopy, signal recovery, signal analysis, signal modeling and so on. In this study, deconvolution was used to remove the characteristic of the transmitted waveform from the received waveform to obtain a surface response. The simulated waveforms were used to investigate the potential of deconvolution in Full-waveform Lidar data analysis. The results showed that the Gold's method of deconvolution was suitable for solving the problem. [C3565]

#### "Detecting and Identifying Two Stationary-Human-Targets: A Technique Based on Bioradar"

Bioradar is a novel kind of radar combining the technology of radar and biomedical engineering. It can detect vital signals (such as breath, heartbeat, movement, etc.) in a certain distance through the nonmetal substances (such as brick walls, rubble, etc.) without using electrodes or sensors. However, multi-stationary-human-target identifying and locating has not been resolved yet. Based on the Ultra Wide-band (UWB) bioradar, we developed a method combining biomedical signal processing and space-frequency analysis to distinguish two stationary human subjects in different distances and to identify the location of each human subject. Experiments were done to evaluate the effectiveness of the proposed method. In 86 data sets the accuracy of distinguishing two stationary subjects reached 73%. This method may serve as a basis for further studies in developing appropriate 2-Dimension locating image reconstruction models via multi-antenna (static) UWB radar. [C3566]

#### "The correction of spaceborne satellite's yaw steering law based on the star tracker high-precision measurement"

This paper presents a successful example of how the yaw steering law used in the satellite project. Otherwise in the synthetic aperture radar satellite, the theoretic parameter of the yaw steering law can be obtained and optimized on the track, then the expected Doppler centroid will be gotten. [C3567]

#### "On exploring SVDSPM algorithm for more accurate DOA estimation of low altitude target"

There exists SVDSPM (Singular Value Decomposition based on Signal Phase Matching Principle) algorithm for direction of arrival (DOA) estimation. Our aim is to present a different SVDSPM algorithm for more accurate estimation of low altitude target. So a void reference sensor is used to explore the possibility of better performance. In the full paper, VRS-SVDSPM (SVDSPM Using a Void Reference Sensor) algorithm and pertinent experimental research are explained in much detail; here only a briefing is given. The following two topics are discussed: (1) the time delay formula and VRS-SVDSPM algorithm, with the void reference sensor located on the minus of z-axes; (2) analysis of experimental results. The results show preliminarily that: (1) VRS-SVDSPM algorithm can estimate low altitude target when CBF (Conventional Beamforming) and MUSIC (Multiple Signal Classification) can not; (2) the side lobe with VRS-SVDSPM is lower compared with that with CBF; (3) with VRS-SVDSPM algorithm, the bias of azimuth is 0.6 degree and the bias of elevation is 2.4 degree. [C3568]

#### "Performance analysis of self-calibration algorithm for concentric-UCA"

A new decoupling algorithm is proposed to estimate DOA of concentric uniform circular arrays (C-UCA). The new algorithm can calibrates mutual coupling of the inner sub-arrays, compensate for mutual coupling between sub-arrays, and then estimate DOA of signal sources. This algorithm transforms joint problem into cascade problem and gets the parameters by one dimension spectrum peak value searching, which avoids multidimensional nonlinear searching of multi-parameters joint estimation. The simulation and theoretic analysis validate the good performance of the proposed algorithm. [C3569]

#### "A new real time Range-Doppler imaging algorithm"

This paper firstly describes the processing of Range-Doppler imaging algorithm and FFT interpolation for range cell migration correction, and then forms a improved range-doppler algorithm for SAR imaging with combining the two methods, which has much less computation time. In order to eliminate computation further, the Pruning FFT technique is used. [C3570]

#### "ISAR super-resolution imaging based on sparse representation"

Super-resolution imaging technique can improve resolution of ISAR image. Traditional methods based on spectrum estimation need to know the number of scattering centers in advance, and match two-dimensional poles in two-dimensional imaging. This paper researches sparsity of ISAR frequency signal and two-dimensional signal, and make super-resolution imaging equal to signal sparse representation. By Basic Pursuit algorithm, a clearer image is obtained without the number of scattering centers estimation and match processing. [C3571]

