A method and a system for remotely monitoring a person includes a portable unit including a self-recharging battery, the portable unit being adapted to monitor a biological parameter and a physical location of the person, a global positioning satellite transmitting global positioning system (GPS) data to the portable unit, and a central unit disposed remotely from the portable unit, the central unit being in communication with the portable unit via a ground station. [A2401]

"Emergency flashing light mechanism"

An emergency flashing light mechanism includes one or more emergency flashing lights, a processor, a transmitter, and a receiver. The emergency light flashing mechanisms can exchange information with the vehicles, pedestrians and other components of a traffic complex via their respective transmitters and receivers. The emergency flashing light mechanisms can process such information and override control lights having red, yellow and green lights. The emergency flashing lights can selectively respond to emergency vehicles. [A2402]

"Radio-interrogated surface-wave technology sensor"

Radio-interrogated surface-wave technology sensor, in which the sensitive element (12) is an impedance which is electrically connected as termination to a surface-wave structure (26) of the sensor. [A2403]

"Method and apparatus for ultra precise GPS-based mapping of seeds or vegetation during planting"

An ultra precise seed planter apparatus and method for generating a centimeter accuracy map of the location of seeds or vegetation as they are planted from an agricultural planting machine. The apparatus is fitted with a GPS receiver feeding a data logger, and optical sensors that are placed adjacent seed or vegetation dispenser. The data logger monitors GPS time and UTM coordinates, as well as the optical sensors. Ground speed and azimuth are also monitored. The seeds or vegetation are time-tagged as they are dispensed, and software is used to process the dispensing time and GPS location data and estimate the exact coordinates of each seed or plant and its distance from adjacent seeds or plants. As a result, a precise planting map is generated. The invention may also be used to determine the location to dispense seeds or vegetation, and activating the dispenser when that location is reached. [A2404]

"Method and apparatus for recognizing shape of road"

A transmission wave is applied to a predetermined angular range in a width-wise direction of a vehicle. Object-unit data pieces containing at least data pieces representing distances to objects in correspondence with vehicle-width-wise direction angles are generated on the basis of a reflected wave. A determination is made as to whether each object is moving or stationary on the basis of a speed of the vehicle and a relative speed of the object. From the object-unit data pieces, ones are extracted which are effective for road shape recognition on the basis of a result of determining whether each object is moving or stationary. Ones of the extracted object-unit data pieces which represent monotonically increasing distances as viewed along one of clockwise and counterclockwise angle directions are grouped to generate data representing a road-side-object group. A road edge is recognized on the basis of the data representing the road-side-object group. [A2405]

"Motor vehicle warning and control system and method"

A system and method assists the driver of a motor vehicle in preventing accidents or minimizing the effects of same. In one form, a television camera is mounted on a vehicle and scans the roadway ahead of the vehicle as the vehicle travels. Continuously generated video picture signals output by the camera are electronically processed and analyzed by an image analyzing computer, which generates codes that serve to identify obstacles. A decision computer mounted in the controlled vehicle receives such code signals along with code signals generated by the speedometer or one or more sensors sensing steering mechanism operation and generates control signals. Such code signals may be displayed, and a synthetic speech or special sound generating and warning means used, to warn the driver of the vehicle of approaching and existing hazards. The system may also use the control signals, particularly through application of fuzzy logic, to control the operation of the brakes and steering mechanism of the vehicle to avoid or lessen the effects of a collision. In a particular form, the decision computer may select the evasive action taken from a number of choices, depending on whether and where the detection device senses other vehicles or obstacles. [A2406]

"Satellite method for using radar interferometry to establish a digital terrain model"

The invention relates to a method which consists in launching one behind the other on two close orbits two satellites (S1, S2) each equipped with a high-resolution synthetic aperture radar observing the Earth under an angle of incidence of at least 40.degree., such that the radars observe independently of each other the same strip of terrain, with time interval not more than 10 seconds, preferably of not more than 4 seconds, and preferably not less than 2 seconds between their respective observations. [A2407]

"Method of envelope detection and image generation"

A method of detecting objects reflecting impulse waveforms of generating a detection envelope by receiving a reflected waveform, delaying said waveform by a peak-to-zero delay (PZD) interval. The PZD interval is the time between a maximum energy displacement in the impulse waveform and an adjacent zero crossing. The reflected waveform and its delayed version are squared and then summed to create the envelope. If the envelope is to be defined in terms of voltage, the root of the sum of the squares may be found. Also a method for generating an image using the PZD interval in back-projection techniques is described wherein a sampling point is chosen on each of a plurality of reflected waveforms. The values of the samples are summed and the waveforms are delayed by the PZD interval and the values of the sampling points are again summed. The two sums are squared and added together to generate an image envelope. [A2408]

"Method and apparatus for generating notification of changed conditions behind a vehicle"

According to the present invention, methods and apparatus are provided to generate notification about condition changes behind a vehicle. Information about a first set of conditions behind a vehicle is gathered at a first point in time. Information can be gathered using imaging devices, infrared detectors, distance meters, light intensity sensors, and timing devices. At a later point in time, information about a second set of conditions behind the vehicle is gathered. The information gathered at a first point in time is compared to the information gathered at the later point in time to determine differences between the conditions behind the vehicle. If the differences meet a notification criterion, a notification is generated conveying information about the changed conditions behind the vehicle. [A2409]

"Non-invasive, opto-acoustic water current measurement system and method"

A method and system are provided for measuring water current. An acoustically-modulated beam of radiation is transmitted to a target location on the surface of a body of water. As the beam transits the water, acoustic radiation propagates away from the beam towards the surface and experiences a Doppler shift in frequency relative to the acoustic frequency used for modulation. The Doppler shift is caused by current in the water through which the acoustic radiation transits. The Doppler-shifted frequency is measured as an indication of water current. [A2410]

"Ocean altimetry interferometric method and device using GNSS signals"

A method for performing Earth altimetry comprising the steps of: receiving by an upward-looking antenna onboard a platform above the Earth surface, direct signals having at least two different carrier frequencies transmitted by GNSS satellites in view of the upward-looking antenna, receiving by a downward-looking antenna onboard the platform signals reflected by the Earth surface and having the at least two different carrier frequencies, comparing carrier phases of the direct signals and received reflected signals, at the carrier frequencies, and determining from the phase comparisons a surface height. [A2411]

"Radio system for characterizing and outlining underground industrial developments and facilities"

Most mines and underground facilities employ standardized construction techniques and materials. Such also cannot avoid having some above ground openings to receive utilities, fresh air, supplies, etc. Those or other surface openings are also universally used to discharge ground water, wastes, and other materials. Typical underground facilities have abundant electrical wiring and power demands, both of which can be detected at the surface. Levees with leakage pathways also form electrical conductors. When properly illuminated with remotely generated electromagnetic (EM) radiation, many of these features will "glow" or reradiate the radio energy in an electronic signature unique to the underground facility. Synchronized EM-gradiometer transponders are situated nearby on the ground surface to collect and analyze the "glow". Alternative transmitting devices further includes ways to generate the illumination, and computers for characterizing the return signatures. [A2412]

"Method for detecting and correcting non-linearities in radio-frequency, voltage controlled oscillators"

A method for detecting and correcting non-linearities in radio-frequency, voltage controlled oscillators provides for digitization of the frequency signal by feeding the undelayed frequency signal and a delayed frequency signal generated therefrom into EXOR gates. The digital pulses produced thereform are converted using a low pass filter into a proportional DC voltage value which is proportional to the oscillator frequency and is used as a basis for producing a correction value for the frequency control of the oscillator. [A2413]

"Method and system for displaying target vehicle position information"

A system and method for displaying target vehicle position that combines the data available from a plurality of surveillance sensors. Data from the plurality of sensors is fused to calculate a composite target position and a projected track for each vehicle within the range of the sensors. The composite data is also used to calculate a boundary of certainty for both the position and the projected track. The position, projected track and the boundaries of certainty for each target vehicle can be displayed on a display screen. [A2414]

"Device for representing a control situation determined by a motor vehicle distance control device"

A device for representing on a display device a control situation determined by a motor vehicle distance control device, the distance control device being connected to a sensor which detects the coordinates and the relative speed of the obstacles located ahead of the motor vehicle and relays them to the distance control device, which determines the expected lane of the motor vehicle, the distance control device determining from these data a control object with reference to which the distance of the motor vehicle is controlled. Referring lso a device referring the multiplicity of the data required for distance control in a motor vehicle can be checked in a simple way for their correctness, the distance control device (3) is connected to a display control device (14) which converts the data detected by the sensor (9) and calculated by the distance control device (10) into an approximately true-to-scale plan view of the control situation ahead of the vehicle (1) , which is displayed on the display device (15) . [A2415]

"Path prediction for vehicular collision warning system"

A motor vehicular collision warning system including a scanned beam sensor, a signal processor, and a vehicle interface system that initiates warnings to the driver or adaptively controls the vehicle. Scene data is used to predict the path of the roadway in front of a subject vehicle. Reflections from manmade and natural scene objects are extracted from the scene data to define a linear feature edge. Once the feature edge is determined, the predicted path of the subject vehicle can be determined using information regarding the vehicle trajectory and the feature edge. [A2416]

"Noncoherent gain enhancement technique for non-stationary targets"

A radar system and radar processing method includes a number of aspects for providing improved function. The system and method may employ one or more of the following aspects: timely range-velocity (range-Doppler) compensation for target nonstationarity by integration along hypothesized range-Doppler trajectories, allowing noncoherent integration over an elongated time interval, noncoherent integration of an enlarged signal set obtained from overlapped coherent processing intervals (CPIs) , hypothesized joint multiple accelerations used to generate multiple hypothesized range-Doppler trajectories, and sliding window integration to increase data output rates with use of large noncoherent integration intervals (NCIs) . These aspects allow for improved signal-to-noise ratios, for acquisition and tracking of targets at longer ranges, and for improved target parameter estimation. [A2417]

"Apparatus and method for liquid level measurement in a sounding tube"

A level sensing apparatus for attachment to a vessel to measure levels of contents in a tank of the vessel. The level sensing apparatus includes a housing, a transmitter disposed within and operatively connected to said housing, and an antenna operatively connected to the transmitter for directing electrical and/or mechanical waves in a direction away from the transmitter. The antenna is further adapted to receive electrical and/or mechanical waves. The level sensing apparatus further includes a mounting system affixing the level sensing apparatus to a vessel. The mounting system is adapted such that the mounting system can be placed in a first position while the transmitter is affixed to the vessel, wherein levels of contents in a tank can be measured with electrical and/or mechanical waves, or in a second position while the transmitter is affixed to the vessel, wherein levels of contents in a tank can be measured manually. [A2418]

"Dual mode transmitter-receiver and decoder for RF transponder tags"

An enhanced backscatter RF-ID tag reader system and multiprotocol RF tag reader system is provided. In a multiprotocol mode, the system emits a non-stationary interrogation signal, and decodes a phase modulated backscatter signal by detecting a stronger phase component from quadrature phase representations or determining phase transition edges in a phase of a received signal. The RF tag reader system predicts or follows the phase of the backscatter signal, thereby avoiding interference from nulls in the received signal waveform due to the non-stationary interrogation signal, relative movement or environmental effects. An acoustic RF-ID tag detection system detects the reradiated signal corresponding to respective transformation of a signal in the tag. Detection of either type of RF-ID tags therefore is possible, and the absence of any tag or absence of any valid tag also determined. [A2419]

"Method and device for measuring distance and speed"

Signals are emitted with a FMCW sensor system, are received after reflection at targets and are processed to form a measured signal whose frequency spectrum is analyzed. Discrete, equidistant samples are stored and are arranged in a double Hankel matrix in the existing sequence. This matrix is diagonalized with a singular value decomposition, and an approximation is identified taking only the "principle values" into consideration, in order to calculate the frequencies and their amplitudes therefrom according to known methods. [A2420]

"Self calibration of transponder apparatus"

A method and apparatus is provided for remotely and constantly calibrating a transponder by using the ring around phenomenon. A number of different time varying physical quantities, such as for example temperature, signal level, noise, transmission line flex, frequency, and general operational effects, affect the inherent delay in transponders on a time varying basis. The invention relies on a the ring around phenomenon to produce pulse doublets, wherein the distance between the pulses in the pulse doublets correspond to the instantaneous delay in the transponder. The system is configured so that instantaneous variation in the transmission delay is detected and recognized on a pulse by pulse basis and transmitted to the interrogation device, which then functions to calculate the actual delay. Normal operation of the transponder is not affected by the continuous calibration method, and therefore a special calibration mode is not required. [A2421]

"Method and arrangement for mapping a road"

Arrangement and method for mapping a road during travel of a vehicle having two data acquisition modules arranged on sides of the vehicle, each including a GPS receiver and antenna for enabling the vehicle's position to be determined and a linear camera which provides one-dimensional images of an area on the respective side in a vertical plane perpendicular to the road such that information about the road is obtained from a view in a direction perpendicular to the road. A processor unit forms a map database of the road by correlating the vehicle's position and the information about the road. Instead of or in addition to the linear cameras, scanning laser radars are provided and transmit waves downward in a plane perpendicular to the road and receive reflected waves to provide information about distance between the laser radars and the ground for use in forming the database. [A2422]

"Method and device for detection of em waves in a well"

A method for detecting electrical properties in a geological formation in a well which has within it a tubing string comprising the steps of mounting a transmitter antenna outside of the tubing string in a fixed position with respect to the geological formation, mounting a receiving antenna outside of the tubing string in a fixed position with respect to the geological formation, generating a first series of electromagnetic waves at a first time, receiving a first series of reflected electromagnetic waves in the receiver antenna, transforming the first series of reflected electromagnetic waves to form a first registration, generating a second series of electromagnetic waves at a second time, receiving a second series of reflected electromagnetic waves in the receiver antenna, transforming the second series of reflected electromagnetic waves to form a second registration, and comparing the registrations. Also disclosed is a device for accomplishing the method. [A2423]

"Method and apparatus for determining location of objects based on range readings from multiple sensors"

The invention is a method and apparatus for determining the locations of a plurality of actual objects based on the output of a plurality of range sensors. A multiplicity of range measurements are obtained from a plurality of sensors, each sensor capable of providing a multiplicity of range measurements. The range measurements from the plurality of sensors are correlated with each other to generate a list of potential objects and to order that list of potential objects from highest to lowest likelihood of being an actual object. The order may be based upon a cumulative error of the individual sensor measurements upon which the potential object is based. The ordered list of potential objects is then pared down to a smaller list of actual objects by assuming that the potential object highest in the ordered list as an actual object, and then removing from the list all other lower-ordered potential objects that are based on any of the range measurements upon which the selected object is based. The process is repeated for the next highest potential object remaining on the list until all potential objects on the list have either been selected as an actual object or removed from the list. [A2424]

"Using host vehicle dynamics for side-looking automotive pre-crash sensor aiming control"

The antenna of a side-looking pre-crash sensor (12) is aimed, either electronically or mechanically, in correlation with the travel velocity of a host vehicle (10) . As the forward travel velocity of the host increases, the antenna beam (16) remains aimed laterally, but in an increasingly forward direction. [A2425]

"Ground-penetrating imaging and detecting radar"

A ground-penetrating radar comprises a single resonant microstrip patch antenna (RMPA) that is driven by a three-port directional coupler. A reflected-wave output port is buffered by a wideband isolation amplifier and a reflected-wave sample is analyzed to extract measured values of the real and imaginary parts of the load impedance-the driving point impedance of RMPA. Each such port will vary in a predictable way according to how deeply an object is buried in the soil. Calibration tables can be empirically derived. Reflections also occur at the interfaces of homogeneous layers of material in the soil. The reflected-wave signals are prevented from adversely affecting transmitted-signal sampling by putting another wideband isolation amplifier in front of the input port of the directional coupler. A suppressed-carrier version of the transmitted signal is mixed with the reflected-wave sample, and the carrier is removed. Several stages of filtering result in a DC output that corresponds to the values of the real and imaginary parts of the load impedance. The suppressed-carrier version of the transmitted signal is phase shifted 0.degree. or 90.degree. to select which part is to be measured at any one instant. [A2426]

"Composite device for vehicle"

The object of the present invention is to provide a composite apparatus in which a meter for a vehicle and an obstacle alarm device for a vehicle share a constituting means common to the meter and the obstacle alarm device. The meter and the obstacle alarm device share a buzzer-driving circuit (40) of and a buzzer (50) . [A2427]

"Use of third party ultra wideband devices to establish geo-positional data"

A system, method and article of manufacture are provided for determining a location of a wireless device in a wireless communication system. In general, an initial request is transmitted to wireless devices having known locations for positioning information so that a location can be determined for a first wireless device having an undetermined location. Those wireless devices with known locations that receive the initial request in turn transmit positioning information to the first wireless device. If positioning information from less than a sufficient number of wireless devices with known location is received by the first mobile wireless device, an additional request is then transmitted for responses from these responding other wireless devices. After responses to the request from one or more of these responding other wireless devices are received, communication then occurs with at least a portion of the responding wireless devices to obtain information relating to the distance between the first wireless device and the responding wireless devices it is communicating with. Next, a location of the first wireless device is estimated using the information obtained from these responding other wireless devices and the positioning information received from the wireless devices with known locations. [A2428]

"Object recognition apparatus"

This invention relates to an object recognition apparatus. This apparatus comprises an antenna which emits transmission beams toward a plurality of directions, a receiving circuit which receives reflected signals of the transmission beams from predetermined directions, a distance and direction calculation circuit which calculates distance and direction to objects reflecting the transmission beams based on the transmission beams and the reflected signals, an object pattern storage unit which stores range direction patterns of reflected signals obtained in advance with respect to predetermined objects, an object recognition circuit which compares range direction patterns of the reflected signals received by the receiving circuit with respect to the predetermined directions, with the range direction patterns stored in the object pattern storage unit, and which recognize that a pair of reflected signals from two neighboring directions are signals reflected by the same object. [A2429]

"Apparatus and method for locating objects under a body of water"

An apparatus (10) and method adapted for locating objects under a body of water comprising a frame structure (12) and at least one sensor assembly (16) connected thereto. The sensor assembly (16) is pivotally coupled to the frame structure (12) and includes a rigid member (20) and a geographic location system receiver (42) connected thereto. An arm member (22) is connected to the rigid member (20) and an object detection device (38) is associated with the arm member (22) . The object detection device (38) is operable to detect a density change indicative of an object under the body of water, said object detection device (38) being further operable to emit a signal (46) indicative of the detection of an object under the body of water relative thereto based density change sensed thereby, and its position is known relative to the position of the GPS receiver (42) . The geographic location receiver (42) is operable to emit a signal (50) indicative of the present position of the receiver (42) . An electronic controller (48) coupled to both the object detection device (38) and the geographic location receiver (42) is operable to both receive signals (46, 50) therefrom and to output a signal (52) indicative of the location of the object detected under the body of water. [A2430]

"Driver augmented autonomous braking system"

An enhanced autonomous emergency braking system includes an accelerator pedal operated by the driver and used to control the overall vehicle speed. When a forward detection apparatus detects an imminent contact, the braking system automatically applies braking force to the vehicle while the vehicle engine speed is reduced. The amount of brake force applied is a continuous function of relative speed, relative distance, collision probability and target classification. The braking force may be reduced when the driver or passenger are unbuckled or may be disabled if the driver depresses the accelerator pedal by a predetermined amount. In addition, the amount of brake force applied by the driver is amplified to further enhance braking performance. [A2431]

"Method for determining control data for deploying restraint elements in a vehicle prior to a collision"

A method is indicated according to which the triggering of a restraining device or devices in a vehicle can be adjusted to specific characteristics of the vehicle involved in the impending crash in such a way as to furnish optimum protection for the vehicle occupants. To this end, before a crash between two vehicles, each vehicle transmits data concerning its own vehicle-specific characteristics that can affect the course of the crash, and each vehicle receives the vehicle-specific data transmitted by the other vehicle and derives from them control data for triggering its restraining device or devices. [A2432]

"Method and apparatus for disabling an airbag system in a vehicle"

Apparatus for disabling an airbag system for a seating position within a motor vehicle in which occupant sensors are situated adjacent or on a roof above the seat and the presence or absence of an occupant of the seating position is detected using the occupant sensor (s) . The airbag system is disabled if the seating position is unoccupied. The position of an occupant is detected if the seating position is occupied and the airbag system is disabled if the occupant's position would result in injury to the occupant greater than any injury resulting from non-deployment. Further, the airbag deployment parameters, e.g., rate of inflation and time of deployment, may be modified based on the occupant's position to adjust inflation of the airbag according to proximity of the occupant to the airbag door. [A2433]

"High-frequency dual-channel ground-penetrating impulse antenna and method of using same for identifying plastic pipes and rebar in concrete"

An antenna system for ground-penetrating radar use, comprising first and second co-located antenna element pairs orthogonally oriented with respect to each other. Each of the element pairs includes a transmit element and a receive element. A metallic enclosure (such as a box) shields the element pairs and is open on one side to face a structure to be probed by signals from the transmit elements. The transmit and receive elements are dimensioned, shaped and arranged (a) to achieve low mutual impedance between the elements, (b) to have high sensitivity to reflected signals received from the structure being probed, and (c) to accommodate a desired rise time of a transmit pulse. The transmit elements and receive elements preferably are electrical dipoles but they may also be magnetic dipoles such as slot antennas. When electrical dipoles are employed, they may be formed of elongated diamond-shaped conductive surfaces or be of other appropriate geometries. The transmit and receive elements are positioned within the box and the box dimensioned such that (a) reflections from a top of the box reinforce transmitted signals and (b) the impedance at the feedpoints of the transmit and receive elements is relatively stable as the antenna system is moved over the structure being probed. [A2434]

"Radar-field-of-view enhancement method and apparatus for matching field-of-view to desired detection zone"

A radar field-of-view enhancement method particularly adapted for vehicle radar detection systems having a specified detection zone. In accordance with the invention, a pair of discrete radar beams are employed having differing arc widths. Return signals from the discrete beams are compared and related to the area of a desired detection zone. This approach increases the reliability of detection in the detection zone while minimizing false alarms and missed detection areas. The beams are alternately switched on using discrete sources or by implementing a discrete phase shifting element interposed between the sources. [A2435]

"Mounting for proximity radar"

A sensor carrier assembly for supporting one or a plurality of sensors to facilitate mounting the plurality of sensors to the vehicle. The sensors are mounted to a carrier or mounting beam which is then in turn mounted directly to the vehicle. The mounting beam mounts directly to the vehicle and a bumper covers the mounting beam. Alternatively, the sensor mounts externally to a vehicle body part, such as a bumper. Fastening points for attaching the carrier assembly to the vehicle are preferably placed in proximity to the sensors to assist in maintaining proper orientation of the sensors. [A2436]

"Device and process for measuring distance and speed"

A device and process for measuring distances and/or speeds between a motor vehicle and several objects, like mobile targets and fixed targets, has an FMCW radar system, where the motor vehicle transmits a signal, whose transmitting frequency is modulated with at least two frequency ramps. A device detects the receiving signals from the objects and determines the respective straight lines and the intersecting points of these straight lines in a speed-distance diagram. A sorting device sorts out the intersecting points from fixed targets and the related straight lines. A device outputs the distances and/or the speeds, which correspond to the other intersecting points. [A2437]

"Radar device for detecting response signal"

When a question signal of a transmitting frequency band .DELTA.F1 output from a radar device is received in search and rescue radar transponder (SART) of a wreck ship, a response signal is sent from the SART to the radar device. In the radar device, the response signal and an echo of the question signal are received as a reception signal, intensity of components of the reception signal placed in almost the same frequency band as the transmitting frequency band .DELTA.F1 of the question signal is suppressed to produce a filtered response signal, and components of he filtered response signal placed in a receiving frequency band .DELTA.F2, which does not overlap with the transmitting frequency band .DELTA.F1 of the question signal, are extracted from the filtered response signal as an image signal. Therefore, sea clutter and ground clutter indicated as the echo of the question signal is hardly included in the image signal, and a position of the wreck ship can be detected by using the image signal excellent in a signal-to-noise ratio. Accordingly, the radar device excellent in a detection performance of the position of the wreck ship can be obtained. [A2438]

"Interrogation of an object for dimensional and topographical information"

Disclosed are systems, methods, devices, and apparatus to interrogate a clothed individual with electromagnetic radiation to determine one or more body measurements at least partially covered by the individual's clothing. The invention further includes techniques to interrogate an object with electromagnetic radiation in the millimeter and/or microwave range to provide a volumetric representation of the object. This representation can be used to display images and/or determine dimensional information concerning the object. [A2439]

"Apparatus for detecting turbulent layer"

A turbulent layer detecting apparatus in accordance with the present invention is equipped with a transmitting section that transmits beams of electromagnetic waves, sound waves or light waves into the atmosphere, a receiving section that receives the electromagnetic waves, the sound waves, or the light waves that have been transmitted by the transmitting section and scattered by particulates or the like in the atmosphere, a wind velocity measuring section that measures a beam direction component of a wind velocity at two or more observation points on a beam from a received signal received by the receiving section, or a density measuring section that measures a density at two or more observation points on the beam, and a turbulent layer detecting section that detects the presence of a turbulent layer on the basis of the output of either the wind velocity measuring section or the density measuring section. [A2440]

"Carrierless ultra wideband wireless signals for conveying application data"

A method for conveying application data via carrierless ultra wideband wireless signals, and signals embodied in a carrierless ultra wideband waveform. Application data is encoded into wavelets that are transmitted as a carrierless ultra wideband waveform. The carrierless ultra wideband waveform is received by an antenna, and the application data is decoded from the wavelets included in the waveform. The waveforms of the signals include wavelets that have a predetermined shape that is used to modulate the data. The signals may convey, for example, Web pages and executable programs between mobile devices. The signals are low power and can penetrate obstructions making them favorable for use with a wireless node of a network. [A2441]

"Vehicle travel safety apparatus"

When a turning state of a subject vehicle is detected, the action timing of the contact avoidance support device is slower than when the turning state is not detected. When an action timing determining part 22 estimates that there is the possibility of the subject vehicle coming into contact with the vehicle in front and a turning state of the subject vehicle is detected based on the output from a transversal acceleration sensor S4, a changing rate of the steering angle sensor S5, and a yaw rate sensor S3, a compensation interval calculating part 23 calculates a compensation interval depending on the size of the detected turning state (the amount of the steering angle, the changing rate of the steering angle, and the transversal acceleration) . The action timing of the brake actuator 12 is slowed by this compensation interval. [A2442]

"Combination passive and active speed detection system"

A combination passive and active detection system including a passive speed and range detection system able to sense the speed and range of a moving object and an active speed detection system able to sense the speed and range of a moving object. The passive speed detection system is preferably an electro-optical speed and range detection system. The active speed detection system is preferably a laser speed and range detection system. The combination detection system preferably is selectively operable in a dual operational mode, a "passive-only" operational mode, and "active-only" operational mode, a triggering operational mode, and an active recording operational mode. [A2443]

"Data recovery system for radio frequency identification interrogator"

An RF/ID interrogator is provided for recovering a data signal from an RF/ID tag. The interrogator includes a radio having a receiver portion to receive in-phase (I) and quadrature-phase (Q) signals from the RF/ID transponder transmitted at a predetermined bit-rate, and a processor coupled to the radio for controlling operation of the radio in accordance with stored program instructions. In one embodiment, the interrogator performs over-sampling of the data signal received from the RF/ID tag in order to provide a high data recovery rate. The processor controls the over-sampling of the I and Q signals at a sampling rate higher than the transmitted bit-rate of the I and Q signals to provide plural signal samples that are stored in a buffer memory. The processor compares the relative polarity of successive ones of the plural signal samples. Based on this comparison, data bits are derived from the successive ones of the plural signal samples in correspondence with the number of the successive ones of the plural signal samples having same relative polarity. In another embodiment, the interrogator performs a selection between the I and Q signals in order to achieve optimum data recovery. The processor detects relative signal strength of the I and Q signals, and selects one of the I and Q signals for subsequent processing based on the detected relative signal strength. Data bits are then recovered from the selected one of the I and Q signals. [A2444]

"Patrol speed acquisition in police Doppler radar"

A process and apparatus to automatically determine whether a police radar is installed in a vehicle which has a coupling between a vehicle speed sensor and the police radar. The process automatically, without any operator input, determines the correct ratio between the true ground speed and the frequency output by vehicle speed sensor at that ground speed. The process and apparatus then use that ratio and the frequency from the vehicle speed sensor to establish a software search window that limits the speed range of the search by the police traffic radar for the true ground speed. [A2445]

"Transceiver assembly used in a Doppler-based traffic radar system"

A transceiver assembly is provided for use in a Doppler-based traffic radar system for determining the speed of at least one target. The transceiver assembly includes a cover for receiving therein at least some of the component parts of the transceiver assembly. In other words, the cover is positioned over the component parts of the transceiver assembly which are enclosed by a cap removably attached to the cover. A conical antenna horn and turnstile waveguide cavities are formed from a unitary material. The circuitry associated with the transceiver assembly is modularized such that the circuitry may be removed from the transceiver assembly, or more specifically separated from the microwave components of the transceiver assembly, for testing. [A2446]

"Highly integrated single substrate MMW multi-beam sensor"

A multiple beam array antenna system comprises a plurality of radiating elements provided from stripline-fed open-ended waveguide coupled to a Butler matrix beam forming network. The Butler matrix beam forming network is coupled to a switched beam combining circuit. The antenna can be fabricated as a single Low Temperature Co-fired Ceramic (LTCC) circuit. [A2447]

"Method for locating a concealed object"

Apparatus and methods are disclosed for detecting anomalies in microwave penetrable material that may be used for locating plastic mines or pipes underneath the ground. A transmitter is positioned at a plurality of different positions above the ground. A microwave signal is transmitted that is stepped over a plurality of frequencies. At each position, a plurality of reflections are received corresponding to each of the plurality of frequencies that were transmitted. A complex target vector may be produced at each position that contains complex values corresponding to magnitude, phase, and time delay for each of the plurality of reflections received at that location. A complex reference data vector may be produced, either based on predetermined values or based on data from the received plurality of reflections. A comparison is made between the complex target vector and the complex reference data vector to produce a channel vector. In one embodiment, an operator may be applied to the channel vector such as a complex filter matrix or to add a complex conjugate. A response signal is produced and anomalies are detected by variations in the response signal with respect to the plurality of positions. [A2448]

"Timing and control and data acquisition for a multi transducer ground penetrating radar system"

A multi-channel digital equivalent time sampling (MDETS) device having a programmable logic control that can select, delay or create various triggered signals. The MDETS can function independently or with multiple devices allowing for synchronized acquisition of data. The close proximity of MDETS device to a transmitter and receiver allows for the short time delay for acquiring the data. [A2449]

"Electromagnetic wave radar device mounted on a car"

An electromagnetic wave radar device mounted on a car, which helps improve external appearance of a car without impairing radar function, and is fabricated using a decreased number of parts at a reduced cost. The electromagnetic wave radar device comprises an electromagnetic wave radar body 1 mounted on a car 2 and for transmitting and receiving electromagnetic waves of a predetermined frequency, and a radome portion made of a material which permits the electromagnetic waves to transmit through and covers the electromagnetic radar body, the electromagnetic wave radar body being disposed on the side of the back surface 30A of the bumper 30 of the car, and the radome portion being formed by a portion of the bumper of the car. [A2450]

"Ground penetrating radar system for non-invasive inspection of trees for internal decay"

The method for examining trees comprises directing ground penetrating radar signals into a tree using a radar apparatus connected to a microprocessor control and data acquisition unit via an interface. The tree to be examined is scanned with the radar unit after the radar velocity for that tree is calibrated. The tree is scanned at a selected elevation either by moving a single radar unit along the bark of the tree in a circumferential manner or by moving a radar signal transmitter substantially diametrically opposed to a radar signal receiver along the bark of the tree in a circumferential manner. The microprocessor control and data acquisition unit controls the radar unit and stores and digitizes radar signals for generating a real-time radargram. A cross-sectional map of the tree, a map of the severity, shape, size and location of internal decay and a map of the thickness of remaining wood are then generated from the radargram and the ensemble of saved radar signals. The maps generated from this method may then be examined by tree diagnosticians to determine the extent of the internal damage of the tree. [A2451]

"Method and device for regulating clearance for a vehicle"

The present invention relates to a method for regulating clearance for a vehicle, in which a relative velocity (v.sub.rel) and a relative distance (a) between the vehicle and a second vehicle driving ahead are detected, and a control signal for an adaptive cruise control device is generated from these quantities. The control signal being derived from a danger criterion (G) is determined from the relative velocity (v.sub.rel) and the relative distance (a) , this danger criterion which is weighted with an adaptive factor (AF) representing the individual driving behavior of a vehicle driver, and a control signal initiating a deceleration of the vehicle is generated when the danger criterion (GF) , weighted with the adaptive factor and adapted to the vehicle driver, falls below a defined threshold value (S) . [A2452]

"Slot antenna element for an array antenna"

A multiple beam array antenna system comprises a plurality of radiating elements provided from stripline-fed open-ended waveguide coupled to a Butler matrix beam forming network. The Butler matrix beam forming network is coupled to a switched beam combining circuit. The antenna can be fabricated as a single Low Temperature Co-fired Ceramic (LTCC) circuit. [A2453]

"Position location method and apparatus for a mobile telecommunications system"

In a cellular mobile telecommunications system the position of a mobile station can be estimated in terms of its bearing and range from a cell site. A multi-element direction finding antenna at the cell site receives signals from the mobile station and a receiver circuit estimates the bearing using the relative phase of signals received at different antenna elements and estimates the range by measuring round trip delay of signals to and from the mobile station. Motion of the mobile station can introduce errors into the bearing estimate due to frequency offset and frequency spread when element sampling is non-simultaneous. Compensation for these errors is introduced by using signal samples successively received at the same antenna element to estimate Doppler frequency offset and spread. It is necessary to ensure accurate calibration of the direction finding antenna and the receiver circuit. This is done by injecting calibration signals into the circuit near the antenna or into the antenna itself from a near field probe. Other aspects of calibration, such as antenna position, are calibrated using a remote beacon. A beacon emulating a mobile station but at a fixed, known location, or a beacon at an adjacent cell site may be used. [A2454]

"Phase-based sensing system"

A system for sensing and measuring the relative motion of an object, comprising a transceiver device configured to transmit a signal toward an object, a plurality of detectors offset in phase to receive the transmitted signal and a reflected signal, and a processor configured with logic to measure a phase shift resulting from the relative motion of the object between the transmitted signal and the reflected signal at the plurality of detectors, wherein the processor is further configured with the logic to relate the phase shift to the relative motion of the object. [A2455]

"System and method for tracking and monitoring prisoners using impulse radio technology"

A system, apparatus and method are provided that utilize the communication capabilities and positioning capabilities of impulse radio technology to overcome the shortcomings in conventional prison monitoring systems. Basically, the present invention enables prison personnel to track the movements of a prisoner and/or monitor the vital signs of a prisoner using impulse radio technology that is well suited for a prison environment. [A2456]

"GPS vehicle collision avoidance warning and control system and method"

GPS satellite (4) ranging signals (6) received (32) on comm1, and DGPS auxiliary range correction signals and pseudolite carrier phase ambiguity resolution signals (8) from a fixed known earth base station (10) received (34) on comm2, at one of a plurality of vehicles/aircraft/automobiles (2) are computer processed (36) to continuously determine the one's kinematic tracking position on a pathway (14) with centimeter accuracy. That GPS-based position is communicated with selected other status information to each other one of the plurality of vehicles (2) , to the one station (10) , and/or to one of a plurality of control centers (16) , and the one vehicle receives therefrom each of the others' status information and kinematic tracking position. Objects (22) are detected from all directions (300) by multiple supplemental mechanisms, e.g., video (54) , radar/lidar (56) , laser and optical scanners. Data and information are computer processed and analyzed (50,52,200,452) in neural networks (132, FIGS. 6-8) in the one vehicle to identify, rank, and evaluate collision hazards/objects, an expert operating response to which is determined in a fuzzy logic associative memory (484) which generates control signals which actuate a plurality of control systems of the one vehicle in a coordinated manner to maneuver it laterally and longitudinally to avoid each collision hazard, or, for motor vehicles, when a collision is unavoidable, to minimize injury or damage therefrom. The operator is warned by a heads up display and other modes and may override. An automotive auto-pilot mode is provided. [A2457]

"Measuring circuit for a capacitive sensor for distance measurement and/or space monitoring"

In a measuring circuit for a capacitive sensor for distance measurement and/or space monitoring comprising sensor wire and shielding electrode, a sine signal is applied to the shielding electrode. The sensor wire is connected, via a shielded cable, with one input of an input amplifier which serves as current-voltage converter and whose supply voltage is likewise influenced by the sine signal. The output of the input amplifier is connected with one input of a phase-dependent rectifier arrangement, the sine signal is applied to the other input of the phase-dependent rectifier arrangement, and its output is connected to an analog-to-digital converter. [A2458]

"Method for controlling the average speed of a vehicle"

A method for controlling the average speed of a vehicle over a predetermined time period, or indefinitely, or distance length is described with reference to selecting a desired average speed, measuring an actual speed, and maintaining a cumulative error determined as a function of the difference between the average speed and actual speed and the time over which the actual speed measurement was taken. Based on the cumulative total of speed-time error, a compensatory speed is calculated that will reduce the cumulative speed-time error to an acceptable tolerance range within a selected period of elapsed time. Although particularly applicable to competition situations in which an average speed is dictated for use over a particular competition course, the average speed controlling method can be used in other situations where the average speed of a vehicle must be controlled. [A2459]

"Method of selecting a preceding vehicle, a preceding vehicle selecting apparatus, and a recording medium for selecting a preceding vehicle"

The radius of the curvature of the lane on which a subject vehicle is traveling, is calculated in accordance with the turning condition of the subject vehicle and the velocity of the subject vehicle is obtained on the basis of the steering angle, and the yaw rate. An instantaneous probability of the same lane that the recognized object target exists on the same lane is calculated. In this operation, the instantaneous probability is compensated. That is, the road shape is recognized with delineator or the like. The instantaneous probability of the same lane is compensated on the basis of the recognized road shape. The probability of the same lane is calculated after a predetermined filtering process with the compensated instantaneous probability of the same lane. The preceding vehicle is selected on the basis of the probability of the same lane. [A2460]

"Distance indicating device and method"

A distance indicating device having at least one energy wave generator. Each of the generators have a focusing device to produce a directional focused beam of wave energy. Each of the wave generators have a means for mounting the generator to a vehicle and a means for adjustively positioning the generator to intersect or impact an object at a predetermined distance from the generator or the vehicle on which it is mounted utilizing the point of intersection or impact to determine the distance between the vehicle and a fixed object. An improved method for indicating the distance between a vehicle and a fixed object is also provided utilizing the focused energy wave beam generators of the improved distance indicating device of the invention. [A2461]

"Article tracking system"

System for tracking mobile tags. Cell controllers with multiple antenna modules generate a carrier signal which is received by the tags. Tags shift the frequency of the carrier signal, modulate an identification code onto it, and transmit the resulting tag signal at randomized intervals. The antennas receive and process the response, and determine the presence of the tags by proximity and triangulation. Distance of a tag from an antenna is calculated by measuring the round trip signal time. The cell controllers send data from the antenna to a host computer. The host computer collects the data and resolves them into positional estimates. Data are archived in a data warehouse, such as an SQL Server. [A2462]

"Method and apparatus for measuring velocity and turbulence of atmospheric flows"

A method and apparatus for measuring the parameters of atmospheric turbulent flows utilizes the Doppler shifted frequencies of received radar signals backscattered from sound generated aerodynamically by atmospheric turbulent flows. Doppler frequency bandwidths of the received backscattered signals are used to estimate the atmospheric flow turbulence and the mean frequency within a bandwidth is processed to estimate its radial flow velocity. Total flow velocity and the flow velocity angle with respect to the antenna boresight of the atmospheric turbulent flow may be estimated by estimating the radial flow velocity at two radial positions and processing these radial velocities. Processing of the Doppler data is initiated when the total signal power within the Doppler frequency band exceeds a predetermined power level. [A2463]

"Method and apparatus for activating a crash countermeasure in response to the road condition"

A system for sensing a potential collision of a first vehicle (11) with a second vehicle (72) that transmits a second position signal. The first vehicle has a pre-crash sensing system (10) includes a memory (14) that stores vehicle data and generates a vehicle data signal. A first global positioning system (18) generates a first position signal corresponding to a position of the first vehicle. A first sensor (20) generating sensor data signals from the first vehicle. A receiver (22) receives a second position signal and a road condition signal from the second vehicle. A countermeasure system (40) is also coupled within the first vehicle. A controller (12) is coupled to the memory (14) , the global positioning receiver (18) the first sensor (20) and the counter measure system (40) . The controller (12) determines a distance to the second vehicle in as a function of the second position signal. The controller determines a first vehicle trajectory from the sensor data signals and the position signal. The controller (12) determines a threat level as a function of the distance, the first vehicle trajectory and the road condition signal and activates the counter-measure system in response to the threat level. [A2464]

"Excavator data acquisition and control system and process"

An excavator data acquisition and control system and process for characterizing the subsurface geology of an excavation site, and for utilizing the acquired data to optimize the production performance of an excavator is disclosed. A geologic imaging system and a geographic positioning system are employed to initially survey a predetermined excavation site or route. A geologic characterization unit may also be employed to enhance the geologic imaging data. The acquired data are processed to provide detailed geologic and position data for the excavation site and utilized by a main control unit to optimize excavator production performance. In one embodiment, the main control unit accesses a geologic filter database, which includes geologic profile data for numerous types of geology, when analyzing unknown subsurface geology. Removing geological filter data content corresponding to known geology from the acquired geologic imaging data provides for immediate recognition of unknown and suspect subsurface objects. The geologic imaging system preferably includes a ground penetrating radar system having a plurality of antennas oriented in an orthogonal relationship to provide three-dimensional imaging of subsurface geology. [A2465]

"Device for detecting angle of elevation error in a multiple beam radar sensor"

A method and a radar sensor for determining an elevation angle error of a multibeam radar sensor are described. In order to detect an elevation angle of the multibeam radar system with respect to a predefined target, a plurality of laterally arranged cutting planes at a predefined distance are formed. The values of the corresponding antenna diagrams in each plane are stored in a suitable form, for example, normalized and in a parametric form taking into account the elevation angle .alpha.. In order to reduce the size of the memory, it is sufficient to store one symmetry half for reasons of symmetry if additional information, for example, road clutter values are added, so that the upward or downward direction of the angle can be recognized. By comparing the measured echo values obtained by normalization and application of a quality factor, a corresponding elevation angle .alpha. is obtained for each cutting plane. Using an appropriate histogram, an angle for the maladjustment of radar sensor can be determined from the measured values stored over a longer period of time. [A2466]

"Flexible digital ranging system and method"

Systems and methods that may be used to determine the distance between an orbiting satellite and a ground station. A master clock divider circuit generates clock signals derived from a master clock. A transmit code generation circuit generates pseudo-random number codes and processes the pseudo-random number codes to produce a composite signal having positive and negative correlation peaks that is transmitted to the satellite as an analog signal. A digitizing circuit receives the analog signal transmitted from the satellite, and digitizes the analog signal. A frequency domain matched filter match filters the digitized analog signal to produce correlation peaks contained in the digitized analog signal. A central processing unit comprises a middle code software matched filter that generates an outer code bit, and computes the distance from the ground station to the satellite by calculating the difference between the time that the composite signal was received compared to the time that the composite signal was transmitted and dividing the difference value by the speed of light, and comprises an outer code software matched filter that produces a bit error rate signal indicative of the validity of the computed range value. [A2467]

"Secure I/P"

An improvement in the present radar/IFF equipment used by the military whereby the transponding equipment, when used in crypto-secure Mode 4, is enabled to reply with its unique coded identification number (Mode 2 reply) after it has made its Mode 4 reply. This is accomplished by adding an and gate and a delay means to the present equipment. The and gate is connected to couple the Mode 4 three-pulse interrogation to the delay means if it is received at the same time the I/P activate switch is in its operating position. The delayed three-pulse interrogation signal is coupled to the encoder and activates a Mode 2 reply. The ground equipment is also modified to enable it to faithfully reproduce the entire video output of its interrogator section. [A2468]

"Method and arrangement for obtaining and conveying information about occupancy of a vehicle"

Method and arrangement for obtaining and conveying information about occupancy of a passenger compartment of a vehicle including at least one wave-receiving sensor for receiving waves from the passenger compartment. Information about the occupancy of the passenger compartment is generated based on the waves received by the wave-receiving sensor (s) and transmitted, e.g., through a cellular phone system, to emergency response personnel to enable them to respond accordingly. The information about the occupancy of the passenger compartment may be generated by a processor applying pattern recognition techniques so that any occupants of the seat may be classified and such classification transmitted to the emergency response personnel. The wave received by the wave-receiving sensor (s) may also be used to determine the number of occupants in the vehicle and/or whether the occupants are moving after a crash. [A2469]

"Technique for estimating rainfall from a meteorological radar with polarization diversity"

Process for estimating a precipitation rate by means of a bipolar radar, characterized by the following various steps: the differential phase .PHI.dp and the attenuated reflectivity Z according to at least one of the polarizations H or V are measured by means of said bipolar radar, over a given interval [r.sub.1, r.sub.0] of path radius r with respect to said radar, an estimate of the value K (r.sub.0) of the attenuation at r.sub.0 is determined from the attenuated reflectivity profile thus measured, as well as from the difference in the differential phase between r.sub.0 and r.sub.1 , an estimate K (r) of the specific attenuation at r as a function of the attenuation K (r.sub.0) thus determined and of the attenuated reflectivity profile Z (r) is determined, the rate of precipitation R (r) is determined knowing K (r) . [A2470]

"Landmine locating system"

A landmine detection system comprises a ground-penetrating radar for probing the surface of the ground for landmines and other anomalies. The radar is swept back and forth across a lane while a user proceeds forward. A navigation sensor and processor keep track of all the parts of the lane that have been probed. A user display presents a visual graphic that represents the lane and the parts of it that have been probed. The user is then able to swing the radar to areas that are indicated as having been skipped in previous passes, e.g., to get 100%. coverage. [A2471]

"Apparatus and method for detecting radar obstruction"

An apparatus and method for detecting radar system blockage includes a radar system having an antenna unit configured to transmit radar signals and receive reflected radar signals. In one embodiment, fixed frequency continuous wave radar signals are transmitted, and corresponding reflected signals are sampled and processed to determine a mainbeam clutter signal peak in frequency bins near those corresponding to vehicle speed. If this peak is less than a power threshold, the antenna unit is at least partially blocked. In another embodiment, a number of most recent reflected tracking signal amplitudes are sampled, normalized to a predefined range value and filtered to produce a smoothed tracking amplitude. If the smoothed tracking amplitude drops below an amplitude threshold, the antenna unit is at least partially blocked. The two embodiments may be combined to determine a radar antenna blockage status as a function of both techniques. [A2472]

"Traveling-path estimation apparatus for vehicle"

An object in front of a vehicle is detected. At least one of a steering angle of the vehicle and a yaw rate thereof is detected. First curvature data are generated on the basis of at least one of the detected steering angle and the detected yaw rate. The first curvature data represent a course along which the vehicle will travel. A determination is made as to whether or not the detected object is a stationary object. In cases where the detected object is a stationary object, second curvature data are generated on the basis of the stationary object. The second curvature data represent a course along which the vehicle will travel. The first curvature data and the second curvature data are averaged. Third curvature data are generated in response to a result of the averaging. The third curvature data represent a course along which the vehicle will travel. [A2473]

"Doppler-based traffic radar system"

A Doppler-based radar system and related method are provided for determining the direction and speed of at least one selected target traveling in the same lane as a moving patrol vehicle supporting the radar system independent of the direction of the target relative to the platform. The radar system includes an oscillator to generate a signal, an antenna to transmit the signal toward the at least one target and to receive a return signal reflected from the at least one target, a turnstile in communication with the antenna for receiving the return signal and forming processing signals which are different in phase, and circuitry for determining the direction of the at least one target relative to the platform and the speed of the at least one target dependent upon a mode of operation of the radar system. [A2474]

"Bistatic radar system for centralized, near-real-time synchronized, processing of data to identify scatterers"

The bistatic radar system uses a scanning beam antenna located at the transmitter to transmit a focused beam of high frequency energy into a predefined space, with the transmitted beam comprising a series of pulses. The transmitter also includes apparatus for determining pulse origination data comprising: pulse origination time and direction of propagation for each of the pulses in the transmitted beam emanating from the antenna, where the antenna is scanned in a predetermined scan pattern in at least an azimuthal direction. The bistatic radar system also includes at least one receiver, located at a site remote from the transmitter and includes apparatus for generating pulse component receipt data indicative of receipt of components of the pulses that are contained in the transmitted beam that are reflected from scatterers in the predefined space. The receivers all transmit their data, substantially instantaneously, as received back to a central processor, which synchronizes (collates) the data in order to calculate, in near real-time, vector wind fields, divergence, vorticity, etc. These calculations typically are performed in polar coordinates or can be performed in Cartesian coordinates. Thus, the present bistatic radar system performs near-real-time synchronization, collating, transmission, and processing of data received from one or more bistatic receivers and from a transmitting radar to produce weather data in a more timewise efficient manner. [A2475]

"Radar apparatus"

The invention provides a man-portable, non-ground-contacting, ultra-wide band impulse radar system (1) , the system having separate transmit and receive antennae located in a common non-metallic housing (2) mounted at one end of a lightweight boom (3) , them being a data-processing computer and battery housing (4) mounted at the other end of the boom (3) end acting as a counterweight to the antennae system (2) , and the there being a data display and control unit (6) mounted generally centrally of the boom (3) , the boom (3) being attachable to an ergonomic hamess by which the whole may be carried by an Operator so that the data display and control unit (6) is in clear view of the Operator, and having one or more handle by which the whole may be grasped and swung from side to side while being so carried. [A2476]

"Traffic control system"

A satellite 10 in the sky has an imaging radar and a captured image data transmitting means, and captures an image of a predetermined subject area A including roads R. According to the captured image data concerning the subject area A, a traffic control section 21 grasps the state of traffic in the subject area A, and estimates a state of congestion according to thus grasped state of traffic. Also, according to thus estimated state of congestion, the traffic control section 21 sets parameters such as on/off times of signals. Thus set parameters are sent from the traffic control section 21 to their corresponding signals. The on/off of each signal is controlled according to the set parameters. Hence, the state of traffic in a wide area can be grasped quite accurately, and traffic can be controlled according to thus grasped state of traffic. [A2477]

"Method and apparatus for locating mobile tags"

A method and apparatus for determining tag location is disclosed. Tag reference data may be stored, e.g., in the form of a lookup table, as a trained neural network, and so on, and used to determine the location of tags. Readings used to determine tag location and/or preliminary tag locations may be filtered to produce reliable tag location indications. Packages of user configurable parameters can be provided and used for the filtering of the preliminary tag locations. Confidence levels may also be generated for determined tag locations and used, for example, to indicate how well an asset location system can distinguish between different tag locations. [A2478]

"Radar sensor having a CFAR detector"

A constant false alarm rate (CFAR) detector prevents false radar triggers due to RF interference by proportionally increasing the radar detection threshold as interference increases. The radar operates with a randomized PRF, which randomizes detected RF interference while maintaining echo signal coherence. Post-detection filters provide a signal channel and an interference channel. The interference channel augments the threshold of the signal threshold detector. The interference channel gain can be adjusted to ensure the detection threshold is always higher than noise in the signal channel, thereby eliminating false alarms due to RF interference. Accordingly, the CFAR detector eliminates a major false alarm nuisance, particularly in radar security sensors. Applications for the low-cost system include indoor and outdoor burglar alarms, automotive security alarms, home and industrial automation, robotics, and vehicle proximity sensors. [A2479]

"Method and apparatus for detecting vehicle stop"

A stop determination for a vehicle is provided by requiring simultaneous stop determinations by at least one wheel speed sensor providing output pulses at a rate inversely proportional to vehicle speed and a forward looking radar unit for sensing an object in the vehicle's path and providing a range rate signal with respect to that object. The determination is particularly useful when the time between consecutive pulses at a predetermined minimum speed indicative of an essentially stopped vehicle is greater than a predetermined maximum time period allowed for the determination. Each of the signals complements the other to provide a vehicle stopped determination that is more reliable than either can provide by itself and is workable for most purposes, including stop and go vehicle speed control. [A2480]

"Weather radar"

An antenna section radiates a pulse beam and receives its reflected wave, and a signal processing section observes a rain or cloud occurring region within a covered area based on a signal intensity of the reflected wave. In this case, to obtain wind direction and velocity information for the rain or cloud occurring region, the signal processing section observes Rayleigh scattering-induced Doppler echo components in that region to calculate the wind direction and velocity from a result of the observation. To obtain the wind direction and velocity information for a region other than the rain or cloud occurring area, the beam formed by the antenna section is directed toward the region to be observed so that the signal processing section can observe Bragg scattering-induced echo components based on a received signal of the reflected wave to calculate the wind direction and velocity from a result of the observation. [A2481]

"Radar field-of-view enhancement method and apparatus for matching field-of-view to desired detection zone"

A radar field-of-view enhancement method particularly adapted for vehicle radar detection systems having a specified detection zone. In accordance with the invention, a pair of discrete radar beams are employed having differing arc widths. Return signals from the discrete beams are compared and related to the area of a desired detection zone. This approach increases the reliability of detection in the detection zone while minimizing false alarms and missed detection areas. The beams are alternately switched on using discrete sources or by implementing a discrete phase shifting element interposed between the sources. [A2482]

"Vehicle periphery monitoring device"

A vehicle periphery monitoring device includes a transmitting circuit 3 for generating a transmission wave, an antenna 4 installed on the periphery or in the interior of a door mirror of a subject vehicle for radiating the transmission wave generated from the transmitting circuit as a formed beam having a directivity which propagates over a region expanding over an adjacent lane area from side portions of the subject vehicle toward the rear portion thereof, a receiving circuit 6 for receiving a reflected wave from an object which is in the periphery of the subject vehicle through an antenna 5, an arithmetically operating circuit 2 for arithmetically operating a distance between the subject vehicle and the object on the basis of a period of time required since the transmission wave generated from the transmitting circuit is radiated from the antenna until the transmission wave is reflected by the object and received by the receiving circuit and arithmetically operating a relative velocity from Doppler frequency of a received electric wave or a value of differential from an arithmetically operated distance to judge the risk of collision with the object on the basis of those arithmetically operated results, and LEDs 7 and 8 for announcing the judgement result of the arithmetically operating circuit 2 to a driver in response to the risk. [A2483]

"System and method for communication with radio frequency identification tags using tow message DFM protocol"

The system comprises a plurality of stationary sensors located in an array within certain physical areas. Each sensor comprises a plurality of antenna coils arranged in unique physical orientations and capable of transmitting radio frequency signals of differing phase. The RFID transponder includes an antenna which receives the signals generated by the antenna coils, and compares the phase of at least two of the signals to determined the relative position of the transponder. The antenna coils may emit two direction finding mode (DFM) signals in succession, the first signal with all antenna coils turned on, the second with a subset of the coils turned off. The spatial relationship of the transponder antenna and individual antenna coils precludes all of the signals in each sensor from being rejected by the transponder during emission of both the first and second DFM signal. [A2484]

"Efficient estimation of spectral moments and the polarimetric variables on weather radars, sonars, sodars, acoustic flow meters, lidars, and similar active remote sensing instruments"