#### "Cyclostationary spectrum sensing for Cognitive Radio and multiantenna systems"

In this paper it is shown that cyclostationary spectrum sensing for Cognitive Radio networks, applying multiple cyclic frequencies for single user detection can be interpreted in terms of optimal incoherent diversity addition for "virtual diversity branches" or SIMO radar. This approach allows proposing, by analogy to diversity combining, suboptimal algorithms which can provide near optimal characteristics for the Neyman-Pearson Test (NPT). The analysis is based on the Generalized Gaussian (Klovsky-Middleton) Channel Model, which allows obtaining the above mention NPT characteristics: probability of misdetection (PM) and probability of false alarm (Pfa) in the most general way. Some quasi-optimum algorithms such as energetic receiver and selection addition algorithm are analyzed and their comparison with the noise immunity properties (Receiver Operational Characteristics-ROC) of the optimum approach is provided as well. [C3572]

#### "Navigation Satellite Passive Radar Moving Target Detection and SAR Imaging Based on FRFT"

Conventional radars have less invisibility, but the passive radars based on TV, FM signals also have some restrictions in SAR imaging by a range of issues such as ground electromagnetic environment and signal silence. This paper presents a new method of passive SAR imaging based on navigation satellite signal with single/multiple receive-only mode in FRFT domain. The received reflection of single multiple GPS signals from target is approximately linear FM signals which can be transformed by FRFT for signal frequency and Doppler frequency detection and estimation, especially for the target SAR imaging. Simulation results shown the effectiveness of the algorithm, and help to avoid the multi-target SAR imaging interference. [C3573]

#### "Research and Design of Embedded Radar Information Processor Oriented to Pervasive Computing"

Pervasive computing has been used widely in civilian areas. In the field of aerospace, researchers also have paid more attention to pervasive computing and made scientific researches on it. According to the idea of pervasive computing, an overall program of aircraft design is introduced in this paper. Subsequently a functional schematic of radar information processor embedded in aircraft is presented. The hardware and software design and algorithms of radar information processor are introduced exhaustively. The preliminary exploration research of pervasive computing is accomplished in the aerospace electronic systems by means of this research and design. [C3574]

#### "High-Resolution RCS Measurement Inside an Anechoic Chamber"

Traditionally, continue-wave method is used in Radar Cross Section (RCS) measurement. But high-resolution information is not gained in the system. The frequency-domain data of an anechoic chamber is obtained by stepped-frequency testing. Using inverse Fast Fourier Transform (IFFT), high-resolution time-domain response is achieved. In order to meet the veracious result, unwanted signals should be eliminated. The target interference with the ground is removed by setting up isolation absorbing screen inside an anechoic chamber. It is possible to avoid antenna coupling by reasonable disposition of transmitting antenna and receiving antenna. The more

accurate measurement result is got by using time-gating function in signal processing technique. The results from simulation and experiment show that the accuracy will be improved after this method are used. [C3575]

#### "Research on imaging of SS-BISAR"

Based on the configuration and operating principle of Space-Surface Bistatic SAR (SS-BISAR), the instantaneous range course is analysed and the target's echo model is deduced in this paper. The range-Doppler algorithm fit for SS-BISAR and the effect of receiver on imaging are studied, and in the end this algorithm is validated through simulation. [C3576]

#### "A Kind of Discrete Variable Structure UCAV Guidance Law Restrict by the Entering Angle"

To solve the problem that the UCAV load data link make analog signals guidance law cannot be used directly, a kind of new discrete variable structure guidance law arithmetic is brought out, which takes the restriction of entry angle into consideration, and conquers the buffeting phenomenon when the tradition discrete variable structure control arithmetic get into sliding mode. The simulation results show that the discrete signal guidance law can meet the tactical UCAV indicator. [C3577]

#### "Multitarget tracking in clutter using two-scan data association algorithm and fixed-lag smoothing"

The performance of multitarget tracking in clutter can be improved by using higher accuracy data association algorithm and more efficient state estimation method. This paper presents a novel fixed-lag TSDA-AI smoothing algorithm, which enhances the accuracy of state estimation by using fixed-lag smoothing, and improves the probability of real "measurement-target" combination by using two-scan measurements and the associated amplitude feature in the data association method. Its efficiency has been confirmed by computer simulations. [C3578]

#### "Adaptive receivers for explorative UWB pulses"

Adjustment of receiver systems of radar stations to characteristics of reflection of complex radar-tracking targets allows considerable increasing of signal to noise ratio in the process of application of UWB pulses. Methods of signal processing based on measuring of characteristics of reflection and mathematical models of targets are offered. [C3579]

#### "Efficiency of narrow band Doppler selection of the signal in presence of the scattering from the sea"

Efficiency of narrow-band Doppler selections has been considered. Characteristics of detectors with adaptation of a threshold and rank at various polarizations of radiation and reception are estimated. [C3580]

#### "Research of an Improved Weighted Centroid Localization Algorithm and Anchor Distribution"

Localization plays an important role in Wireless Sensor Networks. This paper proposed a weighted centroid localization algorithm based on received signal strength difference (RDWCL). RDWCL utilizes RSSI difference to calculate weight so as to improve localization precision and reduce the impact of anchor density and environment changing. Anchor distribution is also introduced and analyzed in this paper. Simulation and experiment results show that compared with Centroid and Weighted Centroid, RDWCL has better performance. When anchor nodes are randomly deployed, the accuracy has been improved by 13.5%. When anchor nodes are deployed as grid, the accuracy has been improved by 25.04%. When anchor nodes are deployed as equilateral triangle, the accuracy has been improved by 27.4%. [C3581]

#### "A high resolution 2D omnidirectional synthetic aperture radar scanner at K band"

In this paper a K-band 360° 2D imaging radar utilizing a synthetic aperture scanning principle is introduced. A small omnidirectional antenna is mounted on a rotating platform to create a circular synthetic aperture. Based on a broadband holographic reconstruction principle a high resolution 360° 2D image is calculated after each turn of the platform. The size of the synthetic aperture and thus the lateral resolution of the imaging system are determined by the diameter of the resulting circular antenna trajectory. In contrast to common radar scanner-concepts that utilize highly directional and thus bulky antennas, the proposed scanner concept has the advantage that it uses a small and lightweight omnidirectional antenna. This results in a much more compact radar system with notably relaxed requirements for the scanning mechanics. In addition it will be shown that the use of an omnidirectional antenna allows for very simple options to transfer energy to the radar on the rotation platform. The performance of the proposed SAR radar scanning method is illustrated with a 24 GHz FMCW

radar sensor system. [C3582]

### "Development of wideband crosshole and surface GPR for soil characterization: FDTD modeling and experiments"

Original wide band antennas dedicated to the imaging of the subsurface by crosshole or surface radar for civil engineering application have been developed. The challenge in the developments is twofold: in the case of crosshole radar, the design of a narrow antenna less than 61 cm wide working in the frequency band [0.5;1.5] GHz, and in the case of a surface radar the design of a compact antenna less than 55 cm long working in the frequency range [0.3;1] GHz. FDTD simulations have allowed to propose optimized antenna geometries and to model both types of transmission links in the presence of a layered soil representing a moisture gradient. A first measurement campaign performed in the frequency domain in a clay sand embankment has allowed to validate the theoretical developments associated with the crosshole radar and to extract the dielectric parameters (permittivity and attenuation coefficient) as a function of the depth. The experimental validation of the surface radar will further be made and the performances of both types of radars will be compared. [C3583]

### "Method of space-time processing of non-stationary signals with application of optimal sliding windows and wavelet transforms"

This work is devoted to the development of methods of signal detection, selection and estimation of parameters of space-extended objects with high Q-factor on basis of statistical optimization of either of space-time processing of signals or dynamic scenes in the radio-technical systems. [C3584]

### "An integrated Relative Navigation system using GPS/VISNAV for ultra-close spacecraft formation flying"

To improve the accuracy and better fault-tolerant performance for ultra-close spacecraft formation flying, a Global Position System (GPS)/Vision based Navigation (VISNAV) integrated Relative Navigation and Attitude Determination (RNAD) approach was presented in this paper. Onboard GPS was used for RNAD for formation spacecraft by multi-antennas configuration. The same RNAD information was also achieved by VISNAV system separately by using multiple line-of-sight vectors observations from spacecraft to another. Optimal fusion of RNAD information from both GPS/VISNAV subsystems was achieved by a Federal Kalman Filter (FKF) architecture. Simulation results provided later indicate that the integrated system can provide a total improvement of relative navigation and attitude estimation performance in accuracy and fault-tolerant. [C3585]