A method for estimation of Doppler spectrum, its moments, and polarimetric variables on pulsed weather radars which uses over sampled echo components at a rate several times larger than the reciprocal of transmitted pulse length. The variables are estimated by suitably combining weighted averages of the over sampled signals in range with usual processing of samples at a fixed range location. The invention may be Used on pulsed weather radar, lidars, sonars and accoustic flow meters. [A2485]

"Signal processing method and apparatus, and sonar systems"

Signals entered from receiving transducer elements of 160 channels are multiplexed into 10 signal lines by 10 multiplexers. Each of 10 A/D converters converts the signals of 16 channels from analog from into digital form. The multiplexers are switched with synchronized switching timing to produce 10 pieces of sample data strings with the same timing. 160 pieces of sample data sampled in a steplike form are shifted in phase according to an oblique-line sampling scheme. The signal of the same channel is sampled twice with a phase delay of 90.degree. so that the signal can be converted into complex-valued sample data without increasing the number of processing circuits. [A2486]

"Method for measuring the speed of a vehicle"

The invention concerns a method and a device to measure the speed (v) of a vehicle relative to a road surface. To increase the accuracy of the speed measurement and in order to be able to determine the speed (v) of the vehicle independently of the diameter and the adhesion of a vehicle wheel on the road surface, the invention proposes that the speed (v) of the vehicle is measured directly on the road surface by utilizing the Doppler effect. [A2487]

"Radar device and on-vehicle radar device"

A radar device in which a much more precise demodulation can be made with an inexpensive circuit, free of the output variation of the frequency-modulated transmission signal. The radar device includes an oscillator which produces and outputs a frequency-modulated electromagnetic wave to a switching circuit by way of a directional coupler. The switching circuit uses switching modulation to radiate the electromagnetic wave from a transmitting antenna. The radiated electromagnetic wave after being reflected from an obstacle is received at a reception antenna. A mixer mixes this reception signal and a local signal fed from the directional coupler to produce a mixing signal which is to be fed to a high pass filter. The high pass filter deletes a low frequency output variation noise which is contained in the mixing signal and which occurs in the frequency modulation in the oscillator. The resulting mixing signal is, with the noise deleted, fed by way of an AC amplifier, to a switching demodulating circuit. [A2488]

"Ground penetrating radar system"

A ground penetrating radar system includes a cart configured to be movable along the ground. A computer is mechanically coupled to the cart. A radar electronics module is mechanically coupled to the cart and electrically coupled to the computer. A first antenna array is mechanically coupled to the cart, electrically coupled to the radar electronics module, and oriented to radiate into the ground and receive radiation from the ground. A second antenna array is mechanically coupled to the cart, electrically coupled to the radar electronics module, and oriented to radiate into the ground and receive radiation from the ground. A movement detector, which is configured to detect movement of the cart, is coupled to the computer. The computer is configured to trigger the radar electronics module when the computer detects that the cart has moved a predefined distance. The system uses nearfield beam forming, which is accomplished through fully coherent signal processing and synthetic aperture reception and processing, to image buried objects in three dimensions. The system displays a plan, or top, view and a side view of the area being scanned to provide a three dimensional perspective on a two dimensional computer screen. [A2489]

"Positional data utilizing inter-vehicle communication method and traveling control apparatus"

Predicted future positions are calculated (S11) and arranged into packets (S12) to be transmitted using a communication pattern (for example, a PN series) based on a time and a position of each packet (S13) . Another vehicle calculates its predicted position (S21) and generates a communication pattern based on a result of calculation (S22) so that the generated communication pattern is utilized for reception (S23) . Consequently, data associated with a future position of its own can be selected for enabling reception. An existence probability is calculated, and the state of another vehicle can be accurately understood from the communication of the calculated existence probability, thereby effectively reducing chance of collision. [A2490]

"Method and apparatus for pre-crash threat assessment using spheroidal partitioning"

A method for operating a pre-crash sensing system for a vehicle having an object detecting system and an associated data storage. The method includes partitioning the vehicle operating environment into a plurality of zones wherein each zone represents a different area surrounding the vehicle. In response to detecting an object within any one of the zones, the method activates the zone, and modifies an state of the object detection system and the contents of,the data storage as a function. the active zone. In one embodiment, three zones are disclosed wherein each zone represents a spheroidal area surrounding the vehicle. When the furthest zone is active, all data within the data storage is given approximately equal processing priority. When the middle zone is active, the content of the data storage is modified to prioritize data regarding the detected object for processing. Finally, when the nearest zone is active, the content of the data storage is further modified to provide highest priority to data regarding the detected object. [A2491]

"Vehicular component control systems and methods"

System and method for controlling operation of a vehicle or a component thereof based on recognition of a individual including a processor embodying a pattern recognition algorithm trained to identify whether a person is the individual by analyzing data derived from optical images and an optical receiving unit for receiving images including the person and deriving data from the images. The optical receiving unit provides the data to the algorithm to obtain an indication from the algorithm whether the person is the individual. A security system enables operation of the vehicle when the algorithm provides an indication that the person is an individual authorized to operate the vehicle and prevents operation of the vehicle when the algorithm does not provide an indication that the person is an individual authorized to operate the vehicle. A component adjustment system adjusts the component based on the recognition of the individual. [A2492]

"Weather radar system integrating ground-based weather radar with on-board aircraft weather radar"

A radar displaying system and method for use in displaying weather radar information on a cockpit display of an aircraft receives on-board weather radar information from an on-board weather radar system and ground-based weather radar information up-linked to the aircraft from a ground-based weather radar system. The information from the on-board weather radar system and the information from the ground-based weather radar system are combined to generate composite weather radar information. In response to the composite information, the cockpit display simultaneously displays both on-board weather radar imagery and ground-based weather radar imagery. [A2493]

"Methods and apparatus for stationary object detection"

The present invention provides systems and methods for measuring the likelihood that detected stationary objects are not normally present at a sensed location. Such systems and methods may be used by other systems to which information from the present invention are communicated, for minimizing nuisance alerts in onboard object detection systems such as collision warning, collision avoidance, and/or adaptive cruise control systems. The system includes at least one vehicle mounted sensor capable of sensing at least a target object and providing data related to the target object. The system also comprises a locating device which is capable of determining and providing data related to the location of the machine or vehicle and a processing unit which receives the data from the sensor and the data from the locating device. The processing unit is configured to determine a probability estimate or measure of likelihood that the target object is not a normally present object based upon a comparison to previously recorded data from a reference storage device. The reference storage device stores the previously recorded data acquired from at least one similar sensor and a vehicle locating device while operating in the same geographic area, or stores data derived from such previously recorded data. The invention may enhance vehicle collision warning, collision avoidance and/or adaptive cruise control systems as examples. [A2494]

"Device for determining distance and for transmitting data in a motor vehicle"

A device is proposed for ascertaining distance and transmitting data in a motor vehicle. It has a transmitting arrangement for generating and emitting a radar signal. A receiving arrangement receives a radar signal. It is characterized in that switchover arrangements are provided which cause the transmitting and/or receiving arrangement to operate either in a radar operating mode for detecting the distance and/or speed of a further object, or in a data-exchange operating mode for the exchange of data with a transceiver. Specific functions are enabled in dependence on the data exchange. [A2495]

"Hexagonal-annulus phased array antenna for radar wind profiling on moving platforms"

The inventive antenna uses a high-speed phased-array beam steering technique. By virtue of its geometry and the non-uniform power distribution throughout its many identical elements, the present invention achieves an ability to compensate for platform motion. The present invention also greatly reduces interference from low-angle antenna pattern sidelobes, notably ground- and sea-clutter. These are crucial characteristics for an accurate radar wind profiler. [A2496]

"A-scan ISAR target recognition system and method"

A target recognition system and method wherein only target amplitude data, i.e., coherent A-scan data, is interrogated at each of a plurality of range resolution cells along the radar line of sight path for target recognition. Target aspect angle is ignored within the angular segmentation of the feature library without degrading classification performance. Observed signature characteristics are collected at various aspect angles and through unknown roll, pitch and yaw motions of each anticipated target and provided to a neural network as training sets. The neural network forms feature vectors for each target class which are useful for valid classification comparisons in all sea states, especially in calm and littoral waters. These feature vectors are useful for valid classification comparisons over at least 30 degrees of target aspect angle. [A2497]

"Apparatus and method for detecting a location and an orientation of an underground boring tool"

An apparatus and method for determining a location and an orientation of an underground boring tool by employment of a radar-like probe and detection technique. The boring tool is provided with a device which generates a specific signature signal in response to a probe signal transmitted from above the ground. Cooperation between the probe signal transmitter at ground level and the signature signal generating device provided at the underground boring tool results in accurate detection of the boring tool location and, if desired, orientation, despite the presence of a large background signal. Precision detection of the boring tool location and orientation enables the operator to accurately locate the boring tool during operation and, if provided with a directional capacity, avoid buried obstacles such as utilities and other hazards. The signature signal produced by the boring tool may be generated either passively or actively, and may be a microwave or an acoustic signal. Further, the signature signal may be produced in a manner which differs from that used to produce the probe signal in one or more ways, including timing, frequency content, information content, or polarization. [A2498]

"Process for determining the relative velocity between two moving objects"

The invention relates to a process for determining the relative velocity in the radial direction between two moving objects, using linear frequency modulation with continuous frequency sweeps. A problem in such processes lies in being clearly able. to determine the phase difference. According to the invention, a clear determination is realized by varying the period. length for successive frequency sweeps and using the difference in period length and corresponding phase change in determining the volocity. [A2499]

"Technique for limiting the range of an object sensing system in a vehicle"

An object sensing system is capable of masking certain detected objects such that the system does not provide an alarm. Initially, a projected path of the vehicle is determined by using a current steering angle of the vehicle. Next, a desired warning distance is determined based upon the current steering angle. Then, a current distance to a sensed object, as derived from an object sensor, is determined. Finally, an alarm is provided only if the sensed object is within the desired warning distance. [A2500]

"Determination method for use with analog cellular system"

A method and apparatus for determining the location of a mobile unit within a cellular system. A synchronized signal at a common phase is generated at each base station in a system. The mobile unit transmits a signal tone. Each base station compares the phase of the signal tone to the common phase of the synchronized signal to produce a phase offset. A system controller compares the difference between the phase offset of a first base station and the phase offset of a second base station and determines the difference in distance between the first base station and the mobile unit and the second base station and said mobile unit defining a hyperbolic or linear curve of locations. The system controller compares the difference between the phase offset of the first base station and the phase offset of a third base station and determines the difference in distance between the first base station and the mobile unit and the third base station and said mobile unit defining a second hyperbolic curve of locations. The system controller determines the intersection of the first and the second hyperbolic curves thus determining the location of the mobile unit. [A2501]

"Fuzzy logic based vehicle collision avoidance warning device"

A vehicle collision avoidance warning device comprising a sensing module for detecting engine RPM, fuel throttle depress level, vehicle speed, and relative distance, a fuzzy logic controller coupled to the sensing module for receiving the engine RPM, throttle index, vehicle speed, and relative distance and generating a safety distance value using fuzzy logic, a safety warning device coupled to the fuzzy logic controller and the sensing module for comparing the distance with the safety distance and outputting a warning signal according to the comparison result. [A2502]

"Complex homodyned FSK diplex radar"

A complex frequency shift keyed homodyned diplexed radar system and method that can accurately determine the range of one or more targets where the targets have little or no velocity relative to the radar system. The system and method generates a FSK electromagnetic wave that is reflected off the one or more targets and converted into a delayed or phase shifted baseband signal and undelayed baseband signal where the delayed and an undelayed baseband signal may be analyzed to determine the range of the one or more targets. [A2503]

"Motor-vehicle-mounted radar apparatus"

A target 22 is explored by transmitting an exploration signal 40 at a certain angle while scanning an antenna 23. In the go and return exploration the angle for transmitting the exploration signal is shifted. It is possible to detect the direction of the target 22 with the same accuracy as that in exploration with a more minute angle difference, by combining the exploration results with the angle shifted in a plurality of scans. Relative travel of the target 22 that accompany a plurality of scans is considered as a Doppler shift and a combination of data is used considering the frequency shift. Data that cannot be combined is treated as an unwanted reflective object and the position where unwanted reflecting objects assemble is obtained and the position is determined as a shoulder. The height of a stationary target is determined from the variation in the reflected signal level in an approach to the stationary target. [A2504]

"Determining the condition of a concrete structure using electromagnetic signals"

Ground penetrating radar (GPR) is a technique that may be used to image the inside of a structure by collecting the echoes (or reflections) resulting from electromagnetic signals such as, for example, electromagnetic waves of typically high frequency, being radiated into the structure. Typically, the rebars inside of a reinforced concrete structure are strong radar wave reflectors. Locating deteriorated areas within a reinforced concrete structure may be accomplished by analyzing the reflections, particularly the amplitudes of the reflections, from the rebars in the reinforced concrete structure. Furthermore, the extent of deterioration of these located areas may be determined from such analysis. Significantly, the system and method described herein, when applied to determine the extent of deterioration of one or more areas of a reinforced concrete bridge deck, is effective even if a layer of asphalt is laminated to the surface of the reinforced bridge deck. A method and system for determining a condition of a substantially concrete structure is provided. One or more computer-readable data signals is received, where each data signal represents an electromagnetic signal detected from an area of the concrete structure. One or more of the detected electromagnetic signals include electromagnetic energy reflected from the concrete structure as a result of an electromagnetic signal transmitted into the concrete structure. An extent of deterioration of one or more areas of the substantially concrete structure are determined from the one or more computer-readable data signals. [A2505]

"Reversing aid"

The invention relates to a reversing aid for supporting the driver of a motor vehicle, particularly when parking, comprising at least one transmitter (12) , arranged at the rear end region (10) of the motor vehicle, for emitting measuring beams (14) into the rear danger zone, at least one receiver (16, 16a, 16b) , arranged at the rear end region (10) of the motor vehicle, for receiving beams (20) reflected at at least one detected object (18) , a distance-measuring device for determining the distance (A) between the vehicle and the detected object (18) , and a display device (22) for optically representing the distance (A) from the detected object (18) . Furthermore, the reversing aid comprises a measuring beam horizontal guidance system for the purpose of periodically scanning a predetermined angle range in the horizontal plane, an evaluation device for determining the position of the detected object in the horizontal plane relative to the vehicle rear end and to the extent of the width of the detected object, and a display screen (24) for pictorially representing the position and the extent of the width of the detected object in the horizontal plane relative to the vehicle rear end (10) . [A2506]

"Modulated pulse doppler sensor"

A range gated microwave motion sensor having adjustable minimum and maximum detection ranges with little response to close-in false alarm nuisances such as insects or vibrating panels. The sensor resolves direction of motion and can respond to target displacement in a selected direction and through a selected distance, in contrast to conventional hair-trigger motion sensors. A constant false alarm rate (CFAR) detector prevents false triggers from fluttering leaves, vibrating machinery, and RF interference. The sensor transmits an RF pulse and, after a modulated delay, mixes echo pulses with a mixer pulse. Thus, the echo pulses are modulated at the mixer output while transmit and mixer pulse artifacts remain unmodulated and easily filtered from the output. Accordingly, the sensor only responds to echoes that fall within its minimum and maximum range-gated region, and not to close-in or far-out objects. Applications for the low-cost system include indoor and outdoor burglar alarms, automotive security alarms, home and industrial automation, robotics, vehicle proximity sensors, cardiac motion detection, and a universal radar "bubble" detector. [A2507]

"Environmental location system"

A system and method for determining a location. The system employs encoded information devices dispersed through the environment, each having a non-unique code associated therewith. The codes from the encoded information devices are acquired as a reading device passes nearby, and stored. The codes from a proximate set of information devices are correlated with a map or mapping relation to determine one or more consistent positions within the environment. The information devices are preferably passive acoustic wave transponders, and the mapping relation may be a pseudorandom sequence or a defined map. [A2508]

"Narrowband passive differential tracking system (U)"

The tracking of moving vehicles over long distances without emitting illumination signals is accomplished with a narrowband passive differential tracking system. Instead of Providing especially designed radar transmitters in a bistatic radar system, illuminators of opportunity (which may include UHF and VHF television station) are selected by their geographic locations so that they are in proximity to a moving target. The Doppler-shifted target reflected signals from the illuminators of opportunity are converted into digital data and combined with the independently derived initial target location and used to update the target's position and velocity by correlating the Doppler-shift with geographic coordinates. The correlation can be accomplished with a tracking algorithm which was designed for use in data processing of the signal processing system of the narrowband passive position tracking system. [A2509]

"Multi-sweep method and system for detecting and displaying weather information on a weather radar system"

A system and method for detecting, processing, and displaying weather radar information which uses multiple scans, at differing antenna tilt angles, to generate a single displayed image. This can be used to reduce displaying of ground clutter returns and to simultaneously increase the range of weather information displayed on a single image. [A2510]

"Occupant position sensor and method and arrangement for controlling a vehicular component based on an occupant's position"

Arrangement and method in a vehicle for identifying an occupying item in which information or data about the occupying item is obtained and a pattern recognition system analyzes this information or data with respect to size, position., shape and/or motion to determine what the occupying item is whereby a distinction can be made as to whether the occupying item is human or an inanimate object. The information or data may be obtained by one or more receiver arrays which converts electromagnetic radiation into electrical signals such that the information or data about the occupying item is in the form of one or more electrical signals representative of an image of the occupying item. The same information or data may be used in arrangements and methods for controlling a vehicular component which also include a pattern recognition system for receiving and analyzing the information or data and a control unit for controlling the vehicular component based on the analysis of the information or data about the occupying item with respect to the size, position, shape and/or motion by the pattern recognition system. [A2511]

"Integrated radar and active transponder collision prediction system"

A method and apparatus for permitting a host automotive vehicle to avoid or mitigate the consequences of a collision between the host vehicle and a target automotive vehicle by using a combination of radar derived target information and transponder information. The host vehicle is equipped with a radar system operative detect the target vehicle and generate target data, and a computer which determines a likelihood of collision with target vehicle. If the likelihood of collision is above a certain level, the computer directs the radar system to transmit a directional interrogation system toward the target vehicle. The target vehicle is equipped with one or more transponders that receive the interrogation signal and respond by transmitting a response signal containing information indicating various dynamic and/or static characteristics of the target vehicle. The response signal is received by the host vehicle and is decoded to extract the target vehicle information. The computer then uses the transponder-derived target information along with the radar-derived target information to accurately determine the nature of the impending collision and direct appropriate changes in performance of one or more systems of the host vehicle in order to avoid or mitigate the consequences of the collision. [A2512]

"Volume in space locator"

Methods and apparatus for determining location information corresponding to a volume in space (VIS) that is occupied by a selected target from a remote observation platform through the process of collecting an identification signal from a source at or near the selected target and associating VIS location information data with that signal to identify location information corresponding to the VIS occupied by the target. [A2513]

"Method and apparatus for aligning a beam path for a beam-emitting sensor"

A system and method for aligning the beam path of a beam-emitting sensor arranged on a motor vehicle. Convenient and nevertheless highly precise setting of the beam direction of the beam-emitting element is possible if, when the vehicle is stationary, an external aligning beam propagating along or parallel to an actual direction of travel of the motor vehicle 1 hits a strictly planar surface on the sensor which reflects the aligning beam, the incident aligning beam and the reflected aligning beam are made to overlap as a result of the position of the sensor being changed. [A2514]

"Doppler-based traffic radar system"

A Doppler-based radar system and related method are provided for determining the direction and speed of at least one selected target traveling in the same lane as a moving patrol vehicle supporting the radar system independent of the direction of the target relative to the platform. The radar system includes an oscillator to generate a signal, an antenna to transmit the signal toward the at least one target and to receive a return signal reflected from the at least one target, a turnstile in communication with the antenna for receiving the return signal and forming processing signals which are different in phase, and circuitry for determining the direction of the at least one target relative to the platform. In particular, samples of the processing signals are transformed into the frequency domain and cross-correlated forming cross-correlation components. The radar system selects a target from the imaginary cross-correlation components dependent upon a mode of operation of the radar system and calculates the speed of the at least one target dependent upon a determined direction of the target and displays the speed for the operator's use. Advantageously, the radar system and method of operation allow the speed of the at least one target to be monitored without manual assistance from the operator. [A2515]

"Motor vehicle detector"

Vehicle detector arrangement comprising at least one detector unit (8) comprising at least one sensor (47, 48, 49, 50) , a transmission/reception unit (54) , an energy supply unit and a control unit (51, 52, 53) , whereby the energy supply unit comprises a solar cell module (3) . The transmission/reception unit (54) , the energy supply unit and the control unit (51, 52, 53) are accommodated in a housing (27, 28) and connected to the at least one detector unit (8) , whereby the solar cell module (3) is secured to the outside of the housing (27, 28) . As a result of what is thus autonomous functioning of the vehicle detector arrangement, it can be simply secured, for example, to a bridge (6) , and complicated installation jobs for power supply and data transmission, for example to a traffic routing center, are avoided. [A2516]

"Safety system for vehicles"

A safety system for a vehicle has a number of airbags (100-106) typically sited within a recess (108) in paneling of a vehicle (V) . To avert the possibility of extensive damage caused by an impact, the airbags are selectively deployed. Each airbag (100-106) has a multi-chambered structure (118-122) . The multi-chambered structure of each airbag is further arranged such that the chambers are rupturable separately from one another and are not of a vented type. More preferable, the individual chambers (118-122) are rupturable at different pressures whereby an airbag as a whole provides a cascade of energy absorbing impacts. [A2517]

"Method and apparatus for the highly accurate determination of the filling level of a product in a container"

The invention relates to a method for the highly accurate determination of the filling level (q) of a product (4) in a container (2) , measuring signals being transmitted in the direction of the surface (5) of the filled product (4) and reflected at the surface (5) as echo signals and the filling level (q) in the container (2) being determined by evaluation of the amplitude values (A) and phase values (.psi.) of the reflected echo signals by means of a pulse delay-time method. Furthermore, an apparatus suitable for carrying out the method is proposed. The invention is based on the object of proposing a method and an apparatus which permit highly accurate filling level measurements in containers (2) , even if multipath propagation or multimode propagation occurs. The object is achieved by compensating for errors which occur in the determination of the filling level (q) and are caused by interference signals which interfere constructively or destructively with the echo signals reflected regularly at the surface (5) of the filled product (4) . [A2518]

"Interruption-free hand-held positioning method and system thereof"

An interruption-free hand-held positioning method and system, carried by a person, includes an inertial measurement unit, a north finder, a velocity producer, a positioning assistant, a navigation processor, a wireless communication device, and a display device and map database. Output signals of the inertial measurement unit, the velocity producer, the positioning assistant, and the north finder are processed to obtain highly accurate position measurements of the person. The user's position information can be exchanged with other users through the wireless communication device, and the location and surrounding information can be displayed on the display device by accessing a map database with the person position information. [A2519]

"Vehicle navigational system and signal processing method for said navigational system"

The invention relates to a vehicle navigational system with a radar arrangement and an image sensor arrangement. It is proposed to derive target parameters separately from the receiving signals of the two arrangements and to convey them to data merging means to link the separately derived parameters. Linking can be carried out at different levels of digital signal processing. [A2520]

"Method of detecting fault of radar apparatus using movement distance and radar apparatus for the same"

A radar apparatus mounted on a vehicle includes a detecting section and a fault determining section. The detecting section includes a radar unit and detects a detection object using radar wave radiated from a radar unit toward the detection object and reflected radar wave from the detection target to the radar unit. The fault determining section determines whether any fault has occurred in the radar unit, based on the detecting result of the detection object and a movement distance of the vehicle, and generates a fault detection signal, when it is determined that any fault has occurred in the radar unit. [A2521]

"Radar system mounted on vehicle and capable of detecting degradation of sensitivity"

A radar system mounted on a vehicle includes a radar apparatus, a radome provided for the radar apparatus, a front wiper, a wiper operation detector detecting an operation of the front wiper, a temperature detector detecting temperature outside of the vehicle, and a processing unit. The processing unit estimates whether sensitivity degradation of the radar apparatus is caused, based on the detecting result of the wiper operation detector and the detecting result of the temperature detector. [A2522]

"Method and system for detecting a child seat"

Method and system for detecting the presence of the child seat on the seat including a receiving unit for receiving waves from a space above the seat and a signal-generating component which generates a signal based on the received waves which is indicative of the occupancy of the space above the seat. A different signal is generated for different occupants of the seat when the seat is occupied. A signal from the receiving unit representative of the received waves is analyzed, e.g., by a processor applying pattern recognition techniques, in order to generate the signal indicative of the occupancy of the seat and thereby enable a determination of whether a child seat is present in the seat and optionally the orientation thereof. A wave-emitter may be provided for emitting waves, e.g., ultrasonic or electromagnetic waves, into the space above the seat. One or more other systems or components in the vehicle, e.g., an occupant restraint device, may be affected or controlled based on the signal indicative of the occupancy of the seat, and more particularly, the determination of whether a child seat is present on the seat. [A2523]

"Reduced throughput track data association using look-up tables"

A system for rapidly associating a set of tracks with a set of sensor observations. Look-up tables are formed, with each look-up table being associated with a portion of a geometric surface surrounding the sensor so that the table cells correspond to various directions in free space in which sensor observations may be made. On the edges of each look-up table are overlap boundary rows of cells which contain the same sensor data as cells of the adjacent table. The observations from a sensor are populated into the tables based upon the directional orientation of the observations. Predicted values are calculated for each target object data track, and groups of cells surrounding the predicted values are searched for sensor observation data to match with each track. Having overlap boundary rows for each table which contain redundant data from the edge of the adjacent table allows the search for sensor data to match with a track to be performed within a single table. [A2524]

"Electromagnetic sensor system"

A vehicle (160) such as a motor road vehicle is fitted with an electromagnetic sensor system comprising transmitting means (e.g. 4, 1) for transmitting a radio frequency signal, receiving means (e.g. 2, 6) for receiving reflections of said signal from remote objects, sampling means (20, 28) operable to sample the received reflected signal (or a signal derived therefrom) , and processing means (e.g. 36) for processing the sampled signal, and operable to detect said reflections in the sampled signal, and to determine information on the presence, position and/or range of said object. The system includes filter means (e.g. 34) for preventing radio signals transmitted by other sources or noise spikes from causing interference which results in spurious detections or indications of range by the processing means. [A2525]

"Obstacle detecting system"

The accuracy of determination of a possibility of collision of a vehicle with an object is enhanced without the shortening of a period for detection of the object by an object detecting apparatus. A collision-possibility determining device determines the presence or absence of a possibility of collision of the vehicle with the obstacle by comparing a future locus of movement of the obstacle determined by an obstacle locus determining device based on an output from a radar device, with a future locus of movement of the vehicle determined by a vehicle locus determining apparatus based on outputs from wheel speed sensors and a yaw rate sensor. The period of the detection conducted by the radar device providing data about the obstacle to the obstacle locus determining apparatus is 100 msec, but the obstacle locus determining apparatus, the vehicle locus determining apparatus and the collision-possibility determining apparatus carry out the determination of the possibility of collision at a determination period shorter than the detection period of 100 msec. Thus, it is possible to carry out the determination of the possibility of collision at the shorter determination period without use of a large-sized and expensive radar device, thereby enhancing the determination accuracy. [A2526]

"Method and apparatus for predicting lightning threats based on radar and temperature data"

The invention provides a system and method for predicting areas where lightning strikes are likely to occur by evaluating radar and temperature data. Radar volume data is analyzed to locate cloud tops that extend above a height corresponding to a temperature line of about -10.degree. C. Areas where cloud tops extend above the height of the -10.degree. C. line and that have a radar composite reflectivity greater than 30 dBZ are designated as probable lightning threat areas. Radar movement is tracked across at least two time periods, and a correlation algorithm predicts the future location of lightning threat areas at predetermined time periods (e.g., 10 minutes, 20 minutes, and 30 minutes) based on predicted radar values. A computer display shows the predicted location of the lightning threat areas for the future time periods. In one variation, selected structures or areas (e.g., power lines, factories, or the like) are superimposed on a computer display with predicted lightning threat areas to illustrate where lightning damage is likely to occur. [A2527]

"Accident avoidance system"

System and method for preventing vehicle accidents in which GPS ranging signals relating to a host vehicle's position on a roadway on a surface of the earth are received on a first communication link from a network of satellites and DGPS auxiliary range correction signals for correcting propagation delay errors in the GPS ranging signals are received on a second communication link from a station or satellite. The host vehicle's position on a roadway on a surface of the earth is determined from the GPS, DGPS, and accurate map database signals with centimeter accuracy and communicated to other vehicles. The host vehicle receives position information from other vehicles and determines whether any other vehicle from which position information is received represents a collision threat to the host vehicle based on the position of the other vehicle relative to the roadway and the host vehicle. If so, a warning or vehicle control signal response to control the host vehicle's motion is generated to prevent a collision with the other vehicle. [A2528]

"Surveillance device for signal-echo sensors"

The signal echo monitoring device includes a transmitting unit (5) for broadcasting a transmitted signal (s (t)) which is a group of randomly generated pulses, a receiving unit (6) for receiving an echo signal (e (t)) , reflected by an object (12) , of the transmitted signal and a combined control and evaluation unit (2) including a device (10) for jointly evaluating the transmitted signal (s (t)) and the echo signal (e (t)) with an integrated adaptive filter (14) . The adaptive filter (14) automatically calibrates its impulse response b (t) and may be a digital filter. [A2529]

"Method and system for tracking multiple regional objects by multi-dimensional relaxation"

A method and system for real-time tracking of objects are disclosed. A region is repeatedly scanned providing a plurality of images or data sets having points corresponding to objects in the region to be tracked. Given a previously determined track for each object in the region, an M-dimensional combinatorial optimization assignment problem is formulated using the points from M-1 of the images or data sets, wherein each point is preferably used in extending at most one track. The M-dimensional problem is subsequently solved for an optimal or near-optimal assignment of the points to the tracks, extending the tracking of the objects so that a response to each object can be initiated by the system in real-time. Speed and accuracy is provided by an iterative Lagrangian Relaxation technique wherein a plurality of constraint dimensions are relaxed simultaneously to yield a reduced dimensional optimization problem whose solution is used to formulate an assignment problem of dimensionality less than M. The iterative reducing of dimensions terminates when exact solutions are determined for two-dimensional cases. A recovery procedure is used for determining a higher dimensional assignment problem solution from a problem having one less dimension. The procedure is useful when the reduced dimensional optimizational problem has two constraint dimensions. [A2530]

"Discrimination of detected objects in a vehicle path"

An object sensing system is capable of distinguishing an overhead roadway object, that is not in a host vehicle path, from a substantially motionless roadway object that is in the vehicle path. Initially, a plurality of sensor scan signals are provided into an anticipated path of a host vehicle. Next, a plurality of object return signals that correspond to reflections of the plurality of sensor scan signals from at least one detected stationary object are received. Then, an average amplitude slope of the return signals as a function of the range to the at least one detected stationary object is determined. A sufficiently positive amplitude slope identifies the detected stationary object as an overhead roadway object that is not in the vehicle path. A sufficiently negative amplitude slope identifies the detected stationary object as a substantially motionless roadway object that is in the vehicle path. [A2531]

"Automatic headlamp control system utilizing radar and an optical sensor"

A headlamp control system for a motor vehicle includes a wave transmitting and wave receiving device for detecting objects. The headlamp control system determines the state of the vehicle headlamps based upon objects detected by the wave transmitting and wave receiving device. The wave transmitting and wave receiving device can be a radar, an optical radar, ultrasonic, or the like. An optical sensor can be used to detect ambient light or other vehicles. [A2532]

"System and method for projecting storms using NEXRAD attributes"

The subject invention provides an improved system and method for combining data obtained from the NEXRAD.TM. system of the National Weather Service ("NWS") with geographical and topological database information to achieve an improved and informative graphical storm-tracking display able to project the movement of a storm with a single user-operation. The method of projecting storm movement includes the following steps: collecting NEXRAD data attributes from a weather data source, calculating storm position using the collected NEXRAD attributes, calculating projected storm movement using the storm position and the collected NEXRAD attributes, displaying a graphic representation of the projected storm movement. [A2533]

"Spread spectrum localizers"

A network of localizers determines relative locations in three-dimensional space to within 1 cm by measuring propagation times of pseudorandom sequences of electromagnetic impulses. The propagation time is determined from a correlator which provides an analog pseudo-autocorrelation function sampled at discrete time bins. The correlator has a number of integrators, each integrator providing a signal proportional to the time integral of the product of the expected pulse sequence delayed by one of the discrete time bins, and the non-delayed received antenna signal. Using pattern recognition the arrival time of the received signal can be determined to within a time much smaller than the separation between bins. Because operation of standard CMOS circuitry generates noise over a large frequency range, only low-noise circuitry operates during transmission and reception. A stage in the low-frequency clock uses low-noise circuitry during transmissions and receptions, and standard circuitry at other times. [A2534]

"Doppler-based traffic radar system and related method of operation without detection"

A Doppler-based traffic radar system determines a speed of a moving target from a platform while substantially eliminating the possibility of detection by an operator of the moving target utilizing a traffic radar detector. The radar system limits a period of time the system is initially transmitting. The radar system is adapted to determine the speed of the target and display the speed. Dependent upon the displayed rate of speed, the radar system operator further has the ability to halt operation of the radar system with respect to the particular target or to reinitiate transmission of the transmit signal for subsequently tracking the speed of the moving target. [A2535]

"System and method for intrusion detection using a time domain radar array"

A system and method for highly selective intrusion detection using a sparse array of time modulated ultra wideband (TM-UWB) radars. Two or more TM-UWB radars are arranged in a sparse array around the perimeter of a building. Each TM-UWB radar transmits ultra wideband pulses that illuminate the building and the surrounding area. Signal return data is processed to determine, among other things, whether an alarm condition has been triggered. High resolution radar images are formed that give an accurate picture of the inside of the building and the surrounding area. This image is used to detect motion in a highly selective manner and to track moving objects within the building and the surrounding area. Motion can be distinguished based on criteria appropriate to the environment in which the intrusion detection system operates. [A2536]

"CDMA communications and geolocation system and method"

A spread-spectrum CDMA communications system for locating remote units, and for communicating message data between a plurality of remote units and a base station. The spread-spectrum CDMA communications system includes a plurality of base stations and a plurality of remote units. A base station has a spread-spectrum modulator for spread-spectrum processing the message data, and a transmitter for transmitting the spread-spectrum processed-message data, combined with a generic-chip-code signal, from the base station to a remote unit. The base station also has an antenna, and spread-spectrum detectors for recovering message-data communicated from the remote units. A remote unit has an antenna, and a detector coupled to the antenna for recovering data communicated from the base station. The detector includes a spread spectrum demodulator. Also, the remote unit has a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator and a transmitter. The base station has a range circuit, which compares the generic-chip-code signal generated at the base station with the generic-chip-code signal received from the remote unit, for determining a range between the remote unit and the base station. [A2537]

"System and method for locating radio frequency identification tags using three-phase antenna"

A system and method for determining the position of a radio frequency identification (RFID) transponder with respect to a sensor. In one embodiment, the system comprises a plurality of stationary sensors located in an array within certain physical areas. Each sensor comprises a plurality of antenna coils arranged in unique physical orientations and capable of transmitting radio frequency signals of differing phase. The RFID transponder includes an antenna which receives the plurality of signals generated by the antenna coils, and compares the phase of at least two of the signals to determine the relative position of the transponder. In a second aspect of the invention, the aforementioned antenna coils emit two direction finding mode (DFM) signals in succession, the first signal with all antenna coils turned on, the second with one of the coils turned off. The spatial relationship of the transponder antenna and individual antenna coils precludes all of the signals in each sensor from being rejected by the transponder during emission of both the first and second DFM signal. Hence, the transponder is kept in constant communication with the sensor in all orientations. In another embodiment, the location of the transponder with respect to two or more sensor (s) is determined through measurement of the intensity of the signals received by the antenna coil of the transponder. The invention also includes a system and method for transmitting data between a sensor and a dormant (motionless) RFID transponder using a hand-held high intensity RF probe. [A2538]

"Method for determining the vertical distance between an object and a device with a variable position"

The invention relates to a method for determining the perpendicular distance between an object and a device whose position varies, in particular a motor vehicle, in the case of which device a first sensor which is arranged on this device emits a signal which is reflected by the object, and this reflected signal is received by this first sensor, in which case the delay time of the signal from transmission to reception is used by the first sensor to determine the distance between the first sensor and the object. In order to determine the perpendicular distance to the object, this distance is used to determine all the possible positions of the object with respect to the first sensor, the signal reflected by the object is furthermore received by a second sensor, which is likewise arranged on the device whose position varies, and the delay time of the signal from the first sensor to the second sensor is used to determine a path from the first sensor to the object and from this object to the second sensor, from which path all the possible positions of the object with respect to the second sensor are determined, the positions determined by the first sensor and the second sensor with the same distance are then compared with one another, and the perpendicular distance to the device whose position varies is determined for those positions of the object which are detected by both the first sensor and the second sensor. [A2539]

"Talking buried object detector"

A spoken word-producing detector identifies objects by comparing signatures of detected objects with stored signatures of known objects. When the signatures compare, the detector produces stored word sounds associated with the detected object identifications. An annunciator produces the words from pre-digitized human voice sounds. A screen displays the words. [A2540]

"Method and system for controlling a vehicular system based on occupancy of the vehicle"

A vehicle interior monitoring system to identify, locate and/or monitor occupants, including their parts, and other objects in the passenger compartment in which waves are transmitted into a space in the passenger compartment in which an occupying item might be situated and a receiver receives waves modified by passing through the space in the passenger compartment in which the occupying item might be situated. Outputs from the receiver are used to affect another system in the vehicle. Also, the outputs may be analyzed, e.g., by computational means employing pattern recognition technologies, to classify, identify and/or locate the contents. In general, the information obtained by the identification and monitoring system is used to affect the operation of some other system in the vehicle. When the system is installed in the passenger compartment of an automotive vehicle equipped with an airbag, the system determines the position of the vehicle occupant relative to the airbag and, e.g., disables deployment of the airbag if the occupant is positioned so that he/she is likely to be injured by the deployment of the airbag. [A2541]

"Car radar testing"

A method and device for testing the function of a radar. A diode (21) with variable radar radiation impedance is arranged in the beam path (23) inside the antenna unit (4, 6) of the car radar and is fed with alternating current for simulating a radar target at a distance from the antenna unit. The obtained target data for the simulated target are compared to the expected target data for testing the function. [A2542]

"Broadband CDMA overlay system and method"

A spread-spectrum CDMA communications system for communicating data between a plurality of users to a plurality of spread-spectrum units. The spread-spectrum communications system is located within a same geographical region as occupied by an existing FDMA, proposed TDMA or any other mobile-cellular system. The spread-spectrum CDMA communications system includes a plurality of spread-spectrum-base stations and a plurality of spread-spectrum units. A spread-spectrum-base station has a comb filter for notch filtering predetermined channels of the mobile-cellular system, a device for converting the format of the data into a form for communicating over radio waves, a spread-spectrum modulator for spread-spectrum processing the data, and a transmitter for transmitting the spread-spectrum-processed converted data from the spread-spectrum-base station to a spread-spectrum unit. The spread-spectrum-base station also has an antenna, and spread-spectrum detectors for recovering data communicated from the spread-spectrum units. A spread-spectrum unit has an antenna, and a detector, including a spread-spectrum demodulator, coupled to the antenna for recovering data communicated from the spread-spectrum-base station, and the spread-spectrum unit has a spread-spectrum modulator, a transmitter, and a device for converting the format of the data for communicating over radio waves. [A2543]

"Method and system for detecting turbulence with reduced errors resulting from vertical shear components"

A system and method for enhancing turbulence detection, display and alerting with avionics weather radars which includes automatically making multiple scans, measuring a wind velocity gradient at varying elevations, and comparing the measured gradient to known predetermined wind velocity gradients over known elevation variations, wherein the predetermined gradients have known vertical shear components, and using a vertical shear component information in making determinations regarding the existence of turbulence. [A2544]

"Multi-sweep method and system for mapping terrain with a weather radar system"

A system and method for detecting, processing, and displaying ground mapping radar information which uses multiple scans, at differing automated antenna tilt angles, to generate a single displayed image. This can be used to increase the scanned area of a ground display so as to allow a complete sampling of the ground ahead of the aircraft. [A2545]

"Automobile unsafe following distance warning system"

An automobile unsafe following distance warning system, located in an installed vehicle, for assessing whether a safe following distance is present between the installed vehicle and a front vehicle which is traveling immediately in front of the installed vehicle, comprising a sensor unit for determining the distance between the front vehicle and the installed vehicle, and for determining the speed of the installed vehicle. A threshold safe following distance is determined from the measured speed of the installed vehicle. An initial warning light is illuminated to notify the driver that the actual following distance is less than the threshold safe following distance. A severe warning light, a buzzer, and a vibration unit are activated to notify the driver that the actual following distance is much less than the threshold following distance and that a dangerous situation exists. [A2546]

"Surface acoustic wave transponder configuration"

An acoustic wave identification transponder device, having a substrate, an electroacoustic transducer generating an acoustic wave in said substrate and a set of encoding elements disposed in a path of the acoustic wave for modifying the acoustic wave, having elements which reflect portions of the acoustic wave having a component orthogonal to the incident wave. The reflectors may be, for example, trackchangers or reflective arrays compressors (RAC) . The wave may be phase-amplitude modulated for increased efficiency expressed in bits per tap. Such phase amplitude modulation is preferably imposed by partial beam width phase delay elements disposed within an acoustic beam path. [A2547]

"Spread spectrum localizers"

A network of localizers determines relative locations in three-dimensional space to within 1 cm by cooperatively measuring propagation times of pseudorandom sequences of electromagnetic impulses. Ranging transmissions may include encoded digital information to increase accuracy. The propagation time is determined from a correlator circuit which provides an analog pseudo-autocorrelation function sampled at discrete time bins. The correlator has a number of integrators, each integrator providing a signal proportional to the time integral of the product of the expected pulse sequence delayed by one of the discrete time bins, and the non-delayed received antenna signal. With the impulses organized as doublets the sampled correlator output can vary considerably in shape depending on where the autocorrelation function peak falls in relation to the nearest bin. Using pattern recognition the time of arrival of the received signal can be determined to within a time much smaller than the separation between bins. Because operation of standard CMOS circuitry generates noise over a large frequency range, only low-noise circuitry operates during transmission and reception. To provide the time accuracy necessary for distancing, a high-frequency clock operates during inter-localizer communications. The high-frequency clock uses a phase-lock loop circuit to increase the clock rate and a programmable delay to provide still finer time graduations. A stage in the low-frequency clock uses low-noise circuitry during transmissions and receptions, and standard circuitry at other times. [A2548]

"FM pulse Doppler radar apparatus"

AN FM pulse Doppler radar apparatus performs pulse modulation of modulating waves having repeatedly increasing and decreasing frequency, transmits thus modulated waves, receives at each range gate having an interval equivalent to a pulse width, reflected waves reflected from an object, determines a distance according to the range gate, and calculates the distance to the object and the relative velocity of the object based on the difference between frequencies of the transmission waves and the received waves. The apparatus includes a velocity determining unit for determining velocity of the radar-mounted vehicle and a comparison-and-detection unit for comparing the detected distance according to the range gate and the distance calculated based on the difference between the frequencies of the transmission waves and the received waves. The comparison-and-detection unit detects, based on the velocity of the vehicle and the relative velocity between the vehicle and the object, a distance error due to an error in transmission frequency bandwidth. [A2549]

"Method of reducing clutter and mutual interference in a coherent doppler radar system"

A method is proposed for use on a coherent Doppler radar system for the purpose of reducing the clutter and mutual interference in the coherent Doppler radar system. The echoed radar signal from the target object is converted into a Range-Doppler Domain output signal. If the Range-Doppler Domain output signal indicates the presence of mutual interference, a Crisscrossing CFAR method is selected to compute for the CFAR back-ground value, otherwise an Area CFAR method is selected. A target-detection logic circuit is then used to obtain the radar information about the target object. By the proposed method, the output signal of the target-detection logic circuit is substantially free from clutter and mutual interference, which is further converted into a radar display signal to drive a radar display unit to display the location and velocity of the target object. [A2550]

"Obstacle recognition system for vehicle"

Height-wise positions of objects are detected on the basis of distances to the objects from a vehicle, angles of the objects in a width-wise direction of the vehicle, and angles of the objects in a height-wise direction of the vehicle. A plurality of objects, which satisfy conditions predetermined depending on physical characteristics of delineators, are determined to be objects composing a delineator group. When the detected height-wise position of an object in the delineator group which is nearest to the vehicle corresponds to a predetermined value or less, the delineator group is determined to be a delineator group on a road surface. A determination is made as to whether each object in the on-road-surface delineator group is a non-delineator in response to conditions of the detected height-wise positions of the objects in the on-road-surface delineator group. [A2551]

"Radar apparatus"

A radar apparatus is provided that can correctly extract the necessary point for a determination related to the safe travel of one's automotive vehicle among objects such as automotive vehicles moving at an angle in front and constructed objects. The radar apparatus of the present invention provides antennas that transmit beams in a plurality of directions and receive the reflected waves from objects as received signals. The objects that generated these reflected waves are detected. In addition, this radar apparatus provides a reflected location detection device that detects the reflected locations that are the generation source of the reflected waves for this plurality of directions, a grouping device that groups each of these detected reflected locations into a group of single or plural reflected locations assuming they belong to the same object, and a device that extracts reflected locations having the shortest distance from the moving body from among these grouped reflected locations to serve as reference points related to the safe travel of this moving body. [A2552]

"High performance vehicle radar system"

A radar system is described for use in vehicular applications. The radar system is particularly suited to backup warning systems and side-object warning systems. The radar minimizes many of the problems found in the prior art by providing programmable delays and programmable gain. The radar uses a range search algorithm to detect and sort targets at various ranges within the field of view of the radar. Each target range corresponds to a particular delay and gain setting. The radar searches for targets at the various ranges by running a target search algorithm. for each target range, the search algorithm causes the proper time delay and gain setting. Targets within the selected range are detected and catalogued. A display is used to warn the driver of the vehicle of the presence of targets at the various ranges. The warning may be visual and/or audible. [A2553]

"Apparatus and method for microwave imaging and excavation of objects"

A microwave imaging excavator for the detection, imaging and excavation of objects on or buried beneath the surface of the ground, such as metallic and dielectric land mines. A continuous wave stepped frequency ground penetrating radar signal is transmitted into the ground from a waveguide antenna mounted in one spade of a double spade auger. Direct breakthrough energy, signals reflected from the surface and the buried objects are received by an identical waveguide antenna mounted in the opposite spade. The spectra reflected from different buried objects become more distinct when the spectrum radiated spans the natural electromagnetic resonance of those objects. These signals are recorded as the twin-spaded auger is mechanically scanned over the ground in two mechanical rotational states of polarization. When the auger spades are on either side of a buried mine they are closed to grasp the mine which is then removed from the ground. [A2554]

"Method and device for classifying overhead objects"

The present invention relates to a method for classifying objects detected by a vehicle mounted radar located in front of said vehicle for transmitting a radar microwave signal and for receiving reflexes thereof from objects positioned in front of said vehicle, said melted comprising the steps of: tracking a radar reflex from an object located in front of said vehicle as the calculated distance from said vehicle to said object, as derived based upon the time of flight of said radar reflex, decreases, monitoring changes in the amplitude of said radar reflex from said object is said calculated distance from said vehicle to said object decreases, and classifying said object as an overhead object or a ground level object based upon the said changes in the radar reflex amplitude. [A2555]

"Radar and method therefor"

A radar (300) comprises a transceiver (302) for transmitting pulses directed to a subsurface area of interest (102) and for receiving a reflected wave (210) from the subsurface area of interest. The pulses have a pulse duration and amplitude constrained by the equation, d.sup.2.vertline.E.vertline.e/m.ltoreq.1 Angstrom, where d is the pulse duration in seconds, E is the pulse amplitude in volts/meter, e equals the charge of an electron in Coulombs, and m equals the mass of an electron in Kg. A processing device (304) , in communication with the transceiver, processes the reflected wave and displays an image of the subsurface area of interest and identifies the material composition of subsurface objects that have known properties that vary as a function of the pulse duration and amplitude. [A2556]

"Method of manufacturing an enclosed transceiver"

The present invention teaches a method of manufacturing an enclosed transceiver, such as a radio frequency identification ("RFID") tag. Structurally, in one embodiment, the tag comprises an integrated circuit (IC) chip, and an RF antenna mounted on a thin film substrate powered by a thin film battery. A variety of antenna geometries are compatible with the above tag construction. These include monopole antennas, dipole antennas, dual dipole antennas, a combination of dipole and loop antennas. Further, in another embodiment, the antennas are positioned either within the plane of the thin film battery or superjacent to the thin film battery. [A2557]

"Underground storage tank monitoring system and method"

An underground storage tank monitoring system and method uses special micropower impulse radar probes, with one such probe being inserted into each storage tank. The micropower impulse radar probes use flexible waveguides which extend downward to the tank bottom such that micropower radar impulses travel to and from the liquid surface via a wave guide, with the lapse between emission and reception of the impulse indicating a distance from the probe, and thus a liquid level. Each micropower impulse radar probe is connected to a dedicated spread spectrum transmitter which collects level and status information from the probe, encodes and transmits it to a matching spread spectrum receiver nearby. The receiver converts the coded signals into electrical signals and forwards them to a processor, a modem and a back-up battery are located. The processor stores the liquid level information for later transmission, along with liquid dispensed and liquid replaced information, to a central monitoring site via the modem. [A2558]

"Distance detecting method and its apparatus"

A signal having periodicity is transmitted to a communication station B based on a reference timing generated by a timer which a communication station A has, while the communication station B, which has received a transmitting signal of the communication station A, receives a signal generated based on a reference timing generated in its internal section and transmitted, and a phase difference between the transmitting signal and the received signal is detected so as to detect a distance between the communication station A and the communication station B. [A2559]

"Accident avoidance system"

System and method for preventing vehicle accidents in which the absolute position of the vehicle is determined, e.g., using a satellite-based positioning system such as GPS, and the location of the vehicle relative to the edges of the roadway is then determined based on the absolute position of the vehicle and stored data relating to edges of roadways on which the vehicle may travel. A system or component within the vehicle is initiated, e.g., an alarm or warning system, or the operation of a system or component is affected, e.g., an automatic guidance system, if the location of the vehicle approaches close to an edge of the roadway or intersects with an edge of the roadway. [A2560]

"Vehicle surroundings monitoring apparatus"

Distance image outputted from an image processor is read by a recognition/judgment computer, in which the distance image is divided into strips having a specified interval and a histogram is prepared for each strip. Based on the histogram, the position of solid objects and the distance thereto are obtained and these positional data of the solid objects are classified into groups of solid object and groups of side wall. Further, the position of a wall surface forming a boundary of a road is detected from the data of the groups of side wall. On the other hand, assuming a wall surface model composed of a series of nodes, respective nodes are determined and corrected by the data of side wall. Thus obtained nodes form a successive wall surface along a curved road. [A2561]

"Reflector circuit"

A reflector circuit is provided which responds to illuminating radiation with corresponding output radiation of increased magnitude relative to the illuminating radiation. The circuit comprises an antenna for receiving the illuminating radiation and emitting corresponding output radiation, a delay line providing a frequency selective limiting and signal storage characteristic and an amplifier assembly incorporating a reflection amplifier for providing signal amplification. The reflection amplifier is capable of providing high gains approaching +30 dB at relatively low current consumption, for example, tens of microamperes. The antenna provides an input signal upon receipt of the illuminating radiation, a portion of which is amplified, frequency selectively filtered, and then stored for a period after which it is emitted as the output radiation from the circuit. Switches may be incorporated and are operable to counteract spontaneous oscillation within the circuit. [A2562]

"On-vehicle DBF radar apparatus"

An on-vehicle DBF radar apparatus is mounted on a vehicle and is arranged to detect an object around the vehicle by scanning with radar beams synthesized by digital signal processing. The radar apparatus has a lane shape acquiring section for acquiring a shape of a lane on which the vehicle is driving. In the radar apparatus a scanning range of the radar beams is limited according to the shape of the lane acquired by the lane shape acquiring section. The radar apparatus has advantages of high detection rate and detection accuracy. [A2563]

"Following distance alarming apparatus and following distance displaying apparatus that display difference between measured following distance and that at which warning is given"

A following distance displaying apparatus which enables visual confirmation how much more approach between a preceding vehicle and a subject vehicle makes a distance at which an alarm of a following distance alarming apparatus operates, after a lapse of a predetermined time from when the preceding vehicle and the subject vehicle entered a follow-up travel state, indicates an alarm distance at which the alarm of the following distance alarming apparatus operates which is set in advance corresponding to the then following distance to the preceding vehicle and an approach distance representing a difference between the subsequently measured following distance and said alarm distance. [A2564]

"Radar system for motor vehicle"

An automotive radar system having an oscillator is described, the oscillator generating a high-frequency signal only in intervals as a function of a control signal during operation of the radar system. The oscillator includes a microwave diode, in particular a Gunn diode or an Impatt diode, accommodated inside a casing-like body. At least one of the following components, an ohmic resistor, a transistor or an IC is arranged so that it is thermally connected to the casing-like body or to an element thermally connected to the latter, the component having at least one additional function in the circuit configuration of the radar system other than generating heat. This guarantees that the oscillator will oscillate reliably even at very low temperatures and in particular in chopping operation. [A2565]

"Vehicular radar"

A vehicular radar includes a transmitter for outputting a transmitted electromagnetic wave, an antenna unit for radiating the transmitted electromagnetic wave and receiving a electromagnetic wave reflected by an object to be detected as a received electromagnetic wave, a receiver for detecting the reflected electromagnetic wave received by the antenna unit, and a signal processor for processing an output signal from the receiver to output information about the object. The antenna unit includes a single electromagnetic radiator for radiating the transmitted electromagnetic wave, a single reflector for reflecting the transmitted electromagnetic wave from the electromagnetic radiator and radiating the transmitted electromagnetic wave as a beam, and a reflector swinging device for swinging the reflector so as to successively change a direction of the beam. The reflector swinging device includes a first arm, a second arm, a swinging pivot, a cam and a cam follower. [A2566]

"Method and sensor for detecting foreign bodies in a medium with a radar"

A method of detecting foreign bodies in a medium with a radar having a transceiver, and including emitting a radar wave through a wall surface into the medium with the transceiver, detecting a radar signal reflected in the medium, pre-processing the reflected radar signal and subjecting the pre-processed radar signal to evaluation and assessment, determining a characteristic of a foreign body at a stationary position of the transceiver with an algorithm which is based on a pre-processed, digitalized receivable signal, which characteristic permits to recognize differences between a shape of the reflected radar signal and stored comparison values, and conducting a comparison assessment of the shape differences of the reflected signal against predetermined threshold values. [A2567]

"Method and a system for monitoring plurality of movable objects"

A method and a system for monitoring a plurality of movable objects, wherein each of the objects is equipped with a transponder with which a stationary node is arranged to communicate. Each transponder is caused to reply to a unique signal from the node and each transponder that sends a response signal gives to the response signal a transponder identification addition. A node is caused to detect the speed and direction at which each transponder moves towards and away from the node. Movement of the transponder relative to the node is evaluated by node associated means on the basis of the speed and direction of the transponder. A register over those transponders with which the node shall communicate is set-up for each node. A plurality of separate nodes are provided and each node is provided with such a register. The nodes are arranged to communicate with one another, so as to enable a node to record in its monitoring register a transponder from another node. [A2568]