### "The evaluation method of space objects collision"

With the rapid development of space technology, more and more spacecrafts have been launched into space. At the same time, the number of space debris increases dramatically and the probability of collision between space debris and spacecrafts arises accordingly. Some evaluation methods should be studied to evaluate the collision effect. According to different collision modes, this paper introduces some evaluation methods through analyzing tracking data obtained by measurement equipment and proposes relevant evaluation standards based on different collision degrees. [C3586]

### "Data association for GM-PHD with track oriented PMHT"

Gaussian Mixture probability hypothesis density (GM-PHD) filter is a closed-form solution to the probability hypothesis density filter, which could estimate states and time-varying number of targets based on theory of random finite set. Probability multiple hypotheses tracking (PMHT) is a multi-target tracking algorithm combining data association and expectation-maximization. However, GM-PHD can not give trajectories of target because of its disability of providing identity of target. Furthermore, PMHT need known number of targets and several frames trajectories of targets at first which are difficult in practical application. Firstly, we propose track oriented PMHT tracker (TO-PMHTT), then an approach of data association combining the advantage of GM-PHD with TO-PMHTT is designed in this paper. GM-PHD acts as the pre-filter of TO-PMHTT when there are no crossing targets in the scenario, while interaction between GM-PHD and TO-PMHTT is performed when targets enter crossing zone. Computer simulation results show that the method can provide association for both separated and crossing targets tracking. [C3587]

### "A novel adaptive square root recursive least squares filter algorithm of SINS/SAR integrated navigation systems"

In strapdown inertial navigation system (SINS) synthetic aperture radar (SAR) integrated navigation systems, the

time-varying parameter estimation is a challenging problem because SAR measurements are fairly few and have unequal interval. In such case, the common Kalman filter algorithm can't be convergent. Furthermore, the traditional recursive least squares (RLS) algorithm is difficult to estimate the time-varying parameter. This paper proposed a novel adaptive square root recursive least squares (ASRRLS) filter algorithm of SINS/SAR integrated navigation systems. The first characteristic of ASRRLS is introducing adaptive fading factors based on the orthogonality principle, which can effectively track the parameters' varying. The second characteristic of ASRRLS is taking covariance square root matrix instead of covariance one in the filter algorithm, which can avoid filtering divergence and improve the filter convergence speed. The ASRRLS filter algorithm is deduced and the performance is rigorously analyzed. Simulation results demonstrate the feasibility and effectiveness of the proposed approach. [C3588]

#### "Recognition method studies for radar and communication signals based on spectral correlation"

In order to address the increasing complexity of electromagnetic environments and adapt to the demanding need of the integrative electronic warfare, it is necessary to study the integrative reconnaissance technology for radar and communication signals from single-platform. At present, the systemic study of integrative reconnaissance has just begun, and the automatic recognition of modulation types is a very important research area in this field. The exploration of the method presented us the following discoveries. First, it utilizes the duty ratio to separate the two types of signals; secondly, based on the excellent features of the second order cycle spectrum it gives the spectral correlation characteristics of the conventional communication and pulse compression radar signals using the CA method; then, we refer the characteristic parameter and allow signals to be automatically identified. The simulation results verify the feasibility and correctness of this method. [C3589]

#### "Analysis of Return Signal Mechanism in Ship-Board Radar"

This paper analyzes interactions between return signals and ship-board radar. The corresponding theoretical model proves that the first-order, Bragg sea-wave spectrum's widened width in ship-board radar coincides with the theoretically spreading width analyzed in our model, creating a foundation for the research of signal resolution and clutter background statistics in ship-board radar. [C3590]

#### "Multipath Mitigation of Low Elevation for Passive Monopulse Radar Based on FRFT"

A novel algorithm for mitigating multipath effect of low elevation for passive monopulse radar based on the fractional Fourier transform (FRFT) is proposed with constructing the multipath model in this paper. Reflection LFM signal filtered and mitigated in FRFT domain. The statistical analysis is also performed which perfects the method theoretically, simulation results are provided to show the validity of our method. [C3591]

#### "Decomposition of Maneuvering Target RCS Based on Wavelet Analysis"

Considering maneuvering target RCS which changes along with the pose of target acutely, this paper brings forward a method which makes maneuvering target RCS decompose RCS of certain pose and RCS of random pose. RCS of certain pose is sensitive to the change of maneuvering target pose and it depends on the pose strongly. And RCS of random pose can be processed as noise. Basing on the characteristic, the paper uses wavelet analysis to process maneuvering target RCS sequence with De-noising. Use this method, we can obtain the RCS sequence of De-noising changed with pose( RCS sequence of certain pose). This paper also use Matlab to simulate and to validate feasibility of this method. [C3592]

#### "A Novel Crossbar Scheduling for Multi-FPGA Parallel SAR Imaging System"

In multiprocessors system, crossbar scheduling networks have been widely used for system interconnection among processors or modules in SOC (System on Chip). In this paper, a parallel SAR (Synthetic Aperture Radar) image processing system which is composed of five FPGA PE (Process Element)s is taken for the basic research platform. Then a novel compact crossbar scheduling network for multi distributed parallel PEs is proposed for communication among PEs. Different scheduling strategies are provided for different kinds of source data streams which are from external raw data and PEs. In addition, resynchronization makes data streams of all PEs synchronous when all data streams are not entirely consistent due to the efficiency of memory access and bus burst transfer. Simulation and synthesis show that only little device resource is utilized by the proposed crossbar scheduling network to meet the requirements of the system. The maximum throughput of the crossbar could be above 20Gbps when the operating frequency is 100MHz, and the minimum latency is three clock cycles. The proposed crossbar scheduling as a sub-module could be easily integrated into SAR real-time imaging system. [C3593]

### "The Application of Unsupervised Clustering in Radar Signal Preselection Based on DOA Parameters"

With the deterioration of electronic environment, using signals DOA (direction of arrival) parameters has great significance to preselect multiple radar pulses. Cluster analysis as an important means of data classification, is gradually applied to radar signal sorting. In this paper, a novel method of signal sorting flowsheet is proposed based on Fuzzy Clustering to sort emitters DOA as data objects, with dynamic clustering for reference and Gaussian distance function instead of Euclidean distance. This method avoids establishing enormous similar matrix and adapt to the change of the number of emitters. The result of simulation demonstrates that this method is effective. [C3594]

### "The Monopulse Angle Estimation Based on the Radon-Ambiguity Transform"

On the condition of amplitude-comparison monopulse radar system, for measuring the direction of multicomponent sources in the space which have same modulation format, an algorithm of Direction-of-Arrival (DOA) estimation based on Radon-Ambiguity Transform is proposed. The typical signal model is built up, and when the time-of-arrival is very approximate, it is discussed how to extract the signal amplitude of each source. And then the algorithm's results of angle measurement is given. [C3595]

### "Parameter Estimation of LFM Signal with Narrowband Jamming Based on CS"

Based on Compressive Sensing (CS), parameter estimation of Linear Frequency Modulation (LFM) signal could be done by using fewer sampling data. At the present time, there is no method that could resolve the problem that the result of parameter estimation of LFM signal with narrowband jamming is not satisfied well. As a result, this paper proposes a resolution to this problem. A Multi-component dictionary which could matching LFM signal and narrowband jamming both is constructed in this paper. And based on the Multi-component dictionary we can obtain a more effective sparse representation of signals, and then we could get a better parameter estimation of LFM signal. The experiment result shows that we could obtain more accurate parameter estimation of LFM signal with narrowband jamming by using the method this paper proposed than by others under the same condition of samples. [C3596]

### "Visualized Feature Fusion and Style Evaluation for Musical Genre Analysis"

Different kinds of features in time domain, spectral domain and cepstral domain are used for musical genre classification. In this paper, through the fusion of short-term timbral features and long-term rhythmic feature, we propose a novel method where: musical genre vector is constructed using the likelihood ratio of GMM (Gaussian Mixture Model) and radar chart is applied to provide visualized style evaluation for musical genre analysis, a promising performance is achieved over our database consisting of seven different types of music. Because of the fuzzy definition of musical genres, we also investigate the music with dual-genre based on musical genre vector and radar chart. [C3597]