"Method and device for adjusting a distance sensor"

The present invention relates to a method and an apparatus for adjusting the alignment of a beam characteristic of a distance sensor, in particular of a proximity radar for a motor vehicle. An apparatus for positioning a motor vehicle, preferably a headlight aiming device, is joined to the target object for the distance sensor. Also provided is a service unit with which measured values or data of the distance sensor can be read out. On the basis of at least one predefined criterion, the measured values or data are analyzed in such a way that necessary displacement directions of the distance sensor can be displayed by way of the service unit. Preferably the capability of the distance sensor to determine angular positions of detected target objects is utilized. Otherwise adjustment is performed to predefined reception levels. [A2569]

"Method and apparatus for detecting an object on a side of or backwards of a vehicle"

A method and apparatus are described for detecting obstacles in the "blind spot" of a motor vehicle's side mounted mirrors. Advantageously, the inventive apparatus is mounted on the vehicle as an attachment to the side mirror system or adjacent to it. The invention determines the presence of an obstacle in a sensing volume that encompasses the "blind spot". The invention relies on the time-of-flight measurement of preferably short infrared pulses to locate obstacles. Multiple sensors are used to provide area coverage. If any sensor detects an obstacle within its predefined range limits then an indication is provided by a display unit at the side mirror location. The system can be used on both sides of the vehicle and each side operates independently. [A2570]

"Precision all-weather target location system"

An apparatus to determine the three-dimensional location of an airborne platform relative to a target area using two separate antenna assemblies positioned on the airborne platform. The first antenna assembly is adapted to transmit energy downward toward a surface location directly beneath the airborne platform, while the second antenna assembly is adapted to transmit energy forward towards the target area remote from the surface location. A single transmitter is associated with both of the antenna assemblies for transmitting signals toward the surface location and the target area. A receiver coupled to the antenna assemblies receives and detects the signals corresponding to the transmitted energy as reflected by the target area and the surface location. A radar processor is coupled to the receiver and is adapted to determine the range between the airborne platform and the surface location and determine the three-dimensional height of the target area from the detected signals. The radar processor also extracts two-dimensional gray scale imagery of the target area from the detected signals. The apparatus also incorporates three geolocated stored references, one of terrain heights of the surface location and target area, one of the intensity image of the surface location, and the third of two-dimensional gray scale imagery of the target area. A height correlator compares the elevation measurements produced by the both the downward and forward looking platform sensors to the stored reference of terrain heights. The intensity of the radar return is also matched with a stored reference of intensities of the surface area. An image correlator for matching the extracted gray scale imagery of the target area to the stored reference of gray scale imagery is provided. A navigational processor then determines the three-dimensional location of the platform relative to the target area based on the correlation results of the height correlator and the image correlator. [A2571]

"Method for determining range of vision"

A method via which the range of vision in a vehicle's field of view can be determined precisely, so that with the help of range-of-vision information the driver can be advised to modify his driving style. The contrast of an object detected by a radar or lidar sensor is measured by a monocular video sensor, and the range of vision is determined from the measured values supplied by the radar or lidar sensor and by the monocular video sensor. Alternatively, the distance to and contrast of at least one object can be measured by a binocular video sensor, the range of vision then being determined from the measured contrast and distance values. [A2572]

"Device with a nonradiative dielectric waveguide with coupling gap"

A device with a nonradiative dielectric waveguide which operates in a microwave band or in a millimeter wave band. The device with a nonradiative dielectric waveguide is, for example, an oscillator, a circulator, a coupler or the like. The device has a pair of parallel conductors, a dielectric strip which is disposed between the conductors and propagates a high-frequency electromagnetic wave in a specified mode, a mounting surface which is formed on one of the conductors, and an end surface which is defined by an end of each of the conductors so as to be vertical to a traveling direction of the electromagnetic wave propagated in the dielectric strip. An end of the dielectric strip is exposed at a corresponding end surface of the device. [A2573]

"Bias estimating method for a target tracking system"

The present invention is in general related to automatic alignment in multi-sensor target tracking. The process of the invention repeatedly generates estimates for sensor bias errors (b) by minimising a function, given on one hand by the magnitude of the discrepancy between measurements (M) and a measuring model, where the measuring model is a function of the unknown target location and unknown bias parameters, and on the other by the bias parameters and their predetermined statistical distributions (15) . In a preferred embodiment of the present invention, the minimizing step is performed by linearising components of the function around an approximate target position (normally obtained from the tracker (10)) and around nominal (typically zero) bias errors, and the function is subsequently minimized with respect to target positions as well as to the bias parameters (b) . In addition, possible time dependence of the bias parameters are modelled by the incorporation of process noise. [A2574]

"System and method for detecting and displaying wind shear"

A computer based method of detecting and displaying rotational wind shear. Radial wind velocities within first and second adjacent gate sweeps produced by a radar system are detected in a predetermined geographic area, and are compared at points of equal radial distance from the radar system. The radial location of gate to gate wind shear at positions between the radar system and the boundary of the radar systems range are identified and compared to a predetermined threshold wind velocity value to determine the location of high priority gate to gate wind shear. The high priority gate to gate wind shear is then graphically displayed relative to its geographic location on a graphical representation of the predetermined geographic area. A computer based system for detecting and displaying rotational wind shear is also disclosed. [A2575]

"Vehicle speed control system using wireless communications and method for controlling the same"

Disclosed a vehicle speed control system using wireless communications, the system including a driving state detecting unit for detecting a driving state and outputting corresponding signals, a transmitter/receiver for outputting low-strength signals, an electronic control unit for receiving the signals of the transmitter/receiver and establishing an ISA mode if necessary, determining if a present driving state corresponds to a first driving state, determining if the driver has performed deceleration operations and performing control into the first driving state if needed, an engine control unit for outputting signals for control of the throttle valve opening, a throttle valve electronic control unit for outputting electrical signals to a throttle valve to control the same, and a display for displaying a present mode and a vehicle state. A method for controlling the system comprises the steps of receiving signals from an RF transmitter/receiver to determine if a vehicle is in a first driving state, establishing an ISA mode and performing display of the ISA mode, determining a present driving state for comparison with the first driving state and performing display to inform the driver of the result of the comparison, determining if the driver has performed a deceleration operation if the present driving state does not correspond to the first driving state, disengaging the ISA mode and enabling full control of the vehicle by the driver if the present driving state corresponds to the first driving state or if the driver has performed a deceleration operation, and controlling an engine control unit via CAN communications if the driver has not performed a deceleration operation. [A2576]

"Method for processing radar signals"

A method for procession radar signals for a radar arrangement which is moving in relation to its environment, in particular a road vehicle radar due method include analyzing a plurality of object traces formed by objects to be detected, to determining a current moving direction, and, in response to a deviation of this moving direction from the alignment of the radar arrangement, correcting the object angle determined when detecting the objects within the scope of the angular resolution of the radar arrangement on the basis of the determined deviation, and relating it to the moving direction. [A2577]

"Portable safety mechanism with voice input and voice output"

A portable safety mechanism housed in a cane, a walking stick or a belt-carried housing. In each of such embodiments, the portable safety mechanism includes a processor, a transmitter, a receiver, and an outside image sensor or scanner, a warning device such as an audible warning device or warning light. The scanner may, for example, sense the shape of a traffic signal or the color of a traffic signal. The portable safety mechanism may further be housed in a wheelchair or walker. The portable safety mechanism may employ computer telephony technology. [A2578]

"Running surroundings recognizing apparatus"

A running surrounding recognizing apparatus is provided. The running surrounding recognizing apparatus is capable of accurately recognizing information in regard to running of a self-vehicle even if a mounting position of a sensor for running surrounding recognition is changed, and to provide a vehicle running control apparatus using the running surrounding recognizing apparatus. The running surrounding recognizing apparatus 1 comprises a communication part 11, a sensing region determining part 12 for determining a sensing region sensed by the running surrounding recognizing apparatus 1 and a sensing part 13. The communication part 11 is connected to external units through a bus 1200 to communicate data in regard to a mounting position of the running surrounding recognizing apparatus 1 on a vehicle. The sensing region determining part 12 determines the sensing region sensed by the running surrounding recognizing apparatus 1 based on the data in regard to a mounting position of the running surrounding recognizing apparatus 1 on a vehicle received through the communication part 11. The sensing part 13 outputs a sensed result based on the sensing region determined by the sensing region determining part 12 through the communication part. [A2579]

"Monitoring antenna system"

A monitoring system incorporates antennas that transmit signals at predetermined frequencies, the transmitted signals are received by tags located in the active monitoring area of the antenna which then transmit signals back to the antenna. The antennas are tuned to each desired frequency prior to driving the antennas to transmit at the desired frequency. The system transmits a range of frequencies in a sequence that uses overlapping frequency steps. The monitoring system is also constructed having a variable configuration resulting in the ability to be reconfigured under program control to conform to varying system requirements. The integrated monitoring system employs programmable formats for reconfiguration such that upon program input from a host computer the system can assume predetermined configurations to conform to the particular tasks for the specific application. The monitoring system incorporates an antenna system that employs digitally controlled, differentially driven, scanning transceivers, and walk through magnetic induction antennas positionable in various configurations to maximize detection of tags being transported through the antenna system. [A2580]

"Radar apparatus"

A vehicular radar apparatus comprising a radar beam transmission device and a reception device, and a processing unit for detecting the position of a target object from transmission signals and reception signals. The processing unit has a preceding vehicle judgment circuit for judging if a vehicle travelling in front of a subject vehicle in the same direction is the same vehicle as previously detected or not, and a signal strength comparing device for comparing the signal strength of a current reception signal reflected from the preceding vehicle, with a signal strength of a reception signal reflected from the preceding vehicle a predetermined comparison reference time prior, to thereby calculate a change amount in signal strength. When the change amount calculated by the signal strength comparing device drops beyond a previously set threshold value and it is judged by the preceding vehicle judgment device that the preceding vehicle is the same vehicle, it is judged that the detection sensitivity of the radar apparatus has dropped. [A2581]

"Electronic distance-determining apparatus and electronic security system equipped therewith"

An electronic apparatus for determining the distance between two objects has an interrogation signal generator for generating and transmitting an interrogation signal, and a response signal receiver. An evaluation unit is situated in one object, and interrogation signal reception means and response signal generation means in the other object. According to the invention, the evaluation unit is set up for determining a distance-indicative phase difference between the interrogation signal and the response signal. An electronic security system, such as a vehicle locking system of the keyless-go type, having a distance measurement of this type is also included. [A2582]

"Digital electronic locator"

A digital electronic locator which assists in locating the position and direction of an object/animal/person is described. Three configurations of the locator are presented, the first one is the basic configuration which gives an alerting means (Audio and/or visual) to indicate the location of an object/animal/person, the second configuration of the locator, in addition to providing the facility offered by the basic configuration, indicates the direction of an object/animal/person, the third configuration of the locator is used for locating person, in addition to providing the facilities offered by the basic and the second configuration it provides the direction of the searcher to the person being located who can, as well, acknowledge that he/she has been found. [A2583]

"Door control apparatus"

Door control apparatus for vehicles including at least one sensor viewing at least one region in the vicinity of a door, logic circuitry responsive to the sensor for providing at least one region clear output signal and automatic door opening and door closing apparatus responsive at least to the absence of a region clear signal to cause opening of the door and responsive at least to the presence of a region clear output signal to cause closing of the door. [A2584]

"Side impact airbag system with anticipatory sensor"

An airbag passive restraint system for protecting an occupant adjacent the door in a side impact including an airbag arranged in the door to inflate inward from the door and a side impact anticipatory sensor determining that an accident requiring deployment of the airbag is about to occur prior to the accident. The sensor is arranged to receive waves generated by, modified by or reflected from an object about to impact the vehicle resulting in the accident and is designed to identify the object based on a pattern of the received waves and determining whether the identified object will cause an accident requiring deployment of the airbag. The system also includes an inflator coupled to the sensor for inflating the airbag if the sensor determines that an accident requiring deployment of the airbag is about to occur. [A2585]

"Preventing the collision of a vehicle with an obstacle"

A process and device are disclosed for preventing a vehicle from colliding with an obstacle during parking. The object of the invention is therefore to ensure that a collision can be reliably avoided without any additional intervention of the drive. In a device with at least one sensor for generating signals which represent the distance between the vehicle and an obstacle, the signals are processed in an evaluation unit. When at least one distance-representing signal falls below a limit value, a warning signal is generated. This warning signal drives a control valve which generates a pressure difference between the working chamber and the vacuum chamber in a brake booster when the warning signal is generated. This pressure difference causes the braking pressure to rise in the wheel brake cylinder and therefore slows the vehicle down to a standstill. [A2586]

"Method and system for determining a position of a transceiver unit utilizing two-way ranging in a polystatic satellite configuration including a ground radar"

A method and system for determining the position of an object, such as an aircraft, utilizes two-way ranging with a polystatic satellite configuration and ground radar. A ground transceiver at a first known location provides a bidirectional communication path between the ground transceiver and the object wherein the ground transceiver transmits a first ranging signal to the object and the object transmits a second ranging signal to the ground transceiver in response to the first ranging signal. A first communication transceiver at a second known location provides a first unidirectional communication path between the first communication transceiver and the object wherein the first communication transceiver performs one of transmitting a third ranging signal to the object and receiving a third ranging signal from the object in response to the first ranging signal. A second communication transceiver at a third known location for providing a second unidirectional communication path between the second communication transceiver and the object wherein the second communication transceiver performs one of transmitting a fourth ranging signal to the object and receiving a fourth ranging signal from the object in response to the first ranging signal. A signal processor determines a first, second and third path length, and determines the position of the object based on the first, second and third known locations and the first, second and third path lengths. [A2587]

"Gate for radar-mounted vehicle, having partition walls not grouped or detected by radar apparatus"

A gate such as a tollgate in an expressway for radar-mounted vehicles is disclosed, by which an erroneous operation of the mounted radar apparatus can be prevented and through which the radar-mounted vehicles can smoothly pass. The gate includes two partition walls which limit a passage. The positions of the front ends of the partition walls are separated in front and behind, or the front end of one or both of the partition walls has a structure for suppressing the frontward reflection of each radiated electric, optical, or acoustic beam incident on the relevant front end. [A2588]

"Method and apparatus for sharing vehicle telemetry data among a plurality of users over a communications network"

In an Integrated Air Traffic Control System, apparatus, method, and software for sharing vehicle telemetry information between a plurality of sensors of different types and a plurality of users of different types utilizes a communications network coupling together the plurality of sensors and the plurality of users. A plurality of sensor processor devices are respectively coupled to the plurality of sensors, each sensor processor device being configured to receive vehicle telemetry information from its associated sensor, and to convert the receive vehicle information into common vehicle data of a type common to the plurality of users. A plurality of user processor devices are respectively coupled to the plurality of users, each user processor device being configured to receive a demand signal from its associated user and to transmit it to said communications network when it determines that its associated user has a predetermined vehicle profile which requires improvement. Each of the plurality of sensor processor devices receives the demand signal from the communications network and transmits its common vehicle data to the communications network when it determines that its associated sensor can provide vehicle information which improves the vehicle information profile. [A2589]

"Vehicle impact detection sensor system"

A vehicle impact detection sensor for providing an input variable for an activation logic unit or for generating an activation signal for an active occupant protection system, has a radar transmitter and a radar receiver which are arranged on a sensor-carrying superstructure of the vehicle. The radar receiver receives radar waves which are emitted by the radar transmitter and reflected at an impact-relevant reflexion surface that moves relative to the sensor-carrying superstructure in the event of an impact. A Doppler frequency evaluation unit uses the frequency of the transmitted radar waves and the frequency of the radar waves reflected from the impact-relevant reflexion surface to determine the associated Doppler frequency and detects therefrom a relative movement of the impact-relevant reflexion surface with reference to the sensor-carrying vehicle superstructure. The impact-relevant reflexion surface is a surface permanently connected to the vehicle, preferably, an outer surface of the vehicle. [A2590]

"Vehicle warning system and method based on speed differential"

The present invention provides a method, apparatus and article of manufacture for detecting the presence of one or more target vehicles and determining a distance and speed of the targeted vehicles relative to a targeting vehicle. When predetermined threshold conditions are satisfied, warning signals are output from a computer system to alert a driver of the one or more targeted vehicles. In addition, steps may be taken to determine whether the targeting vehicle and the one or more targeted vehicles will converge to create a congested condition. If so, the speed of the targeting vehicle maybe adjusted. [A2591]

"Intrusion detection process and device"

The invention relates to an intrusion detection process for detecting an intrusion within a space, in which at least two acoustic or electromagnetic signals are emitted at different frequencies (f.sub.1, f.sub.2, . . . f.sub.n) inside said space, at a point inside said space, a signal is received that is the combination of the signals emitted and reflected in said space, the characteristics of the demodulated signals of different frequencies are compared to establish the presence or absence of an intrusion, an intrusion signal is generated when the presence of an intruder is confirmed. The invention also proposes an intrusion detection device implementing the process according to the invention. [A2592]

"Vehicle surroundings monitoring device"

A vehicle surroundings monitoring device capable of performing distance measurement as desired even in a short-distance range to provide unerring alarm information to a driver. The monitoring device for monitoring surroundings around a vehicle has a transmitting antenna provided in a door mirror assembly of the vehicle to radiate transmitted waves through a mirror surface of the door mirror, and a receiving antenna provided in the door mirror assembly to receive reflected waves from an object existing near the vehicle through the door mirror surface. The monitoring device also has a stray electric wave limiting member for reducing electric wave components straying from the transmitting antenna into the receiving antenna. The stray electric wave limiting member is formed as an electric wave absorbing member provided between opening surfaces of the door mirror corresponding respectively to the transmitting and receiving antennas, a metal plate provided between the transmitting and receiving antennas, an electric wave absorbing member provided between the transmitting and receiving antennas and the door mirror except in front of the opening surfaces of the door mirror corresponding to the antennas, or a matching layer provided between the antennas and the door mirror. [A2593]

"Optimum edges for speakers and musical instruments"

The invention presents a design of optimum edges for antennas of loudspeakers, microphones, hydro-speakers, hydro-phones, brass and wind instruments, and ultrasonic transducers. These edges have a serrated-roll shape, and enhance the acoustical field strength uniformity. Loudspeakers, hydro-speakers, and ultrasonic transducers will become more effective in radiating acoustical power. The quality of these apparatuses are enriched. The musical tone emitted by loudspeakers, brass and wind instruments becomes more smooth, mellow, rich, clean, and elegant. [A2594]

"Motion detector"

The invention relates to a motion detector or proximity switch for detecting moving objects, wherein a high frequency electromagnetic radiation is generated by a free running oscillator and transmitted via a transmitter antenna. The transmitter antenna detects the Doppler modified radiation reflected by the moving object as a function of its phase position or amplitude variation. The radiation is compared with the transmitted radiation parameters in an evaluation device with a view to producing an output signal. The inventive detector is characterized in that it included a free running oscillator having a feedback guaranteed by at least one transmitter antenna ANT RX and at least one receiver antenna ANT TX which are oriented towards the object and coupled via a side or leakage radiation. [A2595]

"Tag communication protocol & system"

A method of communicating to a RF tag having a low power mode and a scan mode with a radar and an interrogator. The method comprises the steps of alternating the RF tag between the low power mode and the scan mode and then transmitting a wake-up call to the RF tag with the radar. Next, the wake-up call is received from the radar by the RF tag when the RF tag is in the scan mode. Once the wake-up call has been received, the radar will transmit a downlink message to the RF tag. Upon receipt of the downlink message, the RF tag will send an uplinked message to the radar. After the uplink message has been sent to the radar, the RF tag will return to the low power mode. By alternating the RF tag between the low power mode and the scan mode, the power consumption of the RF tag is greatly reduced thereby increasing the battery life thereof. [A2596]

"Method and system for directing a following device toward a movable object"

An automated object following system includes a tracker associated with a following device, and a guider associated with an object to be followed. The tracker includes a first processor, and at least two transducers for generating an encoded ultrasonic signal. Each transducer has a control input communicating with the first processor for emitting an encoded ultrasonic signal generally toward the guider in response to a command signal from the first processor. The encoded ultrasonic signals carry signal source identification information. A radio frequency (RF) receiver communicates with the first processor for receiving from the guider an encoded RF signal carrying distance and direction information of the guider relative to the tracker to be used for steering the following device toward the object to be followed. [A2597]

"Method and arrangement for controlling deployment of a side airbag"

Arrangement and method for controlling deployment of a side airbag to protect a vehicular occupant during a crash. The presence and/or position of the occupant is/are determined and deployment of the airbag is controlled based thereon. A transducer receives waves from a space above a seat portion of the seat and a signal representative of the presence and/or position of the occupant is generated based on the received waves. The transducer may transmits waves into the space above the seat portion. The transducer may be mounted in a door of the vehicle and possibly adjacent the airbag module. Deployment of the airbag can be suppressed, the time at which deployment of the airbag starts, the rate of gas flow into the airbag, the rate of gas flow from the airbag and/or the rate of deployment of the airbag is/are controlled based on the presence and/or position of the occupant. [A2598]

"Method of manufacturing an enclosed transceiver"

The present invention teaches a method of manufacturing an enclosed transceiver, such as a radio frequency identification ("RFID") tag. Structurally, in one embodiment, the tag comprises an integrated circuit (IC) chip, and an RF antenna mounted on a thin film substrate powered by a thin film battery. A variety of antenna geometries are compatible with the above tag construction. These include monopole antennas, dipole antennas, dual dipole antennas, a combination of dipole and loop antennas. Further, in another embodiment, the antennas are positioned either within the plane of the thin film battery or superjacent to the thin firm batter. [A2599]

"Emergency locator and communicator"

A system and method for instantly summoning assistance to the location of an emergency. A mobile unit providing subscriber communications with an operator or emergency service provider includes a beacon signal generator for directing service providers to the location of the emergency. Subscriber communications are established using an existing personal communication system. The beacon signal generator transmits a wideband spread spectrum that is analyzed at receiving stations to determine the location of the mobile unit. [A2600]

"Radar apparatus for vehicle"

A radar apparatus for use on a vehicle has a radar beam scanning mechanism for scanning a scan area with a radar beam substantially in parallel to a road surface on which the vehicle is running, and an object detector for receiving reflected waves of the radar beam to create a detected object image, based on the reflected waves. The object detector is provided with a ghost determination device for determining whether a detected object image created is a ghost. Therefore, the radar apparatus can eliminate a detected object image determined as a ghost out of detected object images created. [A2601]

"Device for mounting a distance sensor on a motor vehicle"

A device for mounting a distance sensor, in particular a proximity radar device, on a motor vehicle, the distance sensor being accommodated in a closed housing, the housing being moveably attached to a support and the support being attachable in an immoveable manner to the motor vehicle. The device is characterized in that the housing is attachable to the support by at least three screws arranged in an L-shape relative to each other, that the screws, in the installed state of the distance sensor, are able to be screwed from its front side, and that a screw-out protection is provided for at least two of the screws. [A2602]

"Low power radar level transmitter having reduced ground loop errors"

A low power radar level transmitter having reduced ground loop errors and a related method are disclosed. A microwave termination is couplable to a reference voltage such as earth ground and is coupled to a microwave transceiver through at least one low frequency isolator. The microwave transceiver generates a microwave signal along the termination which is reflected by a process product interface. A level calculator is coupled to the microwave transceiver to calculate a level of the process product based upon the received, reflected signal. A process loop communicator is coupled to the level calculator and couplable to a process control loop to communicate the calculated level across the process control loop. A power supply is couplable to the process control loop and provides power to all electrical components of the transmitter with energy received from the process control loop. [A2603]

"FM-CW radar system for measuring distance to and relative speed of target"

An FM-CW radar is provided which may be employed in anti-collision systems or cruise control systems installed in moving objects such as automotive vehicles. The radar analyzes a beat signal in frequency to produce peak frequency components in a modulated frequency-rising range wherein the frequency of a frequency-modulated radar wave transmitted from the radar increases and a modulated frequency-falling range wherein the frequency of the radar wave decreases. If one of peak frequency pairs, each of which is made up of each of the peak frequency components in the modulated frequency-rising range and one of the peak frequency components in the modulated frequency-falling range, lies within a given lower frequency range, the radar identifies the one of the peak frequency pairs as radar data arising from a moving object appearing suddenly in a radar detection zone. [A2604]

"Safety running system for vehicle"

In a safety running system, a transverse travelling distance resulting when a subject vehicle travels to a current position of an oncoming vehicle is calculated based on the vehicle velocity and yaw rate of the subject vehicle, a relative transverse distance of the oncoming vehicle relative to a vehicle body axis of the subject vehicle is calculated based on a relative distance, relative velocity and relative angle between the subject vehicle and the oncoming vehicle detected by a radar information processor. When a relative transverse deviation obtained by subtracting the transverse travelling distance from the relative transverse distance resides within a range and that state continues to exist over a predetermined time period, it is judged that there is a collision possibility of the subject vehicle with the oncoming vehicle, and automatic steering is performed so as to avoid a collision. [A2605]

"Safety running system for vehicle"

In a safety running system, a transverse travelling distance resulting when a subject vehicle travels to a current position of an oncoming vehicle is calculated based on the vehicle velocity and yaw rate of the subject vehicle, a relative transverse distance of the oncoming vehicle relative to a vehicle body axis of the subject vehicle is calculated based on a relative distance, relative velocity and relative angle between the subject vehicle and the oncoming vehicle detected by a radar information processor. When a relative transverse deviation obtained by subtracting the transverse travelling distance from the relative transverse distance resides within a range and that state continues to exist over a predetermined time period, it is judged that there is a collision possibility of the subject vehicle with the oncoming vehicle, and automatic steering is performed so as to avoid a collision. [A2606]

"Method and system for controlling vehicle speed based on vehicle yaw rate and yaw acceleration"

In an adaptive vehicle speed control system, a method and system for controlling the speed of the vehicle while the vehicle is traversing a curved path. The method and system include sensing the yaw rate of the vehicle, determining the yaw acceleration based on the yaw rate, and determining a maximum allowed speed of the vehicle on the curved path based on the yaw rate and the yaw acceleration. The method and system also include limiting the speed of the vehicle on the curved path to a value no greater than the maximum allowed vehicle speed. [A2607]

"FM-CW radar system for measuring distance to and relative speed of a target"

An FM-CW radar is provided which may be employed in anti-collision systems or cruise control systems installed in moving objects such as automotive vehicles. The radar produces a first spectrum using a portion of a beat signal in a frequency rising range wherein the frequency of the radar wave increases and a second spectrum using a portion of the beat signal in a frequency falling range wherein the frequency of the radar wave decreases and moves the second spectrum by frequency shifts which are determined as a function of the speed of a radar-mounted vehicle and corrected for compensating various errors involved in measuring the speed of the vehicle to form spectrum groups each consisting of the frequency components moved by one of the corrected frequency shifts and frequency components in the other of the first and second spectra. The radar selects an optimum one of the spectrum groups for use in determining target data. [A2608]

"Apparatus and method for locating missing persons, animals, and objects"

A micropower transponder operates in conjunction with a constellation of low-to-medium Earth-orbiting communication satellites. The transponder is attached to a person, animal, or object. The location of a missing person, animal, or lost object is ascertained by locating the transponder associated with that person, animal, or object. The transponder may be hidden in the individual's hair, timepiece, jewelry, or article of clothing, may be swallowed by the individual, may be implanted under the individual's skin, or incorporated into an inconspicuous hand-held device such as a cellular telephone, pager, or calculator. The transponder includes a receiver for receiving an interrogation radio signal and a transmitter for transmitting a response radio signal. The transponder transmits the response radio signal in response to the interrogation radio signal if the interrogation radio signal includes a code matching the access code stored in the transponder. The Doppler shift in frequency of the response radio signal is measured and the Doppler shift is used to determine the location of the transponder. [A2609]

"Vehicle control method and vehicle warning method"

In order to occur a collision warning to prevent the collision in accurate by detecting the preceding vehicle or target, a vehicle lane position estimation device comprising a means for measuring a distance between said host vehicle and said preceding vehicle or a oncoming vehicle, a direction angle from said host vehicle, an angular velocity and a velocity of said host vehicle, a means for calculating lateral and longitudinal distance between said host vehicle and said preceding vehicle or said oncoming vehicle, a means for capturing a front stationary object, a means for obtaining movement of the preceding vehicle or position of the oncoming vehicle, and a means to estimate a lane position of said front stationary object from a relationship of the stationary object being captured and the preceding vehicle being obtained and a positional relationship with the oncoming vehicle. [A2610]

"Vehicle running control apparatus, vehicle running control method, and computer program product having the method stored therein"

In a vehicle running control apparatus and method, the change of a difference in frequency between an electromagnetic wave signal transmitted from a vehicle and an electromagnetic wave signal reflected from an object is detected. Information inclusive of a distance between the object and the vehicle and a relative speed of one of the object and the vehicle to the other is generated on the basis of the change in frequency difference. A desired speed is generated on the basis of the generated information and information of the running of the vehicle so that the change in frequency difference is generated. A signal for control of the speed of the vehicle is generated on the basis of the desired speed. [A2611]

"Method for the detection especially of small sea targets"

A method for the detection of a target by a radar in the presence of noise, the detection being performed on M antenna rotations, comprises at least: a first step for the estimation of the Doppler frequency (f) of the target, a detection step, the target being detected if an associated variable Z is greater than or equal to a predetermined threshold S, the variable Z being defined according to the following relationship: ##EQU1## D.sub.t being the time domain [-t.sub.0, t.sub.0], t.sub.0 being fixed as a function of the possible errors of framing of the signals from rotation to rotation, D being the frequency domain .left brkt-bot.f.sub.d -f.sub.0, f.sub.d +f.sub.0.right brkt-bot., f.sub.0 fixed as a function of the possible errors of estimation of the Doppler frequency, z being the signal at the analyzed antenna rotation referenced "0", at the analyzed range gate references "0", z.sub.i.sup.k being the signal obtained by tracking at the rotation i of the signal z, in taking account of the tracking error in any, i.e., offset by k range gates with respect to the estimated range gate, C.sub.z,.sub.z.sub..sub.f .sub..sup.k (t,f,G) being the Cohen transform of the signals z and z.sub.i.sup.k with a kernel G, computed at the time t and the frequency f, C.sub.z.sub..sub.i .sub..sup.k, .sub.z.sub..sub.j .sub..sup.l (t,f,G) being the Cohen transform of the signals z.sub.i.sup.k and z.sub.j.sup.l of the kernel G, computed at the time t and at the frequency f, 2N.sub.d +1 being the number of range gates taken into account, according to the tracking error if any, N (i, k, j, 1) being a standardization. [A2612]

"Transmission system and coding communication method for a transmission system"

The conventional combination cannot realize an efficient road traffic system as a whole. A transmission system has a plurality of modules installed at different positions along a predetermined road. Each of the plurality of the modules includes a receiving section for receiving an input signal and a transmission section for transmitting an output signal on the basis of the input signal according to a predetermined radio scheme. Each of the plurality of the modules receives and transmits a signal, whereby the whole or part of the information contained in the signal is transmitted along the whole or part of the predetermined road. This transmission system can construct an efficient integrated road traffic system as a whole. [A2613]

"Radiometry system with an aperture synthesis type antenna and its application to hyper-frequency imaging"

A radiometry system including an aperture synthesis antenna array type, including plural antenna elements, distributed in an antenna plane relative to at least one axis, according to a determined law. Each antenna element includes first and second coupling probes sensitive to hyper-frequency electromagnetic signals with dual linear polarization in quadrature (arbitrarily referred to as horizontal and vertical polarizations) . The probes are connected two by two with electric receiving circuits to create a synthetic aperture. The horizontal (f.sub.H1 -f.sub.H4) and vertical (f.sub.V1 -f.sub.V4) coupling probes of successive antenna elements (e.sub.A1 -e.sub.A4) are oriented in the antenna plane (At') , along each of the axes (.DELTA.) , such that at least one of the horizontal or vertical probes (f.sub.H1 -f.sub.H4, f.sub.V1 -f.sub.4) presents a 180.degree. phase shift from one antenna element to the other (e.sub.A1 -e.sub.A4) , with the phase shift obtained by a sequential 90.degree. rotation of those probes (f.sub.H1 -f.sub.H4, f.sub.V1 -f.sub.V4) . Further, 180.degree. phase shifts (.PHI..sub.H2, .PHI..sub.V3, .PHI..sub.H4, .PHI..sub.V4) are applied onto the outputs of the horizontal (f.sub.H1 -f.sub.H4) and vertical (f.sub.V1 -f.sub.V4) coupling probes, when one of the orientations of an antenna element (e.sub.A1) is taken as the phase origin reference, in order to compensate for the 180.degree. phase shifts with respect to the corresponding coupling probes (f.sub.H1 -f.sub.V1) of the reference antenna element (e.sub.A1) . [A2614]

"Radar systems"

In a radar system it is necessary to distinguish signals reflected from wanted targets such as aircraft from those reflected from fixed terrain features, known as clutter. The clutter signals can in some cases be significantly stronger than the wanted signals. One method for dealing with land clutter is the use of a high resolution clutter map. The area around the radar is considered to be divided into cells, and an array of background signal estimates is maintained for these cells. Whenever a signal is received by the radar, it is compared with the stored background level for the cell it occupies, and a detection is only reported if the signal exceeds the background by a pre-set threshold. Received signals are also used to modify the stored background levels so that the clutter map adapts to the reflections from clutter which are present over long periods. Clutter maps have so far only been used successfully for radars at fixed locations. In the case of a ship-borne radar near land, a conventional clutter map will not work well. This is because as the ship moves, the positions of land scatterers relative to the ship will not be fixed. Individual terrain features will therefore be moved from one clutter map cell to another. In the cell into which a strong scatterer moves, the land clutter reflections will be reported as targets until the stored background has had time to adapt to the new higher level. Similarly, in the cell which the scatterer has left, the stored background level will be higher than necessary, and may cause actual targets to be suppressed until it has had time to adapt to the new lower clutter level. [A2615]

"Method of moment estimation and feature extraction for devices which measure spectra as a function of range or time"

The computation system of the present invention comprises an improved method of moment estimation for devices which measure spectra as a function of range or time. The preferred embodiment of this system is illustrated as part of an automated meteorological monitoring system for the accurate real time detection of meteorological phenomena, such as winds, wind shear and turbulence. This automated meteorological monitoring system uses a standard weather radar transmitter to scan a predetermined volume of space with a stream of radar pulses to determine the characteristics of meteorological phenomena that are extant in the predetermined volume. The computation system of the present invention utilizes novel signal processing algorithms in the improved method of moment estimation to excise the valid data from the returns echoes, which are corrupted by the presence of contaminating signals. Separating the valid data from the noise in this manner improves the responsiveness and accuracy of the system in which this method is implemented. [A2616]

"Method for correction of a signal of at least one sensor on the basis of which a path curve can be determined, on which the vehicle is moving"

The present invention relates to a method for correction of a signal of at least one sensor, on the basis of which a path curve can be determined, on which the vehicle is moving, with the vehicle having a device by means of which the environment of the vehicle can be identified, and with the correction of the signal of the at least one sensor being carried out in that, at at least one point in time, the object location expected at at least one further point in time of an object which is identified as being stationary is determined on the basis of the vehicle speed and of the signal of the at least one sensor, and in that, at the at least one further point in time, the object location of the object which is identified as being stationary is recorded, with a correction of the signal of the at least one sensor being carried out on the basis of the discrepancy between the expected object location and the recorded object location. [A2617]

"Location finding using a single base station in CDMA/TDMA systems"

A location or position of a wireless mobile unit is determined using only measurements from a single base station. A distance between the wireless mobile unit and the base station is calculated utilizing a roundtrip delay value of an RF uplink signal received from a wireless mobile unit. Thereafter, an angle of arrival of the received signal is determined using measurements of the received signal from each of a plurality of antenna sectors of a multi-sector antenna. The angle of arrival is determined based upon stored antenna signal measurements of the multi-sector antenna, wherein a combination of different sector signal measurements corresponds to a single angle measurement. Using the determined distance and angle of arrival, a position or location of a wireless mobile unit can easily be determined using only measurements of the single base station. [A2618]

"System and method for person or object position location utilizing impulse radio"

A System and Method for Person or Object Position Location Utilizing Impulse Radio, comprising a plurality of reference impulse radios, an object or person to be tracked having a mobile impulse radio associated therewith, an architecture with an associated positioning algorithm associated with said plurality of impulse radio reference radios and said mobile impulse radio, and display means for displaying the position of the person or object whose position is to be determined. [A2619]

"Use of a device in a vehicle, using which the environment of the vehicle can be identified by means of radar beams"

The present invention relates to a method for correction of a signal which is derived from wheel rotation speed signals and represents the vehicle speed, wherein the vehicle has a device by means of which the environment of the vehicle can be identified, and wherein the correction of the signal which is derived from the wheel rotation speeds and represents the vehicle speed is carried out on the basis of the speed at which objects in the environment which are identified as being stationary move relative to the vehicle. [A2620]

"System and method for position determination by impulse radio"

A system and a method for position determination by impulse radio using a first transceiver having a first clock providing a first reference signal and a second transceiver placed spaced from the first transceiver. The system determines the position of the second transceiver. The second transceiver has a second clock that provides a second reference signal. A first sequence of pulses are transmitted from the first transceiver. The first sequence of pulses are then received at the second transceiver and the second transceiver is then synchronized with the first sequence of pulses. A second sequence of pulses are transmitted from the second transceiver. The first transceiver receives the second sequence of pulses and the first transceiver is synchronized with the second sequence of pulses. A delayed first reference signal is generated in response to the synchronization with the second sequence of pulses. A time difference between the delayed first reference signal and the first reference signal is then measured. The time difference indicates a total time of flight of the first and second sequence of pulses. The distance between the first and the second transceiver is determined from the time difference. The direction of the second transceiver from the first transceiver is determined using a directional antenna. Finally, the position of the second transceiver is determined using the distance and the direction. [A2621]

"Method for multi-directional anticipatory arming of vehicle restraints"

A method for multi-directional anticipatory arming of restraint systems in a motor vehicle includes the steps of monitoring outputs from impact radar sensors located on the vehicle. The method also includes the steps of determining whether an impact range is less than a predetermined value, obtaining a closing velocity (CV) , and determining a supervisory time window (STW) . The method further includes the steps of determining whether at least one of the CV and STW are within predetermined limits and setting a velocity arming flag to activation of the restraint systems if the CV and STW are within the predetermined limits. [A2622]

"System and method for distance measurement by inphase and quadrature signals in a radio system"

A system and a method for distance measurement utilizes a radio system. The distance is measured by determining the time it takes a pulse train to travel from a first radio transceiver to a second radio transceiver and then from the second radio transceiver back to the first radio transceiver. The actual measurement is a two step process. In the first step, the distance is measured in coarse resolution, and in the second step, the distance is measured in fine resolution. A first pulse train is transmitted using a transmit time base from the first radio transceiver. The first pulse train is received at a second radio transceiver. The second radio transceiver synchronizes its time base with the first pulse train before transmitting a second pulse train back to the first radio transceiver, which then synchronizes a receive time base with the second pulse train. The time delay between the transmit time base and the receive time base can then be determined. The time delay indicates the total time of flight of the first and second pulse trains. The time delay comprises coarse and fine distance attributes. The coarse distance between the first and second radio transceivers is determined. The coarse distance represents the distance between the first and second radio transceivers in coarse resolution. An in phase (I) signal and a quadrature (Q) signal are produced from the time delay to determine the fine distance attribute. The fine distance indicates the distance between the first and second transceivers in fine resolution. The distance between the first and second radio transceivers is then determined from the coarse distance and the fine distance attributes. [A2623]

"Method and system for determining a regulator object"

A method for determining a control object which is situated in an expected traveling corridor of a vehicle whose distance from the control object is measured and adjusted to a desired distance. The method for reliably determining the control object which enables reliable distance control even in the event of momentary and sudden changes in the traveling corridor of the vehicle determines an object corridor which covers the traveling corridor and is wider than the traveling corridor of the vehicle, control with respect to the control object being effected as long as the latter stays in the object corridor of the vehicle. [A2624]

"Device for acquiring lane path indicative data"

A device for acquiring data indicative of the path of a lane is provided. The device incorporates a lane detection sensing circuit, an object position sensing circuit that detects at least the distance of an object located in front of the vehicle and its directional angle relative to the direction of vehicle motion, and a sensing circuit for the vehicle's own motion. An estimating device is provided that is supplied with lane recognition measurement data, object position measurement data, and measurement data on the vehicle's own motion. As a function of the vehicle's own motion, the estimating device determines the lane curvature and/or the transverse position of an object ahead of the vehicle relative to the lane by estimation, using a presettable estimation algorithm including a dynamic vehicle motion model. The device preferably includes a Kalman filter for this purpose, and is used, for example, in road vehicles. [A2625]

"Interference preventing device for vehicle"

The present invention prevents the interference of vehicles traveling on-coming to each other when a plurality of vehicles are traveling on-coming to each other on a traveling path with a predetermined road width without increase in cost caused by setting a wide course width and without a drop in work efficiency caused by decreasing velocity. If one of the vehicles detects the other vehicle by its obstacle detection means when the vehicles are traveling on-coming to each other, the vehicle which detects the other vehicle begins deceleration to stop itself. At the same time, this vehicle transmits a deceleration control command for stopping the other vehicle to the other vehicle via transmission/reception means, therefore the other vehicle starts deceleration even if this vehicle cannot detect an obstacle. The present invention is also applied when unmanned vehicles using autonomously guidance traveling based on the course data and traveling position data or an unmanned vehicle and a manned vehicle pass each other on the going and coming paths immediately adjacent to each other, where each vehicle has communication means for transmitting traveling position data of the respective vehicle and receiving traveling position data of the other vehicle, an unmanned vehicle has approach detection means for detecting the approach of the other vehicle based on its own traveling position data and position data of the other vehicle, and traveling control means for shifting its own vehicle toward the road shoulder side at detection of an approach. [A2626]

"Method of determining the distance between and object and a device of varying location"

A system and method for determining the distance between an object and a device of varying location, in which a first or second sensor arranged on the device emits a signal which is reflected by the object. The reflected signal is received by the sensor transmitting the signal and by the respective other sensor, and an evaluation device determines the propagation times between the transmission of the signal and the reception of the signal for each sensor and determines therefrom all the possible positions of the objects relative to the device of varying location referred to the sensor. The distance from the motor vehicle being determined from the corresponding positions of the measurements. A highly accurate result of the distance measurement is permitted in conjunction with a minimum evaluation time, the evaluation device determines corresponding positions from the measured data in a first, very accurate evaluation method and subsequently determines further corresponding positions on the remaining unverified measured data in a second, less accurate evaluation method. [A2627]

"Mobile communication apparatus with distance measuring unit"

A first station can communicate with a second station by radio. The second station has a function of repeating a received radio signal. A radio communication apparatus in the first station includes a first device for transmitting a first radio-frequency signal containing a predetermined pseudo-noise code signal toward the second station. In the radio communication apparatus, detection is made as to a first timing at which the first device transmits the first radio-frequency signal. A second radio-frequency signal is received by the radio communication apparatus after the first device transmits the first radio-frequency signal. The second radio-frequency signal is converted into a baseband signal. A memory stors the predetermined pseudo-noise code signal. Calculation is made as to a correlation between the baseband signal and the predetermined pseudo-noise code signal stored in the memory. A second timing at which the calculated correlation peaks substantially is detected. The time interval between the first timing and the second timing is calculated. The distance between the first station and the second station is calculated on the basis of the calculated time interval. [A2628]

"Methods and arrangements for determining the position of an occupant in a vehicle"

Arrangements and method for determining the position of an occupant of a vehicle situated on a seat in the vehicle in which the position of the seat or a part thereof, e.g., the seat portion or back portion, is determined relative to a fixed point of reference to thereby enable an approximation of the position of the occupant to be obtained. The payout of a seatbelt from a seatbelt retractor can be measured and used to better provide the actual position of the occupant. An additional approximation of the position of the occupant can be obtained by receiving waves from the space above the seat in order to improve the determination of the likely, actual position of the occupant. Once the position of the occupant is determined, it can be used in the control of a deployable occupant restraint device such as an airbag. [A2629]

"Follow-up cruise control apparatus"

To maintain a predetermined distance to each of obstacles ahead of own vehicle, a follow-up cruise control apparatus calculates traveling direction target acceleration and deceleration of own vehicle, and treats, as s safe acceleration and deceleration, the product of the traveling direction target acceleration and deceleration and a weight coefficient determined by a distance between the front obstacle and the center line of the course of own vehicle. The follow-up cruise control apparatus selects a front obstacle having a safe acceleration and deceleration with the highest degree of risk of collision, from among all front obstacles ahead of own vehicle. Based on the safe acceleration and deceleration of the front obstacle, the follow-up cruise control apparatus prevents own vehicle from dangerously closely approaching or colliding with the front obstacle by restricting the driving power of own vehicle typically determined by an acceleration operation by a driver or by amplifying the braking power of own vehicle typically determined by a braking operation by the driver. [A2630]

"Range rate aiding in a pulsed radar system"

A timing and control method and apparatus (111) for performing precise range rate aiding includes a range gate delay means (114) for generating an estimate of the range gate delay (135) each pulse repetition interval as a function of the initial range (134) and velocity (133) provided by a processor (104) . The range gate delay (135) is converted into a coarse delay (138) defining the integral number of clock cycles preceding the range gate, and a fine delay (139) for positioning a range gate to within a fraction of a clock cycle. Fine temporal control is achieved using programmable delay lines (117) and (118) , which retard various control signals, including the system clock signal (131) , in accordance with the fine delay (139) . A modified signal (126) then drives a counter means (119) which outputs a signal (128) that defines an analog-to-digital sampling window beginning at the elapse of the range gate delay (135) . The apparatus (111) may further include a rate reducing means (115) for reducing the frequency at which the range gate delay (135) is generated, thereby permitting the delay (135) to be precisely regulated to within a fraction of a nanosecond over a period of multiple pulse repetition intervals. [A2631]

"Obstacle detection system for a vehicle"

An obstacle detection system for a vehicle which is capable of detecting nearby and remote objects successfully by use of a combination of an electromagnetic wave sensors and ultrasonic wave sensors. The system of the present invention includes a plurality of ultrasonic wave sensors each transmitting an ultrasonic wave around the vehicle and receives a reflected wave thereof for detection of nearby obstacles around the vehicle, and an electromagnetic waver sensor which transmits an electromagnetic wave in a forward direction of the vehicle and receives a reflected electromagnetic wave thereof for detection of a remote obstacle. The system includes a vehicle speed sensor is provided for sensing a speed of the vehicle. A detection unit detects a presence of the nearby obstacle based upon the reflected ultrasonic wave when the vehicle speed equals to a predetermined reference speed or less, and detects a position of the remote obstacle relative to the vehicle only based upon the reflected electromagnetic wave when the vehicle speed exceeds the reference speed. The detection unit issues a nearby signal upon detection of the nearby obstacle and issues a remote signal when the position of the remote obstacle is within a predetermined long distance from the vehicle. A warning unit gives warnings respectively in response to the nearby and remote signals. [A2632]

"System and method for projecting storms using NEXRAD attributes"

The subject invention provides an improved system and method for combining data obtained from the NEXRAD.TM. system of the National Weather Service ("NWS") with geographical and topological database information to achieve an improved and informative graphical storm-tracking display able to project the movement of a storm with a single user-operation. The method of projecting storm movement includes the following steps: collecting NEXRAD data attributes from a weather data source, calculating storm position using the collected NEXRAD attributes, calculating projected storm movement using the storm position and the collected NEXRAD attributes, displaying a graphic representation of the projected storm movement. [A2633]

"Hierarchical data matrix pattern recognition system"

The present invention relates to a hierarchical artificial neural network (HANN) for automating the recognition and identification of patterns in data matrices. It has particular, although not exclusive, application to the identification of severe storm events (SSEs) from spatial precipitation patterns, derived from conventional volumetric radar imagery. To identify characteristic features a data matrix, the data matrix is processed with a self organizing network to produce a self organizing feature space mapping. The self organizing feature space mapping is processed to produce a density characterization of the feature space mapping. The self organizing network is preferably completely unsupervised. It may, under some circumstances include a supervised layer, but it must include at least an unsupervised component for the purposes of the invention. The "self organizing feature space" is intended to include any map with the self organizing characteristics of the Kohonen Self Organizing Feature Map. The frequency vector of a CAPPI image that has been derived is a data abstraction that can be displayed directly for examination. In preferred embodiments, it is presented to a classification network, e. g. the standard

CPN network, for classifying the density vector representation of the three dimensional data and displaying a representation of classified features in the three dimensional data. A novel methodology is preferably used for incorporating vigilance and conscience mechanisms in the forward counterpropagation network during training. [A2634]

"Methods of tagging an object having a conductive surface"

A transponder module includes a circuit board having top and bottom surfaces and an inverted-F receive antenna formed on the circuit board. The receive antenna includes a ground plane formed on one of the surfaces and an active element formed above the ground plane. The module also includes a RF engine having an input coupled to the receive antenna, an output and a power supply input. The module additionally includes a RF decoupling network having first and second ports. The first port is coupled to the output of the RF engine. The module further includes an inverted-F backscatter antenna coupled to the second port of the RF decoupling network. The backscatter antenna includes a second ground plane formed on one of the surfaces and a second active element formed above the second ground plane. A method of tagging an object having a conductive surface includes coupling a transponder module including a low profile antenna to the conductive surface such that a ground plane contained in the transponder module is adjacent the conductive surface of the object and transmitting a signal from the low profile antenna to an interrogator, the signal including information relevant to the object. [A2635]

"Vehicle collision warning system"

A vehicle collision warning system includes a distance measuring device for measuring a distance from a subject vehicle to an obstacle in front of the subject vehicle, a speed detecting device for detecting a speed of the subject vehicle, a control device for receiving signals from the distance measuring device and the speed detecting device and estimating a possibility of collision to the obstacle based on the received signals, and an alerting device electrically connected to the control device. When the control device determines that there is a possibility of collision, the alerting device receives a signal from the control device and emits a first alarm to the subject vehicle and provides a second alarm to a following vehicle without awaiting an action of a driver of the subject vehicle. [A2636]

"GPS vehicle collision avoidance warning and control system and method"

GPS satellite (4) ranging signals (6) received (32) on comm1, and DGPS auxiliary range correction signals and pseudolite carrier phase ambiguity resolution signals (8) from a fixed known earth base station (10) received (34) on comm2, at one of a plurality of vehicles/aircraft/automobiles (2) are computer processed (36) to continuously determine the one's kinematic tracking position on a pathway (14) with centimeter accuracy. That GPS-based position is communicated with selected other status information to each other one of the plurality of vehicles (2) , to the one station (10) , and/or to one of a plurality of control centers (16) , and the one vehicle receives therefrom each of the others' status information and kinematic tracking position. Objects (22) are detected from all directions (300) by multiple supplemental mechanisms, e.g., video (54) , radar/lidar (56) , laser and optical scanners. Data and information are computer processed and analyzed (50,52,200,452) in neural networks (132, FIGS. 6-8) in the one vehicle to identify, rank, and evaluate collision hazards/objects, an expert operating response to which is determined in a fuzzy logic associative memory (484) which generates control signals which actuate a plurality of control systems of the one vehicle in a coordinated manner to maneuver it laterally and longitudinally to avoid each collision hazard, or, for motor vehicles, when a collision is unavoidable, to minimize injury or damage therefrom. The operator is warned by a heads up display and other modes and may override. An automotive auto-pilot mode is provided. [A2637]

"System and method for detecting and displaying wind shear"

A computer based method of detecting and displaying rotational wind shear. Radial wind velocities within first and second adjacent gate sweeps produced by a radar system are detected in a predetermined geographic area, and are compared at points of equal radial distance from the radar system. The radial location of gate to gate wind shear at positions between the radar system and the boundary of the radar systems range are identified and compared to a predetermined threshold wind velocity value to determine the location of high priority gate to gate wind shear. The high priority gate to gate wind shear is then graphically displayed relative to its geographic location on a graphical representation of the predetermined geographic area. A computer based system for detecting and displaying rotational wind shear is also disclosed. [A2638]

"Player position detection system"

A system for locating players on a field includes first and second directional scanning antennas located adjacent the field. A transponder carried by the players detects the radiation from each antenna and transmits timing signals. The timing signals are received at a central station and compared to reference timing signals synchronized with the scanning of the antennas to provide an indication of the angular position of each player from the scanning antenna locations. The actual field position of the players can then be computed. The system can also locate the position of a playing object, such as a ball. [A2639]

"Apparatus for evaluating occupancy of a seat"

An apparatus for evaluating occupancy of a seat in which electromagnetic radiation is emitted into a space above the seat, the emitted electromagnetic radiation returning from the direction of the seat is detected, and a processor determines the presence of an occupying item of the seat based on the detected electromagnetic radiation and if an occupying item is present, distinguishing between different occupying items to thereby obtain information about the occupancy of the seat. The electromagnetic radiation may be visible light or infrared radiation. An apparatus for controlling a deployable occupant restraint device in a vehicle to protect an occupant in a seat in the vehicle during a crash includes the evaluating apparatus and the processor further affects the deployment of the occupant restraint device based on the determined presence or absence of an occupying item and the information obtained about the occupancy of the seat. [A2640]

"Safety running system for vehicle"

In a safety running system, a transverse travelling distance resulting when a subject vehicle travels to a current position of an oncoming vehicle is calculated based on the vehicle velocity and yaw rate of the subject vehicle, a relative transverse distance of the oncoming vehicle relative to a vehicle body axis of the subject vehicle is calculated based on a relative distance, relative velocity and relative angle between the subject vehicle and the oncoming vehicle detected by a radar information processor. When a relative transverse deviation obtained by subtracting the transverse travelling distance from the relative transverse distance resides within a range and that state continues to exist over a predetermined time period, it is judged that there is a collision possibility of the subject vehicle with the oncoming vehicle, and automatic steering is performed so as to avoid a collision. [A2641]

"Dynamic monitoring of vehicle separation"

A system for monitoring operation and location of a first moving vehicle relative to a second moving vehicle. A minimum separation distance between the first and second vehicles is estimated, based on the first vehicle velocity, and optionally on the second vehicle velocity, using location determination (LD) signals received from satellite-based transmitters from GPS, GLONASS and LEO satellites, or from ground-based signal sources such as LORAN signal towers, and using ranging signals from SONAR, RADAR or a similar system. The minimum separation distance is compared with the actual separation distance at selected times, and a vehicle driver is advised if the actual separation distance is too small, if the separation distance is decreasing too quickly, or if the second vehicle velocity is decreasing too quickly. The second vehicle may travel in the same traffic lane, in an adjacent lane, or on a road that intersects the road used by the first vehicle. Where the first and second vehicles travel on separate roads that will intersect, the system estimates whether the second vehicle will stop, or will be able to stop, at the intersection. The second vehicle may be a railroad car, such as a locomotive, or a road vehicle. A maximum vehicle clear-view velocity, consistent with vehicle stopping within a selected distance, is estimated. Road conditions are estimated and compensated for in estimating the minimum separation distance and/or the maximum vehicle clear-view velocity. [A2642]

"Method and apparatus for determining the speed and location of a vehicle"