### "Research on ISAR Imaging Method of Parameter Estimation Based on Optimal Imaging Period"

A clear ISAR image could not be acquired by conventional Range-Doppler (RD) method due to the non-uniformity of angular motion of ships as scatterers caused by the sea wave, thus the method for solving the problem by applying Range-Instantaneous Doppler (RID) methods are used. However, though each scatterer could be resolved from the echoes, such methods suffer from heavy calculation burden due to the searching process. An ISAR imaging method of parameter estimation based on optimal imaging period is proposed. The method chooses optimal data from all received echoes, and then achieves imaging by parameter estimation according to each range bin's Doppler data. The effects of choosing imaging period on parameter estimation is analyzed, and the steps of accomplishing the proposed method are developed. The result of estimation on real data manifests that better ISAR image can be acquired by applying the method proposed. [C3598]

### "Tri-iterative Three-Dimensional Space-Time Adaptive Processing Based on Correlation Matrix for Airborne Radar"

Because of employing elevation adaptivity, three-dimensional space-time adaptive processing (3D STAP) can achieve better performance than conventional two-dimensional (2D) STAP at the cost of higher computational load and sample support requirement. To overcome these shortcomings, a tri-iterative 3D STAP method based on correlation matrix for airborne radar is developed. In the proposed method, the quadratic cost function used in the optimum STAP is converted into three quadratic functions by using submatrices of the space-time correlation matrix, and the full dimension weight vector can be separated into three lower dimensional weight vectors. By iteratively optimizing these lower dimensional weight vectors, the proposed method can significantly decrease the

computational load and training samples requirement. Experiment results using both simulated data and measured radar data demonstrate the effectiveness of the proposed method. [C3599]

### "WLAN Indoor Tracking Method via Improved Particle Filter Algorithm"

WLAN Indoor tracking system is presented based on the comparison between the off-line pre-stored Radio-map and new recorded signal strength in the on-line phase to estimate user's motion trajectory. Furthermore, the improved particle filter tracking algorithm that consists of the particles-reference points (P-RPs) transferring for getting the likelihood function and velocity estimation from the ANN positioning results is also discussed in this paper. And also, the experiment shows that this improved particle filter tracking algorithm achieves great accuracy performance in tracking trajectory aspect without any velocity-measurement hardware. Finally, the feasibility and effectiveness of this improved WLAN indoor particle filter tracking algorithm are verified without velocity-measurement hardware. [C3600]

### "Estimation and Registration of Relative System Biases in Fire-Control Radar Network"

Fire-control radar network uses data fusion to form more accurate estimate of a target track, the prerequisite of normal data fusion is the system bias registration. In fire-control radar network, due to the existence of the approximating bias of coordinate conversion model and time synchronization bias, data fusion process brings the immitted system biases besides inherent system biases. This paper developed a system bias registration method based on Kalman filtering theory. The inherent system bias and immitted system bias are considered for modeling. The simulation results are presented and discussed. It is found that the method given in this paper is in effect. [C3601]

### "Propagation Analysis of ELF Electromagnetic Emission below the Cut-Off Frequency in Ionosphere"

The aim of this paper is to show the propagation and polarization characteristic of some types of ELF electromagnetic emission below the cutoff frequency observed by DEMETER satellite. All the analysis is based on multi-component measurement method of electric and magnetic field in ELF band. According to the wave vector and planarity and ellipticity of polarization, we can judge the property of electromagnetic emission below the cutoff frequency. Then it will help us analysis the origin of emission further. In is this paper, only three types of emission are analyzed, and their emission origins are guessed. [C3602]