Disclosed is a method and apparatus for measuring the speed of a vehicle by transmitting a wave beam directed at the vehicle, receiving a part of the wave beam reflected by the vehicle, comparing the reflected beam part with the transmitted wave beam and deriving from this comparison the speed of the vehicle, wherein during the speed measurement the position of the vehicle is also determined. A vehicle committing an offense can thus be identified unambiguously in a recording which is made after detection of the speeding offense. The speed of the vehicle can be determined from a difference in wavelength detected during the comparison between the reflected beam part and the transmitted wave beam, while the position of the vehicle is determined from a time lag detected during the comparison between the moment of transmitting and the moment of receiving the reflected beam part. [A2643]

"Method for processing radar signals"

For a radar device arranged above a reflecting surface, a method is suggested for estimating the height of an object above the surface. This method does not require a refined angle resolution for the radar antenna and is based solely on the processing of signals. The invention makes use of the appearance of an interference pattern for the radiation field of the radar antenna, which normally is viewed as a disadvantage, by evaluating the intensity modulation of a signal received from an object moving in radial direction to the radar device within the surveillance range. Together with the measured distance to the object, this is used to estimate a value for the height of the object above the road surface. [A2644]

"Radar method used in a motor vehicle"

The invention relates to a radar method for an automatic intelligent traffic control (AICC) in a motor vehicle. The use of a frequency modulation continuous wave method (FM-CM) is suggested in order to securely detect the distance to, relative speed and angle of a preceding motor vehicle. It is furthermore suggested according to the invention that when using an A/D converter 5 with 8-bit resolution, the necessary dynamics are generated by means of a level switchover, that the R, V information is generated in FFTs [Fast Fourier Transformations] 6 with blocked R and V-FFTs, that the useful signals are separated from the noise in a detection device 7 by means of a R-dependent adaptive CFAR threshold, that in a track formation 8, the detection is directly assigned to the tracks and that the association of a detection i to a track j is in the process computed as probability r (i, j) . [A2645]

"Vehicular front monitoring apparatus"

A vehicular front monitoring apparatus which can reliably recognize a road configuration ahead of an own-vehicle through simpler computation. The apparatus comprises a distance measuring unit for radiating electromagnetic waves or the likes in plural directions, and detecting distances from an own-vehicle to a plurality of objects around the own-vehicle and lateral positions of the objects relative to a running direction of the own-vehicle, thereby measuring object positional data on coordinates defined by the running direction and a transverse direction of the own-vehicle, a road curvature estimating unit for estimating a curvature of a road ahead of the own-vehicle through Hough transform of the object positional data measured by the distance measuring unit, and a vehicle's own lane determining unit for determining whether other vehicles running ahead are in the same lane as the own-vehicle or not based on the curvature of the road estimated by the road curvature estimating unit. [A2646]

"Vehicle with object detection device"

An object detection device for detecting objects in a rear lateral area of a vehicle includes zero-contact radiation-based scanners for scanning such area, and an evaluation unit connected to the scanners. According to the invention, the evaluation unit evaluates the time sequence of the scanning information from two or more strip-shaped portions of the area under observation, with horizontal components that are differently inclined to the lengthwise direction of the vehicle or are offset from one another in the lengthwise direction of the vehicle. The evaluation unit distinguishes objects moving in the travel direction of the vehicle from standing and oncoming objects, based on the response sequence for the portion under observation. [A2647]

"Radar interferometry device"

The invention relates to radar interferometry apparatus comprising at least one emitter satellite (E) and a constellation of receiver satellites (S) . The receivers are accurately synchronous and their orbits have the same eccentricity which is different from that of the orbit of the emitter. During one orbital period, the satellites travel round a relative ellipse (G) over which they are uniformly distributed. The invention provides applications specifically to measuring ocean currents, measuring world topography, and differential interferometry. [A2648]

"Rocket trajectory estimating method, rocket future-position predicting method, rocket identifying method, and rocket situation detecting method"

There is provided a rocket trajectory estimating method comprising the steps of: measuring a GLOS angle of a flying rocket a tracking system, passing the GLOS angle data through a batch filter to reduce noises, estimating a rocket trajectory on the basis of the GLOS angle data, the noises of which have been reduced, passing the resulting rocket trajectory data through a Kalman filter to reduce biases, and estimating the rocket trajectory again on the basis of the corrected GLOS angle data and the positional information of the tracking system. Thus, there is provide a rocket trajectory estimating method capable of reducing observation errors (noises and biases) of a tracking system of a passive ranging system, which does not have need of any laser range finders, to enhance the accuracy of rocket trajectory estimation. [A2649]

"Environmental location system"

A system and method for determining a location. The system employs encoded information devices dispersed through the environment, each having a non-unique code associated therewith. The codes from the encoded information devices are acquired as a reading device passes nearby, and stored. The codes from a proximate set of information devices are correlated with a map or mapping relation to determine one or more consistent positions within the environment. The information devices are preferably passive acoustic wave transponders, and the mapping relation may be a pseudorandom sequence or a defined map. [A2650]

"Scanning apparatus"

Scanning apparatus which scans input radiation from a scene and output radiation is transmitted to a receiver system, for example a millimetre wave imaging camera or a radar receiver by a rotatable reflective plate having an axis of rotation passing through the centre of its surface, secondary reflector and static reflector, wherein the secondary reflector is a second rotatable reflective plate having a common axis of rotation with the first rotatable reflective plate, wherein the common axis of rotation is inclined at a non-zero zero angle .theta..sub.b to the normal to the second reflective plate. The normal to the first rotatable plate is inclined at a small angle to the common axis of rotation, typically a few degrees and forms the secondary reflector. The static reflector may be a polarising roof reflector through which radiation is input to and output from the apparatus. The apparatus also includes a 45.degree. Faraday rotator or a birefringent surface such as a Meander-line. An additional Faraday rotator and an inclined polariser may be included in the apparatus and arranged such that radiation output to the receiver system may be separated from the path of input radiation. Alternatively, the scanning apparatus may include a reflector lens arrangement, such that focused output radiation may be output directly to the receiver system. [A2651]

"Fast acquisition of GPS signal corrupted by doppler or time delay effects"

An RF translator is placed on an artillery shell. The RF translator receives a GPS signal, converts the GPS signal to an S band signal, and then transmits the S band signal. The S band signal is received by a ground antenna and it is converted back to an L1 GPS signal. The transmission of the S band signal to a ground antenna induces two effects which make fast direct P (Y) acquisitions difficult. First, since the artillery shell is moving, a carrier Doppler is induced on the S band signal. Second, the time delay caused by the transmission of the S band signal affects the nominal code phase for acquisition. Acquisition of GPS signals corrupted by second frequency data effects require special compensation if fast direct P (Y) code acquisition is desired. A carrier Doppler and a code phase compensation term allow the GPS ground receiver software to focus its search window for the carrier frequency (code rate) and the code phase (time delay) . By adding in these new compensation terms, small centered searches can be used and fast direct P (Y) code acquisition is possible. [A2652]

"Relative velocity detecting apparatus for automotive vehicle"

In a relative velocity detecting apparatus for an automotive vehicle applicable to an automatic vehicular velocity control system to follow up a preceding vehicle, an inter-vehicle distance detector is provided which is disposed on the vehicle so as to be oriented toward a forward detection zone of the vehicle to detect an inter-vehicle distance to the preceding vehicle which is running ahead of the vehicle, to recognize whether the preceding vehicle has entered the forward detection zone and to derive the inter-vehicle distance value lrn (n=1, 2, . . ., n) whenever a predetermined period of time has passed when recognizing that the preceding vehicle has entered the forward detection zone, a relative velocity calculator is provided to perform a band pass filter calculation for the inter-vehicle distance value lrn, the band pass filter being expressed as: CF0.multidot.S/ (S.sup.2 +CF1.multidot.S+CF0) , wherein CF0 and CF1 denote constants, and to calculate a relative velocity value vr of the preceding vehicle to the vehicle according to the above equation, and an initial value setting section is provided to set a first initial value lr0 of the inter-vehicle distance value and a second initial value vr0 of the relative velocity value in the band pass filter calculation by the relative velocity calculator during a run of the vehicle. [A2653]

"System for processing weather information"

A method for automatically generating weather alerts in disclosed. Weather related data is automatically collected and processed to detect the presence of storm cells, their location, direction and speed. Alerts are automatically generated when necessary. These alerts contain information related to the nature of the storm cell, its location, the specific geographic areas likely to be affected by the storm cell, and the storm cell's expected time of arrival at each specific geographic area. [A2654]

"Underground pipe locating system"

A system for locating and identifying underground pipes, utilizing a ground-probing radar. The ground-probing radar system includes an antenna module and a transmit/receive sub-system. The system also includes a digital signal processing sub-system for processing the received signal to extract data corresponding to detected differences in dielectric constant and a master controller. The system still further includes a positioning sub-system, a display sub-system, a user interface and a data storage mechanism, display data and said operating parameters. [A2655]

"Moving object control system"

A method is provided for controlling two objects relatively moveable with respect to each other. A plurality of receivers are provided for detecting a distinctive microwave signal from each of the objects and measuring the phase thereof with respect to a reference signal. The measured phase signal is used to determine a distance between each of the objects and each of the plurality of receivers. Control signals produced in response to the relative distances are used to control the position of the two objects. [A2656]

"Marine vessel traffic system"

The marine Vessel Traffic System (VTS) is an improved radar harbor surveillance sensor, computer and display system that monitors marine harbor traffic, provides advisories to vessels in areas selected by the system operators, and provide the operators of the system with an early warning of unacceptable traffic conflicts in the confined waterways of the harbor. The VTS collects harbor traffic information from multiple remote sensor collection sites around the harbor and integrates, records, merges and presents the remote site data onto a single operator display, selected from a plurality of operator displays. VTS provides quick accurate computer generated graphic display of the harbor traffic, possible surface and subsurface conflicts, and key vessel identification information and the VTS documents incidents and traffic conditions for the Coast Guard or other waterway authorities. [A2657]

"Apparatus for calculating deflection of central axis of an obstacle detecting apparatus mounted on a vehicle and apparatus for correcting the deflection of central axis, and system for controlling distance to a preceding vehicle traveling ahead"

The present invention aims to facilitate easy correction of the center axis of an obstacle detecting apparatus for a vehicle by calculating deflection of the center axis with respect to the vehicle. Each of most obstacles recognized as moving objects is a preceding vehicle 93, and when the subject vehicle 91 is moving straight, the preceding vehicle 93 is detected in a position straight ahead of the subject vehicle 91. If the optical axis 95 of the transmitting/receiving section 31 is oriented straight ahead of the subject vehicle 91, the preceding vehicle 93 will be detected on the optical axis 95. On the other hand, when the optical axis 95 deviates from the center axis of the vehicle, the preceding vehicle 93 is detected in a position deviated from the optical axis 95 by an angle .theta. m. In this case, the value .theta. of deflection of optical axis 95 is equal to -.theta. m. In addition, by determining whether or not the relative velocity vector component of an obstacle is within a given range, the accuracy of calculation can be bettered with data of vehicles moving in an adjacent lane and data of vehicles moving along a curve being removed. [A2658]

"Sensing apparatus"

An apparatus for determining various physical quantities such as temperature, pressure, stress, strain, distance and the like in a manner such that a change in the physical quantity of interest results in a measurable change in the frequency of oscillation of a signal generated within the apparatus. [A2659]

"Moving body detection system"

A moving body detection system for detecting moving bodies by transmitting and receiving signals between the moving bodies. Each moving body transmits an ID code capable of identifying the moving body itself. A detection side moving body receives the ID code signal based on changes in driving conditions, discriminates the received ID signal, and transmits a detection signal with the ID code and the ID code of the detection side moving body itself added thereto. A non-detection side moving body receives the detection signal, and transmits a response signal with its own ID code and the ID code of the detection side moving body added if the ID code added to the detection signal is the same as its own ID code. Furthermore, the detection side moving body receives the response signal and measures the distance to the non-detection side moving body having the same ID code as the response signal. [A2660]

"Communication module for a means of transportation"

A communication module for a vehicle including an automobile, a vessel or the like, the communication module being disposed on a back side or inside of an identification plate of the means of transportation. The communication module is formed of a millimeter wave integrated circuit section and a plane antenna section. The millimeter wave integrated circuit section has two conductive plates arranged in parallel with each other, and a dielectric stripline and an electric element disposed between the conductive plates. The plane antenna section has two conductive plates arranged in parallel with each other, a dielectric stripline disposed between the conductive plates and a slot made in one of the conductive plates. At least a respective one of the conductive plates of the millimeter wave integrated circuit section and a respective one of the conductive plates of the plane antenna section are integrated in a plane. The identification plate is made of a material which transmits a millimeter wave with a small loss, for example, polycarbonate, polybutylene terephthalate, polypropylene reinforced with glass fiber, ABS resin or the like. [A2661]

"Method for use with analog FM cellular telephones"

A method for determining the location of a mobile unit within a cellular system. A synchronized signal at a common phase is generated at each base station in a system. The mobile unit transmits a signal tone. Each base station compares the phase of the signal tone to the common phase of the synchronized signal to produce a phase offset. A system controller compares the difference between the phase offset of a first base station and the phase offset of a second base station and determines the difference in distance between the first base station and the mobile unit and the second base station and the mobile unit defining a hyperbolic curve of locations. The system controller determines the intersection of the first and second hyperbolic curves thus determining the location of the mobile unit. The mobile station transmits the signal tone on a second channel that is distinct from a first channel over which user information is transmitted. The mobile station switches to the second channel in response to a request by a base station to the mobile station. [A2662]

"Signal processing method in a motor vehicle radar system and radar system therefor"

A signal-processing method for a motor-vehicle radar arrangement is specified, which method provides more extensive information on the traffic situation in observation direction by evaluating echo signals deflected at the road surface. [A2663]

"Method and apparatus for performing three-dimensional alpha/beta tracking"

A computer-implemented method and apparatus for performing alpha-beta tracking, which generate an alpha curve, representing position errors between a predicted three-dimensional position and a reported three-dimensional position of the track of interest at a plurality of times, generate a beta curve, representing velocity errors between a predicted velocity and a reported velocity of the track of interest at the plurality of times, plot the alpha curve and the beta curve in a probability versus error plane, determine an acceleration and a change in acceleration for the track of interest at each of the plurality of times, and perform three-dimensional alpha-beta tracking on the track of interest such that as the three-dimensional alpha-beta tracking moves along the alpha curve and the beta curve in the probability versus error plane in a first direction, when a magnitude of the change in acceleration is negative, the three-dimensional alpha-beta tracking continues to move along the alpha curve and the beta curve in the first direction and when the magnitude of the change in acceleration is positive, the three-dimensional alpha-beta tracking moves along the alpha curve and the beta curve in a second direction, opposite to the first direction. [A2664]

"Transponder system for localization of an object"

A transponder system is provided which presents a light weight portable or mobile system for localization of movable objects, e.g., for surveillance of valuable transports and the like. The small unit constituting the transponder contains a receiver (1) of paging type, a decoder (2) , a logic unit (3) , a transmitter portion (10) , a built-in antenna and power supply (11) . The system is controllable by an existing tested radio system for paging. One advantage of utilizing an already existing paging system is that functionality is well tested and a general covering range is obtained. In addition, costs for building up and operation of a paging system are eliminated. Control information being sent to the transponder includes a number of symbols defining a certain basic function for the built-in marker transmitter (10) and symbols which constitute control code and control data for the specific function. Consequently at least the frequency, transmit power and transmitting sequences of the marker transmitter are controllable. [A2665]

"Transponder modules, RF tagging system, method of operating a transponder module and methods of tagging an object having a conductive surface"

A transponder module includes a circuit board having top and bottom surfaces and an inverted-F receive antenna formed on the circuit board. The receive antenna includes a ground plane formed on one of the surfaces and an active element formed above the ground plane. The module also includes a RF engine having an input coupled to the receive antenna, an output and a power supply input. The module additionally includes a RF decoupling network having first and second ports. The first port is coupled to the output of the RF engine. The module further includes an inverted-F backscatter antenna coupled to the second port of the RF decoupling network. The backscatter antenna includes a second ground plane formed on one of the surfaces and a second active element formed above the second ground plane. A method of tagging an object having a conductive surface includes coupling a transponder module including a low profile antenna to the conductive surface such that a ground plane contained in the transponder module is adjacent the conductive surface of the object and transmitting a signal from the low profile antenna to an interrogator, the signal including information relevant to the object. [A2666]

"Method and apparatus for disabling an airbag system in a vehicle"

Method and apparatus for disabling an airbag system for a seating position within a motor vehicle in which one or more electromagnetic wave occupant sensors are situated in a roof above the seat, the presence or absence of an occupant of the seating position is detected using the electromagnetic wave occupant sensor (s) , the airbag system is disabled if the seating position is unoccupied, the proximity of an occupant to the airbag door is detected if the seating position is occupied and the airbag system is disabled if the occupant is closer to the airbag door than a predetermined distance, i.e., out-of-position. Further, the airbag deployment parameters, e.g., rate of inflation and time of deployment, may be modified to adjust inflation of the airbag according to proximity of the occupant to the airbag door. The presence or absence of the occupant is preferably accomplished using pattern recognition techniques to process the waves received by the electromagnetic wave-occupant sensor (s) . [A2667]

"Apparatus and method for controlling inter-vehicle distance to another vehicle traveling ahead of automotive vehicle equipped with the apparatus and method"

In control apparatus and method for controlling an inter-vehicle distance to another vehicle traveling ahead of the vehicle, an inter-vehicle distance from the vehicle to another vehicle running on a traffic lane at the detected inter-vehicle distance from the vehicle is detected through an inter-vehicle distance detector, a follow-up running control for the vehicle is performed by a vehicular running controller such that the vehicle runs behind the other vehicle, maintaining a predetermined inter-vehicle distance to the other vehicle, and a vehicular velocity variation inhibit command is generated and outputted to the vehicular running controller to maintain a vehicular running state immediately before the inter-vehicle distance detector changes from a first state in which the inter-vehicle distance to the other vehicle is being detected into a second state in which the inter-vehicle distance becomes indetectable is continued for a duration of time until the vehicle passes the traffic lane by the inter-vehicle distance immediately before the inter-vehicle distance detector changes from the first state into the second state. [A2668]

"System for providing Geolocation of a mobile transceiver"

A method and means for locating a transceiver remote from a base station operating in a spread spectrum mode, including determining the angle of arrival of a remote emission from the transceiver and the range of the remote emission and then calculating the geolocation of the remote transceiver therefrom. [A2669]

"Methods for modulating a radiation signal"

A reflector having a mechanically deformable portion of at least one reflective surface is disclosed. By deforming the portion of the reflective surface, discontinuity is introduced in that portion of the reflective surface. The discontinuity in the reflective surface scatters incident radiation signals so as to cause attenuation in the reflected signal. By selectively deforming the portion of the reflective surface, the reflected signal can be modulated to encode data thereon. The mechanically deformable portion of the reflective surface preferably comprises plates integrally formed therein. [A2670]

"Method for detecting a target by means of a high pulse repetition frequency radar system"

The invention particularly relates to the detection of fast-flying targets by means of an HPRF radar system that operates with a plurality of switchable pulse-repetition frequencies (PRFs) . In the method, a high velocity resolution is attained, which permits a reliable detection of a multiple-target situation. At the same time, a precise range determination is attained with a high range resolution by means of a pure transit-time measurement of the pulses. The length of the used range gates is selected to correspond to the anticipated target length. [A2671]

"Vehicle speed detection system"

Correction for compensating for errors caused by the pitching movement of a vehicle is executed with high accuracy at low cost. The ground speed of the vehicle sensed by a Doppler sensor is corrected with angular velocities with respect to the center of gravity of the vehicle. In this correction, the center of rotation of the vehicle and the rotation of the Doppler sensor itself during the pitching movement of the vehicle are taken into account. In order to mount the Doppler sensor at a high level in the vehicle without increasing the output power of the sensor, arrangement is made such that the relationship between the difference between the actual installation level of the Doppler sensor and a reference installation level and the amount of correction of beam depression angle is stored in a look-up table, the beam depression angle corresponding to the actual installation level of the Doppler sensor is calculated through correction with the corresponding correction amount of the table, and the sensed ground speed of the vehicle is corrected with the calculated beam depression angle. [A2672]

"Method and device for determining the probable path to be covered by a vehicle"

A method and a device for determining a future travel-course progression or travel-course range of a vehicle whose traveling speed is controllable as a function of a distance to preceding-traveling vehicles, the future course range being determined at least on the basis of a course progression of one preceding-traveling vehicle. Moreover, a lateral offset is determined for all detected preceding-traveling vehicles. The determined future course range is limited on the basis of detected stationary objects. [A2673]

"Receiver system"

The invention relates to a receiver system for the reception of a series of ultrashort, pulsed electromagnetic signals. Signals of this type usually require an extremely fast-acting receiver, necessarily situated in close proximity to the antenna. According to the invention, the presence of several passive components near the antenna will suffice. [A2674]

"Object detecting device"

An area is divided by a plurality of parallel lines parallel to a vehicle body axis CL of a vehicle V, into fifteen detection areas K1 to K15 each having a width of 1.6 m, and each of the detection areas K1 to K15 is divided by a distance address at a distance of every 0.5 m to define a large number of measure-shaped regions. It is determined whether a target T exists in any of the regions, by adding together received reception level signals of laser beams reflected in the regions and comparing a value resulting from the adding with a threshold value. The widths of the detection areas K1 to K15 assume a constant value irrespective of distance to the target and hence, even when the target T exists at a point closer to the vehicle, the reception level signals of waves reflected from a wider area of the target T can be added together, leading to an enhanced detecting ability. [A2675]

"Sensor mounting"

A mounting for attaching a sensor (10) in a vehicle bumper comprises a housing (12) within which a sensor holder (14) can be angularly adjusted. The sensor holder (14) has a part-spherical surface which is biased against a part-spherical seat (22) within the housing (12) by means of a spring (28) acting through a bearing rest (26) and a bearing cup (24) , these parts being retained within the housing (12) by a thrust washer (30) and a retaining clip (32) . [A2676]

"Surroundings monitoring apparatus for an automotive vehicle"

A surroundings monitoring apparatus for an automotive vehicle, which may readily predict a road geography such as a road radius only by lane information of a vehicle and a relative position, includes a radar head 1 for detecting objects that are present around the subject vehicle and for outputting the positional information of the objects in a predetermined detection coordinate system, a vehicle identifying device (step S3) for classifying the vehicles travelling along the road and objects other than the vehicles out of the objects and a road geography prediction device (step S4) for predicting the road geography based upon the position of the travelling vehicles and the lane information in accordance with an output of the radar head and an output of the vehicle identifying device (step S3) . [A2677]

"Motor vehicle warning and control system and method"

A system and method assist the driver of a motor vehicle in preventing accidents or minimizing the effects of same. In one form, a television camera is mounted on a vehicle and scans the roadway ahead of the vehicle as the vehicle travels. Continuously generated video picture signals output by the camera are electronically processed and analyzed by an image analyzing computer, which generates codes, that serve to identify obstacles. A decision computer mounted in the controlled vehicle receives such code signals along with code signals generated by the speedometer or one or more sensors sensing steering mechanism operation and generates control signals. Such code signals maybe displayed, and as synthetic speech or special sound generating and warning means used to warn the driver of the vehicle of approaching and existing hazards. The system may also use the control signals, particularly through application of fuzzy logic, to control the operation of the brakes and steering mechanism of the vehicle to avoid or lessen the effects of a collision. In a particular form, the decision computer may select the evasive action taken from a number of choices, depending on whether and where the detection device senses other vehicles or obstacles. [A2678]

"Method for vehicle data dependent range measurement from a vehicle"

The invention concerns an ultrasound parking aid system which emits warning signals when an echo signal lying within an audibility window exceeds a given threshold value. Hitherto, an audibility window or the sensitivity of the system was adapted to fixed data of the vehicle and/or the roadway. According to the invention, the sensitivity, audibility window or even the emission response is adapted as a function of varying dynamic data of the vehicle or roadway. [A2679]

"Registration method for multiple sensor radar"

The invention is a method for radar registration by determining initially unknown azimuth and range biases (errors) in a system of multiple, overlapping coverage radars. Track data from multiple radar systems corresponding to a common target are associated into track pairs. Track pair data is then used to calculate state vectors in a multi-dimensional vector space (preferably six-dimensional) , with state vector components corresponding to both position and velocity information. From these state vectors an average normalized statistical distance is calculated, where the averaging is over multiple track pairs. An azimuthal bias parameter (and preferably also a range bias parameter) are then varied to minimize the average normalized statistical distance, thereby finding the best estimates of the corrections required to register the multiple radars. [A2680]

"Swept-step radar system and detection method using same"

An apparatus and method for detecting an object and determining the range of the object is disclosed. A transmitter, coupled to an antenna, transmits a frequency-modulated probe signal at each of a number of center frequency intervals or steps. A receiver, coupled to the antenna when operating in a monostatic mode or, alternatively, to a separate antenna when operating in a bistatic mode, receives a return signal from a target object resulting from the probe signal. Magnitude and phase information corresponding to the object are measured and stored in a memory at each of the center frequency steps. The range to the object is determined using the magnitude and phase information stored in the memory. The present invention provides for high-resolution probing and object detection in short-range applications. The present invention has a wide range of applications including high- resolution probing of geophysical surfaces and ground- penetration applications. The invention may also be used to measure the relative permittivity of materials. [A2681]

"Wide-angle, static and positional anticipatory object detection system"

A wide angle, static, positional anticipatory object detection system includes a transducer device for transmitting a modulated carrier signal and receiving the modulated carrier signal reflected from an object, a detection device for detecting a plurality of Doppler shifted harmonic components from the reflected modulated carrier signal, a range determining device responsive to the amplitudes of at least two of the harmonic components being equal for determining the instantaneous range of the object and, a predetermined distance thereafter, to a predetermined difference between the amplitudes of at least two of the harmonic components. The system also includes a Doppler period measurement device responsive to at least one of the harmonic components for measuring the Doppler periods of that harmonic component and a collision decision device, responsive to the range determining device and the Doppler period measurement device, for indicating that a collision with the object is imminent and the offset of the collision from the detection device before contact is made. [A2682]

"Method of manufacturing an enclosed transceiver"

The present invention teaches a method of manufacturing an enclosed transceiver, such as a radio frequency identification ("RFID") tag. Structurally, in one embodiment, the tag comprises an integrated circuit (IC) chip, and an RF antenna mounted on a thin film substrate powered by a thin film battery. A variety of antenna geometries are compatible with the above tag construction. These include monopole antennas, dipole antennas, dual dipole antennas, a combination of dipole and loop antennas. Further, in another embodiment, the antennas are positioned either within the plane of the thin film battery or superjacent to the thin film battery. [A2683]

"Vehicle position determination system and method"

A vehicle position determination system for determining the position of a moving vehicle having a transponder includes a first and second antennas operable to receive periodic radio frequency data signals from the transponder when the transponder is moving through a first or second predetermined coverage zone, respectively. The first and second coverage zones partially overlap and each have a width that is orthogonal to the travel path of the moving vehicle and a length that is parallel to the travel path of the moving vehicle. A processor counts the number of periodic data signals received by each of the antennas from the transponder during a time period and determines based on the count a probable location of the vehicle. The vehicle location information can be provided to an imaging system to discriminate between transponder and non-transponder equipped vehicles. [A2684]

"Radar device for vehicle"

A radar device for vehicle comprising a means for transmitting electromagnetic waves, a means for receiving the electromagnetic waves reflected by a target object, a signal processing means for obtaining a range, a relative velocity, and receipt intensity of the target object based on an output from the transmitting means and an input in the receiving means, a scanning means for changing directions of transmitting and receiving the electromagnetic waves, and an operating means for calculating a direction of the target object based on the receiving intensity of the target object in a plurality of directions, wherein the amounts of AGC in the receiving means in the plurality of directions are independently controlled, whereby a maximum detectable range as an inherent performance of radar is not deteriorated under any driving situation and a position of the preceding vehicle is securely detected. [A2685]

"Wide area time domain radar array"

A system and method for high resolution radar imaging using a sparse array of time modulated ultra wideband (TM-UWB) radars. Two or more TM-UWB radars are arranged in a sparse array. Each TM-UWB radar transmits ultra wideband pulses that illuminate a target, and at least one receives the signal returns. The signal return data is processed according to the function being performed, such as imaging or motion detection. The TM-UWB radar array operates in several modes. In a first mode, each TM-UWB radar transmits and receives back scattering returns, and at least one TM-UWB radar receives forward scattering returns. In a second mode, each TM-UWB radar transmits but only one of the radars receives signal returns, both back and forward scattering. In a third mode, each TM-UWB radar transmits and receives back scattering signal returns, but neither receives forward scattering returns. TM-UWB radios can be used to perform other functions, such as handling communications between the radars and determining the distance separating one radar from another. [A2686]

"Electromagnetically coupling nonradiative dielectric waveguides"

A device with a nonradiative dielectric waveguide which operates in a microwave band or in a millimeter wave band. The device with a nonradiative dielectric waveguide is, for example, an oscillator, a circulator, a coupler or the like. The device has a pair of parallel conductors, a dielectric strip which is disposed between the conductors and propagates a high-frequency electromagnetic wave in a specified mode, a mounting surface which is formed on one of the conductors, and an end surface which is defined by an end of each of the conductors so as to be vertical to a traveling direction of the electromagnetic wave propagated in the dielectric strip. An end of the dielectric strip is exposed at a corresponding end surface of the device. [A2687]

"Method and apparatus for controller power train of motor vehicle"

The vehicle power train control method and apparatus according to the invention secures both operability and safety by controlling an actual acceleration/deceleration to a target acceleration/deceleration requested by a driver under safe traveling condition, and changing the target acceleration/deceleration so as to take precedence for safe traveling if the driver encounters a dangerous traveling condition. According to the invention, acceleration/deceleration and speed of a motor vehicle are detected, a target acceleration/deceleration is determined, and a road condition such as a road gradient or presence or absence of a forward motor vehicle is detected to decide whether the road condition is dangerous. The target acceleration is changed if the condition is decided to be dangerous. [A2688]

"Vehicle radar system"

A radar system adapted to be installed on a vehicle (1) is operable to detect objects in different fields of view of the system. The system has transceiver means (2, 3, 44, 46) for transmitting a radar signal and receiving the signal after the latter has been reflected from an object to be detected. A reflected signal is sampled by sampling means (12, 66) during a succession of sampling periods each of which is delayed with respect to a corresponding portion of the transmitted signal. The gating of the reflected signal effectively generates range shells, each of which corresponds to the time taken for a transmitted signal to reach an object at the shell, and to be reflected back to the system and is hence related to the delay between the transmission of the signal and the corresponding sampling period. The range shells define the field of view of the system, which can be changed by altering said delay. Such alterations are carried out under the control of control means which is connected to sensor means for detecting a property of the operation of the vehicle, determining a required position of the field of view, and setting the field of view of the system accordingly. The range shell positions, and hence fields of view, can also be changed by selecting alternative transmitters and/or receivers of the transceiver means. There is also shown a motor road vehicle which has a radar system comprising a pair of transmitter antennas at two alternate corner regions of the vehicle and a pair of cooperating receiver antennas of the other two corner regions. Certain embodiments of the system also have the facility to generate range shells which are swept over an area around the vehicle or which track detected objects. [A2689]

"Parking aid for a motor vehicle having sensors with substantially the same detection area"

A parking aid for a motor vehicle, which measures the distance between an object and the motor vehicle in a contactless manner and has a plurality of sensors which are arranged on the motor vehicle, each sensor emitting a signal and receiving the signal reflected from an object located in the direction of the beam, and an evaluation device connected to the sensors determining the distance between the object and the motor vehicle from the signals received. The outlay for electrically synchronizing the sensors is reduced and which nevertheless allows reliable detection of the actual object for accurate measurement of the distance, has three sensors which are arranged directly next to one another to provide approximate coverage of the same detection area, whereby the main beam of each sensor having approximately the same beam angle. [A2690]

"Dynamic optimal sensor employment for searching an area"

A dynamic optimal sensor employment system and method is used for searching an area. Each time the sensor in the search vehicle is activated, the dynamic optimal sensor employment system ("the system") determines which areas were searched at that moment. It does this by using a terrain database, information about the sensor state when it scanned (azimuth, elevation, mode, etc.) , and a line-of-sight algorithm. The system determines this instantaneous coverage not only for the primary search vehicle, designated "ownership", but also for other teammates who report scan information to ownship via digital messages. The system maintains a dynamic history of all areas (e.g. 30 meter by 30 meter square "cells" of ground) that have been searched. Each cell has a counter that indicates how many time it has been scanned, and each time cells are scanned with ownship or team sensors the counter is incremented. Cells that are too steep or otherwise non-trafficable by a land vehicle, such as a lake or a river, are marked ahead of time to indicate there is no need to search them. The system then dynamically determines what sensor activations are required to search the areas that are known to be trafficable but have not yet been scanned by ownship or teammates. Specifically, it determines the time, location, direction, field-of-view, and altitude that best satisfy an optimization criteria, and then automatically activates the sensor to generate this coverage. [A2691]

"Method and system for controlling vehicle speed based on vehicle yaw rate and yaw acceleration"

In an adaptive speed control system for a vehicle, a method and system are provided for controlling a speed of the vehicle while the vehicle is traversing a curved path. The method includes sensing a yaw rate of the vehicle, determining a yaw acceleration based on the yaw rate, and determining a maximum allowed speed of the vehicle on the curved path based on the yaw rate and the yaw acceleration, the maximum allowed speed being capable of varying continuously. The method also includes limiting the speed of the vehicle on the curved path to a value no greater than the maximum allowed vehicle speed. The system includes a sensor capable of sensing a yaw rate of the vehicle, and a controller capable of determining a yaw acceleration based on the yaw rate, and capable of determining a maximum allowed speed of the vehicle on the curved path based on the yaw rate and the yaw acceleration, the maximum allowed speed being capable of varying continuously. The controller of the system is also capable of limiting the speed of the vehicle on the curved path to a value no greater than the maximum allowed vehicle speed. [A2692]

"Parking aid"

The device has a transmitting and receiving device for electromagnetic radiation which is arranged in the region of a bumper and includes an RF circuit arranged on a support plate and at least two substantially planar antennas that interact with the RF circuit. The antennas are fixed on a plastic sheet. A printed circuit board has perforations for the passage of radiation from the RF circuit to the antennas. Spacers having a precise longitudinal extent are inserted into the perforations, and the plastic sheet is bonded onto the underside of the printed circuit board such that the antennas each bear on a spacer. [A2693]

"Vehicle safety sensor"

A vehicle safety sensor allows a vehicle operator such as a truck driver to detect the presence of adjacent objects in order to avoid collision with same. In one embodiment, three detection ranges providing feedback with various lights and sounds can be used with separate sensors, with some sensors automatically made "live" upon reversing or turning of the vehicle, and some sensors being manually activated, such as when a overpass is encountered. [A2694]

"Side impact airbag systems"

A variable inflation rate inflator system for inflating one or more airbags including an inflator for releasing a gas into the airbag (s) , a first anticipatory crash sensor for determining that a crash requiring an airbag will occur based on data obtained prior to the crash and, upon the making of such a determination, triggering the inflator means to release gas into the airbag (s) to thereby inflate the same at a first inflation rate, and a second crash sensor for determining that a crash requiring an airbag will occur or is occurring and, upon the making of such a determination, affecting the inflator such that an additional quantity of gas is released thereby into the airbag (s) to thereby inflate the airbag (s) at a second inflation rate greater than the first inflation rate. Also, an airbag passive restraint system for protecting an occupant sitting in the seat adjacent the side door is disclosed including at least one airbag arranged to be inflated between the occupant and the side door, a sensor for detecting that a crash requiring deployment of the airbag (s) is required, an inflator for releasing a gas into the airbag (s) to inflate the same and which is triggered by the sensor to release gas into the airbag (s) in response to the detection by the sensor of a crash requiring deployment of the airbag (s) , and a system for permitting the occupant to be displaced away from the side door upon inflation of the airbag (s) and thereby increase the space between the occupant and the side door. [A2695]

"Method for discovering the location of a living object and microwave location device for realizing the same"

The method includes radiating an RF signal within a time Tt, receiving a reflected signal within a fixed time Tr equal in duration to the fixed time Tt of the radiated signal plus a delay .tau..sub.d between the end of the signal radiation and the beginning of the reflected signal reception. Once a modulated component is detected, a level of the component is measured and the reception time of the reflected signal is modified. This is carried out until the level of the modulated component decreases relative to that of the initially reflected RF signal and until the signal stops coming in. A distance is further determined from the reception time of the reflected signal with the modulated component. The method can be implemented using a microwave locator comprising a modulator and a transmitter which includes an oscillator, a power splitter and a transmitting antenna. A receiver comprises a receiving antenna, a microwave receiver, a preamplifier/demodulator and a signal processing unit. The modulator is tunable. The apparatus further includes a first pulse modulator in the transmitter and a second pulse modulator in the microwave receiver. The modulator has a control output which is connected to a control input of the second pulse modulator so that the receiver receives the reflected signal with a delay relative to the end of the signal radiation by the transmitter, and the enable time of the microwave receiver is modified. The signal processing unit measures a level of the modulated component. [A2696]

"Quick response perimeter intrusion detection sensor"

An Ultra Wideband (UWB) short-range radar system is used for the detection of targets in clutter. Examples of targets on the ground include human walkers, crawlers and runners, and vehicles. The UWB sensor can also be used to detect small approaching boats in different levels of sea clutter or airborne targets like hang gliders. One of the primary differences between this device and other UWB radar sensors is the manner in which the bias on the threshold detector is set as well as the logic circuitry used to find targets in clutter while maintaining a low false alarm rate. The processing is designed to detect targets in varying degrees of clutter automatically. There may be no front panel controls other than an ON-OFF switch. The system is lightweight, low-cost, and can be easily installed in minutes. [A2697]

"Apparatus for magnetically decoupling an RFID tag"

A resonant circuit tag includes an integrated circuit for storing data and an antenna circuit for generating a first local field and resonating at a first predetermined radio frequency. A second circuit including an inductive coil selectively generates a second local field such that a sum of the first and second local fields approaches zero. The second circuit thus allows the resonant tag to be selectively decoupled from its environment. [A2698]

"Method for determining object movement data"

The velocity vector of a moving object is precisely determined by using radar measurements of the angle to and the radial speed of a moving object. This can be done in a radar system comprising one or more units. The technique also makes it possible to precisely determine the range to a moving object from a single moving radar unit. [A2699]

"Apparatus for detecting relative velocity"

In order to produce relative velocity signals in accordance with the relative velocity between a following and a preceding vehicle, a Doppler signal transmitter, which targets the preceding vehicle, is attached to the following vehicle. The thus obtained Doppler signals impinge on a signal processor which analyzes the frequency spectrum of the Doppler signal. Velocity signals are formed from the frequencies within this frequency spectrum, which frequencies lie outside the range of those frequencies caused by the velocity of the following vehicle moving relative to the surface. [A2700]

"Method of detecting relative direction of motion of a radio frequency (RF) tag"

A method of determining relative motion between a base station and an RF Tag is disclosed, wherein a property of the RF field at the position of the tag is determined at a first time and at a second time and is used to calculate the relative motion. [A2701]

"Automatic curve sensor calibration method for an automotive CW/ICC system"

An improved system for accurately determining the travel path of a host vehicle and the azimuth angle of a target vehicle through an automatic calibration that detects and compensates for FLS mis-alignment and curve sensor drift. Selected FLS tracking data (range and azimuth angle) are transformed to cartesian coordinates and characterized by a second order curve fitting technique to determine both FLS misalignment and curve sensor bias. Successively determined FLS misalignment and curve sensor bias values are averaged and used to correct subsequently supplied azimuth angle and curve sensor data, thereby compensating an underlying control for both sensor misalignment and curve sensor bias. [A2702]

"Method and apparatus for detecting road circumstances around a traveling vehicle and a recording medium for storing a related software program"

The present position of a previously recognized stationary object group (SOp) is estimated based on past position data and the movement of the traveling vehicle during a past time (.DELTA.T) . A clearance (Mwr, Mwl) between a traveling vehicle (Mx) and an adjacent stationary object group (Mxr, Mxl) is obtained based on the estimated position data. A clearance (Twr, Twl) between a preceding vehicle (Tx) and an adjacent stationary object group (Txr, Txl) is obtained based on the estimated position data and the position data of the preceding vehicle. A same lane judgement is performed to judge whether the traveling vehicle (VM) and the preceding vehicle (VT) are traveling on a same traffic lane based on at least one of the detected clearances (Mwr, Mwl, Twr, Twl) . [A2703]

"Pulse doppler target detecting device"

A target detection device of the electromagnetic transmitter-receiver reaction type comprising a radio frequency oscillator which is integral with its radiating system and detector. It incorporates a pulse modulator which drives the oscillator to periods of high power transmission and a signal processing system to reject unwanted data and to effect detonation of the warhead at the optimum point on its trajectory. [A2704]

"Vehicle rearview mirror display system"

A vehicle blind spot detection display system displays indications from a blind spot detector. The system includes a first indicator assembly positioned on the vehicle in the vicinity of an exterior mirror and adapted to producing an indication at least of the presence of an object adjacent the corresponding side of the vehicle. A second indicator assembly is provided on the vehicle interior mirror assembly and adapted to producing an indication at least of the presence of an object adjacent the same corresponding side of the vehicle. In this manner, redundant indications are provided at both the interior and exterior mirrors in order to assist the driver in a premaneuver evaluation of conditions surrounding the vehicle. [A2705]

"Excavator data acquisition and control system and process"

An excavator data acquisition and control system and process for characterizing the subsurface geology of an excavation site, and for utilizing the acquired data to optimize the production performance of an excavator. A geologic imaging system and a geographic positioning system are employed to initially survey a predetermined excavation site or route. A geologic characterization unit may also be employed to enhance the geologic imaging data. The acquired data are processed to provide detailed geologic and position data for the excavation site and utilized by a main control unit to optimize excavator production performance. In one embodiment, the main control unit accesses a geologic filter database, which includes geologic profile data for numerous types of geology, when analyzing unknown subsurface geology. Removing geological filter data content corresponding to known geology from the acquired geologic imaging data provides for immediate recognition of unknown and suspect subsurface objects. The geologic imaging system preferably includes a ground penetrating radar system having a plurality of antennas oriented in an orthogonal relationship to provide three-dimensional imaging of subsurface geology. [A2706]

"Run environment recognizing apparatus"

Described herein is a run environment recognizing apparatus. The run environment recognizing apparatus comprises an imaging device for sensing the direction of traveling of a host vehicle as imaging vision, a radar for detecting the direction of traveling of the host vehicle as a detection range, an image processing device for recognizing traveling lanes, leading vehicles and stationary objects located ahead of the host vehicle, based on the image information sensed by the imaging device and the result of detection by the radar, and a display for displaying the results of recognition by the image processing device. The image processing device includes means for setting vehicle regions indicative of the leading vehicles within the image information, based on the result of detection by the radar. Thus, the influence of the leading vehicles in the process for recognizing the traveling lanes within the image information is eliminated by the vehicle regions. [A2707]

"Spatial interferometry"

An interferometer comprises a non-uniform beam splitter (34) which splits an incoming beam (30) of energy into two beams (36, 38) . The two beams (36, 38) are taken from parts of the incoming beam (30) which overlap. The two beams (36, 38) are fed spacially separated energy feeds (44, 46) and then fed to a comparator to produce sum and difference channels (54, 58) . The sum and difference channels (54, 58) are guided to a means for detecting a difference in phase (60) between the sum and difference channels (54, 58) . [A2708]

"Radar ice sounder with parallel doppler processing"

A radar ice sounder which employs parallel Doppler processing obtains more reliable and accurate radar ice sounding. The invention uses both incoherent and coherent techniques, in the same paradigm, to achieve simultaneously high Signal-to-Noise Ratio, high Signal-to-Speckle standard deviation Ratio, and high Signal-to-Clutter Ratio. [A2709]

"Method of operating a multi-antenna pulsed radar system"

A method for operating a radar system using at least two antennas provides an increased angular resolution for determining the angular position, radial velocity, and/or distance to a reflection object. A plurality of successive measuring phases are carried out in at least one measuring process. In each measuring phase, operation is repeatedly switched between a transmitting operation in which a transmitted signal pulse is emitted, and a receiving operation in which reflection signals are detected as received signals in the pulse pause interval between successive transmitted pulses. In at least one measuring phase, two different neighboring antennas of the radar system are used respectively as the transmitting antenna for emitting the transmitted signal and as the receiving antenna for detecting the reflected signal. In this manner, the respective receiving antenna monitors only the angular range of overlap between the emitted beam of the transmitting antenna and the field of view of the receiving antenna. The information provided by the detected signals in this overlapping angular range achieves an increased angular resolution. The method is particularly suitable for operating a separation distance warning system for a motor vehicle. [A2710]

"System and method for intrusion detection using a time domain radar array"

A system and method for highly selective intrusion detection using a sparse array of time modulated ultra wideband (TM-UWB) radars. Two or more TM-UWB radars are arranged in a sparse array around the perimeter of a building. Each TM-UWB radar transmits ultra wideband pulses that illuminate the building and the surrounding area. Signal return data is processed to determine, among other things, whether an alarm condition has been triggered. High resolution radar images are formed that give an accurate picture of the inside of the building and the surrounding area. This image is used to detect motion in a highly selective manner and to track moving objects within the building and the surrounding area. Motion can be distinguished based on criteria appropriate to the environment in which the intrusion detection system operates. [A2711]

"Method for determining a desired response to detection of an obstacle"

A method is disclosed for responding to the detection of an obstacle in the path of a mobile machine as the mobile machine traverses the path at a work site. The method includes the steps of scanning a field of interest, detecting the presence of an obstacle, and determining a set of parameters as a function of the mobile machine, the obstacle, and the work site. The method also includes the steps of determining a level of predictability of motion of the obstacle, defining ranges of a plurality of zones as a function of the level of predictability and the parameters, and initiating an action in response to the obstacle being in one of the zones. [A2712]

"Enhanced range transponder system"

An identification and telemetry system including an interrogator (1) containing an interrogator antenna (2) for generating at an interrogation frequency, an interrogtion signal. The interrogation signal is adapted to excite over an electromagnetic coupling path (M1) at least one coded label (3) containing a label antenna (4) and a label microcircuit (5) . The coded label is adapted to extract energy from the label antenna and to generate a label reply signal. The label reply signal is adapted to be conveyed to a label reply antenna and, via an electromagnetic coupling path, to a receiver in the interrogator. The label antenna is placed in proximity to a further antenna (6) being a parasitic antenna coupled electromagnetically (M2, M3) with the interrogator antenna and with the label antenna so as to enhance transfer of power between the interrogator and the coded label. [A2713]

"Transponder communication of ORVR presence"

The present invention provides a fuel delivery system capable of controlling a fuel dispenser's vapor recovery system based on the absence or presence of an on-board vapor recovery system on the vehicle. This system includes a fuel dispenser having a vapor recovery system, a controller capable of controlling the vapor recovery system, a receiver and an antenna operating in conjunction with the receiver to receive a signal emitted from a transponder on a vehicle indicative of the absence or presence of an on-board vapor recovery system, in addition to a type of vehicle tank or characteristic thereof. When the controller determines from the transponder signal information relating to on-board vapor recovery and/or tank characteristics, the controller will control its vapor recovery system accordingly. [A2714]

"Focused narrow beam communication system"

A system for establishing and utilizing a wireless communication system using a lens antenna having a dielectric material lens. The lens focuses output radio frequency (rf) signals into narrow beam rf signals which are directed to a specific receiving communication device. The lens focuses input rf signals onto signal processing equipment. A communication system between two or more communication devices which utilizes a dielectric material lens and signal processing equipment can be used for point-to-point or point-to-multipoint communication. [A2715]

"Object recognizing apparatus for vehicle and the method thereof"

A stereoscopic optical system images a stereoscopic picture image, a stereoscopic image processing section calculates a three-dimensional distance distribution from the stereoscopic picture image, and an object recognizing section recognizes objects from the distance distribution information to calculate a relative position of the objects with respect to the vehicle. On the other hand, a travelling amount of the vehicle is detected by a steering sensor and a rear wheel rotation sensor. Then, an object positional information calculating section calcuLates a new relative position of the objects based on the relative position information memorized in a memory section and the calculated travelling amount of the vehicle and the memory section memorizes the new positional information. And, a bumping judgment outputting section judges the possibility of bumping against the objects based on the new relative position of the objects with reference to memorized information about the external shape of the vehicle. If it is judged therein that there is a possibility of bumping, the bumping judgment outputting section outputs a warning signal to an indicating section. [A2716]

"Vehicle control system having obstacle detector"

A vehicle control system having a laser radar for detecting an obstacle present ahead on a course of travel of the vehicle, and control device for operating a brake or an alarm based on an output of the laser radar when a distance from the vehicle to the obstacle is less than a first predetermined value or is less than a third predetermined value. In the system, a millimeter-wave radar, which is inferior to the laser radar in position detection accuracy, but is superior in weather-proof operation, is provided. When the laser radar is inoperative, the control device operates the brake or alarm based on the output of the millimeter-wave radar when the distance is less than a second predetermined value (less than the first predetermined value) or is less than a forth predetermined value (greater than the third predetermined value) , thereby expediting the alarm initiation to alert the vehicle driver at an appropriate time, while ensuring the proper brake initiation, so as not to cause the vehicle driver to experience annoyance. [A2717]

"Methods and arrangements for controlling an occupant restraint device in a vehicle"

Arrangements and method for controlling a deployable occupant restraint device in vehicle, such as an airbag, in which a crash sensor determines whether deployment of the occupant restraint device is required as a result of the crash and an occupant position sensor determines the position of the occupant. Deployment of the occupant restraint device is controlled based on the determination by the crash sensor if deployment of the occupant restraint device is required and the position of the occupant. The position of the occupant is determined preferably by ascertaining the position of the seat or a part thereof, e.g., the seat portion or back portion, relative to a fixed point of reference to thereby enable an approximation of the position of the occupant to be obtained. The payout of a seatbelt from a seatbelt retractor can also be measured and used to better provide the actual position of the occupant. An additional approximation of the position of the occupant can be obtained by receiving waves from the space above the seat in order to improve the determination of the likely, actual position of the occupant. [A2718]

"Arrangement and method for detecting objects from a motor vehicle"

A motor vehicle object-detecting arrangement includes a distance controller having a distance-sensing device for emitting and receiving object-reflected measuring beams in different directions and having an evaluation unit. The measuring beams received by the distance-sensing device are appraised as a function of the geometry of the road on which the vehicle is being driven. for this purpose an appraisal device receives information from the distance sensing device and from a transmitter unit which supplies information on the road geometry of the road. The appraisal device appraises the measuring beams reflected from different directions as a function of the information on the road geometry. [A2719]

"System and method for detecting and displaying wind shear"

A computer based method of detecting and displaying rotational wind shear. Radial wind velocities within first and second adjacent gate sweeps produced by a radar system are detected in a predetermined geographic area, and are compared at points of equal radial distance from the radar system. The radial location of gate to gate wind shear at positions between the radar system and the boundary of the radar systems range are identified and compared to a predetermined threshold wind velocity value to determine the location of high priority gate to gate wind shear. The high priority gate to gate wind shear is then graphically displayed relative to its geographic location on a graphical representation of the predetermined geographic area. A computer based system for detecting and displaying rotational wind shear is also disclosed. [A2720]

"Device for detecting obstacles, for use in vehicles"

A device for detecting obstacles, for use in vehicles, capable of correctly detecting obstacles without driving up the cost. the device includes a signal processing device 3 for detecting an obstacle Z based on reception signals A, B from a plurality of sensor devices 1, 2, wherein the signal processing device includes detection region-setting devices 31, 32 for dividing the region around the vehicle into a plurality of detection regions, probability-of-presence operation devices 33, 34 for operating the in-the-region presence probabilities P, Q of obstacle, a probability distribution operation device 35 for operating the in-the-region presence probabilities for each of the detection regions, and an obstacle detection device 36 for judging the regions S where the obstacles exist based on the in-the-region presence probabilities R in the distribution of presence probabilities, wherein the obstacle detection device judges detection regions exhibiting the in-the-region presence probabilities that are larger than a predetermined threshold value to be the regions where the obstacles exist among the in-the-region presence probabilities in the detection regions in the distribution of presence probabilities. [A2721]

"Apparatus and method for controlling an underground boring tool"

An apparatus and method for determining a location and an orientation of an underground boring tool by employment of a radar-like probe and detection technique. The boring tool is provided with a device which generates a specific signature signal in response to a probe signal transmitted from above the ground. Cooperation between the probe signal transmitter at ground level and the signature signal generating device provided at the underground boring tool results in accurate detection of the boring tool location and, if desired, orientation, despite the presence of a large background signal. Precision detection of the boring tool location and orientation enables the operator to accurately locate the boring tool during operation and, if provided with a directional capacity, avoid buried obstacles such as utilities and other hazards. The signature signal produced by the boring tool may be generated either passively or actively, and may be a microwave or an acoustic signal. Further, the signature signal may be produced in a manner which differs from that used to produce the probe signal in one or more ways, including timing, frequency content, information content, or polarization. [A2722]

"Lens arrangement suited for focusing radar waves"

In a lens arrangement for collimating radar waves for distance sensors, in particular for motor vehicles, several sublenses are arranged integrally next to one another. A lobe enlargement necessary for angular analysis is thereby achieved. The range is only slightly reduced as compared to a lens having a surface area of the same size. [A2723]

"Vehicle data acquisition system"

A data acquisition system is disclosed where a first communication device transmits a transmitted signal to a second communication device. The second communication device encodes the transmitted signal with a code generating a retransmitted signal. The retransmitted signal is then transmitted back to the first communication device. The code can be indicative of an environmental element, such as a traffic sign. The first communication device can determine a distance to the environmental element by monitoring a time for the retransmitted signal to arrive. The first communication device can also encode the transmitted signal with information, such as voice for example. [A2724]

"Super-resolved full aperture scene synthesis using rotating strip aperture image measurements"

A spinning strip aperture imaging radiometer sensor system and data processing method for synthesizing a super-resolved scene estimate (super-resolved scene) from a plurality of image frames acquired by the strip aperture imaging sensor system. One embodiment of the imaging system comprises a rotating strip aperture wide field of view telescope, a two dimensional detector array for detecting images in the focal plane of the telescope, rotation compensation apparatus for preventing rotational smear during the integration time of the detectors, a signal processor for recording a plurality of image frames of a scene that is imaged by the telescope as it rotates around its optical axis, and an estimation processor employing the present method for synthesizing the super-resolved scene estimate from the recorded images. The super-resolved image synthesis method uses a plurality of rotating strip aperture measurements within the strip aperture passband and within the passband of an equivalent bandlimited synthesized full circular aperture to estimate the spatial frequency information outside the total measurement passband, and/or outside the passband of the equivalent bandlimited synthesized full circular aperture, as well as within the equivalent bandlimited passband. Knowledge of the spatial response function of the strip aperture, the spatial response function of the detector array, noise statistics, and the temporal registrations of each of the recorded strip aperture images permits synthesis of the super-resolved full aperture image by the sensor system and image synthesis method. The super-resolved image synthesis method may be employed in the spatial domain, the spatial frequency domain, or both. [A2725]

"Excitation method and ultra-wide bandwidth antenna for ground penetrating radar systems"

A novel method of creating and detecting ultra wide bandwidth signals in a ground penetrating radar context. [A2726]

"Cutting device with elevation regulation"