An integrated Relative Navigation system using GPS/VISNAV for ultra-close spacecraft formation flying. / Junli Chen, Xiaoliang Wang, Xiaowei Shao, Dengping Duan. // 2010 3rd International Symposium on Systems and Control in Aeronautics and Astronautics (ISSCAA). - Harbin, 8-10 June 2010. - P. 803-808. ↑
- C3586.** Xinfeng Wang. The evaluation method of space objects collision. / Xinfeng Wang, Yanjun Li, Gongyou Wu, Rongzhi Zhang. // 2010 3rd International Symposium on Systems and Control in Aeronautics and Astronautics (ISSCAA). - Harbin, 8-10 June 2010. - P. 849-852. ↑
- C3587.** Shicang Zhang. Data association for GM-PHD with track oriented PMHT. / Shicang Zhang, Jianxun Li, Binyi Fan, Liangbin Wu. // 2010 3rd International Symposium on Systems and Control in Aeronautics and Astronautics (ISSCAA). - Harbin, 8-10 June 2010. - P. 386-391. ↑
- C3588.** Yunjie Qu. A novel adaptive square root recursive least squares filter algorithm of SINS/SAR integrated navigation systems. / Yunjie Qu, Wenhui Wang, Lu Zhang, Bangqing Li, Kai Yu. // 2010 3rd International Symposium on Systems and Control in Aeronautics and Astronautics (ISSCAA). - Harbin, 8-10 June 2010. - P. 1142-1145. ↑
- C3589.** Xiao-lin Zhang. Recognition method studies for radar and communication signals based on spectral correlation. / Xiao-lin Zhang, Wen-ting You, Qiang Guo, He-yang Cao. // 2010 3rd International Symposium on Systems and Control in Aeronautics and Astronautics (ISSCAA). - Harbin, 8-10 June 2010. - P. 363-366. ↑

- C3590.** Zhang Zhong. Analysis of Return Signal Mechanism in Ship-Board Radar. / Zhang Zhong, Dingqun Maqinglin. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 703-706. ↑
- C3591.** Qian Wei-qiang. Multipath Mitigation of Low Elevation for Passive Monopulse Radar Based on FRFT. / Qian Wei-qiang, Qiao Xiao-lin, Zhu Xiang-peng, Wei Yu-mei. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 948-951. ↑
- C3592.** Tong Jun. Decomposition of Maneuvering Target RCS Based on Wavelet Analysis. / Tong Jun, Shan Ganlin. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 972-976. ↑
- C3593.** Huanghui Shen. A Novel Crossbar Scheduling for Multi-FPGA Parallel SAR Imaging System. / Huanghui Shen, Jing Wang, Chenyu Yuan, Zhensong Wang, Weimin Zheng. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 394-397. ↑
- C3594.** Xiang-Peng Zhu. The Application of Unsupervised Clustering in Radar Signal Preselection Based on DOA Parameters. / Xiang-Peng Zhu, Ming Jin, Wei-Qiang Qian, Shuai Liu, Yu-Mei Wei. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 956-959. ↑
- C3595.** Yu Nan. The Monopulse Angle Estimation Based on the Radon-Ambiguity Transform. / Yu Nan, Jin Ming, Qiao Xiao-lin. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 824-828. ↑
- C3596.** Bing Liu. Parameter Estimation of LFM Signal with Narrowband Jamming Based on CS. / Bing Liu, Ping Fu. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 487-490. ↑
- C3597.** Qingjun Yao. Visualized Feature Fusion and Style Evaluation for Musical Genre Analysis. / Qingjun Yao, Haifeng Li, Jiayin Sun, Lin Ma. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 883-886. ↑
- C3598.** Jiang Yicheng. Research on ISAR Imaging Method of Parameter Estimation Based on Optimal Imaging Period. / Jiang Yicheng, Yin Songqiao. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 513-516. ↑
- C3599.** Jie He. Tri-iterative Three-Dimensional Space-Time Adaptive Processing Based on Correlation Matrix for Airborne Radar. / Jie He, Da-zheng Feng, Xiang Cong, Hui Lv. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 715-718. ↑
- C3600.** Yubin Xu. WLAN Indoor Tracking Method via Improved Particle Filter Algorithm. / Yubin Xu, Jingyu Liu, Lin Ma, Lang Peng. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 1078-1082. ↑
- C3601.** Hong Xu. Estimation and Registration of Relative System Biases in Fire-Control Radar Network. / Hong Xu, Zhuangzhi Han, Qiang He, Chaoxuan Shang. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 5-8. ↑
- C3602.** Haiyan Yu. Propagation Analysis of ELF Electromagnetic Emission below the Cut-Off Frequency in Ionosphere. / Haiyan Yu, Hongjuan Zhou, Bingxia Cao, Xiaolin Qiao. // 2010 First International Conference on Pervasive Computing Signal Processing and Applications (PCSPA). - Harbin, 17-19 Sept. 2010. - P. 799-802. ↑