There is described a cutting device for fabric and similar material which comprises a cutting table on the surface of which a material support is mounted, a cutting tool which is moveable over the table to penetrate and cut material lying on the support, and a control arrangement which measures the distance to the table surface under the support and thereby controls the depth of cutting tool penetration so that it extends a predetermined distance into the support, independently of applied pressure on the cutting tool. [A2727]

"Autonomous vehicle arrangement and method for controlling an autonomous vehicle"

An autonomous vehicle and method for controlling it includes an input unit to receive one or more travel orders, a route planning unit containing at least one position finding device and digital street map, a vehicle path generating a unit, an array of sensors including at least one range sensor for detecting objects and at least one range sensor for detecting the condition features of the route, a collision avoidance unit, a vehicle condition data recognition unit, a vehicle control unit and a unit for controlling the vehicle actuator system based on the signals generated by the vehicle control unit, wherein the array of sensors includes at least two essentially horizontally directed range sensors at the front of the vehicle, at least one range sensor at the rear area of the vehicle, at least one trackable range sensor on the roof of the vehicle and directed at the roadway, ultrasonic sensors and/or microwave radar sensors arranged on each side of the vehicle, and at least one camera located in each of the front and rear areas of the vehicle. [A2728]

"Vehicle operator alert process"

A method is disclosed for analyzing range and range rate data obtained by a vehicle obstacle detection system to determine whether the dynamic situation justifies alerting the vehicle operator of reducing the speed of the vehicle. Assumed values of vehicle and obstacle deceleration are used with known and assumed values of their velocities to calculate limiting warning distances that in turn are used to calculate an estimated warning distance. The estimated distance is compared with the range value as a basis of determining whether an alert is made. [A2729]

"Mobile unit detection system"

A mobile unit detection system or information system in which the existence of a car or other mobile unit which must be paid attention to can be detected only upon receiving a necessary signal. The mobile unit detection system or information system detects a mobile unit through communication between the car and the mobile unit. The car includes a device for judging the operating condition of the car and transmitting a detection signal based on the result. The mobile unit may transmit a response signal upon receiving the detection signal so that the car is able to detect the existence of the mobile unit. [A2730]

"Article tracking system"

System for tracking mobile tags. Cell controllers with multiple antenna modules generate a carrier signal which is received by the tags. Tags shift the frequency of the carrier signal, modulate an identification code onto it, and transmit the resulting tag signal at randomized intervals. The antennas receive and process the response, and determine the presence of the tags by proximity and triangulation. Distance of a tag from an antenna is calculated by measuring the round trip signal time. The cell controllers send data from the antenna to a host computer. The host computer collects the data and resolves them into positional estimates. Data are archived in a data warehouse, such as an SQL Server. [A2731]

"Synthetic aperture processing for diffusion-equation-based target detection"

A method and system for target detection processing transmits energetic pes into a media in which the energetic pulses propagate diffusively. Diffusively propagating reflections of the energetic pulses from a target are transformed into corresponding wave propagating reflections satisfying a conventional wave equation. The wave propagating reflections are then processed in accordance with a synthetic aperture processing technique. [A2732]

"Itinerary monitoring system for storing a plurality of itinerary data points"

Method and apparatus for a base station or interrogator station to monitor the itinerary of one or more vehicles or other movable assets. Each vehicle or other movable object includes a satellite navigation receiver with circuitry for computing the geographic position of the object, and a memory for storing a history of positions computed at a number of different times during the itinerary of the object. Each movable object further includes a radio transceiver which transmits the stored position history to the base station. [A2733]

"Method for estimating gain and phase imbalance using self-calibrating monopulse angle discriminants in a monopulse radar system"

A processing method or algorithm is for use with a monopulse radar system that provides accurate position information in a cross-range direction for ground moving targets detected using the monopulse radar system. The method corrects the phase of each detected moving target on an individual basis, and thus more accurately compensates for the phase error introduced into each target in a random fashion as a result of noise. The direction of angle correction is determined from clutter data. A gain correction factor includes a term for antenna effects to provide for a more accurate gain correction factor calculation. [A2734]

"Passive surface wave sensor which can be wirelessly interrogated"

In a passive surface wave sensor for measured value determination, a measured value is transmitted by radio from a remote measuring location to an interrogation device, which transmits energy by radio to a sensor element as an interrogation pulse. The surface wave sensor is suitable for contactless measured value acquisition. A surface wave configuration is the sensor element and a surface wave reference element is provided for phase discrimination and/or propagation time measurement. As a further development, a sensor operated with chirped transmitting signals and having chirped reflectors is provided, in which the configuration has a reference function in place of the reference element. A sensor constructed in such a way that it has a chirped function has the characteristics of an imminently temperature-compensated sensor for measuring other physical or similar variables. [A2735]

"Process for controlling the operation of a motor vehicle airbag"

The process comprises the determination of the position, particularly the distance between a passenger or driver and the deployment center of the respective airbag and controlling the deactivation of said airbag or a modulation of its deployment as a function of said position or said distance in order to avoid or reduce the risks of accidents due to the inflation of the airbag when the passenger occupies an abnormal position. [A2736]

"Method and apparatus for sensing the orientation of a mechanical actuator"

A system for determining the extended length or orientation of a hydraulic actuator, or of an implement or joint, is disclosed herein. Electromagnetic (EM) bursts such as ultra-wideband or frequency pulses are generated and applied to a transmitter unit attached to a stationary or moveable portion of the actuator. The EM bursts are launched by the transmitter toward a receiver located on the other of the stationary or moveable portion of the actuator. The time for the EM bursts to travel between the associated antennas of the transmitter and the receiver is determined and converted into a position signal representing the distance therebetween. [A2737]

"Antenna system"

A multiface phased array antenna, with each antenna face being provided with a plurality of T/R modules. To preclude the occurrence of crosstalk among the different antenna faces, caused by the steep edges of transmitted RF pulses, these pulses are delayed per T/R module with a delay selected from a predetermined time interval. [A2738]

"Radar device"

A radar device for detecting distances and relative speeds of obstructions such as preceding vehicles has a stationary object identifier for identifying stationary objects such as roadside guard rails and the like and a stationary object eliminator for eliminating data identified as pertaining to such stationary objects. The stationary object identifier detects peak densities in a beat spectrum detected as a difference between transmitted and received frequencies of a radar beam modulated to rise and fall in frequency periodically and identifies peak groups having peak densities above a predetermined value as stationary objects. Therefore, it is possible to detect a stationary roadside object on the basis of peak densities. The stationary object eliminator eliminates data of peak groups identified as stationary objects by the stationary object identifier and thereby removes them as objects of combination processing for pairing rise side beat frequencies with fall side beat frequencies. As a result the amount of processing required for this pairing is reduced and the occurrence of wrong pairings is reduced and it is possible to eliminate the unnecessary calculation of distances and relative speeds of roadside objects. [A2739]

"Modulatable reflectors and methods for using same"

A reflector having a mechanically deformable portion of at least one reflective surface is disclosed. By deforming the portion of the reflective surface, discontinuity is introduced in that portion of the reflective surface. The discontinuity in the reflective surface scatters incident radiation signals so as to cause attenuation in the reflected signal. By selectively deforming the portion of the reflective surface, the reflected signal can be modulated to encode data thereon. The mechanically deformable portion of the reflective surface preferably comprises plates integrally formed therein. [A2740]

"Spaceborne scatterometer"

A scatterometer orbiting around the earth globe comprises a single fanbeam radar antenna which is rotated around a vertical axis, at a slow rotation rate. The antenna foot-print sweeps a circular disc. The slow conical sweep combined with the motion of the satellite on which the scatterometer is mounted results in highly overlapping successive sweeps such that an image pixel is revisited many times during an overpass. The pixels in the radial direction are resolved by range-gating the radar echo. The radar operates in the C-band. The scatterometer is intended, in particular, to determine wind speed and direction over the ocean. [A2741]

"System and method for position determination by impulse radio"

A system and a method for position determination by impulse radio using a first transceiver having a first clock providing a first reference signal and a second transceiver placed spaced from the first transceiver. The system determines the position of the second transceiver. The second transceiver has a second clock that provides a second reference signal. A first sequence of pulses are transmitted from the first transceiver. The first sequence of pulses are then received at the second transceiver and the second transceiver is then synchronized with the first sequence of pulses. A second sequence of pulses are transmitted from the second transceiver. The first transceiver receives the second sequence of pulses and the first transceiver is synchronized with the second sequence of pulses. A delayed first reference signal is generated in response to the synchronization with the second sequence of pulses. A time difference between the delayed first reference signal and the first reference signal is then measured. The time difference indicates a total time of flight of the first and second sequence of pulses. The distance between the first and the second transceiver is determined from the time difference. The direction of the second transceiver from the first transceiver is determined using a directional antenna. Finally, the position of the second transceiver is determined using the distance and the direction. [A2742]

"Method for modeling roadway and method for recognizing lane markers based on the same"

A method for modeling a roadway and a method for recognizing lane markers based on the modeling method. The method for recognizing lane markers of roadway for a vehicle by getting image information about the roadway and information about the speed and steering angle using a camera and a sensor attached to the vehicle, includes the steps of modeling the actual roadway on which the vehicle travels, as a structure having a plurality of rectangular plates linked to each other. The modeled plates are overlayed onto the image information about the actual roadway, photographed by the camera, pixels forming the lane markers are extracted, and linear lane marker information is then obtained from the pixels forming the land markers. Then, the linear lane marker information is overlayed onto the modeled plates to recalculate lane marker information using the plates as a frame, and predetermined limitations of the features of the lane markers are applied to the plates onto which the linear lane marker information has been overlayed, to optimize the lane marker information. Then, the roadway on which the vehicle is traveling, is remodeled using the optimized lane marker information, the information about the speed and steering angle of the vehicle measured by the sensor, and the information about the modeled plates, and the position and orientation of the remodeled plates are calculated. Therefore, roadway recognition can be easily achieved using a modeled structure of the roadway, in which a plurality of rectangular plates are linked. Also, the model roadway is repeatedly mapped onto the actual roadway image, so that reliability in recognition of roadway increases. [A2743]

"Meteorological radar precipitation pattern prediction method and apparatus"

Meteorological radar precipitation pattern prediction methods and apparatus are provided, by which operational costs can be reduced, a series of physical processes in a precipitation region and topographical influences can be considered. The main method has the steps of inputting radar images of a precipitation region storing the input radar images as time-series two-dimensional images, calculating various image-feature quantities with respect to two or more of the stored two-dimensional past images, calculating a spatial-temporal transition of the amount of precipitation using an advection-diffusion equation system which indicates various physical effects relating to precipitation phenomena, with the various image-feature quantities as initial values, predicting transition of a pattern with respect to the precipitation region based on results of the calculation, and outputting predicted results as time-series images. Preferably, the advection-diffusion equation system includes time, advection, diffusion, source, sink, and dispersion terms, and a gray-level at each pixel is supplied to the equation as a variable corresponding to an amount of precipitation. If the advection-diffusion equation system includes an advection term which is a product of an advection vector and the first derivative with respect to a gray-level of a relevant pixel in a precipitation pattern, the amount of precipitation is varied according to transition of advection vectors. [A2744]

"Obstruction detecting apparatus"

In the obstruction detection apparatus incorporated in a vehicle (11) , ultrasonic wave transmitter/receiver (16 to 19 171) for changing a combination of transmitting of ultrasonic waves and of receiving of reflected ultrasonic waves, a CPU (20) calculates a distance between the vehicle (11) and an obstruction and stores data corresponding to the calculated distance into the distance table (23) , and the LC display device (27) displays the obstruction on display bars of a lattice shape corresponding to the data stored in the distance table (23) , and a buzzer (26) sounds an alarm for a driver. [A2745]

"Method and apparatus for rejecting rain clutter in a radar system"

A method and apparatus for detecting the presence of objects in a vehicle operator's blind spots. The apparatus comprises a side-facing Doppler radar system using continuous wave (CW) transmission with frequency modulation (FM) operation from a frequency modulation switching technique. The radar system determines the presence, range and closing rate of detected targets. The radar system detects targets even when operated in adverse weather conditions and will not generate false warnings due to rain clutter caused by wet roads and other wet surroundings. The radar system uses ranging techniques to reject false targets that are detected outside of a predetermined target detection zone. In accordance with the present invention, the radar system indicates that a target is detected if and only if any part of the target is within the detection zone and it: (1) remains in front of the antenna for at least TH1 seconds, (2) is at a range between Range.sub.min and Range.sub.max , and (3) is moving faster than Closing-Speed.sub.min relative to the antenna. By rejecting targets that are closer than Range.sub.min feet to the antenna, false alarms due to rain clutter are dramatically reduced. Also, by rejecting targets that are further than Range.sub.max feet from the antenna, the radar system reduces false alarms caused by wet foliage and other wet "non-road" surroundings. In one embodiment, the radar system uses a patch array antenna oriented into a diamond-shape configuration to effectively create a natural linear amplitude taper that aids in rejecting clutter caused by wet road surfaces. [A2746]

"Monitoring mechanism of obstacle detecting apparatus for vehicle"

A monitoring mechanism of an obstacle detecting apparatus for a vehicle can be applied to various kinds of obstacle detecting apparatuses and is preferable for judging whether good or bad. Accordingly, the obstacle detecting apparatus for a vehicle having an outgoing device (51) for outgoing a medium (Lo) to a traveling direction of a vehicle (B) , an incoming device (52) for incoming a reflected medium (Li) from an obstacle (D) and a calculating device (53) for defining an existence of the obstacle (D) on the basis of a difference between the outgoing and incoming mediums (Lo, Li) is provided with a monitoring mechanism (6) comprising a rotating device (61) integrally supporting the outgoing and incoming devices (51, 52) in a freely rotatable manner, a reflecting device (62) reflecting the outgoing medium (Lo) to the incoming device when a rotating angle (.theta.) of the rotating device is within a predetermined angle range (.theta.1 to .theta.2) , a rotating angle detecting device (63) of the rotating device, and a judging device (65) comparing at least one of the incoming medium (Li) and a distances (E) calculated by the calculating device (53) with standards (L1 to L2, E1 to E2) corresponding to the at least one when the rotating angle (.theta.) from the rotating angle detecting device is within a predetermined angle range (.theta.1 to .theta.2) and further judging an abnormality in the obstacle detecting apparatus. [A2747]

"Adjustable shield for vehicle mounted toll collection identifier"

A holder is provided for the reception and selective shielding of an electronic vehicle identifying device conventionally used in conjunction with automatic toll collection. The holder includes a shielding portion which is manually actuated by the vehicle operator when it is desired to permit communication between the signal of the vehicle identifying transponder and an externally located interrogator which ascertains the presence of the vehicle. [A2748]

"System and method for projecting storms using NEXRAD attributes"

The subject invention provides an improved system and method for combining data obtained from the NEXRAD.TM. system of the National Weather Service ("NWS") with geographical and topological data base information to achieve an improved and informative graphical storm-tracking display able to project the movement of a storm with a single user-operation. The method of projecting storm movement includes the following steps: collecting NEXRAD data attributes from a weather data source, calculating storm position using the collected NEXRAD attributes, calculating projected storm movement using the storm position and the collected NEXRAD attributes, displaying a graphic representation of the projected storm movement. [A2749]

"Object detecting system for vehicle"

An object detecting system for a vehicle detects an object based on output data from a distance sensor mounted on the vehicle. The distance sensor is capable of detecting a distance between the subject vehicle and the object along longitudinal and lateral directions of the subject vehicle. The output data from the distance sensor is associated on XY coordinates having a Y axis indicative of the longitudinal direction of the subject vehicle and an X axis indicative of the lateral direction with the respect to the subject vehicle in a coordinate developing device. The number of output data from the distance sensor which are located in a plurality of cells, defined by dividing the XY coordinates at predetermined distances in the X-axis and Y-axis directions and the XY coordinates for every cell, are output as cell information from a cell dividing device. In an object discerning device, the same labels or identifiers are assigned to the cells adjacent to one another, based on the cell information output from the cell dividing device, and barycentric position coordinates for every label are determined. Thus, it is possible to shorten the time required for a proximity determining process, while avoiding a reduction in accuracy of the coordinates of the object. [A2750]

"Radio frequency identification interrogator signal processing system for reading moving transponders"

An RF/ID interrogator recovers a backscattered data signal from a moving RF/ID transponder by combining the received in-phase (I) and quadrature-phase (Q) components of the signal in a manner that cancels out the amplitude nulls and phase reversals caused by movement of the RF/ID transponder. More particularly, the RF/ID interrogator comprises a radio having a transmitter portion to provide an RF carrier signal and a receiver portion to receive the I and Q signals from the RF transponder. A bandpass filter is coupled to the radio to remove direct current (DC) components from the I and Q. A processor coupled to the radio and the filter executes stored instructions to combine the filtered I and Q signals and recover the original backscattered data signal therefrom. In an embodiment of the invention, the processor estimates a phase angle .beta. (t) between the I and Q signals and the RF carrier by calculating an arctangent of a ratio of the filtered Q and I signals. Thereafter, the processor recovers the backscattered data signal by summing a product of the filtered I signal and the cosine of the estimated phase angle .beta. (t) with a product of the filtered Q signal and the sine of the estimated phase angle .beta. (t) . [A2751]

"Method and apparatus for recognizing stationary objects with a moving side-looking radar"

A radar system including a means for distinguishing signals returned from (i.e., reflected by) objects that are stationary with respect to earth (i.e., "stationary objects") from signals returned from objects that are moving along with a host vehicle (i.e., the vehicle upon which the radar system is mounted) . The system includes a radar antenna having a relatively narrow beam width centered at a "squint" angle .theta.. When the antenna is aimed such that the center of the beam is at a squint angle of .theta.=60.degree., the Doppler frequency of signals that are reflected from targets that are stationary along the roadside is significantly higher than the frequency of signals reflected from targets that are in the blind spot to the right-rear of the host vehicle and which are moving along with the host vehicle. [A2752]

"Random noise automotive radar system"

An automotive radar system for use with an automotive control system such as a collision avoidance or smart cruise control system, for example. A wide-bandwidth, random noise signal generated at an RF frequency that is transmitted by a transmitter and reflected from targets in the vicinity of the system. The random noise modulation is sampled prior to transmission in a noise source sampler and this sampled image of the transmitted noise is stored and passed through a series of delay stages that are formed in a correlator. The noise signal reflected from objects is processed by a homodyne receiver and also sampled in a receiver sampler. The noise samples from the signal return are passed to the correlator where they are cross correlated with the delayed images of the transmit noise. The output from the correlator for each unit of delay (range gate) is processed in a digital signal processor to find the range and closing velocity (Doppler frequency) of objects in the field of view. The output (range gate) of the correlator where the delay of the sampled transmit modulation equals the transmit delay of the signal transmitted from the radar system to the object and back, contains the range and closing velocity of the objects. At delays (ranges) where there are no objects to reflect the signal, the outputs of the correlator contain noise. Output signals from the digital signal processor are coupled to the automotive control system which processes the output signals to control the vehicle to avoid collision with the detected targets. [A2753]

"Excavator data acquisition and control system and process"

An excavator data acquisition and control system and process for characterizing the subsurface geology of an excavation site, and for utilizing the acquired data to optimize the production performance of an excavator is disclosed. A geologic imaging system and a geographic positioning system are employed to initially survey a predetermined excavation site or route. A geologic characterization unit may also be employed to enhance the geologic imaging data. The acquired data are processed to provide detailed geologic and position data for the excavation site and utilized by a main control unit to optimize excavator production performance. In one embodiment, the main control unit accesses a geologic filter database, which includes geologic profile data for numerous types of geology, when analyzing unknown subsurface geology. Removing geological filter data content corresponding to known geology from the acquired geologic imaging data provides for immediate recognition of unknown and suspect subsurface objects. The geologic imaging system preferably includes a ground penetrating radar system having a plurality of antennas oriented in an orthogonal relationship to provide three-dimensional imaging of subsurface geology. [A2754]

"Method and apparatus for recognizing whether traffic drives on the right or on the left"

A method and an apparatus based thereon are described for the automatic recognition of whether, in a traffic situation or in a traffic environment, vehicles are driving on the right or on the left. Said method is used in a motor vehicle as part of adaptive speed control. The prevailing direction of traffic flow is determined on the basis of other vehicles, which are traveling toward the cited vehicle. for this purpose, a frequency distribution is created as a function of a lateral, preferably directional distance y, a center of gravity S of this frequency is determined, and then it is determined on what side of the controlled vehicle this center of gravity S is located. [A2755]

"Frequency hopping spread spectrum passive acoustic wave identification device"

A system and method for interrogating a passive acoustic transponder, producing a transponder signal having characteristic set of signal perturbations in response to an interrogation signal, comprising a signal generator, producing an interrogation signal having a plurality of differing frequencies, a receiver, for receiving the transponder signal, a mixer, for mixing the transponder signal with a signal corresponding to the interrogation signal, to produce a mixed output, an integrator, integrating the mixed output to define an integrated phase-response of the received transponder signal, and an analyzer, receiving a plurality of integrated phase-responses corresponding to the plurality of differing frequencies, for determining the characteristic set of signal perturbations of the passive acoustic transponder. [A2756]

"Device and method for sensing and protection of persons and objects"

An electronic device including a wave transmitter covering a determined spatial sensing field, and a wave receiver for controlling an automatic device, a radiating antenna including a waveguide having lateral faces and slots arranged on one of the lateral faces, wherein the slots radiate in planes substantially perpendicular to a longitudinal direction of the waveguide, and wherein the wave transmitter and the wave receiver are arranged at one end of the waveguide, a matched load arranged at an opposite end of the wave guide, substantially identical reflectors arranged over substantially the whole length of the waveguide, wherein the reflectors extend essentially symmetrically with respect to longitudinal plane of symmetry of the waveguide and making a predetermined angle with one another, and wherein the waveguide and the reflectors are composed of at least one piece. [A2757]

"System and method for distance measurement by inphase and quadrature signals in a radio system"

A system and a method for distance measurement utilizes a radio system. The distance is measured by determining the time it takes a pulse train to travel from a first radio transceiver to a second radio transceiver and then from the second radio transceiver back to the first radio transceiver. The actual measurement is a two step process. In the first step, the distance is measured in coarse resolution, and in the second step, the distance is measured in fine resolution. A first pulse train is transmitted using a transmit time base from the first radio transceiver. The first pulse train is received at a second radio transceiver. The second radio transceiver synchronizes its time base with the first pulse train before transmitting a second pulse train back to the first radio transceiver, which then synchronizes a receive time base with the second pulse train. The time delay between the transmit time base and the receive time base can then be determined. The time delay indicates the total time of flight of the first and second pulse trains. The time delay comprises coarse and fine distance attributes. The coarse distance between the first and second radio transceivers is determined. The coarse distance represents the distance between the first and second radio transceivers in coarse resolution. An inphase (I) signal and a quadrature (Q) signal are produced from the time delay to determine the fine distance attribute. The fine distance indicates the distance between the first and second transceivers in fine resolution. The distance between the first and second radio transceivers is then determined from the coarse distance and the fine distance attributes. [A2758]

"Integrated proximity detector for antennas"

A method and apparatus for detecting the presence of objects such as persons in front of a high-frequency communications antenna comprising a transmitting element connected to a circulator. The circulator is connected to an antenna system which transmits the signal pursuant to a designated communications or other application. The circulator is also connected to a regulator circuit which measures a reflected signal received from the circulator. The regulator circuit thereupon initiates a reduction or termination in power from the transmitting element, and/or initiates an alarm, when the regulator circuit detects a reflected signal having a magnitude indicating the presence of the object to be detected. [A2759]

"Positioning determination using one low-Earth orbit satellite"

A system and method for determining the position of a user terminal (for example, a mobile wireless telephone) in a low-Earth orbit satellite communications system. The system includes a user terminal, at least one satellite with a known position and velocity, and a gateway (that is, a terrestrial base station) for communicating with the user terminal through the satellites. The method includes the steps of determining a range parameter and a range-rate parameter. A range parameter represents a distance between the satellite and the user terminal. A range-rate parameter represents a relative radial velocity between that satellite and the user terminal. The position of the user terminal on the Earth's surface is then determined based on the range parameter, the range-rate parameter, and the known position and velocity of the satellite. [A2760]

"Radar sensor for a vehicle"

A compact, multi-beam motor vehicle radar sensor is described, which is placed in a housing, with an antenna arrangement consisting of a dielectric lens (15) and at least two first antenna feeds (161 to 163, 181 to 183) , which are arranged along a first straight line (20) and form a first row of antenna feeds, wherein at least one further antenna feed (164 to 165, 184 to 185) is provided, which is arranged in such a way that at least one further row of antenna feeds is formed along a further straight line (21) , wherein this further row can be congruently represented on the first row by a rotation around an imagined point of rotation (M) . Such a motor vehicle radar sensor can be very simply and cost-effectively adapted to different installed positions. [A2761]

"Lane change alarm for use in a highway vehicle"

A lane change alarm using data for a highway track. A highway track database provides geographical location points for a track of a highway lane. A differential global positioning system (DGPS) receiver provides a vehicle location. A longitudinal track matching code matches the vehicle location against a track location and provides a longitudinal direction and a transverse distance to an alarm gate. The alarm gate indicates an alarm condition unless a lane change signaler is operated for indicating that the lane change is intentional. The highway track database is created using a similar DGPS receiver by determining and recording highway track location points for a selected highway lane while driving on the highway lane. [A2762]

"Dual mode transmitter/receiver and decoder for RF transponder tags"

An enhanced backscatter RF-ID tag reader system and multiprotocol RF tag reader system is provided. In a multiprotocol mode, the system emits a non-stationary interrogation signal, and decodes a phase modulated backscatter signal by detecting a stronger phase component from quadrature phase representations or determining phase transition edges in a phase of a received signal. The RF tag reader system predicts or follows the phase of the backscatter signal, thereby avoiding interference from nulls in the received signal waveform due to the non-stationary interrogation signal, relative movement or environmental effects. An acoustic RF-ID tag detection system detects the reradiated signal corresponding to respective transformation of a signal in the tag. Detection of either type of RF-ID tags therefore is possible, and the absence of any tag or absence of any valid tag also determined. [A2763]

"Distance indicator system for golf"

A golf distance indicator system provides measurement and display of the distance between a golfer and the pin on the green he is approaching. The system comprises a portable unit carried by the golfer and an target unit located on the pin. With the portable unit, the golfer selects the hole he is playing then activates the system. The portable unit sends a wireless coded message to an intended target unit. When a target unit receives a message, it analyzes the message to see if it should respond. If the target unit determines that it should respond, it sends a coded responding message to the portable unit. When the portable unit receives a responding message, it analyzes the responding message to see if the responding message originates from the intended target unit. If it does, the portable unit calculates a distance based on the elapsed time for the communications and the speed of the communications. The results are displayed on the portable unit. [A2764]

"Method and an apparatus for controlling an oscillator for generating a linear frequency sweep by use of a phase-locked loop"

A method and an apparatus for controlling a radar oscillator for use in the traffic field, in particular for a car radar, for generating a linear frequency sweep. A phase-locked linearization loop generates a linear frequency sweep controlling a phase-locked oscillator loop, which has a considerably broader bandwidth than the linearization loop. [A2765]

"Enhanced impulse radar system"

An impulse radar system useful, for instance, for ground penetration provides three dimensional images of targets. The radar system includes an antenna array with an arrangement of elements that is irregular so that the spacing between elements is different, thereby minimizing redundancy of path geometry between the array elements and the target. This feature reduces unwanted array sidelobes. The radar system incorporates circuitry which permits the utilization of each array element as either a transmitter or receiver antenna element. This dual utilization increases the effective number of elements in the antenna array, providing increased gain and system resolution. The radar system receiver utilizes multiple antenna array receiver elements, each of which is connected sequentially, through a solid state switch, to a single analog to digital converter, thereby providing a digitized signal for processing and display. This arrangement requires only a single analog to digital converter, thereby reducing size, cost, and errors due to analog to digital converter non-linearities. [A2766]

"Apparatus for detecting magnetostrictive resonator and traffic system"

A magnetostrictive resonator detection apparatus includes a transmission section for transmitting a resonance frequency of a magnetostrictive resonator, and a reception section for detecting a resonance frequency oscillated by the magnetostrictive resonator. [A2767]

"Method and apparatus for an autonomous cloud radar"

A cloud radar apparatus is mounted on a portable containerized unit, a number of which may be located at various positions throughout the planet. Cloud radar data from each unit are periodically measured and stored and made available to researchers, upon request, through the Internet or other network. The system comprises two computers operating on different operating systems. A first computer uses a first operating system which allows it to readily interface with various radar equipment using an IEEE 488 interface or the like, to monitor the health of the equipment and operate the equipment. A second computer system uses a second operating system in a multi-user mode which allows it to readily access and manipulate data files and transfer data over the network. Communication between the two computers is achieved by allowing the first computer to log into the second computer as one of the multiple users. The first computer may upload data to the second computer using a FTP protocol or the like. A second user in the second computer may generate cloud radar images and apply calibration data to received data to produce calibrated data. A third user may be logged onto the second computer to handle data transfers to and from the network. By using two computers with operating systems selected for optimum performance with their respective tasks, the system of the present invention allows for completely autonomous operation of a remote radar site with automated collection and distribution of cloud radar data. [A2768]

"Method for range measurement and contour detection by means of microwaves"

A method provides for contactless measurement of the range between a transceiver unit for microwaves in the frequency band from 1 to 100 GHz and an object to be investigated using a pulse principle. The microwaves are focused onto the surface by an antenna to detect the contour of the object. In particular, the surface of a bolt produced using a spray compacting method can be detected. [A2769]

"Meteorological radar apparatus"

A meteorological radar apparatus which calculates a shift of the pulse synchronization of a transmission pulse signal output from a transmission unit and corrects the transmission timing of the transmission pulse signal based on the shift of the pulse synchronization so that the Doppler velocity of a reference target becomes zero, thereby preventing deterioration in the measurement accuracy of the Doppler velocity caused by the shift of the pulse synchronization of the transmission pulse signal. [A2770]

"Warning device for distance between cars"

A warning device for a distance between cars, for measuring a distance between a car and an object in front of the car, judging the possibility of danger on the basis of distance data thus obtained, and generating an alarm in the case where it is judged to be dangerous. The warning device provides a first alarm (a rear-end collision alarm) generated in a condition of alert which necessitates deceleration or braking, and a second alarm (an alarm for a distance between cars) generated in a condition of alert which does not necessitate deceleration nor braking, the first and second alarms, respectively, being judged by separate formulae for determining. Accordingly, it is possible to positively generate an alarm when deceleration or braking is necessitated. Further, the warning device discriminates a kind of an object being measured (a moving body, obstruction, guardrail or the like) to judge danger according to the kind of the discriminated object. Accordingly, it is possible to improve reliability of an alarm and, in particular, to reduce incorrect alarms such as by a guardrail. [A2771]

"Object locating system"

A portable system is provided that is operational for determining, with three dimensional resolution, the position of a buried object or a proximately positioned object that may move in space or air or gas. The system has a plurality of receivers for detecting the signal from a target antenna and measuring the phase thereof with respect to a reference signal. The relative permittivity and conductivity of the medium in which the object is located is used along with the measured phase signal to determine a distance between the object and each of the plurality of receivers. Knowing these distances, an iteration technique is provided for solving equations simultaneously to provide position coordinates. The system may also be used for tracking movement of an object within close range of the system by sampling and recording subsequent positions of the object. A dipole target antenna, when positioned adjacent to a buried object, may be energized using a separate transmitter which couples energy to the target antenna through the medium. The target antenna then preferably resonates at a different frequency, such as a second harmonic of the transmitter frequency. [A2772]

"Method for automatically controlling motor vehicle spacing"

In the method for automatically controlling the spacing of motor vehicles described in the specification, a lane width for a controlled vehicle which is defined for evaluation is varied as a function of transverse velocities of vehicles detected ahead of the controlled vehicle. [A2773]

"Process for measuring distance with adaptive amplification"

A process for determining the distance between a distance sensor and an object, wherein an analog input signal is directed to a transmitter of the distance sensor. The transmitter emits a wave which is reflected by the object. A receiver of the distance sensor receives the reflected wave and thereupon emits an analog output signal whose level is dependent upon the distance and/or the type of object. The output signal is amplified by a subsequently added amplifier. The amplifier signal is directed to an analog/digital converter and is converted into a digital signal. The digital signal is directed to an evaluation circuit for the computation of a distance value. The signal amplification of the amplifier is controlled in an adaptively dependent manner on the level of the output signal and/or in a manner dependent on the signal value of an amplification signal made available by the evaluation circuit which is characteristic of an anticipated distance range. [A2774]

"Oblique scanning ground penetrating radar"

A ground penetrating radar uses an oblique or grazing angled radiation beam to provide improved coupling of radar energy into the earth reducing forward and back scatter and eliminating the need to traverse the surface of the earth directly over the investigated volume. [A2775]

"Doppler radar speed measuring unit"

A Doppler radar speed measuring module, that is self-contained and handheld, is fabricated on a multilayer PCB (printed circuit board) containing at least one antenna array and electronic circuitry. In one embodiment the antenna array is located on a top side and electronic circuitry is located on a bottom side opposite the antenna, with a ground plane layer sandwiched between the antenna array and the circuitry. The electronic circuitry includes a dielectric resonator stabilized oscillator, a microwave amplifier, a microwave mixer, a microwave coupler, voltage regulators, mechanical switches, and a display to indicate the measured speed of a moving target. The oscillator generates a very stable microwave signal which is split with part of the signal fed to a mixer and part fed to a transmit antenna. In one embodiment plated through vias electrically connect the two sides together. A transmitted signal reflects off of a moving target and is received by a receive antenna. The receive signal is electrically conducted from the receive antenna to the opposite side by plated through vias and is mixed with the oscillator signal to produce a low frequency Doppler beat signal. The Doppler signal is amplified, filtered and digitized by the A/D. A microcontroller is programmed to determine the moving target speed from the Doppler signal frequency, and drive a display to show the result. [A2776]

"Ground penetrating radar with synthesized end-fire array"

In a ground penetrating radar system, A-scan images of subsurface targets lying along the antenna boresight axis can be substantially improved and generated in real-time by employing a synthetic aperture, end-fire array, despite the inhomogeneous nature of the subsurface volume. The synthetic aperture, end-fire array is achieved by generating electro-magnetic (EM) ultra-wideband impulses at a number of precise locations along the antenna boresight access, shifting the returned EM signals in the time domain according to the corresponding antenna boresight location, and then integrating the shifted, returned EM signals. [A2777]

"Alarm apparatus for alarming driver of vehicle and method of alarming the same"

An alarm apparatus for alarming a driver of a vehicle is provided. The alarm apparatus includes a first indicator disposed on a front center console inside the vehicle, a second indicator located in a windshield of the vehicle, a radar unit, a vehicle speed sensor and a controller. In operation, when a distance between the vehicle and the one ahead is less than a first alarm distance, the first indicator is activated to display the alarm. Further, when the distance is less than a second alarm distance smaller than the first alarm distance, the second indicator is activated to display the alarm. Even if the driver does not gaze ahead but the instruments, it is possible for the driver to look at the first indicator activated more frequency than the second indicator, thereafter shift his eyes ahead and finally brake the vehicle after confirming the preceding vehicle with composure. [A2778]

"Object detecting system for vehicle"

An object detecting system for a vehicle includes a radar. The radar includes an electromagnetic wave transmitting device for transmitting an electromagnetic wave in a direction of movement of the vehicle and a reflected wave receiving device for receiving a reflected wave from an object which exists ahead of the vehicle in the direction of movement of the vehicle. A determining device determines the presence or absence of an obstacle in the direction of movement of the vehicle based on the result of the detection by the radar. In the object detecting system, the radar can detect objects in a plurality of vertically different detection areas, respectively. In addition, it is clear in which areas the object has been detected. Thus, it is possible to appropriately determine whether there is a possibility that the object is an obstacle to the vehicle. [A2779]

"Predictive impact sensing system for vehicular safety restraint systems"

An improved safety restraint system for a motor vehicle including: safety restraint device such as a seat belt and air bag (s) for protecting an occupant during a crash, a processor for predicting the collision of an obstacle with the motor vehicle and for generating an output signal to activate various actuators, actuators for activating the restraint devices in dependence with an output of the sensors various sensors including a radar microwave or millimeter wave system for generating and propagating electromagnetic radiation waves and to receive reflected waves, the transmitted and received waves being of predetermined frequency, wavelength, spectrum, duration and power to provide a desired sensing range and response. [A2780]

"Predictive collision sensing system"

A relatively narrow beam of either RF or optical electromagnetic radiation is scanned over a relatively wide azimuthal range. The return signal is processed to detect the range and velocity of each point of reflection. Individual targets are identified by clustering analysis and are tracked in a Cartesian coordinate system using a Kalman filter. The threat to the vehicle for a given target is assessed from estimates of the relative distance, velocity, and size of each target, and one or more vehicular devices are controlled responsive to the assessment of threat so as to enhance the safety of the vehicle occupant. In a preferred embodiment, a quantized linear frequency modulated continuous wave RF signal is transmitted from and received by a multi-beam antenna having an aziumthal range of at least +/-100 degrees and an individual beam width of approximately 10 degrees. [A2781]

"Modulated backscatter sensor system"

A radio communication system includes an Interrogator for generating and transmitting a radio signal. One or more Tags contained within the radio communication system receive the radio signal. A Backscatter Modulator modulates the reflection of the radio signal using a subcarrier signal, thereby forming a reflected modulated signal. The Interrogator receives and demodulates the reflected modulated signal. Based upon the characteristics of the demodulated signal, the Interrogator can determine the identity of the Tag, and the relative velocity of the Tag with respect to the Interrogator. The Interrogator can also determine if motion exists in the vicinity of the Interrogator, even when no Tag is present, without the need for a separate motion detection system. The characteristics of the demodulated signal, can also be used to determine the characteristics of motion of the Tag, such as the vibrational frequency. Alternate embodiments allow the Interrogator to transmit a first information signal to one or more tags, specifying which Tags should respond using Modulated Backscatter, so that the characteristics of only particular Tags can be determined. Further alternate embodiments allow the Tag to input analog data, and perform analog to digital conversion of that data. This data may be then transmitted to the Interrogator using Modulated Backscatter. Alternately, this data may be used as input to calculations performed in the Tag in order to analyze the frequency characteristics of the analog input. The Tag can also, based upon the results of these calculations, identify an abnormal condition and notify the Interrogator of the existence of such a condition. [A2782]

"Radio-interrogated surface-wave technology sensor"

Radio-interrogated surface-wave technology sensor, in which the sensitive element (12) is an impedance which is electrically connected as termination to a surface-wave structure (26) of the sensor. [A2783]

"Vehicle on which millimeter wave radar is mounted"

The present invention relates to a vehicle with a millimeter wave radar by which not only a distance and a relative velocity can be measured but also traffic information of other various kinds can be obtained. A reflector (4a) which is installed at a predetermined position (5) near a road along which the vehicle (1) is traveling and changes the reflection intensity of a reflected wave (3b) every predetermined period of time to indicate a road state (X) near the predetermined position (5) and traffic information with the change (N1) , a memory unit (6) which is mounted on the vehicle (1) and in which the change (N1) and an operation command (S1) of the vehicle (1) based upon the change (N1) are stored beforehand, being made to correspond to each other, and a control unit (8) which is mounted on the vehicle (1) , reads the operation command (S1) corresponding to the change (N1) detected by the millimeter wave radar from the memory unit (6) and supplies the read operation command (S1) to a vehicle operating means (7) of the vehicle (1) to operate the vehicle (1) are provided. [A2784]

"Signal processing and systematic phase coding for mitigation of range and velocity ambiguities in Doppler weather radars"

A method for resolving range ambiguities and separating overlaid signals in a Doppler weather radar is proposed. for uniform PRT transmission, it consists of a special deterministic code for phases of the transmitted pulsed, and associated decoding and processing of return signals. In the decoding process when the signal from one range interval is made coherent, the signal from the other range interval has a multiple split spectrum. The multiple spectra have the same shape but are offset from each other. Processing steps to separate the overlaid signals and a procedure to estimate the spectral moments are given. One crucial aspect in this procedure is the magnitude domain deconvolution. The magnitude domain deconvolution is also applied to a staggered PRT transmission scheme whereby it enables the estimation of spectral parameters with much lower standard error than the known methods. Moreover, the magnitude domain deconvolution combined with special spectral processing solves the outstanding problem of ground clutter filtering in the staggered PRT sample sequence. [A2785]

"Radar system for observing weather phenomena with improved radar system parameters"

A radar system and method for observing weather phenomena which sets a weather model corresponding to weather conditions, determines the attenuation of a radio wave due to the atmosphere and particles based on the weather model, calculates a radar range using the attenuation of the radio wave, and determines radar system parameters based on the radar range. [A2786]

"Vehicle position detection system"

A system which accurately detects a position of a vehicle on a road regardless of weather is disclosed. Radio wave reflecting bodies are placed on a road, and transmitter-receiver which can transmit and receive radio waves of wavelength is longer than a millimeter are placed on a vehicle. Based on a ratio of reception strength of the transmitter-receiver in the right and left of the vehicle, a displacement of the vehicle relative to the radio wave reflecting body is detected. The radio wave reflecting bodies have apertures or notches in a predetermined interval so that the radio wave signals reflected thereby has periodicity, and can be distinguished from other objects on the road. [A2787]

"Radio frequency identification transceiver and antenna"

An enclosed transceiver includes an integrated circuit and a battery together laminated between two films. Printed conductors on each film couple operative power to the integrated circuit. Other printed conductors form an antenna coupled to the transceiver for sending and receiving signals. In a preferred embodiment, the integrated circuit has three terminals. The first terminal is connected to a first side of a thin film battery. The second terminal is connected to a first side of a printed loop antenna. The third terminal serves two purposes being connected to the second side of the battery and to the second side of the loop antenna. The enclosing films are treated with silicon nitride for hermeticity. Enclosed transceivers of the present invention are suitable for mass production in web, sheet, and tape formats. Such transceivers are useful as stamps, labels, and tags in object tracking systems including systems for mail delivery, airline baggage tracking, and inventory control. [A2788]

"Periodic probe mapping"

A method and apparatus for processing a time domain reflectometry (TDR) signal having a plurality of reflection pulses to generate a valid output result corresponding to a process variable for a material in a vessel. The method includes the steps of determining an initial reference signal along a probe, storing the initial reference signal as an active reference signal, periodically detecting a TDR signal along the probe in the vessel, and computing the output result using the TDR signal and the active reference signal. The method also includes the steps of determining an appropriate time for updating the active reference signal, automatically computing an updated reference signal at the appropriate time, and overwriting the active reference signal with the updated reference signal for use in subsequent computations of the output result. [A2789]

"System and method for intelligent cruise control using standard engine control modes"

A method for implementing an intelligent cruise control using standard engine control modes includes determining the distance and closing rate relative to a forward object or vehicle and using this information to implement a distance control mode and a speed control mode. The distance control mode maintains a selectable headway range relative to a forward object or vehicle and may include accelerating the vehicle or decelerating the vehicle by defueling, engaging an engine brake, or downshifting the transmission when engine speed permits. The speed control mode maintains a selectable cruising speed if no target vehicle is detected. This cruising speed set point also functions as an upper limit while in the distance control mode. The system and method effect the intelligent cruise control functions utilizing control logic external to the electronic engine control module utilizing the engine speed control mode or engine speed and torque limiting control mode of SAE J1922 or SAE J1939 standards. Alternatively, a cruise control limit speed may be broadcast via SAE J1587 to reduce the vehicle speed upon approaching a forward vehicle so as to reduce the need for driver intervention. The invention may periodically switch between engine control modes to avoid any control mode timeout imposed by some engine manufacturers. [A2790]

"Microwave antenna array for a motor vehicle radar system"

A microwave antenna arrangement, made up of a focusing element and at least one feeder element, in which arrangement, to attain a small size, at least one component support is arranged in a spatial area between the focusing element and the at least one feeder element, electronic or electrical components being located on the component support. The component support has a cut-out to allow passage of the electronic waves. The component support and the electronic or electrical components are provided for processing signals other than those received or emitted by the at least one feeder element. [A2791]

"Radar apparatus installed on vehicle for producing correct detecting result"

A radar apparatus installed on a vehicle includes a transmission section and a reception section. The transmission section has at least a transmission antenna, and emits a transmission wave toward a detection area in a front of the vehicle. The transmission wave may be reflected by a reflector such as a preceding vehicle to produce reflection wave, and the detection area includes a plurality of sub-areas. The reception section has at least a reception antenna, and receives and detects the reflection wave. A detecting unit detects a reflector indication data indicative of a reflector attribute for every sub-area for a current detection cycle based on the detecting result by the reception section. Also, the detecting unit determines whether the detected reflector indication data are correct, by use of the detected reflector indication data, to determine that the detected reflector indication data are final reflector indication data when it is determined that the detected reflector indication data is correct. A correcting unit corrects an incorrect part of the detected reflector indication data to a correct reflection indication data to produce the final reflector indication data, when it is determined that the part of the detected reflector indication data is not correct. A determining unit determines whether there is the reflector in the detection area, based on the final reflector indication data. [A2792]

"Vehicle with millimeter-wave radar"

The present invention relates to a vehicle with a millimeter-wave radar capable of traveling without incurring ground clutter and without the influence of pitching of the vehicle. Accordingly, a millimeter-wave transmitting/receiving antenna (2) fixed on the front surface of the vehicle (1) has an antenna beam width (.theta.) of about 4 degrees, an antenna fixing height (h) measured from a ground surface of about 1 meter to 2 meters, and a horizontal angle (.beta.) of a center (C) of the antenna beam of not less than -4 degrees. This vehicle may also be provided with a storage element (231) for storing course data (A) for the vehicle (1) in advance, an extraction element (232) for extracting a superimposed object (P3) , and an identification element (233) for comparing the superimposed object (P3) with the course data (A) and identifying the superimposed object (P3) . [A2793]

"Terrain bias compensator for doppler navigation systems"

A terrain bias compensator for a Doppler navigation system utilizes an auxiliary beam with each beam of the Doppler system to form Doppler beam pairs. The axis of the auxiliary beam is slightly offset from the axis of the main beam and is positioned so that the two axes are in the same vertical plane. After slant range compensation, the amplitudes of the Doppler spectrum of each beam is averaged over a predetermined time interval. The difference between the mean amplitudes of the two beams is divided by the offset angle to establish an amplitude per degree correction factor which is applied to the main beam signal returns to establish a main beam amplitude corrected Doppler spectrum. [A2794]

"Method for measuring the ground speed of a vehicle by means of radar using reflection of electromagnetic waves from the driving surface"

A method for measuring the speed (V) of a vehicle (1) relative to the ground, of the type using the deviation in frequency associated with the Doppler effect between a transmitted wave (3) sent by radar (2) solidly connected to the vehicle and a reflected wave (4) reflected by the ground, characterized in that radar of the type allowing simultaneous measurement of the relative distance (D) and the relative speed (V) between the vehicle and the ground is used, and that the distance measurement is used to validate the speed measurement. [A2795]

"Moving object high-accuracy position locating method and system"

In an automated roadway system having transponders or data-stations spaced at known positions along the roadway, a vehicle mounted system determines the position of a vehicle moving along the roadway. A vehicle borne transmitter transmits a spread spectrum transmit signal which is pseudo (PN) encoded. The transmitted signal is received by the transponder which emits a reply signal back to a vehicle borne receiver. The receiver also receives a second signal which may be a reply signal from the same transponder or a reply signal from an adjacent transponder. The system then measures a time difference between transmission of the vehicle originated interrogation signal and receipt of its corresponding reply signal to determine the distance between the vehicle and the transponder or reflector. Based on the determined distances, the positions of the transponders and the distance that the vehicle has traveled during its communications, the position of a vehicle is determined using triangulation methods. The interrogation signals may be spread spectrum signals that are pseudo-random (PN) encoded. When the signal is detected by a receiver in the transponder or in the vehicle receiver, the PN code is synchronized to the incoming signal to accomplish maximum correlation. The phase delay between the transmitted PN code and received PN code is used to determine the distances between the vehicle and the transponder. The periodically located transponders produce a reply signal including a PN code and embedded data which represents the transponder identification and its position, or other data which is desirable to transmit between the transponder and the vehicle traveling the roadway. [A2796]

"Information indicator for vehicle"

An information indicating device having an LED and a light transmitting structure is disposed within a line of sight of a vehicle operator so as to transmit light from the LED to the vehicle while the operator is driving the vehicle. A distance sensor measures a distance between a vehicle body and an object near it. An emission control circuit controls the LED based on an output of the distance sensor, thereby indicating predetermined information, such as a distance warning to the operator. An indicating portion is disposed on an end of a corner pole or a fender marker to receive light from the LED and transmit light to the vehicle operator without requiring the vehicle operator to substantially look away from the direction the vehicle is traveling or a mirror showing the driver the vehicle's traveling direction. [A2797]

"Animal body detecting system utilizing electromagnetic waves"

An animal body detecting system adapted to be mounted on a vehicle is capable of simply and accurately detecting whether or not an animal exists, i.e. for detecting a distance to an object in front of the vehicle and for discriminating whether or not the object is an animal at the same time, by utilizing electromagnetic waves. The system is comprised of transceiver devices for emitting a radio wave of a first frequency of 10 GHz and that of a second frequency of 60 GHz whose frequency is higher than the first frequency in the same direction and for receiving reflected waves, and discriminating devices for generating material detection data indicative of whether or not a combination, i.e. a ratio or a product, of receiving levels of the reflected waves of the respective frequencies is a combination of the case when the reflecting object is an animal body. It further comprises a detector for detecting a distance to the reflecting object based on the emitted waves and the received reflected waves. The system utilizes the discrimination result of whether or not the object is an animal and the measured distance thereto when traveling at night, in controlling the distance between vehicles and in controlling a vehicle speed. [A2798]

"System for detection and measurement of atmospheric movement"

A system for the detection and measurement of atmospheric air movement irregularities such as wind velocity vector, wind shear, downdraft, clear air turbulence, aircraft induced vorteces and turbulence, in particular along a glidepath near airports, whereby an air volume under investigation is illuminated by a radio wave transmitter with a beam of coherent electromagnetic energy and a resulting wave field is received and processed in processor means to derive information on the existence of said atmospheric irregularities and furthermore to give specific measurements of related parameters, comprising at least one receiver for said resulting wave field, which is due to scattering in said air volume, positioned at a bistatic location having a selected distance from said transmitter, characterized by acoustic transmitter means located between said transmitter and said at least one receiver, and adapted to emit acoustic waves into said air volume, with frequency and beamwidth of the acoustic waves chosen such that a resulting disturbance of the dielectric constant of air in said air volume, contributes to said scattering. [A2799]

"High performance vehicle radar system"

A radar system is described for use in vehicular applications. The radar system is particularly suited to backup warning systems and side-object warning systems. The radar minimies many of the problems found in the prior art by providing programmable delays and programmable gain. The radar uses a range search algorithm to detect and sort targets at various ranges within the field of view of the radar. Each target range corresponds to a particular delay and gain setting. The radar searches for targets at the various ranges by running a target search algorithm. for each target range, the search algorithm causes the proper time delay and gain setting. Targets within the selected range are detected and catalogued. A display is used to warn the driver of the vehicle of the presence of targets at the various ranges. The warning may be visual and/or audible. [A2800]

"Bathroom fixture using radar detector having leaky transmission line to control fluid flow"

Methods and devices for controlling the flow of fluid in fixtures, such as bathroom, restroom, or kitchen fixtures, using a radar detector with a leaky transmission line and fixtures using such methods and devices are provided. A bathroom fixture, in accordance with one embodiment of the invention, includes a fluid conduit, a radar detector for detecting one or more characteristics of one or more objects in a sensor field based on reflected electromagnetic signals from the one or more objects in the sensor field, and a controller coupled to the fluid conduit for controlling a flow of fluid in the fluid conduit in response to the detected one or more characteristics. The radar detector in particular includes a leaky transmission line for transmitting electromagnetic signals to form the sensor field and receiving the reflected electromagnetic signals. In accordance with one aspect of the invention, the sensor field is restricted from selected areas associated with spurious signals, such as areas of flowing water, areas near other fixtures, etc. The use of a radar detector with a leaky transmission line can, for example, improve the control of fluid flow in fixtures, such as bathroom fixtures. [A2801]

"Systems and methods for determining the distance between two locations"

A distancing system comprising radio frequency transceivers and data processing circuits. The radio frequency transceivers allow data transmission via a high frequency radio signal. The transmission and receipt of these radio signals can be timed to estimate distance. But the data processing circuits operate at local clock frequencies, and one cannot be sure at what point a give radio frequency signal was received to a resolution greater than one-half cycle of the local clock signal. The data processing circuits periodically "skip" to resynchronize with incoming data streams. These skips occur at intervals corresponding to the frequency difference between the local clock frequencies. This frequency difference can be used to pinpoint fairly precisely when a given radio frequency signal was received in a previous half-cycle of the local clock. Distances can thus be calculated based on a coarse timing value generated based on the local clock of one of the distancing units and first and second fine timing values generated based on the skips at one or both of the distancing units. [A2802]

"Vehicle-mounted radar apparatus"

A vehicle-mounted radar apparatus comprises: a transmitting-receiving device 8 including an FM modulator 1 for generating an FM modulation signal, a voltage controlled oscillator 2 for generating an electromagnetic wave subjected to FM modulation by the FM modulation signal, a transmitting antenna 4 for transmitting the FM-modulated electromagnetic wave, a receiving antenna 6 for receiving the electromagnetic wave reflected by a preceding vehicle 5, and a mixer 7 for mixing the FM-modulated electromagnetic wave and the electromagnetic wave from the receiving antenna and for outputting a beat signal, a signal processor 9 for computing a relative velocity and a relative distance with respect to the preceding vehicle on the basis of the beat signal, and a scanning mechanism 12 for rotatively driving the transmitting-receiving device, wherein a modulation period of the FM-modulated electromagnetic wave and a rotation angle range of the scanning mechanism are changed in accordance with the relative velocity and the relative distance with respect to the preceding vehicle. [A2803]

"Dynamic monitoring of vehicle separation"

A system for monitoring operation and location of a moving first vehicle relative to a second vehicle. A minimum separation distance between the first and second vehicles is estimated, based on the first vehicle velocity, and optionally on the second vehicle velocity, using location determination (LD) signals received from satellite-based transmitters from GPS, GLONASS and LEO satellites, or from ground-based signal sources such as LORAN signal towers, and using ranging signals from SONAR, RADAR or a similar system. The minimum separation distance is compared with the actual separation distance at selected times, and a vehicle driver is advised if the actual separation distance is too small, if the separation distance is decreasing too quickly, or if the second vehicle velocity is decreasing too quickly. The second vehicle may travel in the same traffic lane, in an adjacent lane, or on a road that intersects the road used by the first vehicle. Where the first and second vehicles travel on separate roads that will intersect, the system estimates whether the second vehicle will stop, or will be able to stop, at the intersection. The second vehicle may be a railroad car, such as a locomotive, or a road vehicle, such as an automobile, bus or truck. A maximum vehicle clear-view velocity, consistent with vehicle stopping within a selected distance, is estimated. Road conditions are estimated and compensated for in estimating the minimum separation distance and/or the maximum vehicle clear-view velocity. [A2804]

"Fog piercing ranging apparatus and method"

An apparatus and method for accurately determining a target distance in adverse weather conditions utilizing both LASER and RADAR is disclosed. The radar signals are used to determine an approximate range which is then used as a gating window for the determination of which laser reflection is from the actual target as opposed to a reflection from the atmospheric interference. The method basically comprises the steps of initiating a radar pulse in the direction of a target and receiving a reflection, transmitting a laser signal and receiving a plurality of reflections, determining an approximate range based on the radar signals, and using this approximate range to ascertain which of the laser reflections is from the target. This determination is preferably made by generating a gating signal and gate width from the radar signals and passing the set of laser range signals through the gate to eliminate the false signals and select the signal that survives the gate as the accurate target range. [A2805]

"Automatic vehicle identification system capable of vehicle lane discrimination"

A system of vehicle identification with a first interrogator that uses a Lower SideBand (LSB) receiver to receive a modulated signal from a vehicle transponder and a second interrogator that uses an Upper SideBand (USB) receiver to receive another modulated signal. The two interrogators are adjacent to each other at a toll plaza, and operate at different carrier frequencies to force a signal frequency bandgap between communication signals in adjacent vehicle lanes. [A2806]

"Vehicle obstacle detecting system"

A vehicle obstacle detecting system having a combination of different kinds of detectors, such as a laser radar and a millimeter-waver radar, to detect an obstacle present ahead of the course of vehicle travel. The system determines whether the detection output of the laser radar is similar to that of the millimeter-wave radar. When the result is positive, obstacle avoidance control is conducted based on the output of either the laser radar or the millimeter-wave radar. When the result is negative, it is determined that the laser radar (the detector normally of superior performance) is degraded and, based on the output of the millimeter-radar, obstacle avoidance control is conducted. With this, the outputs of the different kinds of detectors are fused and unified optimally, enabling effective obstacle avoidance control. [A2807]

"Surveillance method for wide areas"

A method for monitoring large surface areas. A thermal camera and an electromagnetic radar are rotated about a vertical axis to scan the area. The area is divided into sector-like surface elements. Monitoring criteria are established for each of the surface elements. Movements in the surface area being monitored are detected by the radar. The thermal camera is used to detect objects different, in temperature, from their surroundings. Detected objects are located in a surface element and identified in accordance with the monitoring criteria using at least one of the radar and thermal camera. [A2808]

"Method for determining the precipitation ratio by double polarization radar and meteorological radar for implementing such process"

A method for determining precipitation rate including on the basis of the signals received on the two polarization channels H and V of the radar, in firstly determining an estimate of the precipitation rates R.sub..alpha. in each range gate i along the radar beam for a single polarization, then a first estimated value (I.sub.1) of the integral of the precipitation rates and, finally, on the basis of the attenuated reflectivity coefficient (Z.sub.H.alpha. (r)) , an estimate of the unattenuated differential reflectivity coefficient (Z.sub.DRs (r)) . Furthermore, the measured value of the attenuated differential reflectivity coefficient (Z.sub.DRs (r)) is determined, and the integral (I.sub.2) of the precipitation rates is deduced therefrom, then is compared with the first estimated value (I.sub.1) so as to iteratively adjust a parameter (.alpha.) of the method when applied to the polarization H alone. When .alpha. has been adjusted, corrected values of the unattenuated reflectivity coefficient and the precipitation rate are provided. [A2809]

"Radar sensor for use in motor vehicles"

In order to make the connecting lines from at least one transmitting antenna element and at least one receiving antenna element to a common oscillator as short as possible, the receiving antenna element is arranged outside the radiation pattern of the transmitting antenna element, the transmitting and receiving antenna elements being oriented in different directions. An arrangement deflects the reflected radar beams onto the receiving antenna element and/or deflect the radar beams emitted by the transmitting antenna element in a desired direction. [A2810]

"Phase-comparator-less delay locked loop"

A delay locked loop clock circuit employs an analog control loop for generating picosecond-accurate clock delays. A linear analog comparison circuit operating on integrated DC levels replaces the usual digital phase comparator for substantially improved timing accuracy. In operation, clock pulses from a first delay path are integrated and applied to a loop control amplifier. Clock pulses from a second delay path are integrated and applied to a differencing input of the loop control amplifier. The loop control amplifier regulates the delay in the second delay path to balance the integrated clock pulse voltages against externally applied control voltages. The delay between the first path and the second path is thereby precisely controlled by external voltage inputs. The first and second path clock output timing relationship is directly measured by analog voltage devices, eliminating error-prone high-speed phase comparators employed in prior art approaches. [A2811]

"Method and apparatus for detecting obstacles using multiple sensors for range selective detection"

A method and apparatus is disclosed to detect an obstacle in the path of a mobile machine. The present invention scans a field of interest by each of a plurality of obstacle sensor systems, weights the scanned data received from the obstacle sensor systems, and determines at least one characteristic of the obstacle as a function of the weighted scanned data. [A2812]

"Rangefinder"

For improving the measuring precision, a reference unit (REF) is juxtaposed with a continuous wave radar (DSR) . This reference unit (REF) comprises a surface wave element (OFW) for generating a signal delayed relative to the transmission signal. A mixed signal is formed from the delayed signal and the transmission signal with a mixer (MI2) , this mixed signal being utilized in combination with the measured signal stemming from the continuous wave radar (DSR) for determining the distance. [A2813]

"Vehicle with millimeter-wave radar"

The present invention relates to a vehicle with a millimeter-wave radar capable of accurately detecting stationary objects around the vehicle while positively accepting ground clutter. Accordingly, the vehicle is provided with a millimeter-wave transmitting/receiving antenna (2F) fixed thereto with the center (C) of an antenna beam directed to a road surface (5) , and a discrimination element (6) for classifying detected objects (4) by discriminating between objects (4a) the distance (L) to which varies with a movement of the vehicle and objects (4b) the distance (L) to which does not vary with a movement of the vehicle. [A2814]

"Method of manufacturing an enclosed transceiver"

The present invention teaches a method of manufacturing an enclosed transceiver, such as a radio frequency identification ("RFID") tag. Structurally, in one embodiment, the tag comprises an integrated circuit (IC) chip, and an RF antenna mounted on a thin film substrate powered by a thin film battery. A variety of antenna geometries are compatible with the above tag construction. These include monopole antennas, dipole antennas, dual dipole antennas, a combination of dipole and loop antennas. Further, in another embodiment, the antennas are positioned either within the plane of the thin film battery or superjacent to the thin film battery. [A2815]

"Near-range proximity sensor having a fast-tracking analog"

A proximity sensor having a generator providing a signal of which a small portion is used as a reference signal and the remaining portion is radiated out towards a target. The radiation reflected from the target is equalized and/or normalized relative to the reference signal. The signals are compared in terms of relative phase relationship. This relationship implies the distance of the target from an antenna. An example target may be a rail wheel. A certain part of the wheel is measured in terms of distance from the sensor. This distance may determine wheel wear. Such wear is gauged relative to a threshold signal or reference distance. Also, speed and direction of the rail wheel can be determined from the signal reflected back to the proximity sensor. [A2816]

"Vehicle-mounted radar apparatus"

A variable-scanning-speed mechanical driving unit is provided for providing control in such a manner as to acquire data while continuously changing in a range of a scanning angle the direction of an antenna unit for transmission and reception of radio waves. A so-called warning mode which is primarily aimed at the prevention of a collision is set, and a data updating period is shortened by making the scanning speed for transmitted radio waves and received radio waves so relatively high so as to shorten the data updating period. In a case where a so-called follow-up mode which is primarily aimed at follow-up traveling is set, the scanning speed for transmitted radio waves and received radio waves is made relatively low so as to extend the data updating period. Accordingly, the vehicle-mounted radar apparatus can be used as a following-distance warning apparatus or a following-distance controlling apparatus, to make it possible to obtain such as resolutions of the relative distance and relative velocity and a data updating period which are optimally suited for one's own vehicle and a driver in correspondence with the situation during actual use of the apparatus. [A2817]

"Method for detecting a radar target"

The invention relates to a method of detecting a radar target, especially a sea target, in the presence of clutter caused by ocean waves in particular. To detect a radar target within a predeterminable region, first a measurement window corresponding to this region is formed in the video range of the radar system, and a frequency distribution is determined for all pulse-height values (amplitudes) within the measurement window. The average value and the standard deviation can be determined from the distribution, from these values, a hit-recognition threshold is determined and used to decide whether a pulse-height value is to be associated with a radar target to be detected. [A2818]

"Vehicle-mounted radar apparatus"

Data is acquired by transmitting radio waves or by receiving radio waves by means of a fixed beam provided in a vehicle-mounted radar apparatus, and an antenna unit is provided which has such an antenna gain that a straight line-of-sight distance with respect to each straight line-of-sight angle from a subject vehicle to a preceding vehicle traveling on a subject-vehicle lane is set as a maximum detection distance. Therefore, it is possible to detect a preceding vehicle traveling on a subject-vehicle lane from a subject vehicle, and not detect objects such as vehicles which are present in a longer distance than is necessary, thereby alleviating a burden on signal processing. [A2819]

"Locating system and method employing radio frequency tags"

A locating system and method employs a plurality of radio frequency readers arrayed with respect to a region having a plurality of zones within which a plurality of radio frequency tags are to be located. Each reader identifies those tags present within its coverage area. The coverage areas of all the readers taken together substantially cover the region and at least part of the coverage area of each reader overlaps at least part of the coverage area of at least one other reader. A data processor receives the identification of the tags within the coverage area of each reader and applies a set of locating rules to determine therefrom in which zone within the region each identified tag is located. [A2820]

"Apparatus and method for fleet control when unmanned and manned vehicles travel together"

An apparatus and a method for fleet control when manned and unmanned vehicles travel together, and prevents mutual interference when manned vehicles simultaneously travel with unmanned vehicles on the same traveling course. To this end, in the apparatus, the unmanned vehicle includes an unmanned vehicle position detecting device, an unmanned vehicle transmitter/receiver, and an unmanned vehicle controller. The manned vehicle includes a manned vehicle position detecting device, a manned vehicle transmitter/receiver, a manned vehicle controller) , and an alarm device. The manned vehicle controller compares unmanned vehicle position data and manned vehicle position data, and outputs an alarm signal for avoiding the unmanned vehicle when the unmanned vehicle travels ahead of the manned vehicle and the distance up to the unmanned vehicle is shorter than a predetermined value. [A2821]

"Vehicle mounted radar apparatus"

In a vehicle mounted radar apparatus such as a pulse Doppler radar, electromagnetic waves produced by an oscillator can be prevented from returning therefrom a reception system by means of a transmission system. The vehicle mounted radar apparatus includes the oscillator for generating electromagnetic waves, a transmitter for transmitting the electromagnetic waves generated by the oscillator to a target, a receiver for receiving electromagnetic waves reflected from the target, a switch for connecting the transmitter to an antenna during transmission of the electromagnetic waves, and for connecting the antenna to the receiver during reception of the electromagnetic waves, a signal processor for calculating a distance between the vehicle and the target, and also a relative speed between the vehicle and the target based upon the electromagnetic waves transmitted to the target and reflected from the target, and a power supply interrupter for interrupting the supply of voltage to the transmitter. Accordingly, during reception of the electromagnetic waves, the supply of voltage to the transmitter is turned off by the power supply interrupter, so that transfer of the electromagnetic waves from the transmitter to the receiver can be prevented. [A2822]

"Method and arrangement for avoiding and/or minimizing vehicle collisions in road traffic"

In the method and arrangement for avoiding and/or minimizing collision situations in road traffic described in the specification, a first plurality of sensors provides a representation of the surroundings of the motor vehicle, a second plurality of sensors senses the vehicle operating characteristics and a seat occupancy detector detects seat occupancy in the vehicle. The data relating to the surroundings and the vehicle operating characteristics are supplied to an evaluation unit which is connected to a plurality of vehicle control actuators which are actuated, if necessary, based on seat occupancy in the vehicle to avoid a collision or to produce in the minimum damage in a collision. [A2823]

"Hierarchical data matrix pattern recognition and identification system"

The present invention relates to a hierarchical artificial neural network (HANN) for automating the recognition and identification of patterns in data matrices. It has particular, although not exclusive, application to the identification of severe storm events (SSEs) from spatial precipitation patterns, derived from conventional volumetric radar imagery. To identify characteristic features a data matrix, the data matrix is processed with a self organizing network to produce a self organizing feature space mapping. The self organizing feature space mapping is processed to produce a density characterization of the feature space mapping. The self organizing network is preferably completely unsupervised. It may, under some circumstances include a supervised layer, but it must include at least an unsupervised component for the purposes of the invention. The "self organizing feature space" is intended to include any map with the self organizing characteristics of the Kohonen Self Organizing Feature Map. The frequency vector of a CAPPI image that has been derived is a data abstraction that can be displayed directly for examination. In preferred embodiments, it is presented to a classification network, e.g. the standard CPN network, for classifying the density vector representation of the three dimensional data and displaying a representation of classified features in the three dimensional data. A novel methodology is preferably used for incorporating vigilance and conscience mechanisms in the forward counterpropagation network during training. [A2824]

"Moving subject recognizing system for automotive vehicle"

A moving subject recognizing system for recognizing a subject, such as a pedestrian, moving toward a forward path of a vehicle to avoid a collision against the subject scans a field ahead the vehicle to detect a transverse velocity of a subject moving in a transverse direction and a longitudinal distance of the subject in a direction of the traveling path which are compared with a first and a second threshold value, respectively, and recognize that the subject is in danger of entering the traveling path and hit by the vehicle when the transverse velocity is greater than the first threshold value and the variation of the longitudinal distance is smaller than the second threshold value. [A2825]

"Antenna apparatus"

An antenna apparatus for use as in an automobile collision warning system has a primary radiator for radiating a high-frequency radio wave beam, a reflecting member for reflecting the radio wave beam, an actuating mechanism for actuating the reflecting member, and a lens such as a dielectric lens for converging the radio wave beam reflected by the reflecting member to reduce an angle of divergence of the radio wave beam. [A2826]

"Release device for passenger restraint systems in a motor vehicle"

The invention relates to a triggering control device for occupant restraint systems in a vehicle whose triggering readiness can be influenced as a function of collision-relevant parameters. According to the invention, collision parameter detection comprises object detection, which can detect a collision object before a collision occurs in an area near the vehicle, and can determine at least a relative speed. Whenever a collision object is detected, a signal generator delivers a collision parameter signal that depends on the relative speed determined. In a preferred embodiment the collision parameter detection unit also determines the intrinsic speed of the vehicle and whenever no collision object is detected, the signal generator supplies a collision parameter signal influenced by the intrinsic speed. [A2827]

"Method of protection against impacts between two vehicles by at least on inflatable member and device for implementing it"

A method of protection against impacts between two vehicles by means of an member, in which each of the vehicles includes an inflatable member adapted to be deployed under control of a signal commanding opening of the inflatable member, the method including the steps of detecting from a first vehicle an impending collision of the two vehicles, transmitting from the first vehicle a first signal commanding opening of the inflatable member associated with the first vehicle, receiving the first signal commanding opening of the inflatable member associated with the first vehicle, by the second vehicle, and transmitting to the second vehicle a second signal commanding opening of the inflatable member associated with the second vehicle. A device for implementing the above method is also disclosed. [A2828]

"Device for directional transmission and/or receiving of electromagnetic waves"

In a device for directional transmission and/or receiving of electromagnetic waves, including at least one antenna element and a dielectric lens, there is arranged between them a prefocusing dielectric body for avoiding overradiation of the lens. In order to simplify adjustment, the lens has an extended surface, is preferably pot-shaped, and forms, in conjunction with a baseplate, a hermetically sealed housing for unencapsulated ICs. [A2829]

"Vehicle collision radar with randomized FSK waveform"

An automotive radar incorporates a repetitive randomized equivalent LFM sequence of frequencies for improved immunity to jamming from other automotive radars. Each frequency in the sequence is of sufficient duration to travel round trip over the detection range of the radar. The Doppler shift in the received signal is estimated by performing a spectral analysis on similar frequency components of the received signal, and is then removed from the entire received signal. The received signal is then reordered so as to form an equivalent LFM received signal, and is compared with a similarly reordered image of the transmitted signal so as to estimate the range to the target. The randomization sequence, initial start frequency, or initial start time of the repetitive sequence are varied to minimize the effects of jamming by other radars, and this variation can be directionally dependent. [A2830]

"Method and apparatus for recognizing a vertical misalignment of a clearance sensor"

A method and an apparatus on the basis of which a vertical misadjustment or misalignment of a clearance sensor, which is installed in or on a motor vehicle, can be recognized. Pitch motions of the motor vehicle are determined, for example via sensors, in the form of pitch angles, and are correlated in an analysis and control device with data and/or signals which were generated or prepared by the clearance sensor, and which contain the target detections or target detection losses. [A2831]

"Angular shift determining apparatus for determining angular shift of central axis of radar used in automotive obstacle detection system"

An angular shift determining apparatus is provided which may be employed in an automotive obstacle detection system designed to determine a distance to and angular direction of a target tracked by a radar. The angular shift determining apparatus determines an angular shift of the central axis of radiation of radar waves from the longitudinal center line of a vehicle equipped with the obstacle detection system based on a relative position of the target and removes from the determined angular shift an error component produced when a preceding vehicle traveling with a lateral offset from the system vehicle is tracked as the target and an error component produced when a stationary object located on a curved road is tracked by the radar as the target to mathematically project an actual angular shift of the central axis of radiation of radar waves. [A2832]

"Method and device for the removal of ambiguity in distance, applied especially to frequency-shift keying continuous-wave radars"

Disclosed are a method and a device for the removal of ambiguity in distance. The method computes the distance of the targets detected by the radar using several estimation functions (21, 22, 23) . When the estimation functions give substantially the same result, the targets are defined as being in the field of non-ambiguous distances and when the estimation functions give different results, the targets are defined as being in the domain of ambiguous distances. Application especially to frequency-shift keying, continuous-wave radar for automobile traffic control. [A2833]

"Speedometer assisted patrol speed search for DSP traffic radar"

A digital signal processor (DSP) traffic radar utilizing pulses from the patrol vehicle's electronic speedometer to steer the DSP's search of Doppler return information for the patrol vehicle's radar return signal, to improve target identification and minimize inaccuracies. In moving mode, when the patrol vehicle comes to a stop, no pulses are received by the DSP and therefore the patrol speed is set to zero, eliminating false association with other moving targets. [A2834]

"Vehicle having a scanning system"

A vehicle having a scanning system for zero contact scanning of one or several mutually spaced road areas and having an analyzing system connected behind the scanning system. The analyzing unit is equipped for determining the roll-over angle, the roll-over moment, the vehicle load condition and/or the road condition via measured data detected and supplied by the scanning system. The resulting data is particularly suitable for the early determination of dangerous influences on the driving dynamics of a vehicle. [A2835]

"Obstacle recognition system for automotive vehicle"

An obstacle recognition system for automotive vehicles is provided which is designed to distinguish preceding vehicles from other objects and uses data thereof in intervehicle distance control, for example. The system includes a radar unit and a preceding vehicle determining circuit. The radar unit receives a signal produced by reflection of at least one of transmitted radar signals from an obstacle present in a given obstacle detectable zone to determine a distance to the obstacle and a horizontal and a vertical angle of the obstacle from a preselected reference direction. The preceding vehicle determining circuit includes a two-dimensional shape data producing circuit that produces two-dimensional shape data of the obstacle on a two-dimensional plane in a width-wise and a vertical direction of the system vehicle based on the distance and the horizontal and vertical angles determined by the radar unit and a non-vehicle determining circuit that determines the obstacle as an object other than the vehicle when the two-dimensional shape data of the obstacle lies out of an ordinary vehicle shape range. [A2836]

"Meteorological radar system"

A meteorological radar system that can continuously and detailed observe an object. The search radar section continuously searches for an atmospheric phenomenon as a target within a wide search range while the search radar control section rotatably scans the search radar antenna. The scanning range deciding section decides the scanning range of an observation radar section from the location of an atmospheric phenomenon detected by the atmospheric phenomena detecting section with the data obtained by the search radar section and thus sets the observation radar control section in the observation radar section to the scanning range. The observation radar antenna can continuously observe a narrow scanning area corresponding to an object with narrowed beams while the search radar section continues its searching operation, so that an object can be measured with high space and time resolution. [A2837]

"Method and apparatus for predicting a crash and reacting thereto"

A method and apparatus are described for predicting a crash and reacting thereto. Advantageously, the inventive apparatus is mounted on a vehicle and determines the time-to-impact for approaching obstacles that are within a limited distance from the host vehicle. The sensing distance from the vehicle is set by signal processing of reflected signals and rejection of all responses corresponding to a distance greater than the preset limiting value. The effect of the invention is the projection of a sensing envelope or barrier outwards from that portion of the vehicle provided with the invention. Intrusion into this envelope is sensed for appropriate action, so as to provide a warning of 10 to

40 milliseconds prior to a collision. The invention relies on time-of-flight measurement of preferably short infrared pulses to locate the obstacle. Multiple sensors are used to provide area coverage and to determine size and extent of the obstacle. for each sensor, an algorithm determines if the measured data indicates a collision. An additional algorithm is used to determine if the signals from all sensors collectively warrant a warning signal to vehicle safety systems. The system can be deployed in the front of the host vehicle for warning of frontal impact, and at the sides for warning of side impact. The system can also be used at the rear for backup obstacle warning. Advantageously, the systems for side, front and back are independent. [A2838]

"Method and system for determining position of a cellular mobile terminal"

A method and system are disclosed by which a round-trip calculation is used to determine the distance between a mobile radio station (MS) and a radio base station (BS) using the apparent uplink and downlink signal propagation air-times (e.g., T-up and T-down) . As such, no absolute time reference is required. The MS and BS report to a service node in the mobile network the local departure and arrival times of the uplink and downlink signals, and calculate the apparent air-times, T-up and T-down. The distance, D, between the MS and BS can be calculated as D=c (T-up+T-down) /2, where "c" equals the speed of light. The distances, D1, D2 and D3, to at least three base stations whose locations are known, can be used in a triangulation algorithm to determine the MS's position. [A2839]

"Broadband CDMA overlay system and method"

A spread-spectrum CDMA communications system for communicating data between a plurality of users to a plurality of spread-spectrum units. The spread-spectrum communications system is located within a same geographical region as occupied by an existing FDMA, proposed TDMA or any other mobile-cellular system. The spread-spectrum CDMA communications system includes a plurality of spread-spectrum-base stations and a plurality of spread-spectrum units. A spread-spectrum-base station has a comb filter for notch filtering predetermined channels of the mobile-cellular system, a device for converting the format of the data into a form for communicating over radio waves, a spread-spectrum modulator for spread-spectrum processing the data, and a transmitter for transmitting the spread-spectrum-processed converted data from the spread-spectrum-base station to a spread-spectrum unit. The spread-spectrum-base station also has an antenna, and spread-spectrum detectors for recovering data communicated from the spread-spectrum units. A spread-spectrum unit has an antenna, and a detector, including a spread-spectrum demodulator, coupled to the antenna for recovering data communicated from the spread-spectrum-base station, and the spread-spectrum unit has a spread-spectrum modulator, a transmitter, and a device for converting the format of the data for communicating over radio waves. [A2840]

"Different models for RF signal train generators and interferoceivers"

Interferoceivers are apparatus which use optical fiber loop based radio frequency (RF) signal train generators to store transient pulses and regenerate their identical replicas for analysis. The present invention further advances the art of RF signal train generators and interferoceivers in investigating acoustical, electromagnetic, and optical transient phenomena. The disclosure includes mechanisms for tuning the interferoceivers, and means for forming synthetic images with chaotic pulses or pulses of opportunity. [A2841]

"Active vehicle deceleration in an adaptive cruise control system"

A vehicle adaptive cruise control system having active deceleration control provides for appropriate decelerations consistent with the objectives of preventing the vehicle from violating a desired minimum distance from a preceding vehicle and efficient utilization of road space through minimization of inter-vehicle spacing. [A2842]

"Antenna-shared distributor and transmission and receiving apparatus using same"

An antenna-shared distributor is provided such that a non-conductor section is provided in a part of two conductor planes, a dielectric resonator which resonates in the HE111 mode is disposed between the conductor planes, and first and second dielectric strips whose respective end portions face the dielectric resonator are disposed, forming first and second dielectric lines and further, a voltage-controlled oscillator and a mixer are connected to the first and second dielectric lines, respectively. [A2843]

"Doppler-based traffic radar system"

A Doppler-based radar system used to determine the speed of a selected moving target includes an array of selectable filters and related method for determining the speed of the selected moving target traveling in the same lane as a moving patrol vehicle supporting the radar system independent of the direction of the target relative to the platform. This allows the speed of the target vehicles traveling in the same lane and in the same direction as the patrol vehicle to be monitored without manual assistance from the operator. The radar system is further adapted in a stationary mode of operation to determine the speed of a selected moving target independent of the location of the patrol vehicle. This is accomplished by selectively filtering either all approaching or receding targets depending upon the traffic scenario. [A2844]

"Radar apparatus installed on vehicle for managing reflector information"

A radar apparatus installed on a vehicle includes a transmission section, a reception section and a processing section. The transmission section includes at least a transmission antenna, and emits a transmission wave toward a detection area in front of the vehicle. The transmission wave is reflected by a reflector to produce a reflection wave, and the detection area includes a plurality of sub-areas. The reception section includes at least a reception antenna, and receives and detects the reflection wave. The processing section detects a reflector indication data indicative of a reflector attribute based on the detecting result by the reception section, and then determines whether there is the reflector in the detection area, based on the reflector indication data. Also, the processing section manages the reflector indication data over a management area which is wider than the detection area. [A2845]

"Method and apparatus for directing a pursuing vehicle to a target with intelligent evasion capabilities"

A method and apparatus for directing a pursuing vehicle, such as a torpedo, on an intercept trajectory from a launching vehicle to a target vehicle th evasion capabilities. Models of the pursuing vehicle and evading target provide proposed trajectories based upon various environmental considerations. A guidance system uses estimates of initial operating parameter solutions, such as gyro angle, alertment time and intercept time, to begin a convergent, iterative process that defines final operating parameter solutions from which the guidance parameters are determined and transferred to the pursuing vehicle at launch. During each iteration, the solution determines an alertment time and an alertment bearing from the target vehicle to the pursuing vehicle at the alertment time. A selected evasive strategy includes a turn that is calculated relative to the alertment bearing. [A2846]

"Apparatus and method for imaging with wavefields using inverse scattering techniques"

An apparatus and method for rapid real time imaging with wavefield energy using a C.P.U. programmed to process data derived from wavefield energy that has been transmitted and scattered by an object so as to reconstruct a wavefield image of the object. Electronic signals are propagated and are transduced into wavefield energy waves which in turn are propagated toward the object. Detectors detect the wavefield energy waves scattered by the object. The detected wavefield energy waves are then electronically processed and input into a high-speed digital computer which may comprise a C.P.U. and/or a C.P.U. in combination with an array or parallel processor. Data is also prepared and input to the computer representing the incident field and the computer then reconstructs a high-quality image of the object having high spacial resolution and including actual properties of the object. The media in which the object is embedded may be fluid or solid, homogeneous, or layered (such as stratigraphic layering, or ocean velocity layers, or layering of composites in nondestructive imaging applications) , or may consist of porous material (either sedimentary deposits or composites in nondestructive testing) . [A2847]

"Highway vehicle guidance system"

A radar highway motor vehicle guidance apparatus for guiding a land vehicle along a roadway using a backward looking and a forward looking, lateral position sensing, monopulse tracking radar guidance apparatus which transmits radar pulses backward and forward of the vehicle. The pulses are reflected back to the vehicle by a stripe distributed along the roadway. The stripe is a frequency selective surface which generates retro-reflective grating lobes at an operating frequency of the tracking radar. Operating the radar at two frequencies allows the radar to look at regions spaced at two different distances from the front of the vehicle. Highway related information may be encoded in the frequency selective surface by variations in the shape or dimensions of the frequency selective stripe morphology in order to modulate the reflected signal with highway information which is then also detected at the radar receiver. Target discrimination is enhanced by using pseudo random codes and matching antenna polarization with stripe polarization. [A2848]

"Method and apparatus for sensing piston position"

A system for determining the position of a piston moveable within a cylinder, or of an implement or joint, is disclosed herein. Electromagnetic (EM) bursts such as ultra-wideband or frequency pulses are generated and applied to a transmitter/receiver unit. The EM bursts are launched by the transmitter via a focusing antenna assembly from an end of the cylinder housing towards the piston. The fluid in the cylinder housing is in electrical communication with the piston such that a surface of the piston represents an electrical impedance discontinuity which causes the EM bursts to be reflected back to the receiver. The time for the EM bursts to travel from the transmitter to the piston and for the reflections to travel back to the receiver via the antenna assembly is determined and converted into a position signal representing the piston's position. A compensation signal can be used to compensate the position signal for variations in a parameter of the fluid within the cylinder. The parameter may be the dielectric constant, and the variations may be caused by factors such as temperature, contamination and fluid type. The compensation circuit can include a pulse level analyzer, resonance circuit, mini-dipstick, or a capacitance circuit. [A2849]

"Angle extent estimation method for a motor vehicle object detection system"

A method of operation for a motor vehicle object detection system is described, in which the extent angle of an identified target is accurately determined by applying a point source scatterer identification technique to data at the periphery of a composite return. Return amplitude data from one or more complete scans of the sensor beam are collected and compared with a target threshold to identify objects in the viewing angle, thereby forming an array of amplitude data associated with successive beam positions for each identified object. In each array, the left-most and right-most pair of amplitude data points associated with successive beam positions are selected and individually used to compute the angle of a point source scatterer which would be responsible for that data pair. The computed scatterer angles are taken as the left and right edges of the target and used to determine the angle extent of the identified object, which in turn, enables reliable determination as to whether the identified object is in or out of the vehicle travel path, and what, if any, vehicle response is appropriate to maintain a given headway or avoid a collision with the object. [A2850]

"Spread spectrum localizers"

A network of localizers determines relative locations in three-dimensional space to within 1 cm by cooperatively measuring propagation times of pseudorandom sequences of electromagnetic impulses. Ranging transmissions may include encoded digital information to increase accuracy. The propagation time is determined from a correlator circuit which provides an analog pseudo-autocorrelation function sampled at discrete time bins. The correlator has a number of integrators, each integrator providing a signal proportional to the time integral of the product of the expected pulse sequence delayed by one of the discrete time bins, and the non-delayed received antenna signal. With the impulses organized as doublets the sampled correlator output can vary considerably in shape depending on where the autocorrelation function peak falls in relation to the nearest bin. Using pattern recognition the time of arrival of the received signal can be determined to within a time much smaller than the separation between bins. Because operation of standard CMOS circuitry generates noise over a large frequency range, only low-noise circuitry operates during transmission and reception. To provide the time accuracy necessary for distancing, a high-frequency clock operates during inter-localizer communications. The high-frequency clock uses a phase-lock loop circuit to increase the clock rate and a programmable delay to provide still finer time graduations. A stage in the low-frequency clock uses low-noise circuitry during transmissions and receptions, and standard circuitry at other times. [A2851]

"System for and method of determining the location of an object in a medium"

The depth of a metal object (for example) beneath the ground (for example) is measured by measuring propagation times of electromagnetic radiation travelling in two different paths within the ground, each from a transmission location via reflection from the object to a receiver location. There should be either multiple transmitter locations, multiple receiver locations or both and the spacing in the ground plane between the transmitter and receiver locations is known. By mathematically manipulating the propagation times for reflected signals travelling in different paths, dependence on the permittivity of the ground itself can be eliminated from the calculation of depth. [A2852]

"Antenna cluster for a motor road vehicle collision warning system"

A motor vehicle collision warning system 1 comprises an obstacle sensing system 3 including a plurality of sensors 5 together capable of sensing obstacles around the vehicle 7 and generating obstacle of concern signals when obstacles are sensed, and a warning control system 9 for receiving the obstacle of concern signals and for determining whether a collision warning signal should be generated. The sensing system includes at least one antenna cluster 11 mounted in the region of a corner 13 of the vehicle 7, the antenna cluster 11 comprising a radar transmit antenna 15 and two receive antennas 17 and 19. The transmit antenna 15 is mounted between the receive antennas 17 and 19. Receive antenna 17 faces towards the front of the vehicle and receive antenna 19 faces towards the rear of the vehicle. A trigger means 21 triggers the operation of the transmit antenna 15 and one or both of the receive antennas 17 and 19. [A2853]

"Alarm sensor and antenna arrangement"

A microwave frequency Doppler vehicle intruder alarm comprises an oscillator 3, a mixer 2 and an amplification stage 4, 5 having its output applied to a low-pass filter 7, whose output is split into two branches. A first branch, comprising a rectifier diode and a comparator, provides a signal on its output when a significant level of non-carrier microwave signals is received. This branch is sensitive to signals having Doppler frequencies of 0-200 Hz, which includes the intruder indicative frequencies. A second branch, comprising an amplifier 8, a high pass filter 9, and a comparator 10, provides an output signal on the detection of a significant level of signals in the 40-200 Hz band, which frequencies are indicative of externally generated interference. A logic element 15 mutes the output of the alarm when the second branch indicates the presence of externally generated interference. An antenna arrangement (FIG. 3, not shown) generates a rectangular radiation field which provides optimum coverage of the interior of a vehicle by being mounted in the roof thereof. Steering of the radiation field to provide optimum illumination when the arrangement is mounted off-center on the roof is achieved by the use of a shunt capacitor to effect a phase difference in signals applied to respective ones of first and second antennae. [A2854]

"Advanced signal process for a material storage measuring device"

An advanced signal processing technique accurately discriminates and estimates a small sinusoidal signal in close proximity from one or more large sinusoidal signals. The technique involves using digital processing techniques to accurately estimate the frequency (96) , amplitude (94) and phase (98) of the one or more large sinusoids and then using this estimate to obtain an accurate estimate of the small sinusoidal signal by subtracting the large sinusoid from the data to obtain a residual and reprocessing the residual. [A2855]

"Method and apparatus for precise noncoherent doppler tracking of a spacecraft"

A method and apparatus are disclosed for making precise velocity measurements of a spacecraft using a two-way noncoherent Doppler tracking system. The received uplink and transmitted downlink frequencies on-board the spacecraft are compared with the resulting information being included in the downlink signal and used to cancel spacecraft oscillator drift rate effects in the two-way Doppler measurement made by the ground station. The information can also be used to characterize the drift rate of the spacecraft oscillator, thus permitting periods of accurate one-way Doppler tracking by the ground station. To improve accuracy, the times at which the measurements comprising the information would have been observed on the ground are inferred from the measurement of a signal generated by the spacecraft, e.g., the telemetry frame start times, made by the ground station. [A2856]

"Wake filter for false alarm suppression and tracking"

A processing technique suitable for use with a search radar system which minimizes the false detection of targets. Rather than rely on a predetermined target trajectory, such as a straight line trajectory in range time space, the processing technique in accordance with the present invention is not based on a target dynamics model. The system in accordance with the present invention relies on past detections and assigns a confidence level to detections which are in the wake of a previous detection. A wake function is used to determine the amount by which each detection recursively accrues confidence based on a limited record of past detections. A detection is declared when the confidence level exceeds a predetermined threshold. As detections are encountered in range time space, such detections are used to form wakes based on the wake function which are used to assign confidence levels for future detections. [A2857]

"Radar angle determination with music direction finding"

An apparatus and method for target-angle determination using lower-frequency radars having compact non-moving antennas over broad viewing sectors. Use of direction finding (DF) in place of beam forming and scanning eliminates the need for conventional, physically large phased-array antenna systems. The described DF algorithm advances the art over previously described least-squares DF by allowing numerically efficient and robust resolution of multiple targets at closely spaced angles. When used with coastal HF ocean surface current and wave monitoring radars where sea echo is the target, the method extracts complex current patterns. The high degree of singularity of the antenna signal covariance matrix is exploited and used as the basis for extracting angles with minimal averaging. More receive antenna elements can be added at convenient locations to handle more complex target angle scenarios. [A2858]

"Method and apparatus for detection of a moving speed of a mobile terminal in mobile communication"

In accordance with the present invention, there is provided a method and apparatus for detecting a moving speed of a mobile terminal in a mobile communication utilizing time division multiple access system, wherein a measurement is made for a variation in delay of a burst radiowave received from the mobile terminal with reference to a transmission burst signal before a calculation of a moving speed of the mobile terminal is made on the basis of the measured variation in the delay. [A2859]

"Process for measuring the distance between a motor vehicle and an object"

In the case of a process for measuring the distance between a motor vehicle and an object, in the vehicle, in the case of a short distance of the object, the output signals of a first measuring device with a corresponding measuring range and, in the case of a longer distance of the object, the output signals of a second measuring device with a correspondingly longer measuring range are taken into account in a dominating manner. The measuring devices are constructed as analysis devices. The output signal of a single receiver for a single distance generator is supplied to the analysis devices as an input signal. The analysis devices analyze this input signal via an analysis process which is characteristic of the shorter or the longer distance range. [A2860]

"Object detecting system for vehicle"

In an object detecting system for a vehicle to detect an object in accordance with the result of a search operation of the radar, and to allow detection of a deviation of the radar search direction irrespective of the vehicle traveling condition. The stationary object decision unit detects whether or not an object recognized by the object recognition unit as a result of the search operation of the radar is a stationary object. The moving locus of the object, which was determined to be stationary, relative to the vehicle is predicted by the locus prediction unit based on the detected value produced by the motion state detection unit. The actual moving locus of the object, determined as a stationary object, as observed from the vehicle is calculated by the actual locus calculation unit. The predicted value produced by the locus prediction unit and the calculated value produced by the actual locus calculation unit are compared by the comparison device. Based on the result of this comparison, the improper state decision unit decides whether the radar is in an improper state or not. [A2861]

"GPS vehicle collision avoidance warning and control system and method"

GPS satellite (4) ranging signals (6) received (32) on comm1, and DGPS auxiliary range correction signals and pseudolite carrier phase ambiguity resolution signals (8) from a fixed known earth base station (10) received (34) on comm2, at one of a plurality of vehicles/aircraft/automobiles (2) are computer processed (36) to continuously determine the one's kinematic tracking position on a pathway (14) with centimeter accuracy. That GPS-based position is communicated with selected other status information to each other one of the plurality of vehicles (2) , to the one station (10) , and/or to one of a plurality of control centers (16) , and the one vehicle receives therefrom each of the others' status information and kinematic tracking position. Objects (22) are detected from all directions (300) by multiple supplemental mechanisms, e.g., video (54) , radar/lidar (56) , laser and optical scanners. Data and information are computer processed and analyzed (50,52,200,452) in neural networks (132, FIGS. 6-8) in the one vehicle to identify, rank, and evaluate collision hazards/objects, an expert operating response to which is determined in a fuzzy logic associative memory (484) which generates control signals which actuate a plurality of control systems of the one vehicle in a coordinated manner to maneuver it laterally and longitudinally to avoid each collision hazard, or, for motor vehicles, when a collision is unavoidable, to minimize injury or damage therefrom. The operator is warned by a heads up display and other modes and may override. An automotive auto-pilot mode is provided. [A2862]

"Road monitoring device"

A device for improving vehicle driving safety and comfort is disclosed. The main road sign information encountered during a journey is transmitted to the vehicle, the position of the vehicle on the driving surface is continuously monitored, and the road surface is checked for the presence of foreign matter such as mud, snow, ice, etc. A set of transmitting-receiving sensors (C1, C2) suitably arranged on the vehicle and facing the driving surface continuously observes changes in the reflective properties of the observed areas within the sensitivity range thereof. Markings defining lanes and shoulders lined with grassy, gravelly or sandy areas are sensed by the sensors (C1, C2) as soon as the vehicle approaches or drives over them. The signals from the sensors (C1, C2) are processed by an electronic unit (1) controlling an on-board signalling system (2) linked to an alarm system (3) for warning the driver of road hazards and possible unsafe driving (straying off-course, speeding, etc.) . By reacting instantly, the driver thus informed can avoid a potential accident. [A2863]

"Method and apparatus for hazard detection and distraction avoidance for a vehicle"

A system for detecting hazardous conditions during operation of a vehicle. In one embodiment, the system includes a plurality of sensors that monitor a plurality of conditions and transmit condition signals each representing a measure of a condition. A plurality of rate determination circuits is coupled to the sensors and continually receives the condition signals, wherein each rate determination circuit calculates rates of change for the condition, including a baseline rate of change, and outputs a potential hazard value representing a deviation of a rate of change from the baseline rate that exceeds a predetermined threshold value. An evaluation circuit receives the potential hazard value, calculates a new potential hazard value using the potential hazard value and a rate of change for at least one associated condition and determines whether an actual hazard exists by comparing the new potential hazard value with a stored value that corresponds to the condition. [A2864]

"Vehicle obstruction detection system"

A vehicle obstruction avoidance system particularly for reversing a vehicle towards obstructions not visible in the wing mirrors. A radar head is mounted on the rear bumper, the head including a scanner and sensor. The total range of interest is only a few meters and provides very little time for processing echoes from all range cells in the range. The invention provides a system in which only one range cell is processed with each pulse transmission and the range cell is stepped on for the next pulse. [A2865]

"Method and apparatus for calibrating azimuth boresight in a radar system"

A method and apparatus for calibrating azimuth boresight in a radar system. Antenna boresight misalignment can cause radar systems to inaccurately determine the position of targets relative to a platform vehicle. These errors can be corrected by detecting and accurately measuring a boresight offset angle defined as the angle between the radar antenna boresight and the direction of travel of the host platform vehicle. Several antenna boresight calibration techniques are described. A first technique calculates the boresight offset angle by obtaining target range and azimuth angle measurements at two instants in time. The boresight offset angle is determined by the geometric relationship of the offset angle, target range and azimuth values obtained at two successive time instants. A refined approach obtains target range and azimuth values at several successive time instants, calculating interim boresight offset angles at each time instant. The boresight offset angle is computed by averaging the interim boresight offset angles. In second and third calibration techniques, the boresight offset angle is estimated from the azimuth of qualified calibration targets that are substantially aligned with the host vehicle's heading. Several restrictions are imposed upon the potential calibration targets to suppress the erroneous qualification of adjacent vehicle traffic. In accordance with one embodiment of the present invention, the calibration techniques are implemented by software instructions executed by a microprocessor within the radar system. Once the boresight offset angle is detected and calculated, it can be used to calibrate the antenna boresight using either a mathematical or physical calibration approach. [A2866]

"Scanning mechanism for vehicle- mounted radar"

A scanning mechanism for vehicle-mounted radar comprises a first noncircular gear attached to an input shaft, a second noncircular gear meshed with the first noncircular gear, and a connecting link having one end connected to an eccentric pin provided on the second noncircular gear and another end connected to an antenna transmission/reception section, thereby allowing the antenna transmission/reception section to effect swinging motion. Angular accuracy in a frontal direction is improved by delaying the scanning velocity in the frontal direction. [A2867]

"Apparatus for detecting moving ball"

A system is provided with a directional antenna having first and second antenna patterns oriented around an antenna boresight direction. The antenna boresight is oriented in a direction corresponding to a play determinative line on a playing field. Signals are emitted firm a playing object, used as a ball and detect using the two antenna patterns. Comparison of the detected signals provides an output indication when the playing object crosses the play determinative line. [A2868]

"Method and equipment for weather image prediction"

An equipment for weather image prediction comprising: a field extracting portion, which calculates the velocity fields of the local echoes with respect to time and space from a plurality of time sequential frames of weather radar images for a plurality of frames therein, and which segments and extracts a field possessing similar velocities with respect to time and space as one precipitation field from said plurality of frames of weather radar images by employing said calculated velocity fields, a moving velocity estimating portion, which estimates the moving velocity of a precipitation field by obtaining the amount of movement, among the neighboring frames, of the precipitation field segmented and extracted by said field extracting portion, and a forecast image generating portion, which extrapolates a plurality of precipitation fields by employing a distance taken by multiplying the moving velocity of the precipitation field estimated by said moving velocity estimating portion by a desired forecasting time, and which generates a forecast radar image by synthesizing the resulting image. [A2869]

"CDMA communications and geolocation system and method"

A spread-spectrum CDMA communications system for locating remote units, and for communicating message data between a plurality of remote units and a base station. The spread-spectrum CDMA communications system includes a plurality of base stations and a plurality of remote units. A base station has a spread-spectrum modulator for spread-spectrum processing the message data, and a transmitter for transmitting the spread-spectrum processed-message data, combined with a generic-chip-code signal, from the base station to a remote unit. The base station also has an antenna, and spread-spectrum detectors for recovering message-data communicated from the remote units. A remote unit has an antenna, and a detector coupled to the antenna for recovering data communicated from the base station. The detector includes a spread spectrum demodulator. Also, the remote unit has a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator and a transmitter. The base station has a range circuit, which comparers the generic-chip-code signal generated at the base station with the generic-chip-code signal received from the remote unit, for determining a range between the remote unit and the base station. [A2870]

"Partial probe mapping"

A method for processing a time domain reflectometry (TDR) signal having a plurality of reflection pulses to generate a valid output result corresponding to a process variable for a material in a vessel. The method includes the steps of determining a background signal for a probe and detecting a sample TDR signal for the probe in the vessel. At least one transition point is established on the sample TDR signal and the background signal. A portion of the sample TDR signal on one side of the at least one transition point is combined with a portion of the background signal on the other side of the at least one transition point to establish an initial boundary signal, and the initial boundary signal is stored. The method also includes the steps of detecting the TDR signal and calculating the output result using the initial boundary signal. [A2871]

"Enhanced microburst detection system"

A weather radar system (21) utilizing enhanced fuzzy logic processing (300) to detect atmospheric microburst events. In addition to the wind shear likelihood (250) , low level surface reflectivity likelihood (252) , and clutter likelihood (254) used by existing fuzzy logic based microburst detection systems to generate a combined microburst likelihood, one enhancement includes using reflectivity measurements of high level storm activity to generate an independent high level aloft reflectivity likelihood image (310) that corresponds to and confirms the findings of the low level surface reflectivity likelihood (252) . Another enhancement includes using a series of combined likelihoods saved over time (635) for N successive scans of the weather radar system (21) to generate a history likelihood (620) that eliminates spurious detections from one scan to the next. Another enhancement includes generating a microburst strength determination (330) based on the wind speed loss an aircraft would experience when flying through a microburst. [A2872]

"Intelligent walking stick"

A portable safety mechanism housed in a cane, a walking stick or a belt-carried housing. In each of such embodiments, the portable safety mechanism includes a processor, a transmitter, a receiver, and an outside image sensor or scanner, a warning device such as an audible warning device or warning light. The scanner may, for example, sense the shape of a traffic signal or the color of a traffic signal. [A2873]

"Personal messaging system and method"

A pager device received paging messages. The user reads a paging message, selects one of a set of stored, predetermine reply messages, and transmits the selected reply message from the pager. The reply signal is received by one of a set of local cellular receivers, which sends the received signal to a computer for interpretation. The computer initiates an action based on interpretation of the received reply signal. The communication system communicates with large numbers of pagers in a time and energy efficient manner. The pagers are associated with items located in a communication region that is interrogated by an interrogator on a one-to-many basis using broadcast commands, on a one-to-one basis using directed commands or on a combination basis using both methods. Messaging occurs through organized transmission and reception of signals between the pagers and the interrogator. A batch collection protocol uses a combined one-to-many and one-to-one communication system that effectively resolves communication contentions. The batch collection protocol employs a plurality of collection periods which communicate with large or unknown numbers of portable pagers. [A2874]

"Method and apparatus for control of vessel maneuvering"

An improved method and apparatus provide a control of the vessel maneuvering by a determination and displaying of the dangerous relative course zones, wherein the end of the vessel speed-vector should not be located for the object evasion tactic maneuvering and/or collision avoidance maneuvering and should be located for the object pursuit and/or interception tactic maneuvering. The apparatus comprises an object disposition evaluator, a control system, a dangerous criteria setting system, an initial data processor, at least one display and a dangerous relative course zone determiner, including an interface-signal distributor, a logic processor and signal distributor and a data processing system, comprising a trigonometric function processor, a summator, a multiplier-divider and a data processor. The dangerous relative course zones are displayed on at least one indicator, proving the operator with the possibility to evaluate the danger approach situation and instantly select the anti-collision maneuver for collision preventive maneuvering and/or select an optimal maneuver for the assigned vessel tactic maneuvering execution. [A2875]

"Phase difference measuring apparatus and method"

A phase difference measuring apparatus obtains a first receive signal by transmitting and receiving a to-be-measured material in a reference state and a second receive signal by transmitting and receiving a signal wave to and from that material in a measured state. The apparatus finds a reference phase difference .theta..sub.1 from the transmit wave and first receive signal and an apparent phase difference .theta..sub.2 ' from the transmit wave and second receive signal. The apparatus adds the apparent phase difference .theta..sub.2 ' to a product of the number of rotations, n, the apparent phase difference .theta..sub.2 ' passes through a given reference point and an angle of 360.degree. to find a true phase difference .theta..sub.2. The apparatus varies the number of rotations, n, to n+1 when the apparent phase difference .theta..sub.2 ', while being increased, passes through the reference point and that number of rotations, n, to n=n-1 when the apparent phase difference .theta..sub.2 ', while being decreased, passes through the reference point. [A2876]

"Three dimensional beamformed television"

The system provides three-dimensional real time imaging, with features that serve to control acoustic effects that cause interference. Systems are disclosed for medical imaging and other applications in fields that utilize radiated wave signals. The system includes visualization methods to enable guidance of surgical instruments as well as general medical diagnostic usage. The present invention uses a beamformed television method which achieves visual format imaging. Beamformed television includes orthogonal arrays to efficiently resolve two dimensions of a scene with measures to control grating lobes. Beamformed television also includes a method that reduces the time to transmit and receive signals by use of a single burst transmission of multiple frequency codes from each transducer which causes multiple, coded transmit beams that are radiated simultaneously. The addition of step chirp operations achieves highly precise range resolution which makes visual format imaging possible at selected ranges. It also enables a variety of visualization capabilities. The step chirp operation involves repeating the burst transmission at sequentially stepped frequencies. Thus, the frequency codes, that enable the transmit beamforming process, are shifted as a group for each frequency step of the stepped chirp. Frequency domain to time domain conversion using an FFT method efficiently yields range resolved signals. [A2877]

"Radar system, in particular motor vehicle radar system"

In a radar system, which is used particularly in motor vehicles, the angle at which a detected radar target is located are determined by providing that echo signals of the radar target are picked up via at least two reception channels, and their amplitudes are standardized and compared with standardized values, stored in memory, of a duplex antenna graph of the radar system. [A2878]

"Automatic sensor azimuth alignment"

This disclosure relates to a system for automatically measuring and compensating for any angle of misalignment of a forward-looking sensor of a vehicle. The sensor provides data representing the azimuth angle and the range of a target such as another vehicle. for each angle and range reading of the sensor, the location point of the target is estimated, after a series of such readings, the trajectory line of the target is estimated. The angle of misalignment is estimated from the angle between the trajectory line and the path of travel of the host vehicle. In subsequent readings of the sensor, the estimated angle of misalignment is subtracted from the measured azimuth angle to produce an accurate azimuth angle of the target. The accurate azimuth angle is provided for use by another unit such as a collision warning system and/or an intelligent cruise control. [A2879]

"Control equipment for difficult to see or blind spot areas around vehicles, and related method"

A control device for vehicles includes a sensor mounted to the vehicle for detecting an object in a monitored zone adjacent the vehicle and providing a responsive output signal when an object is detected in the monitored zone, a signaling device mounted to the vehicle for providing a speed output signal indicative of a speed of travel of the vehicle, a control unit mounted to the vehicle for receiving sensor output signals and speed output signals, and a warning device mounted to the vehicle for providing a warning signal to a driver of the vehicle, the control unit controlling the warning device to provide the warning signal responsive to the sensor output signal and the speed output signal so that the warning device provides a warning signal only when the sensor detects an object in the monitored zone and the signaling device provides a speed output signal indicating that the speed of the vehicle is below a predetermined value. A related vehicle and method are also disclosed. [A2880]

"Method and system for tracking multiple regional objects by multi-dimensional relaxation"

A method and system for real-time tracking of objects is disclosed. A region is repeatedly scanned providing a plurality of images or data sets having points corresponding to ojbects in the region to be tracked. Given a previously determined track for each object in the region, an M-dimensional combinatorial optimization assignment problem is formulated using the points from M-1 of the images or data sets, wherein each point is preferably used in extending at most one track. The M-dimensional problem is subsequently solved for an optimal or near-optimal assignment of the points to the tracks, extending the tracking of the objects so that a response to each object can be initiated by the system in real-time. Speed and accuracy is provided by an iterative Lagrangian Relaxation technique wherein a plurality of constraint dimensions are relaxed simultaneously to yield a reduced dimensional optimization problem whose solution is used to formulate an assignment problem of dimensionality less than M. The iterative reducing of dimensions terminates when exact solutions are determined for two-dimensional cases. A recovery procedure is used for determining a higher dimensional assignment problem solution from a problem having one less dimension. The procedure is useful when the reduced dimensional optimizational problem has two constraint dimensions. [A2881]

"Method and apparatus for in path target determination for an automotive vehicle using a gyroscopic device"

The present invention concerns a method, an apparatus and an article of manufacture that satisfies the need for determining whether or not an obstacle vehicle is in the path of a host vehicle. Specifically, the present invention satisfies the above stated regardless of whether or not the host vehicle is moving in a straight path or along a curved path. Preferably, input data ("input") is collected from instruments mounted to a host vehicle. The input is used to calculate for the host vehicle the average turn rate, the radius of curvature of the path being traveled, the velocity, and a range from the host vehicle to a obstacle vehicle. Additionally, the input is used to determine the deviation of an obstacle from a 0.degree. reference azimuth extending through the center of a radar beamating from a radar unit mounted to the host vehicle. An obstacle azimuth angle .varies..sub.i is calculated and used to determine whether or not the obstacle is in the path of the host vehicle. After a determination is made as to whether or not the obstacle is in the path of the host vehicle, the results of that determination are sent to and displayed by sensors and displays which designate the results. [A2882]

"Measuring distance"

An object in a storage area or moving vehicle is monitored by attaching an electronic tag to the object. An electronic device detects the presence of the object by communicating with the tag while the object is in storage or is being moved by the vehicle. The tags may also determine the location of an attached object and may reroute the object if it deviates from a given shipping schedule. A group of objects is monitored by two electronic tags, each attached to an object in the group. Each tag has circuitry for communicating information relating to an object in the group to a second tag. Each tag also includes a memory connected to the circuitry that is capable of storing the information, and a controller connected to the memory and the circuitry. A distance is measured by transmitting multiple symbols from one object to another object, having the symbols returned such that the symbols' measured round-trip times are not all identical, and calculating the distance using the measured round-trip times. [A2883]

"Method and apparatus for tracking of organized storms"

A method and apparatus for tracking of organized storms using weather radar images. An image filter approximating the envelope of the organized storm radar image is used to improve tracking of the large scale storm features. The image filter is repeatedly rotated to different orientations at each point in the weather radar images to produce filtered images. The filtered images are provided to an image tracker to generate an array of track vectors. Application of the array of track vectors to the unfiltered image generates a predicted weather radar image. [A2884]

"Scan-type radar apparatus for a vehicle to accurately detect an object in a lane of the radar equipped vehicle"

A scan-type radar apparatus for a vehicle which determines whether an object detected by the radar exists in the lane in which the radar equipped vehicle is moving with a high accuracy while restricting an increase of the manufacturing cost of the radar apparatus. A scan-type radar detects objects existing in a detectable range, the scan-type radar apparatus assuming a vehicle moving lane area corresponding to a vehicle moving lane in which the vehicle is moving based on an operating condition of the vehicle, the vehicle moving lane area being assumed within the detectable range. An actual direction of each of the objects is detected by the scan-type radar with respect to the radar equipped vehicle. A delay direction is calculated when the actual direction detected by an object direction detecting arrangement is changed with respect to time, the delay direction indicating a direction of a virtual position of each object with respect to the vehicle by being provided with a predetermined time delay with respect to a change in the actual direction. It is determined whether each object exists within the vehicle moving lane based on the delay direction. [A2885]

"Semiconductor module having antenna element therein"

A semiconductor module having a compact antenna element capable of providing desired directivity therein has been disclosed. When an electromagnetic-wave radiation window has the capability of a lens, directivity can be set arbitrarily. for improving directivity, a convergent lens for converging millimeter waves or quasi millimeter waves is employed. for impairing directivity, a divergent lens is employed. In the case of the convergent lens, a direction in which radio waves are radiated or received by the antenna element can be set by deviating the center axis of the lens from the center of the antenna element. [A2886]

"Ground penetrating radar with synthesized end-fire array"

In a ground penetrating radar system, A-scan images of subsurface targets lying along the antenna boresight axis can be substantially improved and generated in real-time by employing a synthetic aperture, end-fire array, despite the inhomogeneous nature of the subsurface volume. The synthetic aperture, end-fire array is achieved by generating electro-magnetic (EM) ultra-wideband impulses at a number of precise locations along the antenna boresight access, shifting the returned EM signals in the time domain according to the corresponding antenna boresight location, and then integrating the shifted, returned EM signals. In addition, an incremental, reverse-coherent integration technique is provided. This incremental technique allows for a more rapid generation of the A-scan image. The reverse-coherent integration technique eliminates unintended, stationary targets from the A-scan image, which are caused by coherent noise/clutter sources. [A2887]

"Multiple-beam radar system"

A multiple-beam radar system, in particular for motor vehicle applications. More transmission elements than reception elements are present. The transmission elements present can be activated both individually and also in any desired simultaneous combination. An observable angular region can thereby be widened, in economical fashion, as compared with known radar systems. [A2888]

"Method and system for producing images of an object"

A method and system are provided to produce images of an object. A receiving station is positioned in view of a range-coded signal emitting satellite and the object. The receiving station is sensitive to direct transmission of the range-coded signal and reflections of the range-coded signal from the object. Both range from the receiving station to the object and a Doppler frequency shift history between the receiving station and the object is determined using the direct transmission and reflections of the range-coded signal. An image is formed using the two-dimensional record provided by the range and the Doppler frequency shift history. [A2889]

"Mobile station position determination in a wireless communication system"

Methods and apparatus for determining mobile station position in a wireless communication system are disclosed. A mobile station of the wireless system includes a silent echo generation circuit which receives a transmit time stamp transmitted in a sync channel from a base station, and processes the transmit time stamp to generate a receive time stamp. The silent echo generation circuit transmits the receive time stamp back to the base station on a spurious-like echo carrier which is offset from a data carrier of the wireless system. The base station processes the transmit and receive time stamps to compute a first ranging value, receives corresponding second and third ranging values computed by two other system base stations which receive the echo carrier and its time stamp, and processes the first, second and third ranging values to determine a position vector indicative of the position of the mobile station. The base station then further processes the position vector to determine a bearing for the vector, and converts the result into latitude and longitude coordinates of the mobile station position. The silent echo generation circuit provides mobile position determination capability in the wireless system without significantly increasing the cost, size, weight and power consumption of the mobile station, without requiring a multilayer user interface, and without degrading system voice quality. [A2890]

"Radiotelephone proximity detector"

A radiotelephone proximity detector including a first proximity unit having a receiver and a second proximity unit having a transmitter, wherein the units can be coupled together and the coupling can be detected. One of the units is associated with a radiotelephone and the other with a user. When the units are coupled, they are responsive to the detection of their uncoupling, whereupon the transmitter of the second proximity unit transmits a proximity signal to the receiver of the first unit. The first proximity unit estimates the proximity of the radiotelephone and the user on the basis of the received proximity signal. Thus the two units operate together such that, when coupled, at least one of the units enters a standby mode, and when uncoupled, at least one of the units sends a proximity signal to the other unit. [A2891]

"Multichannel heterodyning for wideband interferometry, correlation and signal processing"

A method of signal processing a high bandwidth signal by coherently subdividing it into many narrow bandwidth channels which are individually processed at lower frequencies in a parallel manner. Autocorrelation and correlations can be performed using reference frequencies which may drift slowly with time, reducing cost of device. Coordinated adjustment of channel phases alters temporal and spectral behavior of net signal process more precisely than a channel used individually. This is a method of implementing precision long coherent delays, interferometers, and filters for high bandwidth optical or microwave signals using low bandwidth electronics. High bandwidth signals can be recorded, mathematically manipulated, and synthesized. [A2892]

"Method of moment estimation and feature extraction for devices which measure spectra as a function of range or time"

The computation system of the present invention comprises an improved method of moment estimation for devices which measure spectra as a function of range or time. The preferred embodiment of this system is illustrated as part of an automated meteorological monitoring system for the accurate real time detection of meteorological phenomena, such as winds, wind shear and turbulence. This automated meteorological monitoring system uses a standard weather radar transmitter to scan a predetermined volume of space with a stream of radar pulses to determine the characteristics of meteorological phenomena that are extant in the predetermined volume. The computation system of the present invention utilizes novel signal processing algorithms in the improved method of moment estimation to excise the valid data from the return echoes, which are corrupted by the presence of contaminating signals. Separating the valid data from the noise in this manner improves the responsiveness and accuracy of the system in which this method is implemented. [A2893]

"Obstacle detecting apparatus and vehicle occupant protecting device using the same"

An obstacle detecting apparatus which detects the distance between an obstacle and a vehicle by two distance measuring sensors, comprising collision angle calculating device in which a plurality of positions of the obstacle is calculated by way of triangulation on the basis of the distance information from the two distance measuring sensors, and a collision angle, which is formed between the obstacle and the vehicle, is calculated by the locus of the obstacle which is calculated by the calculated plurality of positions of the obstacle. [A2894]

"Traffic monitoring system"

A traffic monitoring system has a common housing for a Doppler radar transceiver, a video camera, and a digital computer for processing the Doppler signal. The system also includes a video cassette recorder, a high-speed photographic camera, and a laptop computer for downloading control settings and a program from a diskette or memory card to the digital computer. The digital computer performs an initial self-test by injecting a calibration signal in lieu of a Doppler signal into an electronic interface between the radar transceiver and the digital computer. The radar transceiver generates a Doppler signal having two channels, and the phase between the channels indicates whether a vehicle is approaching or receding from the radar transceiver. The two channels are recorded on the left and right audio channels of the video cassette. Recorded with the video signal is a push-down stack of speeds of vehicles detected on the system, in order to present a record of prevailing traffic conditions when prosecuting a speed violator. The recorded picture may also include a series of successive speed measurements for each vehicle. Although an operator could listen to the Doppler signal, it is preferred that the digital computer activates an audio annunciator to emit a click sound when the system detects a vehicle, and a warbly sound when a detected vehicle exceeds a specified speed limit. [A2895]

"Signal discriminator and positioning system"

A system is described for discriminating between a transmitted signal and background noise comprising a transmitter adapted to transmit a signal including first and second pulses, separated by a predetermined time interval, and a receiver including a pulse detector to detect pulses received from the transmitter, a delay circuit adapted to delay transmission of the first pulse for a predetermined period of time in communication with the detector to receive a pulse therefrom, and an and gate having an output, a first input in communication with the delay circuit and an second input in communication with the detector, the time of transmission between the pulses equaling the time delay of the delay circuit, whereby the and gate allows transmission of a signal only when simultaneously receiving pulses from the detector and the delay circuit. The system can be used in the determination of the distance between two points, or in the location of an object within an area, based upon calculation of the time between transmission of an initial signal and receipt of a return signal. [A2896]

"Vehicular radar apparatus"

Vehicular radar apparatus which enhances the accuracy of detection of a preceding vehicle and the reliability in tracking, by performing operations that use a normal distribution. for the purpose of obtaining a distance between one's own vehicle, on which the radar apparatus is mounted, and a target object, and obtaining a relative velocity from input data based on transmission and reception electromagnetic waves, this radar apparatus provided with a signal processing unit which has operation devices for performing an operation by applying normal distributions to frequencies of detection of the distance and the relative velocity and a target object recognition device for recognizing a target object on the basis of results of an operation to which the normal distributions are applied. The operation device is operative to establish a window corresponding to each target object, and obtain the frequencies of detection of the distance and the relative velocity correspondingly to each of plural data widths or sections of a probability density on a normal distribution curve, and establish a next window from data representing detected frequencies. The target object recognition device is operative to recognize target objects, each of which corresponds to a distance and a relative velocity that are within a same window, as different objects, but recognize target objects, each of which corresponds to a distance and a relative velocity that are not within a same window, as different objects as an identical object. [A2897]

"Method and system for detecting an in-path target obstacle in front of a vehicle"

A method and system for detecting a target obstacle in front of a vehicle traveling on a road includes a radar positioned at a center of the vehicle for transmitting radar waves ahead of the vehicle for use in determining a first position of the objects in front of the vehicle relative to the radar. A lane position measurement device determines a lateral deviation between the center of the vehicle and a lane boundary of the road. Control logic then determines a curvature of the road based on the lateral deviation, independent of the traveling path of the vehicle. The control logic then determines a second position of the objects based on the curvature of the road and the target obstacle based on the second position of the objects. [A2898]

"System for determining the spatial position of a target"

A system for determining the spatial position of a target having an active target adapted to emit energy in response to an active signal and a passive target adapted to reflect energy impinging upon such passive target from an active energy source. A common energy detector is provided for detecting both the energy emitted by the active target and the energy reflected by the passive target. A common processor is provided for determining the spatial positions of both the passive and active targets in response to the energy detected by the common detector. During a sensor cycle the spatial position of the active target is determined and during a sensor cycle the position of the passive target is determined. The sensor cycles may be interspersed or may be the same cycle to enable simultaneous determination of both the active target and the passive target during a single sensor cycle. The system also enables the determination of the spatial position and angular orientation of both a rigid object having affixed thereto active targets and/or another rigid object having affixed thereto passive targets and/or an object having affixed thereto both an active and passive targets. [A2899]

"Altimetric type measurement method for use on a satellite"

An altimetric type measurement method for use on a satellite transmits a pulse towards the surface of the sea and carries out frequency transformation on the return signal resulting from the reflection of this pulse at the surface of the sea. This produces a spectral signal of samples successively comprising: (a) --a first zone with a low amplitude level, (b) --a second zone with a sharply increasing slope ending at a peak, and (c) --a third zone of decreasing slope. Samples of the spectral signal are selected within a selection zone that corresponds to the first and second zones for a predetermined maximal level of the height of the waves at the surface of the sea and maximum likelihood processing is applied only to the selected samples. [A2900]

"Terrain bias compensator for doppler navigation systems"

A terrain bias compensator for a Doppler navigation system utilizes an auxiliary beam with each beam of the Doppler system to form Doppler beam pairs. The axis of the auxiliary beam is slightly offset from the axis of the main beam and is positioned so that the two axes are in the same vertical plane. After slant range compensation, the amplitudes of the Doppler spectrum of each beam is averaged over a predetermined time interval. The difference between the mean amplitudes of the two beams is divided by the offset angle to establish an amplitude per degree correction factor which is applied to the main beam signal returns to establish a main beam amplitude corrected Doppler spectrum. [A2901]

"Digitally-controlled pulse shaper for pulsed radar systems and radar wind profilers"

A digitally-controlled pulse shaper (DCPS) is provided which precisely controls the shape of the leading and trailing edges of a transmit pulse in a radar wind profiler, or pulsed-radar. In the case of pulse coding, where phase transitions are used to segment an otherwise longer pulse, the intra-pulse phase transitions are also shaped. [A2902]

"FMCW radar and method for estimating distance and relative velocity"

A relative distance and relative velocity to a target object is accurately estimated even if an error in slopes of the triangular wave modulation, that is unbalanced upward and downward slopes, or error in absolute values in an FMCW radar exists. A first distance estimator estimates a distance up to the target object based on a sum of a beat wave frequency generated between the upward and downward slopes of the triangular wave and an absolute value of an average frequency modulation factor which is a mean value of frequency modulation factors for the upward and downward slopes of the triangular wave, and a first velocity estimator estimates a relative velocity to the target object based on a time difference of the calculated distance. A tentative frequency modulation factor estimator estimates an absolute value of a tentative frequency modulation factor based on the calculated distance and velocity, and then estimates a more accurate relative velocity to the target object based on the estimated absolute value of the tentative frequency modulation factor and the distance calculated by the first distance estimator. [A2903]

"Automatic horizontal and vertical scanning radar with terrain display"

A weather radar and terrain map display system for aircraft with the terrain elevation and weather information displayed in an easy to read and comprehend presentation. The system includes an antenna for transmitting and receiving radar signals, a receiver for digitizing the reflected radar signals, and a computer for storing the signals and calculating the latitude and longitude coordinates of the locations from which the reflected radar signals were reflected, and for storing terrain elevation data. A display simultaneously shows a plan view image and vertical views of contoured terrain elevation data and the weather conditions found by the radar. The terrain and weather displays are superimposed over one another to enable quick and efficient location of critical terrain and weather conditions. The system can also calculate the latitude and longitude coordinates of the radar echoes without antenna stabilization. [A2904]

"Vehicle-mounted radar apparatus"

An arrangement is provided such that a time counter 5 starts counting an elapsed time after the lapse of a fixed time from the time the output of a beam reference-position detecting means 3 is turned on, such that an angle output value calculated by an angle-calculating means becomes 0 when the direction of a beam emitted from a radar head unit 2 has coincided with a frontal direction of the vehicle. [A2905]

"Radar based highway safety warning system"

A system for transmitting messages, such as safety hazard warning messages, to vehicles causes alerts to be generated in conventional radar detectors and more detailed messages to be provided to drivers with message capable radar receivers. The transmitted radar signal is modulated in frequency or phase or swept in frequency in different directions or at different rates to define the logical state of each bit of the message. A continuous wave (CW) maker signal may also be transmitted to assure detection by a conventional police radar detector and to allow a receiver capable of decoding messages to make adjustments that center an intermediate frequency (IF) generated from the received signal in the receiver IF passband. A message capable receiver decodes the modulated signal to communicate to the vehicle operator the contents of the transmitted message or a stored message corresponding to a transmitted code. The signal modulation is such that conventional radar detectors do not reject the signal but cause an alert to be generated, indicating to the driver the need to reduce vehicle speed to accommodate upcoming road conditions or obstacles. [A2906]

"Vehicles tracking transponder system and transponding method"

A vehicle-tracking radio transponder used in stolen vehicle recovery systems and in which the same transponder is also synergistically accessed for panic or emergency operator activation and for sensed unauthorized moving or starter circuit tampering independently of and without interfering with the stolen vehicle recovery command signal control of the transponder. [A2907]

"Ultra high resolution ranging unit"

A low cost, real time, remote sensor device for accurately measuring distance to an object with a resolution of 1 millimeter or better using phase information from either electromagnetic or acoustic energy. The device repetitiously transmits a swept frequency and decodes the resulting echo to produce a phase gate which is then converted to an accurate measurement of the range from each sweep. A method for measuring the time between two known phase points on a return signal is employed to determine the range measurement. Since the phase of the signal is used to determine range, the resolution is not dependent on bandwidth. [A2908]

"Vehicle steering force correction system"

A system for correcting the steering force of a vehicle having a steering wheel whose rotary motion exerted by a vehicle driver is converted into a turn motion of the steering wheels of the vehicle through a steering mechanism. The system is provided with sensors including a CCD camera for detecting the condition of the road ahead having at least one traffic lane on which the vehicle is traveling and a position of the vehicle with respect to the traffic lane. In the system the desired steering force is determined to be generated by the steering mechanism necessary for keeping the detected position of the vehicle with respect to the traffic lane based on the detected parameter and the steering mechanism is biased such that the steering mechanism generates the desired steering force. Conditions on the next adjacent lanes are monitored and the degree of danger is estimated to determine the biasing force. The system can be realized on muscular-energy steering systems or power-assisted steering systems. [A2909]

"Frequency domain processing of Doppler signals in a traffic monitoring system"

Frequency domain processing is used to determine rapidly whether false signals are present, and to improve the accuracy of speed measurements by rejecting speed measurements that could be inaccurate due to the presence of false signals. A Doppler signal responsive to speed of a moving vehicle is generated by a Doppler radar transceiver. A digital computer transforms the Doppler signal into a frequency domain signal such as an energy spectrum, and the speed of the moving vehicle is computed from the weighted arithmetic mean of the energy spectrum. The mean value, however, is rejected as an indication of speed if the variance of the energy spectrum from the mean exceeds a threshold, or if a differential of the spectrum with respect to frequency exceeds a threshold. The frequency domain processing of the present invention can also be used to reject certain bands of frequencies in the Doppler signal, such as bands of frequencies that differ from the mean value by more than a threshold, and the mean value can then be recomputed to provide an even better indication of the speed of the moving vehicle. Moreover, speed samples computed from successive frames of spectrum can be averaged, and the average value can be rejected as an indication of speed if the variance of the speed samples about the average value exceeds a threshold, or if the difference between successive speed samples exceeds a threshold. [A2910]

"Ground penetrating radar with synthesized end-fire array"

In a ground penetrating radar system, A-scan images of subsurface targets lying along the antenna boresight axis can be substantially improved and generated in real-time by employing a synthetic aperture, end-fire array, despite the inhomogeneous nature of the subsurface volume. The synthetic aperture, end-fire array is achieved by generating electromagnetic (EM) ultra-wideband impulses at a number of precise locations along the antenna boresight access, shifting the returned EM signals in the time domain according to the corresponding antenna boresight location, and then integrating the shifted, returned EM signals. [A2911]

"On-vehicle radar"

When a transmitted and received radio wave is scanned, even if, for example, a large vehicle is running on an adjacent lane, a preceding vehicle running on the same lane as an own vehicle can be sensed and tracked continually. An on-vehicle radar comprises a transmitter receiver 6 for transmitting and receiving a radio wave with a relatively high frequency, and a signal processor 10 calculating a relative distance to an object and a relative velocity of the object on the basis of a radio wave transmitted by the transmitter receiver, reflected from the object, and received by the transmitter receiver. The transmitter receiver controls the power of a transmitted radio wave so that when a radio wave is to be transmitted in any transmission direction other than a specified transmission direction, the power of the transmitted radio wave will be made lower than that of a radio wave to be transmitted in the specified transmission direction, or even if the power of a received radio wave is larger than a given value, the power of the transmitted radio wave will not be decayed, and that when a radio wave is to be transmitted in the specified transmission direction, if the power of a received radio wave is larger than the given value, the power of the radio wave transmitted by the transmitter receiver will be decayed. [A2912]

"Radio scanning system using acoustical surface waves (SW radio scanning system)"

A radio scanning system using acoustical surface waves (SW radio scanning system) includes a transceiver unit and sensor elements defining at least one parameter to be scanned. The transceiver unit has a transmitter transmitting question signals to the sensor elements and a receiver receiving and evaluating answer signals transmitted back by the sensor elements. The transmitter and the sensor elements are constructed in such a way that the question signals and the answer signals are chronologically inverse to one another. The sensor elements have different SW transit times. [A2913]

"System for displaying the characteristics, position, velocity and acceleration of nearby vehicles on a moving-map"

Proximity radar mounted in a vehicle determines the location of other vehicles. Other vehicles detect their own positions and broadcast those positions to all surrounding vehicles. Vehicle position data is plotted on a moving map so the driver can see the location of other vehicles, in some cases with an icon color which matches vehicle color (s) . A driver can open a communication link with drivers who are projected to constitute a collision threat. A fixed radar unit can be positioned at blind intersections and broadcast vehicle location information for vehicles not equipped with the ability to track their own locations. [A2914]

"Vehicle radar safety apparatus"

A vehicle radar safety apparatus employs a radar for detecting an object in front and/or to the rear and sides of a vehicle and for producing an indication of the distance and closing speed between the vehicle and the detected object. A signal processing unit sums the vehicle speed and the closing speed between the vehicle and detected object and compares the summed output with a signal corresponding to the distance between the vehicle and the detected object to provide an output to a display indicating the vehicle's capability of stopping prior to colliding with the detected object. The output from the signal processing unit is optionally applied to an accelerator and/or brake control circuit to automatically slow down the vehicle. A brake pedal override switch is connected to the accelerator and brake controls to override the accelerator and/or brake controls when the vehicle operator depresses the vehicle brake pedal. The radar includes a horn antenna having a plano-convex dielectric lens mounted at an exterior end. The lens has an exterior convex surface shaped to reduce side lobe generation of the transmitted radar wave so as to transmit a radar wave of a minimal beam width at a specified operating frequency and effective radar antenna diameter. [A2915]

"Electromagnetic wave, reflective type, low cost, active proximity sensor for harsh environments"

An electromagnetic, reflective type, active proximity sensor includes a transmitter, the transmitter including a voltage controlled oscillator circuit, a transmitter circular waveguide and a transmitter polarization circuit. The voltage controlled oscillator circuit generates an output signal which is modulated such that the frequency of the output signal varies over time between a range of frequencies. The frequency varying, output signal is provided to the transmitter circular waveguide and propagated to the transmitter polarization circuit where it is circularly polarized in a first circular direction. The circularly polarized, frequency varying, output signal is radiated by the transmitter to the target, where it strikes the target and reflects back toward the sensor to form return signals. The return signals, upon being reflected, rotate in a second circular direction opposite to the first circular direction. The return signals also respectively exhibit one of the frequencies corresponding to the range of frequencies associated with the circularly polarized, frequency varying, output signal. The active proximity sensor also includes a receiver, the receiver including a receiver circular waveguide, a receiver polarization circuit and a detector. The receiver circular waveguide receives the return signals reflected from the target and the receiver polarization circuit circularly de-polarizes the return signals. Next, the detector receives and averages the return signals and generates an output signal which corresponds to the return signals. The active proximity sensor also includes an analog processor/driver circuit for processing the output signal provided by the detector. [A2916]

"Apparatus and method for detecting a location and an orientation of an underground boring tool"

An apparatus and method for determining a location and an orientation of an underground boring tool by employment of a radar-like probe and detection technique. The boring tool is provided with a device which generates a specific signature signal in response to a probe signal transmitted from above the ground. Cooperation between the probe signal transmitter at ground level and the signature signal generating device provided at the underground boring tool results in accurate detection of the boring tool location and, if desired, orientation, despite the presence of a large background signal. Precision detection of the boring tool location and orientation enables the operator to accurately locate the boring tool during operation and, if provided with a directional capacity, avoid buried obstacles such as utilities and other hazards. The signature signal produced by the boring tool may be generated either passively or actively, and may be a microwave or an acoustic signal. Further, the signature signal may be produced in a manner which differs from that used to produce the probe signal in one or more ways, including timing, frequency content, information content, or polarization. [A2917]

"Micro motion sensor"

A microwave motion sensor for detecting multiple levels of motion of a target is disclosed. The motion sensor includes a transceiver for broadcasting a signal into a predetermined area and receiving a reflected signal with a receiver for producing first and second directional signals. A signal conditioning circuit is provided for amplifying the first and second directional signals and digitizing the directional signals. The signal conditioning circuit includes a micro motion amplifier for separately amplifying one of the directional signals and producing a micro motion signal. A processor is provided for receiving the first and second directional signals transmitted by the signal conditioning circuit, and for receiving the micro motion signal. The processor includes a circuit for analyzing the directional signals, and a circuit for comparing the micro motion signal to a threshold. The processor is capable of adaptively switching between a first mode for detecting a threshold level of motion, a second mode for detecting a level of motion which is less than the threshold level of motion, and a third mode for detecting a level of motion which is greater than the threshold level of motion. [A2918]

"Method and apparatus for detecting the presence of a child seat"

Method and system for detecting the presence of the child seat on a seat in which information about contents of the seat is obtained and a signal is generated based on any contents of the seat, a different signal being generated for different contents of the seat when such contents are present on the seat. The signal is analyzed in order to determine whether the contents of the seat include a child seat, and in a preferred embodiment, a child seat in a rear-facing orientation. Another system within the vehicle may be affected or controlled based on the determination of whether a child seat is present on the seat. The analysis of the signal is preferably by pattern recognition techniques that can recognize and thus identify the contents of the seat. [A2919]

"Method and apparatus for sensing piston position using a dipstick assembly"

A system for determining the position of a piston moveable within a cylinder, or of an implement or joint, is disclosed herein. Electromagnetic (EM) bursts such as ultra-wideband or frequency pulses are generated and applied to a transmitter/receiver unit. The EM bursts are launched by the transmitter along a transmission guide from an end of the cylinder housing towards the piston. The transmission guide can be a dipstick mounted within the cylinder housing or the cylinder housing itself. The dipstick or cylinder housing is in electrical communication with the piston such that a surface of the piston represents an electrical impedance discontinuity which causes the EM bursts to be reflected back to the receiver. The time for the EM bursts to travel from the transmitter to the piston and for the reflections to travel back to the receiver is determined and converted into a position signal representing the piston's position. A compensation signal can be used to compensate the position signal for variations in a parameter of the fluid within the cylinder such as dielectric constant caused by factors such as temperature, contamination and fluid type. The compensation circuit can include a pulse level analyzer, resonance circuit, capacitance circuit, compensation dipstick, or second transmitter/receiver circuit configured to measure the piston's position from the opposite end of the cylinder. [A2920]

"Ultra wideband receiver with high speed noise and interference tracking threshold"

An UWB receiver utilizing a microwave tunnel diode as a single pulse detector for short pulse, impulse, baseband or ultra wideband signals. The tunnel diode detector's bias point is set at system start-up, through an automatic calibration procedure to its highest sensitivity point relative to the desired bit error rate performance (based upon internal noise only) and remains there during the entire reception process. High noise immunity is achieved through the use of a high speed, adaptive dynamic range extension process using a high speed, Gallium Arsenide (GaAs) voltage variable attenuator (VVA) whose instantaneous attenuation level is determined by a periodic sampling of the ambient noise environment. Microprocessor-controlled detector time-gating is performed to switch the tunnel diode detector to the receiver front end circuitry for reception of an incoming UWB pulse, and alternately to ground through a resistor to discharge stored charge on the tunnel diode detector. In a second embodiment, two tunnel diode detectors are utilized in parallel, one biased for data detection and the other biased for noise detection, such that data detection can be interpreted based on simultaneous comparison to both a data threshold and a noise threshold. [A2921]

"Imaging radar suitable for material penetration"

A ground penetrating impulse radar system provides three-dimensional images of targets. A moving array of transmitting and receiving antennas provides narrow beamwidths and high gain by real and synthetic aperture beam processing. Narrow pulsewidth impulse signals are utilized to obtain high resolution. Round trip time is calculated for each three-dimensional pixel in a search volume, and is used to process three dimensional imagery. Analog to digital conversion can be utilized, so all signal processing is accomplished digitally. The radar system is applicable to detecting small objects near the surface by using very narrow pulses, and also can be applied to detect large, deep objects by wider pulses. [A2922]

"Observation instrument and remote control handle assembly"

A velocity/speed measurement radar unit incorporates a handle assembly for detachment from a base unit to allow for convertibility from a hand-held unit to a remote controlled radar unit. The removable handle assembly controls the operating parameters and secondary functions of the radar unit in a simple and user friendly manner. The operating parameters are established using multifunctional switches incorporated in the handle assembly, such as a trigger-type switch, rocker switches, and push button switches. The secondary functions are similarly controlled using a rotary encoder/push button switch combination. A microprocessor in the handle assembly receives inputs from the multifunctional switches and generates a corresponding control signal for transmission to the base unit. The handle assembly and base unit communicate via infra-red transmitters and receivers. The handle assembly is ergonomically designed to insure ease of use. The base unit is independently mounted when converted to the remote mode of operation. [A2923]

"Electromagnetic target generator"

The electromagnetic target generator of this invention is used to simulate radar target for the purpose of testing and experimenting on a variety of weapon systems radars. The weapon system radar being tested emits a radar signal which is received by the target generator. The target generator delays, doppler shifts, and reemits the signal for receipt by the weapon system antenna. The simulated target presented to the radar system under investigation has digitally controlled range, radial velocity, coordinated doppler and radar cross section. This provides a realistic radar target return without requiring real targets. The radar system is exercised in inflight and tactical operational configuration and no part of the weapons system radar is bypassed. Delayed radar target replicas are indistinguishable from real target waveforms. The electromagnetic target generator may be used in locations which preclude the use of real radar targets, such as anechoic chambers, and also may be used in the field. [A2924]

"Sensing with active electronic tags"

An object in a storage area or moving vehicle is monitored by attaching an electronic tag to the object. An electronic device detects the presence of the object by communicating with the tag while the object is in storage or is being moved by the vehicle. The tags may also determine the location of an attached object and may reroute the object if it deviates from a given shipping schedule. A group of objects is monitored by two electronic tags, each attached to an object in the group. Each tag has circuitry for communicating information relating to an object in the group to a second tag. Each tag also includes a memory connected to the circuitry that is capable of storing the information, and a controller connected to the memory and the circuitry. A sensor is used to detect the condition of an object and communicate the condition to a tag. [A2925]

"Radio frequency automatic identification system"

A radio frequency automatic identification system detects targets which include solid resonators resonating at several frequencies, attributing information to the frequencies at which the target resonates. Preferred resonators are quartz crystals, which may be made by a process of heating quartz to soften it and cutting crystals to approximate size and resonant frequency. Resonators produced by such a process are measured to determine their actual resonant frequency, and preferably the crystals are sorted into predetermined frequency windows in accordance with their measured resonant frequency. A set of resonators having frequencies corresponding to predetermined data is selected from the sorted groups of resonators and incorporated into a target. The preferred target is an ink-like material having a plurality of resonators disposed in a matrix which is radio frequency transparent at the frequency of interest. Targets are preferably detected by repetitively sweeping the frequency of the interrogating signal through a range which includes the information-bearing range of the system. [A2926]

"Method and apparatus for improved ranging"

A high resolution ranging method is described utilizing a novel modulated waveform, hereafter referred to as coherent burst modulation. In the coherent burst method, high frequency modulation of an acoustic or electromagnetic transmitter, such as a laser, is performed at a modulation frequency. This modulation frequency is transmitted quasi-continuously in the form of interrupted bursts of radiation. Energy from the transmitter is directed onto a target, interacts with the target, and the returning energy is collected. The encoded burst pattern contained in the collected return signal is detected coherently by a receiver that is tuned so as to be principally sensitive to the modulation frequency. The receiver signal is processed to determine target range using both time-of-flight of the burst envelope and phase shift of the high frequency modulation. This approach effectively decouples the maximum unambiguous range and range resolution relationship of earlier methods, thereby allowing high precision ranging to be conducted at arbitrarily long distances using at least one burst of encoded energy. Performance of such method and apparatus is significantly improved through use of phase alternation methods that compensate for non-ideal behavior of the ranging apparatus or of the target and its environment. Such phase alternation methods may be achieved by varying the phase of the transmitter or receiver channels. Moreover, methods for reduction of potential uncertainty in absolute range measurement are taught that make use of coherent signal components at twice the nominal modulation frequency. [A2927]

"Diode receiver for radio frequency transponder"

A passive radio frequency transponder (RF tag) having a diode rectifier receiver circuit outside the tag power rectification circuit, the tag power rectification circuit supplying power to the electronics of the RF tag. An additional innovative low current circuit protect the signal capacitor from overvoltage produced by the signal diode. An innovative circuit also clips the signal and sharpens it. An innovative low current circuit is used as a comparator to sharpen the signal pulses. [A2928]

"Doppler-based radar system self test circuit and related method"

A Doppler-based radar system used in monitoring the speed of moving vehicles includes a self test circuit and related method for independently and remotely testing the operability of the entire radar system including the critical microwave components. The self test circuit includes a low frequency modulation diode positioned adjacent the antenna horn. The modulating diode causes a change in the voltage standing wave ratio seen by the radar system (s) , thereby modulating the energy of the reflected radar test signal. The modulated test signal is compared to the original test signal and a resultant control signal is generated. The radar system is combined with a retarder system controller and a control system computer to provide an industrial control application, such as for controlling railway cars in a hump yard. Any number of additional radar systems/retarder system controllers can be added to expand the application. [A2929]

"Submerged object detection and classification system"

A detection and classification system for underwater objects uses a transting unit and a receiving unit. The transmitting unit comprises a waveform generator, a power amplifier, and a transmitting antenna. The receiving unit comprises a receiving antenna, a pre-amplifier, a first harmonic suppressor, a digitizer, and a computer. The transmitting unit radiates an analog electromagnetic wave signal into a conductive medium such as seawater which the receiving unit detects and analyzes by a differential spectral analysis after conversion of the signal into binary code. The system uses a signal-processing method which includes the steps of determining the size of the underwater object to be detected, transmitting an electromagnetic wave with a wavelength proportioned to the size of the object, performing a spectral analysis of the received signal, performing a spectral analysis at a different time or different location, comparing the two spectra performed, and analyzing the difference between the two spectra. [A2930]

"Process for monitoring traffic for automatic vehicle incident detection"

A process for monitoring traffic for automatic vehicle incident detection using radar waves to detect the vehicles, their instantaneous speed and their distance. The process consists in correlating the information obtained regarding vehicles in one and the same distance bracket during two consecutive processing time intervals, so as to determine, at each instant, the acceleration of each vehicle and a prediction of its speed, and in then detecting an incident in a distance bracket by detecting the passing of the speed of a vehicle below a given speed threshold. The advantages of the process resides in rapid incident detection in regard to a road or motorway network, with a view to informing the users rapidly. [A2931]

"Ultra-wideband impedance sensor"

The ultra-wideband impedance sensor (UWBZ sensor, or Z-sensor) is implemented in differential and single-ended configurations. The differential UWBZ sensor employs a sub-nanosecond impulse to determine the balance of an impedance bridge. The bridge is configured as a differential sample-and-hold circuit that has a reference impedance side and an unknown impedance side. The unknown impedance side includes a short transmission line whose impedance is a function of the near proximity of objects. The single-ended UWBZ sensor eliminates the reference side of the bridge and is formed of a sample and hold circuit having a transmission line whose impedance is a function of the near proximity of objects. The sensing range of the transmission line is bounded by the two-way travel time of the impulse, thereby eliminating spurious Doppler modes from large distant objects that would occur in a microwave CW impedance bridge. Thus, the UWBZ sensor is a range-gated proximity sensor. The Z-sensor senses the near proximity of various materials such as metal, plastic, wood, petroleum products, and living tissue. It is much like a capacitance sensor, yet it is impervious to moisture. One broad application area is the general replacement of magnetic sensors, particularly where nonferrous materials need to be sensed. Another broad application area is sensing full/empty levels in tanks, vats and silos, e.g., a full/empty switch in water or petroleum tanks. [A2932]

"Informational/training video system"

The present invention provides a video-based, combined informational/training system for user activity related applications. In one embodiment, the system (2) includes a video recording assembly (10) and a measuring device (4) located at a user activity site (6) such as a tee box of a golf driving range. A video tape (60) , including activity specific information on a first, pre-recorded portion thereof, is provided to the user for use in the video recording assembly (10) at the user activity site (6) . The video tape (60) is cued for recording user specific information on a second portion of the video tape (60) during a practice session. The sensor (4) determines corresponding parameter information, such as estimated golf ball carry distance, for display on video tape (60) . The video tape (60) and video recording assembly (10) cooperate to provide a mechanism for preventing or discouraging use of unauthorized tapes and to ensure proper usage of the system (2) . [A2933]

"Vehicle steering control system including corrections for map position and detected obstacles"

An azimuth change quantity .theta. of a road during traveling of a vehicle for a time .delta.t is calculated based on road data provided by a navigation system and a vehicle speed provided by a vehicle speed sensor (at step S3 in FIG. 2) . On the other hand, an azimuth change quantity .THETA. of the vehicle is calculated by integrating a yaw rate .gamma. obtained from a yaw rate sensor over the time .delta.t (at step S5) . A deviation D between the azimuth change quantity .theta. of the road and the azimuth change quantity .THETA. of the vehicle is calculated (at step S6) . When the deviation D becomes equal to or larger than a reference value .beta., it is determined that there is a possibility that the vehicle will depart from the road (at step S9) , and a predetermined steering torque is applied to a steering device, so that the deviation is converged into zero (at steps S10 and S11) . [A2934]

"Vehicle steering control system including corrections for map position and inter-vehicle distance"

An azimuth change quantity .theta. of a road during traveling of a vehicle for a time .delta.t is calculated based on road data provided by a navigation system and a vehicle speed provided by a vehicle speed sensor (at step S3 in FIG. 2) . On the other hand, an azimuth change quantity .THETA. of the vehicle is calculated by integrating a yaw rate .gamma. obtained from a yaw rate sensor over the time .delta.t (at step S5) . A deviation D between the azimuth change quantity .theta. of the road and the azimuth change quantity .THETA. of the vehicle is calculated (at step S6) . When the deviation D becomes equal to or larger than a reference value .beta., it is determined that there is a possibility that the vehicle will depart from the road (at step S9) , and a predetermined steering torque is applied to a steering device, so that the deviation is converged into zero (at steps S10 and S11) . [A2935]

"Noise pair velocity and range echo location system"

An echo-location method for microwaves, sound and light capable of using incoherent and arbitrary waveforms of wide bandwidth to measure velocity and range (and target size) simultaneously to high resolution. Two interferometers having very long and nearly equal delays are used in series with the target interposed. The delays can be longer than the target range of interest. The first interferometer imprints a partial coherence on an initially incoherent source which allows autocorrelation to be performed on the reflected signal to determine velocity. A coherent cross-correlation subsequent to the second interferometer with the source determines a velocity discriminated range. Dithering the second interferometer identifies portions of the cross-correlation belonging to a target apart from clutter moving at a different velocity. The velocity discrimination is insensitive to all slowly varying distortions in the signal path. Speckle in the image of target and antenna lobing due to parasitic reflections is minimal for an incoherent source. An arbitrary source which varies its spectrum dramatically and randomly from pulse to pulse creates a radar elusive to jamming. Monochromatic sources which jigger in frequency from pulse to pulse or combinations of monochromatic sources can simulate some benefits of incoherent broadband sources. Clutter which has a symmetrical velocity spectrum will self-cancel for short wavelengths, such as the apparent motion of ground surrounding target from a sidelooking airborne antenna. [A2936]

"Multi-sensor anticipatory object detection system"

A multi-sensor anticipatory object detection system for detecting the instantaneous range, relative velocity, collision angle and point of impact of a colliding object includes a plurality of transducer devices angle a fixed distance in which each said transducer device transmits a modulated carrier signal and receives the reflected modulated carrier signal from an object, a detection device for detecting a plurality of Doppler shifted harmonic components from each said reflected signal, a range determining device, responsive to the amplitudes of said harmonic components, for determining the instantaneous range of said object from each said transducer device, a velocity measurement device, responsive to the frequency of said harmonic components, for determining the relative instantaneous velocity of said object, and an impact decision device, responsive to said range determining device and the velocity measurement device, for determining where, if at all, impact with the object will occur and the angle of the impact prior to impact with the object. [A2937]

"Removing buoy motion from wind profiler moment"

The present invention provides an apparatus and method for correcting buoy motion in Doppler moment estimates. In the present invention, it is assumed that the buoy is stationary over short periods of time, 0.5 seconds for example. The average pitch and roll angles are measured for the 0.5 second period. A short-term Doppler spectrum for a particular beam is computed and stored along with the corresponding average pointing angle. This short-term Doppler spectrum must be averaged with many others to be able to detect the clear air signal. To correct for motion broadening, the present invention shifts each short Doppler spectrum some number of velocity bins before averaging them together. This shifting scales the measured radial velocity at some measured pointing angle to the radial velocity that would have been measured if the antenna was pointing at some initial pointing angle, typically the steering angle if the antenna was level. The wind velocity derived from the average 30 second Doppler spectrum without shifting is used as a first guess. The equations are solved iteratively until spectral width is minimized. [A2938]

"Level gage waveguide process seal having wavelength-based dimensions"

A waveguide assembly for a process sealed level gage includes first and second waveguide portions, a process sealing cavity and a mechanical barrier. The first waveguide portion has a first waveguide bore. The second waveguide portion is fastened to the first waveguide portion and has a second waveguide bore which is axially aligned with the first waveguide bore for communicating microwave signals at a waveguide wavelength .lambda..sub.G between the waveguide bores. The process sealing cavity is formed at an interface between the first and second waveguide portions. The mechanical barrier includes a first shaft section positioned within the first waveguide portion, a second shaft section positioned within the second waveguide portion and a raised annular shoulder positioned at the interface, within the process sealing cavity. The raised annular shoulder has a width, which is measured radially outward from an outside diameter of the shaft sections, of approximately 1/2 .lambda..sub.G and a height, which is measured axially between the first and second waveguide portions, of approximately 1/4 .lambda..sub.G. [A2939]

"Moving target indicator with no blind speeds"

A moving target indicating system wherein a pulse source which generates radiofrequency drive pulses at a predetermined pulse repetition frequency is connected to the inputs of a pair of channels. The first channel includes a phase-dispersive filter having a first phase-slope dispersion characteristic, while the second channel has a phase-dispersive filter having a phase-slope dispersion characteristic which is the negative of that of the first filter. A pulse group comprising the output of the first and the second channels is transmitted periodically as each drive pulse is applied. The pulse repetition frequency is sufficiently low that when transmitted, echos of only one pulse of each group are received at a time. Due to the "matched" or "conjugate" phase-dispersive characteristics of the filters in the respective channels, the first channel operates in reception upon the reflected pulse originally generated in the second channel and compresses it thus resynthesizing or reconstituting a short duration pulse like the original, while the second channel operates in reception upon the reflected pulse generated in the first channel, compressing it to reconstitute a short duration pulse like the original. A canceler is switched between the outputs of the first and second channels to receive the two resulting reconstituted pulses of each group. In the usual application, fixed target information is cancelled out and moving target information is derived for application to a display device. [A2940]

"Method and system for determining a modulus of speed of a carrier of radar"

A method and system for determining a modulus of a speed of movement of a carrier of radar, including (a) illuminating a same zone on the ground laterally, with radar of the carrier, at times t.sub.1 and t.sub.2 , (b) measuring respective distances D.sub.1 and D.sub.2 of the carrier to the same zone at the times t.sub.1 and t.sub.2, and Doppler frequency shifts F.sub.d1 and F.sub.d2 of respective echoes returned by the same zone during the times t.sub.1 and t.sub.2 , and (c) deducing the modulus .vertline.V.sub.h .vertline. of the speed of movement of the carrier based on a relationship ##EQU1## with .lambda. being a wavelength of a radar wave transmitted by the radar. The method and system require neither the locking of the radar to the carrier nor a course drift of the carrier. In this way, precision is improved and it possible to obtain accurate imaging radar modes having images in which distances can be measured with precision. The method and system can use results obtained during radar imaging for calculating the modulus of the speed of movement of the carrier. [A2941]

"Digital synchronization of broadcast frequency"

A dynamic, self adjusting synchronization system for real time control of the frequency and bandwidth of a modulated signal includes a voltage controlled oscillator for generating a carrier signal to be modulated having a predetermined frequency and bandwidth. There is an adjustment device having a center frequency adjustment circuit for providing a voltage level to the voltage controlled oscillator. A modulation generator generates a modulation signal for modulating the carrier signal to produce a modulated carrier signal and a co-generated measurement signal synchronized with the modulation signal. There is a device for selectively inhibiting the modulation signal. A measurement device includes a counter device to selectively count the pulses of the modulated carrier signal for a first predetermined period of time and counting the pulses of the carrier signal for a second predetermined period of time while the modulation signal is inhibited and a measurement circuit, responsive to the co-generated measurement signal, to synchronously define the first predetermined period of time during which the modulated carrier pulses are counted and is responsive to a timing signal to define the second predetermined period of time during which the modulation signal is inhibited for counting the carrier pulses. The adjustment device is responsive to the measurement device, for varying the voltage applied to the voltage controlled oscillator to maintain the predetermined frequency of the carrier signal, and is responsive to the measurement device for varying the voltage applied to the voltage controlled oscillator to maintain the predetermined bandwidth of the modulated carrier signal. [A2942]

"Common transmit module for a programmable digital radio"

A common transmit module of a programmable digital radio has a digital submodule which receives a bit stream and produces a modulated IF signal, and an analog submodule which receives the modulated IF signal and converts the modulated IF signal to a frequency corresponding to a specific type of radio function. The digital submodule includes (a) a sequential/parallel instruction set processor for signal processing and control, (b) a reconfigurable format unit, and (c) a modulator which receives the output signals of the reconfigurable format unit and produces the modulated oscillation signal. The analog submodule includes (a) a tunable local oscillator that produces a tunable local oscillation signal, (b) fixed local oscillators that produce fixed local oscillation signals, and (c) a mixing unit that receives the modulated IF signal, the tunable local oscillation signal and the fixed local oscillation signals, selectively mixes the fixed local oscillation signals with the modulated oscillation signal to produce non-final IF signals, and mixes a non-final IF signal with the tunable local oscillation signal to produce a final converted signal for transmission at the frequency corresponding to the specific type of radio function. [A2943]

"Incremental phase and distance measurement through digital phase signature comparison"

A displacement measuring method that measures phase changes between a reference and a phase-shifted signal from -.infin. to .infin. degrees (limited by the size of counters) in precise incremental steps using a method referred to as Digital Phase Signature Comparison. Digital Phase Signature Comparison uses an n-bit digital pulse train synchronized to a reference signal to sample a binary phase-shifted signal of a known duty cycle. This n-bit sampling creates a unique phase signature which is stored in a memory device. One digital n-bit phase signature is created for each synchronized pulse train. Each stored phase signature is compared with the previous phase signature to determine whether the phase of the phase-shifted signal has changed, the magnitude of that change, and the direction of displacement. Error detection can protect against unknown phase signatures and phase signature transitions, thus ehminating accumulated or incident inaccuracies. [A2944]

"Swept-step radar system and detection method using same"

An apparatus and method for detecting an object and determining the range of the object is disclosed. A transmitter, coupled to an antenna, transmits a frequency-modulated probe signal at each of a number of center frequency intervals or steps. A receiver, coupled to the antenna when operating in a monostatic mode or, alternatively, to a separate antenna when operating in a bistatic mode, receives a return signal from a target object resulting from the probe signal. Magnitude and phase information corresponding to the object are measured and stored in a memory at each of the center frequency steps. The range to the object is determined using the magnitude and phase information stored in the memory. The present invention provides for high-resolution probing and object detection in short-range applications. The present invention has a wide range of applications including high-resolution probing of geophysical surfaces and ground-penetration applications. The invention may also be used to measure the relative permittivity of materials. [A2945]

"Vehicle travel aiding device"

A vehicle travel aiding device for sensing running conditions of the vehicle and outputting vehicle travel supporting information, which is featured by detecting ambient circumstances and road conditions on which the vehicle is and operating driver's brake operation response on accelerator release response and changing the outputting timing or the content of the supporting information according to the detection results. [A2946]

"Method and apparatus for controlling the approach of a vehicle to an obstacle"

In a first distance range to the obstacle, the velocity of the vehicle is limited by the control of the power of the drive unit of the vehicle. In a second distance range which is less than said first distance range, the braking force at the wheel brakes is built up. [A2947]

"Poly-frequency CW doppler radar system with leakage cancellation and method"

A single antenna poly-frequency Continuous Wave (CW) Doppler radar system having leakage cancellation. The system provides for transmitting a plurality of carrier frequency signals and receiving the return signals by means of a single antenna coupled to an antenna interface through which a portion of the transmitted signal may leak. The signal appearing on an output port of the antenna interface is then down-converted to an intermediate frequency (IF) signal by a stable mixing signal. The IF signal is coupled to an adder which in turn is coupled to an output. The IF signal is further split into a pair of cancellation loops for each carrier frequency signal. Each cancellation loop includes a correlator and provides for processing the IF signal with an in-phase or a quadrature-phase signal associated with the carrier frequency signal so that each pair of cancellation loops outputs a feedback signal representative of and equal to the amplitude of the leakage signal only, which feedback signal then being subtracted from the IF signal with the resultant return signal less the leakage signal then being transmitted for further processing. Preferably, a second order linear feedback circuit and phase compensation circuit is provided in each cancellation loop for processing of the IF signal. The disclosed system does not require high precision, high cost oscillators and has particular application in military radars, navigation radars and vehicular collision warning radars. [A2948]

"Common receive module for a programmable digital radio"

A digital submodule is included in a software programmable common receive module for receiving IF signals and producing a serial bit stream. The digital submodule is programmable based on a selected application of a plurality of radio applications and, if present, a selected function of a plurality of functions of the selected radio application. The digital submodule may include an analog to digital converter for converting IF signals received from an analog submodule into digital signals. The digital signals are supplied to a programmable signal processing unit which is configured, according to the selected radio application and, if present, the selected function, to perform control functions, processing and analysis of the digital signals and generate output signals. The output signals are then formatted by a formatting unit producing formatted digital signals. The formatted digital signals are then supplied to a system bus. The programmable signal processing unit may include a digital downconverter for selective use depending on the selected application of radio communication, for generating a base signal. Additionally, a central processing unit is included to perform further signal processing for selected radio application. [A2949]

"Motor vehicle display system and ranging device"

The state of motion of a motor vehicle is indicated to a driver of a following vehicle by employing an array of lamps. The state of motion is determined by sensing vehicle velocity, deceleration being measured either directly via a transducer or being derived from measured velocity. When the subject vehicle is determined to be stationary, the lamps are illuminated in a time dependent sequence to produce an animated visual display in which the lamps are illuminated and selected pairs of lamps are sequentially de-actuated to provide a pattern cyclically moving outwardly from the center to both left and right ends of the array. The approach of the following vehicle to within a pre-set distance of the stationary vehicle is sensed and triggers a change in the display to a static visual display in which an outer pair of lamps remain illuminated. During deceleration, the level of deceleration is indicated by illuminating progressively more lamps with increasing deceleration. [A2950]

"Vehicle steering control system using navigation system"

An azimuth change quantity .theta. of a road during traveling of a vehicle for a time .delta.t is calculated based on road data provided by a navigation system and a vehicle speed provided by a vehicle speed sensor (at step S3 in FIG. 2) . On the other hand, an azimuth change quantity .THETA. of the vehicle is calculated by integrating a yaw rate .gamma. obtained from a yaw rate sensor over the time .delta.t (at step S5) . A deviation D between the azimuth change quantity .theta. of the road and the azimuth change quantity .THETA. of the vehicle is calculated (at step S6) . When the deviation D becomes equal to or larger than a reference value .beta., it is determined that there is a possibility that the vehicle will depart from the road (at step S9) , and a predetermined steering torque is applied to a steering device, so that the deviation is converged into zero (at steps S10 and S11) . [A2951]

"Sensor fusion apparatus and method"

The invented apparatus fuses two or more sensor signals to generate a fused signal with an improved confidence of target existence and position. The invented apparatus includes gain, control and fusion units, and can also include an integration unit. The integration unit receives signals generated by two or more sensors, and generates integrated signals based on the sensor signals. The integration unit performs temporal and weighted spatial integration of the sensor signals, to generate respective sets of integrated signals supplied to the gain control and fusion units. The gain control unit uses a preprogrammed function to map the integrated signals to an output signal that is scaled to generate a gain signal supplied to the fusion unit. The fusion unit uses a preprogrammed function to map its received integrated signals and the gain signal, to a fused signal that is the output of the invented apparatus. The weighted spatial integration increases the fused signal's sensitivity to near detections and suppresses response to detections relatively distant in space and time, from a detection of interest. The gain control and fusion functions likewise suppress the fused signal's response to low-level signals, but enhances response to high-level signals. In addition, the gain signal is generated from signals integrated over broad limits so that, if a detection occurred near in space or time to a detection of interest, the gain signal will cause the fused signal to be more sensitive to the level of the detection of interest. [A2952]

"Vehicle occupant position and velocity sensor"

An occupant position sensor utilizing either ultrasonic, microwave or optical technologies, or seatbelt spool out and seat position sensors, are used as inputs to the primary vehicle crash sensor circuit to permit the longest possible sensing time before the occupant gets proximate to the airbag and is in danger of being injured by the deploying airbag. The sensor further disables the inflatable restraint system if the occupant is in danger of being injured by the system deployment. Separate systems are used for the driver and passenger to permit the optimum decision to be made for each occupant. [A2953]

"Velocity detecting system"

A velocity detecting radar unit that is easy to operate and to view so as to minimize distraction to the operator, particularly when in use in a moving vehicles includes a spotlight unit having a housing with a lens, a light source within the housing and a control wand pivotally mounting the housing for rotation about an axis and including an elongated tube adapted to extend through the windshield pillar of a vehicle. A radar antenna is mounted in the housing to be movable therewith and has a radar transmitting and receiving end extending from the housing oppositely of the spotlight lens. A display module is adapted to display velocity data and other information and is adjustable mounted to the tube at a location thereon remote from the spotlight housing. Similarly, an input or control module including function switches for providing function commands to a controller for the unit is provided and is adjustable mounted to the tube at a location thereon remote from the housing. [A2954]

"Electronic baffle and baffle controlled microwave devices"

Microwave devices incorporate at least one photosensitive baffle that is selectively illuminated changing the baffle's electronic characteristic from being transparent to being reflective of microwave energy. The baffle serves as a gate, tuning element, reflector and the like. Various forms of photosensitive baffles and microwave devices are presented. [A2955]

"Vehicle data acquisition system"

A data acquisition system is disclosed where a first communication device transmits a transmitted signal to a second communication device. The second communication device encodes the transmitted signal with a code generating a retransmitted signal. The retransmitted signal is then transmitted back to the first communication device. The code can be indicative of an environmental element, such as a traffic sign. The first communication device can determine a distance to the environmental element by monitoring a time for the retransmitted signal to arrive. The first communication device can also encode the transmitted signal with information, such as voice for example. [A2956]

"Optical identification and monitoring system using pattern recognition for use with vehicles"

A vehicle interior monitoring system to identify, locate and monitor occupants, including their parts, and other objects in the passenger compartment and objects outside of a motor vehicle, such as an automobile or truck, by illuminating the contents of the vehicle and objects outside of the vehicle with electromagnetic, and specifically infrared, radiation and using one or more lenses to focus images of the contents onto one or more arrays of charge coupled devices (CCD arrays) . Outputs from the CCD arrays, are analyzed by appropriate computational means employing trained pattern recognition technologies, to classify, identify or locate the contents or external objects. In general, the information obtained by the identification and monitoring system is used to affect the operation of some other system in the vehicle. When system is installed in the passenger compartment of an automotive vehicle equipped with an airbag, the system determines the position of the vehicle occupant relative to the airbag and disables deployment of the airbag if the occupant is positioned so that he/she is likely to be injured by the deployment of the airbag. [A2957]

"Electronic equipment for prevention of collisions between vehicles"

An electronic encoder/transmitter encodes acoustic and visual signal pulses for transmission to other vehicles. A device transmits alarm signals instantaneously when the vehicle self collides, becomes blocked in the road, or when the vehicle is on a collision course with another vehicle. The device receives signals from sensors and enters a function to send an encoded radio signal via an antenna. A manual switch may also be used. Signals received by the decoder/receiver may be visualized by colored LEDs placed at a front panel. The transmitted signal is sent to all vehicles driving in the immediate area. The present invention includes acoustic and visible pulses to warn of risks and collisions which may happen in a short distance and not be visible between the vehicles. The present invention also includes an alarm placed on all four sides of the vehicle and connected to an automatic hydroelectric brake system for reducing the speed of the vehicle. An automatic horn is also included, as well as a manual alarm for crossroad proximity. [A2958]

"Traveling-path deduction apparatus and method for vehicles"

A traveling-path temporary-setting unit 21 sets a plurality of temporary traveling paths with different curvatures, and a calculation unit 22 calculates distances between the temporary traveling paths and preceding vehicles detected by a radar unit 1. In case of a properly-set temporary traveling path, the path and running loci of the preceding vehicles are on a concentric circle. In this case, the preceding vehicles are running along this temporary traveling path, and a time change amount of calculated distances is approximately "0". A traveling-path determination unit 23 determines, one temporary traveling path having the minimum time change amount in the distances, as a traveling path of the vehicle. [A2959]

"Identification mark operating with acoustic surface waves"

An identification mark operating with acoustical surface waves includes at least one reflector having higher reflectivity than a reflectivity of other reflectors. [A2960]

"System and method for intelligent cruise control using standard engine control modes"

A system and method for implementing an intelligent cruise control using standard engine control modes includes a distance sensor to determine the distance and closing rate relative to a forward vehicle and use this information to implement a distance control mode and a speed control mode. The distance control mode maintains a selectable headway range relative to a forward vehicle and may include accelerating the vehicle or decelerating the vehicle by defueling, engaging an engine brake, or downshifting the transmission when engine speed permits. The speed control mode maintains a selectable cruising speed if no target vehicle is detected. This cruising speed set point also functions as an upper limit while in the distance control mode. The system and method effect the intelligent cruise control functions utilizing control logic external to the electronic engine control module utilizing the engine speed control mode or engine speed and torque limiting control mode of SAE J1922 or SAE J1939 standards. Alternatively, a cruise control limit speed may be broadcast via SAE J1587 to reduce the vehicle speed upon approaching a forward vehicle so as to reduce the need for driver intervention. The invention may periodically switch between engine control modes to avoid any control mode timeout imposed by some engine manufacturers. [A2961]

"Motor vehicle display system and ranging device"

A display system for motor vehicles provides an array of lamps at the rear of a subject vehicle to provide an indication of the state of motion of the subject vehicle to the driver of a following vehicle. In a first mode of operation, the display indicates a level of warning dependent upon the rate of deceleration of the subject vehicle, the level of warning being determined by deceleration thresholds which are variable in dependence upon the measured speed of the subject vehicle. In a second mode of operation, the lamps provide an indication of the subject vehicle being stationary or near stationary as determined by comparing the measured speed with a threshold speed. An animate display is created by illuminating the lamps and sequentially deactuating selected pairs of lamps to create a pattern cyclically moving semetrically outwardly from the center of the row. The display is discontinued when the speed of the subject vehicle exceeds a second threshold defined independently of the first threshold speed. In a third mode of operation, the display indicates that the subject vehicle is stationary or near stationary in a manner which has less prominence, fewer lamps being illuminated, and in response to detection of a following vehicle being in close proximity to the subject vehicle. [A2962]

"Transmission-reception time correction system"

The invention relates to a transmission-reception system. A transponder receiver unit contained in the key bow of an ignition key has a power circuit that receivers, rectifies and smoothes the carrier wave signal transmitted together with a time reference signal and an enquiry signal from the transmission-reception ECU of a motor vehicle. A microcomputer in the transponder becomes active when the output voltage of the power circuit reaches a predetermined level or higher. When activated, the microcomputer measures the time length of the received reference time signal using the clock signal generated by an oscillation circuit, and calculates a ratio, as a correction coefficient, between the measured time length and a stored reference time value. The microcomputer decodes the enquiry signal while correcting the time information included in the time series pulse signal forming the enquiry signal, using the correction coefficient. [A2963]

"System for preventing rear end collisions"

A system for preventing rear end collisions is provided including a warning light housing with a transparent panel mounted to a rear of the vehicle. A distance detector is directed toward a rear of the vehicle. The distance detector is adapted to detect a distance from a following car. A bulb is provided for illuminating upon the actuation thereof.

Finally, control circuitry is connected between the distance detector, bulb, a speedometer, and a battery of the vehicle. The control circuitry is adapted for receiving a speed of the vehicle from the speedometer and further to calculate a distance per speed value, whereby the control circuitry actuates the bulb only upon the distance per speed value being lower than a predetermined value. [A2964]

"Anti-theft system for a motor vehicle"

An anti-theft system for a motor vehicle includes a transceiver disposed in a motor vehicle and a portable transponder. If a magnetic alternating field of the transceiver is turned on, energy signals are transmitted inductively to the transponder, where they charge an energy storing device. As soon as the alternating field is turned off, a transponder oscillating circuit oscillates at its resonant frequency. This oscillation is transmitted inductively back to the transceiver. In the process, the resonant frequency is measured. Then, the exciter frequency of the alternating field is adapted to the resonant frequency of the transponder, so that the inductive energy transmission is as effective as possible in subsequent charging operations. [A2965]

"Mines having tuned passive electromagnetic reflectors to enhance radar detection"

Metal structures that are resonant to electromagnetic waves are combined h land mines to make them easier to detect using Ground Penetrating Radar. Knowledge of the resonant characteristics in the metal structures enhances detection and identification. [A2966]

"Optical identification and monitoring system using pattern recognition for use with vehicles"

A vehicle interior monitoring system to identify, locate and monitor occupants, including their parts, and other objects in the passenger compartment and objects outside of a motor vehicle, such as an automobile or truck, by illuminating the contents of the vehicle and objects outside of the vehicle with electromagnetic, and specifically infrared, radiation and using one or more lenses to focus images of the contents onto one or more arrays of charge coupled devices (CCD arrays) . Outputs from the CCD arrays, are analyzed by appropriate computational means employing trained pattern recognition technologies, to classify, identify or locate the contents or external objects. In general, the information obtained by the identification and monitoring system is used to affect the operation of some other system in the vehicle. When system is installed in the passenger compartment of an automotive vehicle equipped with an airbag, the system determines the position of the vehicle occupant relative to the airbag and disables deployment of the airbag if the occupant is positioned so that he/she is likely to be injured by the deployment of the airbag. [A2967]

"Ultra wideband ground penetrating radar imaging of heterogeneous solids"

A non-invasive imaging system for analyzing engineered structures comprises pairs of ultra wideband radar transmitters and receivers in a linear array that are connected to a timing mechanism that allows a radar echo sample to be taken at a variety of delay times for each radar pulse transmission. The radar transmitters and receivers are coupled to a position determining system that provides the x,y position on a surface for each group of samples measured for a volume from the surface. The radar transmitter and receivers are moved about the surface, e.g., attached to the bumper of a truck, to collect such groups of measurements from a variety of x,y positions. Return signal amplitudes represent the relative reflectivity of objects within the volume and the delay in receiving each signal echo represents the depth at which the object lays in the volume and the propagation speeds of the intervening material layers. Successively deeper z-planes are backward propagated from one layer to the next with an adjustment for variations in the expected propagation velocities of the material layers that lie between adjacent z-planes. [A2968]

"Roadway ground penetrating radar system"

A roadway ground penetrating radar system is provided for generating a continuous profile of the pavement structure. The profile shows individual layer and sub-surface anomaly depth and thickness. Radar signals are transmitted into the structure using a surface-coupled transmitter antenna and reflected waves are received by an array of surface-coupled receiver antennas located at different known spacings from the transmitter antenna. The different signal travel times are measured. An accurate measure (.+-.5%) of signal velocity through each pavement layer can be calculated using the surface-coupled assembly spacing and travel time information. With the velocity accurately known at each sounding point, using conventional calculations one can determine interface depth and layer thickness, to an accuracy in the order of .+-.5%. In a preferred embodiment, an air-launched "horn" antenna assembly is used in conjunction with the surface-coupled antenna assembly. The horn antenna assembly gives good resolution for layer thicknesses of about 50-100 mm, the surface-coupled antenna assembly gives good resolution for layer thicknesses greater than about 100-150 mm, and gives greater penetration depth. The system can be wheel mounted for advancing continuously along the roadway and the radar data can be synchronized with roadway location. [A2969]

"Method and apparatus for crash sensing using anticipatory sensor inputs"

Anticipatory crash sensors mounted on the front of a vehicle or optionally on the sides sense the speed of approach to an obstacle. A signal processing algorithm determines the ratio of the speed to a threshold and multiplies the output of an accelerometer with the ratio. This enhanced acceleration signal is input to a single point crash sensor algorithm to reduce the time to generate a trigger signal. [A2970]

"Vehicle interior identification and monitoring system"

This invention is a system to identify and monitor contents and/or parts of the passenger compartment of a motor vehicle, such as an automobile or truck, by processing the signal received from the contents or parts using one or more techniques, including neural networks or other pattern recognition systems, and technologies including ultrasonic and electromagnetic radiation. The received signal may be a reflection of a transmitted signal, the reflection of some natural signal within the vehicle, or may be some signal emitted naturally by the object. Information obtained by the identification and monitoring system is then used to affect the operation of some other system in the vehicle such as the airbag, entertainment system, heating and air conditioning system, or the system to darken portions of the mirrors or windshield, among others. [A2971]

"Vibration detection"

The present invention describes a method and device to use radar to measure vibrations of a target object. The invention employs a radar system in which a signal equivalent to an echo from the object when it is not vibrating is subtracted from the actual returning echo signal before that echo signal is detected by the system's receiver so that the signal then actually received by the receiver consists only of that very much smaller component of the echo which is due to the displacements of the vibrating object from its rest position. This echo component is then amplified, and displacements of the object are determined from the amplified signal. The present invention utilizes long wavelength radar signals that can penetrate the ground to buried pipes and objects and permits detection of the effects of vibration on the reflected signals that are unmeasurable by known means. The present invention allows detection of vibrations of an object without making physical contact with it. Thus, measurement of vibrations, for example, of a water distribution pipe buried below ground may be detected. Such pipes vibrate (to produce a typical "hissing" sound) when they leak, and the present invention permits detection of leaks by sensing this vibration in the manner described herein. [A2972]

"Motor vehicle display system and ranging device"

A vehicle display system has a stationary detector and an indicator, which form a stationary vehicle detection apparatus being operative to produce an indicator signal which is indicative of the vehicle being stationary. The vehicle display system also has a vehicle deceleration detector and an indicator. The vehicle deceleration detector measures the magnitude of deceleration of a vehicle and generates a signal to drive the indicator and thereby generate a display indicative of the magnitude of vehicle deceleration. The vehicle deceleration detector is independent of the vehicle braking system. In one embodiment, the indicator is an array of lamps and the stationary vehicle indicator signal is an inanimate display. One embodiment has an additional ranging device that detects a trailing vehicle within a predetermined distance of the vehicle employing the ranging device. The ranging device may be used to initiate a change of the display generated by the vehicle display system. [A2973]

"Vehicle steering device"

A vehicle steering device has a steering inhibition portion that enables the steering device to be switched between a steering inhibition application mode and a steering inhibition release mode--regardless of whether or not the vehicle is being steered by a driver. This arrangement avoids the need to determine whether or not the vehicle is being steered before determining whether or not to inhibit steering. [A2974]

"Anticipatory collision sensor system"

An anticipatory object detection system includes a transducer device for transmitting a modulated carrier signal and receiving the reflected modulated carrier signal from an object, a detection device for detecting a plurality of Doppler shifted harmonic components from the reflected modulated carrier signal, a range determining device responsive to the amplitude of at least two of the harmonic components for determining the instantaneous range of the object, a velocity measurement device, responsive to the frequency of at least one of the harmonic components, for determining the relative, instantaneous velocity of the object. [A2975]

"Automatic vehicle seat adjuster"

An automatic seat adjustment system for a motor vehicle having a passenger compartment with a seat in which an occupant sits. The seat has power mechanisms for moving the seat relative to the passenger compartment from an initial position to an adjusted position, and control mechanisms connected to the power mechanisms for controlling the power mechanisms. Generally, the system includes measurement devices for measuring at least one morphological characteristic of the occupant and generating a first signal representative of the magnitude of that morphological characteristic, a processor including computational means for determining an adjusted seat position based on that measured morphological characteristic and which generates a second signal corresponding to the adjusted seat position, a first input device coupled to the measurement devices and to the processor for inputting the first signal into the processor, and a second input device coupled to the processor and the control mechanisms for inputting the second signal into the control mechanisms. In this manner, the control mechanism is able to affects the operation of the power mechanisms to move the seat to the adjusted position. [A2976]

"Modulating reflector circuit"

A modulating reflector circuit arrangement comprising a transistor configured by means of a feedback arrangement upon operation within a linear region of the transistor's current/voltage characteristic to reflect an incoming amplitude modulated signal with an increased amplitude and a modulator operable to modulate power to the transistor with a periodic waveform in which the reciprocal of the period of the periodic waveform is the required sideband frequency of the reflected signal and the waveform is selected such that the arrangement reflects a substantially single sideband signal. [A2977]

"Apparatus and method for detecting an underground structure"

An apparatus and method for locating an underground object or structure by employment of a radar-like probe and detection technique is disclosed. The underground structure is provided with a device which generates a specific signature signal in response to a probe signal transmitted from above the ground. Cooperative action between the probe signal transmitter at ground level and the signature signal generating device provided on the underground object provides for accurate detection of the subsurface object, despite the presence of a large background noise signal. The depth and, if desired, orientation of the underground object may also be determined using the signature signal generated by the signature signal generating device mounted to the underground object. Orientation information may be encoded on the signature signal or transmitted as an information signal separate from the signature signal. The probe signal may be microwave or acoustic. The signature signal produced by the signature signal generating device mounted to the underground object may be generated either passively or actively. Further, the signature signal may be produced in a manner which differs from the probe signal in one or more ways, including phase, frequency content, information content, or polarization. Also, the signature signal generating device may produce both location and orientation information, without the need for a separate orientation detecting device. Alternatively, orientation and location information may be produced by independent orientation detection and signature signal generating devices. [A2978]

"Modulated retroreflection system for secure communication and identification"

A modulated retroreflection system for secure two-way communication and identification includes a transceiver at a first location and a transponder at a second location. The transponder receiving, modulating, and reflecting the signal back to the transceiver includes a retroreflector having a at least one reflective surface coated with an electro-responsive material. The electro-responsive material modulating the reflection coefficient of the reflective surface thereby modulating signals reflected by the surface. The transponder further includes a modulator electrically connected to the electro-responsive material for applying a modulated bias voltage thereby modulating the refractive index and consequently the electrical phase, and/or amplitude of the reflected signal. [A2979]

"Interferometric moving vehicle imaging apparatus and method"

An interferometric moving target radar imaging system includes a plurality of simultaneously operating apertures, receivers and processing channels which together coherently process RF return signals to image a moving vehicle. The system corrects for the different phase centers of the apertures and interferometrically combines the return signals from different apertures to attenuate the energy from stationary objects. The true azimuth location of the moving vehicle within main beam clutter spread is then determined which facilitates distinguishing between slow moving and stationary objects to detect the moving objects which are then tracked and imaged in the range doppler domain. [A2980]

"Long range RF tag"

A long range identification system is disclosed for utilizing a radio frequency (RF) signal sent by a calling location, such as a mass transit vehicle, as the energy source to power response apparatus at a responding location, such as a route stop of the transit vehicle. The responding signal is then broadcast within the transit vehicle as audio or as a video display of a signal from a character generator, or as both audio and video. The long range identification system includes a RF transmitter at the calling location, a receiver at the responding location for receiving the signal and passively generating RF voltage in response to a particular RF signal of a predetermined frequency, a rectifier, capacitors connected to the rectifier to store charge, a voltage regulator connected to the capacitors and operating when a sufficient charge has developed in the capacitors, a digital code generator identifying the responding location, a transmitter for broadcasting a signal carrying the identifying code, and a receiver and decoder located at the calling location, or elsewhere. [A2981]

"Automotive anti-collision and alarm system"

An estimated travelling curve La (radius Rea) of a system vehicle is obtained based on a first group of sampling data (X1, Y1) through (X5, Y5) . Alarm area WA1a is set as a region surrounded by a pair of circular arcs parallel shifted from curve La by .+-.1 m and a pair of straight lines (Y=Y1 and Y=Y5) . Similarly, an estimated travelling curve Lb (radius Reb) is obtained based on a second group of sampling data (X3, Y3) through (X5, Y5) . Alarm area WA1b is set as a region surrounded by a pair of circular arcs parallel shifted from curve Lb by .+-.1 m and straight lines (Y=Y1 and Y=Y5) . At the entrance and exit of a curved road, values of radii Rea and Reb are differentiated. Hence, the collision judgement is performed by using different alarm areas WA1a and WA1b. [A2982]

"Modulation compensated clamp circuit"

A radio frequency identification (RFID) tag includes a tank circuit for receiving a power signal transmitted on a radio frequency (RF) carrier by a remote interrogator unit. Information is conveyed from the tag to the interrogator by varying a resistive load placed across the tank circuit as a function of data read from memory. Corresponding variations in the reflected signals are then detected by the interrogator. An overvoltage circuit cooperates with a modulation circuit for providing transmission of data even during an overvoltage condition, thus avoiding masking of the signal under such conditions. [A2983]

"Planar array antenna and phase-comparison monopulse radar system"

A planar array antenna comprises a plurality of antenna elements disposed in a predetermined matrix pattern. Feeders extend from a feed to the antenna elements. High-frequency switches cooperatively open or close the feeders connected to antenna elements of at least one row of the matrix pattern located at both a right-end and a left-end regions of an antenna surface. Switching signals are supplied to the high-frequency switches from switching terminals for alternately activating the associated antenna elements, thereby providing two time-divisional array antennas offset in position by a distance corresponding to the width of at least one row of the antenna elements controlled. [A2984]

"Combined speed measuring device detector, speed measuring device and printer for verifying vehicle speed"

The disclosed device enables the user to verify the speed of their vehicle responsive to sensing that a speed measuring device has been used to measure their speed. The device includes a speed measuring device detector designed to sense operation of a speed measuring device. When the detector senses such operation, it activates a speed measuring device mounted on the vehicle which instantaneously measures the vehicle speed and then stores the measured speed for later display and for printing a permanent record, if desired. [A2985]

"Transmission of frame-to-frame reversed polarity signals in a two-way cable TV conversion system"

A bidirectional cable television system provides for transmission of signals from cable subscribers downlink in the same direction as the ensemble of television channels which the cable television system is already constructed to deliver. The subscriber signals may be transmitted over the cable in the blanking intervals of a cable television channel, using the T-NET technique described in U.S. Pat. No. 4,750,036. Alternatively, the signals may be carried over a dedicated channel, or transmitted cochannel along a cable television channel carrying ordinary programming by adding the subscriber information to alternating video frames in alternating polarity to achieve visual cancellation. The subscriber signals are collected after the last distribution line amplifier in the cable downlink. The collected signals are transmitted to a central receiver via wireless or other customary means such as a modem. The collected signals may alternatively be transmitted over the air to the central receiver in the blanking intervals of a broadcast television channel using the T-NET technique. [A2986]

"Method and system for calculating a user account balance in a recognition system"

A system and method in which a transponder (14) is operable to transmit an original user account balance to an interrogator (12) , which in turn calculates a revised user account balance and transmits the revised user account balance to the transponder (14) . In one embodiment of the invention, the transponder (14) is further operable to transmit a verification user account balance back to the interrogator (12) , which then compares verification user account balance to the revised user account balance that was earlier calculated and stored in an interrogator memory. [A2987]

"Method for remotely determining sea surface roughness and wind speed at a water surface"

Transmitted signals are used to remotely assess sea surface roughness and nce wind speed at a water surface. A signal is transmitted from a signal source as it moves either through air or space. A land- or sea-based antenna receives the signal directly from the signal source and indirectly from the signal source by way of reflection of the signal from the surface being examined. The sum of the directly and indirectly received signals form an interference pattern as the signal source is moved. The interference pattern has peak-to-null signal values that are characteristic of the surface conditions being analyzed. Reference interference patterns are then generated for known surface conditions, each of the reference patterns exhibiting "known" characteristic peak-to-null signal values. The peak-to-null signal values of the reference interference patterns are then compared to the peak-to-null signal values generated from the surface being examined. The reference interference pattern having known peak-to-null signal values most closely resembling the peak-to-null signal values generated from the surface being examined is determined. The known surface conditions of this reference interference pattern are then equated with the unknown surface conditions of the surface being examined. By using this technique one can determine the surface conditions of a sea surface as well as the wind speed present at such a surface. [A2988]

"Object detecting process in vehicle"

In a vehicle including a distance sensor capable of detecting longitudinal and lateral distances from a subject vehicle to an object, the following steps are carried out: a step of enclosing some of the detection data, detected by the distance sensor, which exist within a first predetermined distance from one another, into a block having a block label assigned thereto, a step of comparing last and current values of the center of gravity position of each block with each other for every same block label to calculate a relative speed of each block relative to the subject vehicle, a step of determining object data by determining that some of the blocks, which exist within a second predetermined distance from one another and a difference between the relative speeds of which is within a preset value, are the same object, and a step of averaging lateral relative speeds of the blocks in the same object to determine a lateral relative speed of the object relative to the subject vehicle. In this manner, objects whose relative motions relative to the subject vehicle are different from one another are correctly detected, and lateral relative speed of the objects relative to the subject vehicle are accurately detected. [A2989]

"Method of and system for monitoring preceding vehicles"

A distance monitoring system of a vehicle monitors a distance to a preceding vehicle traveling directly ahead of the vehicle to determines whether the preceding vehicle is decelerating by comparing a change in the vehicle speed with a reference value which is varied according to various driving condition in relation in particular to dangers such as collisions against the preceding vehicle. [A2990]

"Apparatus for directing a mobile craft to a rendevous with another mobile craft"

Tracking means for establishing a line-of-sight between a control point towards which the second craft is being guided and tracking the line-of-sight to follow the second craft and deriving a signal .theta..sub.a representing the rate of rotation of the line-of-sight about the control point, monitoring means for deriving a signal e representing the displacement of the first craft from the line-of-sight, a signal representing the range R.sub.m from the control point to the first craft and a signal representing the rate of of change R.sub.m of the range R.sub.m , ranging means for deriving a signal representing the range R.sub.t from the control point to the second craft and a signal representing the rate of change R.sub.t of the range R.sub.t , a computer for deriving representations of .theta..sub.c, .theta..sub.c and .theta..sub.c which satisfy the equation where the difference .theta..sub.c -.theta..sub.a is minimised, control means for deriving from the representations provided by the computer a control signal representing f (e) +R.sub.m .theta..sub.c -2R.sub.m .theta..sub.c where f (e) is a function of e, and, guidance means for causing the first craft to develop an acceleration transverse to the line-of-sight, of a magnitude dependent on the control signal. [A2991]

"Method and apparatus for universal display of alphanumeric data on radar displays"

A radar system embeds information into the radar picture data for display on any display device. The radar receiver communicates weather data to a signal processor which generates a weather array. An I/O processor transmits data in the weather array to a display device via a picture bus. Alphanumeric data which is to be embedded into or combined with the weather array is stored in a message array. Font information for each alphanumeric character is stored in a font array. The message array and the font array are combined and translated into a text array which corresponds to the weather array. Prior to transmitting each radial of data to the display device, the I/O processor copies the appropriate radial data from the text array to the weather array thereby causing the desired alphanumeric characters to be displayed on the display device. [A2992]

"Electronic vehicle toll collection system and method"

A system for automatic collection of tolls includes an in-vehicle toll processor having memory for storing a toll-money-available quantity purchased by the user, and a toll-facility-identification site that transmits a toll-facility-identifier signal indicating the identity of the upcoming toll facility. As the vehicle approaches the identification site, the in-vehicle processor receives the identifier signal and calculates the toll to be debited. When the vehicle passes through the toll facility, the in-vehicle processor transmits its identity, its net balance and the toll, which it debits from an account balance. The in-vehicle processor may increment a low balance, in which case it transmits information which is relayed to a central system for billing. Various means for shutting down delinquent in-vehicle components or identifying offender vehicles are described. [A2993]

"Proximity sensor"

An improved capacitive sensor for detecting the presence of objects in a sensing region. The sensor is a multilayer structure with alternating layer of condutive and insulating materials. The sensor structure has three electrodes: a touch plate, a guard layer, a ground plane, each of which are separated from each other by insulating layers. The sensor is operated by detection electronic circuitry which function in a either a self excited mode or an externally excited mode. This sensor is capable of detecting objects in a sensing region several feet away from the sensing surface and is particularly suitable for automobile applications, such as detecting potentially jamming objects in power (auto-closing) windows, doors, and the like. [A2994]

"Method for locating moving objects"

The method of the invention is mixed and uses, in the forward link, the measurement of the phase of tones modulating a carrier and, in the backward link, a spectrum spread by pseudonoise code, which makes it possible to date the reception of the message. Application to the location of miscellaneous moving objects (land, sea, air, etc.) . [A2995]

"Obstacle recognition system for vehicle"

In an obstacle recognition system for a vehicle, transmission wave is irradiated per given angle for recognizing an obstacle ahead of the subject vehicle based on angle/distance data obtained from received reflected wave. A position of the obstacle is estimated based on a previously recognized position of the obstacle. The estimated position of the obstacle and an actually recognized position of the obstacle are compared so as to determine whether the obstacle currently recognized is identical with the obstacle previously recognized. Relative acceleration is derived for the obstacle which has been determined plural times to be identical with the previously recognized obstacle. When the derived relative acceleration is outside a given range, the corresponding obstacle is excluded from objects of further obstacle recognition. [A2996]

"Weather forecast apparatus and method based on recognition of echo patterns of radar images"

The present invention provides a weather forecast apparatus and a method for the same, to systematically classify a measured radar image based on results of pattern classification of past radar images so as to use the classified radar image. In the present invention, rapid forecasting is possible by making the FNN model previously learn based on data of each class (and indexes for forecast times) obtained by classification of past weather data for every resembling pattern. In addition, a calculation procedure for improving the classifying ability of patterns can be established by varying the procedure for calculating feature quantities with regard to the radar image by using the learning of the TNN model. Furthermore, systematic classification of a pre-learned image can be realized by performing self organization with regard to compound feature quantities extracted from a radar image in the PNN model, a typical example of which is a competitive learning model. [A2997]

"Method of determining the velocity of a radar target"

A method of determining the velocity of a radar target wherein at least two different pulse repetition frequencies are used. Each pulse repetition frequency comprises a predetermined division into equidistant Doppler numbers. for an echo signal, a Doppler number associated with the echo signal is determined for each pulse repetition frequency. Out of two Doppler numbers associated with different pulse repetition frequencies, a nonambiguous Doppler number is subsequently determined which lies within a predetermined velocity nonambiguity range, and the velocity of the radar target is determined from this Doppler number. [A2998]

"Post launch on-board identification friend or foe system"

A post launch identification friend or foe fire control system for a munition has an identification and ranging interrogation unit for mounting on a munition. The interrogation unit transmits an interrogation unit which detects and verifies an incoming identification code from a remote transponder unit in reply to the interrogation code. The range of the remote transponder is determined and a decision signal is provided to the fire control circuit of the munition to enable it to avoid a friendly target, a transponder unit receives the rf carrier signal containing an incoming interrogation code from an interrogation unit on board a munition, validates the incoming interrogation code, and extracts a timing signal from it. An identification code is synchronously generated with the incoming interrogation code using the timing signal. The synchronized identification code is then transmitted back to the interrogation unit on board the munition to confirm the identification of the transponder unit and its range. [A2999]

"Short range electromagnetic proximity detection"

A very low-cost, short-range electromagnetic transceiver uses a low frequency oscillator signal as a means of charging a step recovery diode (SRD) which converts the stored charge into a very short impulse to enable very high energy efficiency frequency multiplication. This impulse is coupled to an antenna which radiates the energy and receives reflections from objects in the vicinity. The energy of the received impulse reflections in an indicator of the distance of the object to the sensor. This system may be used in a vehicle to detect obstructions in its path of motion or a parking facility where it would determine the occupancy of each vehicle parking space. In the parking facility embodiment, information is reported to a central office computer which displays spaces which are not occupied and available for assignment. This system may also be used as a proximity detector for other applications, for example, to automatically detect pedestrians approaching a traffic control signal at a street corner or to detect the proximity of any object to another. [A3000]

"Method for determining the course of another vehicle"

A method for determining the course of another vehicle in relation to one's own vehicle by measuring the position of the other vehicle in relation to one's own vehicle with a transmitter/receiver system, such as a radar system permits course determination both on straight and on bend segments. According to the method, the side location of the other vehicle and one's own vehicle is determined at a position where the other vehicle is level with one's own vehicle, by moving the front vehicle backwards in time and/or moving the rear vehicle forwards in time, on the basis of position measurements of the position of the other vehicle. The side location of the other vehicle is compared with the side location of one's own vehicle, by which a measure of the discrepancy between the course of the other vehicle and the course of one's own vehicle is obtained. According to the invention, the position where the other vehicle is level with one's own vehicle may be determined on the basis of the inertial speed vector of the other vehicle at one or more points in time. [A3001]

"Vehicle blind spot detection display system"

A vehicle blind spot detection display system displays indications from a blind spot detector. The system includes a first indicator assembly positioned on the vehicle in the vicinity of an exterior mirror and adapted to producing an indication at least of the presence of an object adjacent the corresponding side of the vehicle. A second indicator assembly is provided on the vehicle interior mirror assembly and adapted to producing an indication at least of the presence of an object adjacent the same corresponding side of the vehicle. In this manner, redundant indications are provided at both the interior and exterior mirrors in order to assist the driver in a premaneuver evaluation of conditions surrounding the vehicle. [A3002]

"Fog piercing ranging apparatus and method"

An apparatus and method for accurately determining a target distance in adverse weather conditions utilizing both LASER and RADAR is disclosed. The radar signals are used to determine an approximate range which is then used as a gating window for the determination of which laser reflection is from the actual target as opposed to a reflection from the atmospheric interference. The method basically comprises the steps of initiating a radar pulse in the direction of a target and receiving a reflection, transmitting a laser signal and receiving a plurality of reflections, determining an approximate range based on the radar signals, and using this approximate range to ascertain which of the laser reflections is from the target. This determination is preferably made by generating a gating signal and gate width from the radar signals and passing the set of laser range signals through the gate to eliminate the false signals and select the signal that survives the gate as the accurate target range. [A3003]

"Automatic horizontal and vertical scanning radar with terrain display"

A weather radar and terrain map display system for aircraft with the terrain elevation and weather information displayed in an easy to read and comprehend presentation. The system includes an antenna for transmitting and receiving radar signals, a receiver for digitizing the reflected radar signals, and a computer for storing the signals and calculating the latitude and longitude coordinates of the locations from which the reflected radar signals were reflected, and for storing terrain elevation data. A display simultaneously shows a plan view image and vertical views of contoured terrain elevation data and the weather conditions found by the radar. The terrain and weather displays are superimposed over one another to enable quick and efficient location of critical terrain and weather conditions. The system can also calculate the latitude and longitude coordinates of the radar echoes without antenna stabilization. [A3004]

"Method of manufacturing an enclosed transceiver"

The present invention teaches a method of manufacturing a enclosed transceiver, such as a radio frequency identification ("RFID") tag. Structurally, in one embodiment, the tag comprises an integrated circuit (IC) chip, and an RF antenna mounted on a thin film substrate powered by a thin film battery. A variety of antenna geometries are compatible with the above tag construction. These include monopole antennas, dipole antennas, dual dipole antennas, a combination of dipole and loop antennas. Further, in another embodiment, the antennas are positioned either within the plane of the thin film battery or superjacent to the thin film battery. [A3005]

"Vehicle location system"

Method and apparatus for determining vehicle present location using a location determination system (LDS) , such as GPS, GLONASS, Loran or an inertial navigation system, that receives LDS signals from two or more sources. An LDS signal antenna and receiver/processor, an interrogation signal (IS) receiver means and IS responder means are electrically connected and carried on the vehicle. When a vehicle trigger event occurs, a specified vehicle IS is broadcast and is received by the IS receiver means. The IS receiver means causes the LDS receiver/processor to obtain vehicle present location information and to provide such information for the IS responder means, for transmission to an IS contact receiver (selected based upon vehicle present location) . The

IS receiver means and IS responder means are independently selected to be a cellular phone receiver, a paging signal receiver, a WAN/LAN workstation, or an Earth-satellite-Earth radiowave link, such as ORBCOMM.SM.. Optionally, the LDS receiver/processor is kept in a "sleeper" mode, to conserve power until the IS receiver receives and responds to the specified IS, or is periodically activated to update the LDS antenna present location. Presence of the LDS equipment, IS receiver means and/or IS responder means are concealed on the vehicle. In another embodiment, a trigger event sensor is positioned on the vehicle and the responder means is caused to transmit to the vehicle present location information when a vehicle trigger event occurs, such as unauthorized movement of or entry into the vehicle, or collision of the vehicle. [A3006]

"Radar switching system"

An improved switching system for controlling a radar control unit includes a radar hold switch and lock release switch on a remote control. Depression of the hold switch places the radar in a hold or standby mode. Upon depression and holding of the lock switch tracking of the target vehicle occurs. Upon release of the lock switch the displayed vehicle speed will be locked on the lock window of the radar with the radar unit being placed in a standby mode. A subsequent depression and release of the lock/release switch clears the locked target speed and maintains the unit in a standby mode. Underlying logic utilized by the signal processor analyzes signals corresponding to the positions of the hold and lock switches so as to direct the radar into the appropriate mode. [A3007]

"Method and assembly for object detection by a vehicle"

An object detection assembly and method use at least one sensor to detect a signal indicating the presence and location of an object relative to an automotive vehicle. A receiver receives a location signal created by a transmitter. A control unit receives the location signal and identifies the presence and degree of closeness of the object by activating audible and visual indicators. The control unit operates a parameter definer to identify the spatial parameters within which a warning of the existence of the object is to be activated. The control unit receives signals of vehicle speed and transmission state to determine the spatial parameters. [A3008]

"Vehicle longitudinal spacing controller"

A frontmost vehicle and a plurality of following vehicles are driven together in a line as a group. A virtual cell is set for each vehicle, allowing a predetermined distance in front of and behind the vehicle, and a virtual cell front end position of the frontmost vehicle is indicated from outside. A value obtained by adding the length of the virtual cell to the virtual cell front end position is transmitted to the following vehicle as the virtual cell front end position of the following vehicle. A relative position in the virtual cell of each vehicle is detected, and by controlling this relative position to a preset target position, the inter-vehicle distance is reduced and the generation of dilatational waves between the vehicles is prevented. [A3009]

"Method of manufacturing an enclosed transceiver"

The present invention teaches a method of manufacturing an enclosed transceiver, such as a radio frequency identification ("RFID") tag. Structurally, in one embodiment, the tag comprises an integrated circuit (IC) chip, and an RF antenna mounted on a thin film substrate powered by a thin film battery. A variety of antenna geometries are compatible with the above tag construction. These include monopole antennas, dipole antennas, dual dipole antennas, a combination of dipole and loop antennas. Further, in another embodiment, the antennas are positioned either within the plane of the thin film battery or superjacent to the thin film battery. [A3010]

"Managing assets with active electronic tags"

An object in a storage area or moving vehicle is monitored by attaching an electronic tag to the object. An electronic device detects the presence of the object by communicating with the tag while the object is in storage or is being moved by the vehicle. The tags may also determine the location of an attached object and may reroute the object if it deviates from a given shipping schedule. A group of objects is monitored by two electronic tags, each attached to an object in the group. Each tag has circuitry for communicating information relating to an object in the group to a second tag. Each tag also includes a memory connected to the circuitry that is capable of storing the information, and a controller connected to the memory and the circuitry. [A3011]

"Short range micro-power impulse radar with high resolution swept range gate with damped transmit and receive cavities"

A radar range finder and hidden object locator is based on ultra-wide band radar with a high resolution swept range gate. The device generates an equivalent time amplitude scan with atypical range of 4 inches to 20 feet, and an analog range resolution as limited by a jitter of on the order of 0.01 inches. A differential sampling receiver is employed to effectively eliminate ringing and other aberrations induced in the receiver by the near proximity of the transmit antenna, so a background subtraction is not needed, simplifying the circuitry while improving performance. Uses of the invention include a replacement of ultrasound devices for fluid level sensing, automotive radar, such as cruise control and parking assistance, hidden object location, such as stud and rebar finding. Also, this technology can be used when positioned over a highway lane to collect vehicle count and speed data for traffic control. Techniques are used to reduce clutter in the receive signal, such as decoupling the receive and transmit cavities by placing a space between them, using conductive or radiative damping elements on the cavities, and using terminating plates on the sides of the openings. [A3012]

"Arrangement for detecting objects in a region to be monitored"

A transmitter/receiver unit and a reflector unit are installed at opposite ends of a region to be monitored. The reflector unit consists of a receiving antenna whose signal is sent to a surface wave transit time element via a Wilkinson divider or a circulator. The signal returned from the latter is sent by the Wilkinson divider or the circulator to an amplifier that supplies a transmitting antenna, which in turn sends the signal back to the transmitter/receiver unit. Objects in the field of the beam cause a change in amplitude of the reflected signal, so the object can be detected with the help of an analyzer unit, namely an amplitude discriminator in the simplest case. The signals may be pulsed radar signals. It is advantageous, however, to use frequency-modulated signals corresponding to FMCW radar, so the frequency difference between the transmitted and reflected signal can also be used as a criterion for objects present in the monitored region in addition to using the amplitude of the reflected signal. The present invention can be used for monitoring railroad crossings. [A3013]

"Lightning locating system"

A lightning detection system for detecting and locating an initial discharge of an initial leader stroke of a lightning flash. An initial lightning discharge produces a pulse that can be used to accurately detect lightning, and more particularly, the location of the initial lightning discharge. In one embodiment, at least three sensors detect and determine the location of the first pulses from initial lightning discharges using time difference of arrival information of the pulses at each of the three sensors. In another embodiment, a single sensor is used to determine the range of an initial lightning discharge from the amplitude of a corresponding initial detected pulse, and to determine its direction from a crossed loop antenna. An alternative embodiment of a single sensor system determines a distance of a lightning event from a peak amplitude value derived from a pulse amplitude distribution. In a further embodiment, a lightning detection system provides enhanced lightning location by incorporating weather data from a weather radar with detected lightning information. [A3014]

"Auto-cruise system for vehicle"

In an auto-cruise system for a vehicle, when a distance detected by a distance detecting device becomes shorter than a reference distance based on a value detected by a vehicle speed detecting device, a speed reducing command signal is output from a distance regulating device. A travel speed control device is capable of being switched over among a cruise speed control mode for controlling the vehicle speed such that a vehicle speed is equalized to a vehicle speed set by a speed setting device upon non-outputting of a speed reducing command signal, a speed reducing control mode for reducing the vehicle speed upon outputting of the speed reducing command signal, and a speed increasing control mode for increasing the vehicle speed until it is restored to the set vehicle speed in response to the disappearing of the speed reducing command signal. In the speed increasing control mode of the travel speed control device, the acceleration until the restoration of the vehicle speed to the set vehicle speed is set such that it is lowered as the turning state detected by a turning state detecting device is enlarged. Thus, the restoration to the set vehicle speed after speed-reduction can be smoothed to ensure that a driver does not feel a discomfort or a sense of incompatibility. [A3015]

"Method and probe arrangement for the electromagnetic detection of metal objects"

The invention relates to a method and to a probe arrangement for the electromagnetic detection of metal objects. for this purpose several receiving loops are provided, which detect a secondary signal emitted by the sought object. The secondary signals received with the different loops are interconnected and evaluated in object-specific manner. This gives precise information on the position and location of the object to be detected. [A3016]

"Computerised radar process for measuring distances and relative speeds between a vehicle and obstacles located in front of it"

A vehicle radar emits four groups of single-frequency stepped radar pulses. In group A, the frequency of each pulse is a fixed amount higher than that of the preceding pulse. In group B, the frequency of each pulse is a fixed amount lower than that of the preceding pulse. In group C, the frequency of each pulse is the same as that of the preceding pulse. In group D, the frequency of each pulse depends on a modulo algorithm. The signals reflected from other vehicles may readily be processed with inexpensive equipment to discriminate among such other vehicles, and to determine the distance to, and relative speed of, each such vehicle. [A3017]

"traffic surveillance process and device"

A traffic surveillance system measures a speed of a vehicle within a traffic scene, optically records the traffic scene, and reproduces the traffic scene on a display in synchronism with a display of the measured speed. The system includes a speed sensor which measures the speed of the vehicle within the traffic scene and an electro-optical camera having a recording medium in which video signals representing the traffic scene are stored. The camera is equipped with an audio input and output connected to a soundtrack of the recording medium. The audio input receives modulated signals of the measured speed for storage in the soundtrack in synchronism with the video signals. The measured speed signals and the video signals are combined in a video mixer and reproduced on the display. [A3018]

"Compact vehicle based rear and side obstacle detection system including multiple antennae"

A rear and side object detection system for a vehicle based on monolithic millimeter wave integrated circuit technology. A multiple antenna configuration is employed that defines six sensing regions to the right, left and the rear of the vehicle. A sixth sensing region is defined at the right side of the vehicle, a second sensing region is defined at the right side and rear of the vehicle and overlaps the sixth sensing region, a fourth sensing region and a first sensing region extend from the rear on both sides of the vehicle in the adjacent lanes, a third sensing region is defined at the left side of the vehicle and a fifth sensing region is defined at the left side and rear of the vehicle and overlaps the second and third sensing regions. A right side warning signal is issued if an object is detected in a right side detection zone defined by the sixth sensing region or a portion of the second sensing region that does not overlap the fourth or fifth sensing regions. Likewise, a left side warning signal is issued if an object is detected in a left side detection zone defined by the third region and a portion of the fifth sensing region that does not overlap the second or first sensing regions. A back-up warning signal is issued if an object is detected in an overlap region between the second and fifth sensing regions. [A3019]

"Geophysical prospecting apparatus utilizing pulsed electromagnetic signals and having a scanned four-cycle transmitter"

Apparatus for use in a geophysical prospecting method from a vehicle for site plan pictorial representation of inclusions present in substratum soil which reflect modulated electromagnetic oscillations. This apparatus is particularly useful for detecting inclusions such as veins of water, ore beds, pipelines, unexploded bombs, cavities, ammunition and residual fissures. A transmitter and receiver are mounted in the vehicle with a common quartz oscillator in a sawtooth generator. A transmitting antenna and receiving antenna are provided with an amplifier connected to the latter. A pulse shaper employs the width of received triangular pulses from the amplifier to give needle pulses and a color transmitter has four power amplifiers and is a goniometrically scanned four-cycle transmitter, and accordingly the cathode ray tube has four crosswise arranged horizontal sweep coils in addition to the frame coil. The frequency of the frame sweep and scanning signals is 50 Hz and these signals are stabilized using a synchronizing signal obtained from the quartz crystal/oscillator circuit. The crystal frequency typically is 50 kH and the synchronization signals are obtained by a frequency divider network having a ratio of 1000: 1. [A3020]

"Phase difference measuring apparatus and method using a first and second receive signal"

A phase difference measuring apparatus obtains a first receive signal by transmitting and receiving a to-be-measured material in a reference state and a second receive signal by transmitting and receiving a signal wave to and from that material in a measured state. The apparatus finds a reference phase difference .theta..sub.1 from the transmit wave and first receive signal and an apparent phase difference .theta..sub.2 ' from the transmit wave and second receive signal. The apparatus adds the apparent phase difference .theta..sub.2 ' to a product of the number of rotations, n, the apparent phase difference .theta..sub.2 ' passes through a given reference point and an angle of 360.degree. to find a true phase difference .theta..sub.2. The apparatus varies the number of rotations, n, to n+1 when the apparent phase difference .theta..sub.2 ', while being increased, passes through the reference point and that number of rotations, n, to n=n-1 when the apparent phase difference .theta..sub.2 ', while being decreased, passes through the reference point. [A3021]

"Body monitoring and imaging apparatus and method"

A non-acoustic pulse-echo radar monitor is employed in the repetitive mode, whereby a large number of reflected pulses are averaged to produce a voltage that modulates an audio oscillator to produce a tone that corresponds to the heart motion. The antenna used in this monitor generally comprises two flat copper foils, thus permitting the antenna to be housed in a substantially flat housing. The monitor converts the detected voltage to an audible signal with both amplitude modulation and Doppler effect. It further uses a dual time constant to reduce the effect of gross sensor-to-surface movement. The monitor detects the movement of one or more internal body parts, such as the heart, lungs, arteries, and vocal chords, and includes a pulse generator for simultaneously inputting a sequence of pulses to a transmit path and a grating path. The pulses transmitted along the transmit path drive Oh impulse, generator and provide corresponding transmit pulses that are applied to a transmit antenna. The gating path includes a range delay generator which generates timed gating pulses. The timed gating pulses cause the receive path to selectively conduct pulses reflected from the body parts and received by a receive antenna. The monitor output potential can be separated into a cardiac output indicative of the physical movement of the heart, and a pulmonary output indicative of the physical movement of the lung. The impulse generator in the transmit path can be replaced with a pulsed RF generator. [A3022]

"Micropower impulse radar based wheel detector"

A wheel detector for indicating the presence of a rail vehicle on a set of spaced rails is disclosed. The wheel detector transmits a radar pulse signal and samples a portion of the signal corresponding to a target area on one of the rails. The wheel detector will generate an indication signal if a change in the reflectivity of the received signal corresponding to the target area is detected. The wheel detector may additionally include multiple transmitters and receivers to provide redundancy, and be configured to determine the linear velocity and direction of a wheel. [A3023]

"Sensing apparatus using frequency changes"

An apparatus and method for determining various physical quantities such as temperature, pressure, stress, strain, distance and the like in a manner such that a change in the physical quantity of interest results in a measurable change in the frequency of oscillation of a signal generated within the apparatus. [A3024]

"Power steering device"

A power steering device uses a control value set in accordance with a vehicle's detected steering torque to control an actuator, which generates steering assistance power. When the vehicle appears to be on a collision course with an obstacle detected in its steering direction, the control value is modified so as to inhibit the steering. The control value after the modification for the steering inhibition is a function of the control value prior to the modification. When the detected value of the steering torque is greater than the preset value, the function is modified such that the degree of steering inhibition is increased by comparison with a situation in which the detected torque is less than the preset value. [A3025]

"Method and apparatus for cruise control"

A cruise control system arranged to determine whether the closest targeted vehicle ahead of a vehicle being controlled is running in its lane or an adjacent lane and if it is determined that the closest vehicle is running in an adjacent slower lane, allowing the controlled vehicle to overtake the closest vehicle if the way ahead is clear, and if it is determined that the closest vehicle is running in an adjacent faster lane, selecting that closest vehicle as a prime target to control the acceleration of the controlled vehicle unless there is another vehicle running in the same lane as the controlled vehicle which requires deceleration of the controlled vehicle, in which case the vehicle running in the same lane is selected as the prime target. [A3026]

"Apparatus for avoiding crosstalk problems when locating a vehicle travelling along means for propagating electromagnetic waves"

An apparatus for avoiding crosstalk problems when locating a vehicle travelling along an electromagnetic wave propagation path. The apparatus is particularly directed to rail transport. The apparatus includes a transmitter for transmitting electromagnetic waves suitable for propagation along the propagation path. A reflector is included for reflecting the electromagnetic waves which propagate along the propagation path. The apparatus also includes a receiver, a comparator, and a processor. The apparatus is configured so that the transmitter does not transmit electromagnetic waves along the propagation path at the same time that the receiver receives the reflected electromagnetic waves. Because the transmitted waves are not transmitted on the propagation path at the same time as the reflected waves are received, the receiver receives only reflected waves at a time when there is no crosstalk interference between the transmitted and reflected waves. The vehicle's location is determined by comparing the transmitted and reflected waves. [A3027]

"Sensors and methods for sensing displacement using radar"

A sensor for sensing a displacement in a mechanical system using radar utilizes a miniaturized radar transceiver formed, typically, on a silicon chip. The transceiver is mounted to a fixed surface that senses a displacement of a moving surface. The moving surface is typically located in mechanical communication with a system to be sensed. By using appropriate translating circuitry, an accurate determination of the nature of displacement of the mechanical system can be made. Mechanical systems sensed can include rotating and sliding components such as motors, valves and pressure gauges. Sensors according to this invention are highly accurate and reliable. [A3028]

"Signaling means"

A device and method to avoid collisions is described. The device and method is primarily directed to preventing tail-gating by motorists and the avoidance of otherwise resultant collisions. The method and device may also be utilized to detect stationary objects and to alert the driver of a vehicle of an imminent collision. [A3029]

"Autonomous navigation system for a mobile robot or manipulator"

In an autonomous navigation system for a mobile robot or a manipulator which is intended to guide the robot through the workspace to a predetermined target point in spite of incomplete information without colliding with known or unknown obstacles. All operations are performed on the local navigation level in the robot coordinate system. In the course of this, occupied and unoccupied areas of the workspace are appropriately marked and detected obstacles are covered by safety zones. An intermediate target point is defined in an unoccupied area of the workspace and a virtual harmonic potential field is calculated, whose gradient is followed by the robot. Mobile robots with such an autonomous navigation system can be used as automated transport, cleaning and service systems. [A3030]

"Short range, ultra-wideband radar with high resolution swept range gate"

A radar range finder and hidden object locator is based on ultra-wide band radar with a high resolution swept range gate. The device generates an equivalent time amplitude scan with a typical range of 4 inches to 20 feet, and an analog range resolution as limited by a jitter of on the order of 0.01 inches. A differential sampling receiver is employed to effectively eliminate ringing and other aberrations induced in the receiver by the near proximity of the transmit antenna, so a background subtraction is not needed, simplifying the circuitry while improving performance. Uses of the invention include a replacement of ultrasound devices for fluid level sensing, automotive radar, such as cruise control and parking assistance, hidden object location, such as stud and rebar finding. Also, this technology can be used when positioned over a highway lane to collect vehicle count and speed data for traffic control. [A3031]

"Hybrid ultrasonic and radar based backup aid"

A backup aid system, for a vehicle, senses when the vehicle is in reverse gear. Ultrasonic sensors at the rear of the vehicle provide continuous range information to a control module for objects that are detected as being relatively close to the vehicle. A radar system provides range information to the control module for objects detected beyond the range of the ultrasonic system. At low speeds below a predetermined minimum speed level or when the system is placed in the "park" mode for parking, the radar information is ignored and only the ultrasonic information is used to warn the vehicle operator. At a relatively high threshold backup speed, the vehicle operator is immediately warned to slow down, whether or not an object is detected in the vehicle path. Between the lower and upper threshold speeds, both the ultrasonic system and the radar system are used to continuously range and detect any objects that enter their respective detection fields. The control module causes an alarm device to warn the driver as to how close the vehicle is to the closest object. [A3032]

"Obstacle warning system for a vehicle"

An obstacle warning system for a vehicle includes a distance measuring device for emitting a transmission wave or laser light in a given angular range in a direction of a width of the vehicle in a scanning manner, and for detecting a distance between the vehicle and an obstacle in correspondence with a scan angle on the basis of a reflected wave or reflected light from the obstacle. A relative position calculating device calculates a relative position of the obstacle with respect to the vehicle on the basis of the distance detected by the distance measuring device and a corresponding scan angle. A radius calculating device calculates a radius of an estimated relative curved path of the vehicle with respect to the obstacle on the basis of relative positions of at least two points of the obstacle which are calculated by the relative position calculating device. A warning area setting device sets a given warning area on the basis of the width of the vehicle and the radius calculated by the radius calculating device. A warning device executes a given warning process if the obstacle remains in the warning area for a given period of time. [A3033]

"Method and apparatus for controller power train of motor vehicle"

The vehicle power train control method and apparatus according to the invention secures both operability and safety by controlling an actual acceleration/deceleration to a target acceleration/deceleration requested by a driver under safe traveling condition, and changing the target acceleration/deceleration so as to take precedence for safe traveling if the driver encounters a dangerous traveling condition. According to the invention, acceleration/deceleration and speed of a motor vehicle are detected, a target acceleration/deceleration is determined, and a road condition such as a road gradient or presence or absence of a forward motor vehicle is detected to decide whether the road condition is dangerous. The target acceleration is changed if the condition is decided to be dangerous. [A3034]

"Electronic parking and dispatching management method and apparatus"

Method and apparatus for the automatic management of vehicle access to a restricted access area. The system includes at least one base transceiver positioned at least at one location providing an entrance to and an exit from said restricted access area. The system also includes a plurality of vehicle borne transponders, and an independent management computer. As vehicles attempt to access the restricted area, the base transceiver, the vehicle transponders, and the independent management computer communicate to monitor and regulate the vehicle access. According to one embodiment, the invention automatically manages access to a commercial parking facility. In another embodiment, the invention automatically dispatches taxicabs from a corral area. In a further embodiment, the invention controls vehicle access to facilities such as gated communities, and employee and student parking areas. [A3035]

"Method and apparatus for measuring the speed of a moving body"

To measure the speed of a body (1) moving relative to the ground (2) by means of a broad-band Doppler radar (3) fixed to the moving body, two incident radar waves are transmitted successively towards the ground at instants that are close together, and the corresponding reflected waves are picked up, the frequency of at least the first incident wave being time-varying, the signals representative of the first incident and reflected waves are multiplied together, a spectrum is determined for the low frequency component of the product of said two signals, the same operations are performed for second incident and reflected waves, then two peaks that correspond with a certain amount of frequency shift in the two spectra are identified, and the speed of the moving body is determined as a function of the frequencies of these two singular points and as a function of the height of the radar relative to the ground. [A3036]

"FMCW radar system for detecting distance, relative velocity and azimuth of a target obstacle"

Beat signals of respective receiver channels CH1 and CH2, produced by mixing their receiving signals with a transmission signal, are subjected to Fourier transformation to detect the frequency and phase of peak frequency components in both an ascending-section where the frequency of the transmission increases and a descending-section where the frequency of the transmission decreases. Based on peak frequency components derived from the same target, phase differences .DELTA..phi.u (i) and .DELTA..phi.d (j) between receiver channels CH1 and CH2 in the ascending- and descending-sections (steps 210-230) . Relative relationship between the transmission signal and the receiving signal is judged based on the signs of the phase differences. Respective peak frequencies fu (i) and fd (j) , detected as absolute values of frequency differences between the transmission signal and the receiving signal, are given sings in accordance with the judgement result. Then, the distance D and relative velocity V of the target are calculated (steps 240-260) . [A3037]

"Obstacle warning system for a vehicle"

As provided here, an obstacle warning system for a vehicle is capable of issuing an alarm accurately according to the curved state of a road. When the road is curved, the system sets the correction time counter on the basis of the following conditions: whether or not the curvature radius of the curved road is small, whether or not a guardrail is detected immediately ahead of the vehicle, whether or not an erroneously-recognized object, such as a set of guardrail reflectors exhibiting large relative acceleration is immediately ahead of the vehicle, and whether or not the number of obstacles recognized reaches a value indicating that the vehicle is approaching a curved section of the road. When a stationary object enters the field of view indicating that there is a possibility of a collision, the obstacle warning system corrects the warning distance in response to the value of the correction time counter, thus making it possible to avoid a false alarm during cornering. [A3038]

"Apparatus and method for cruise control"

An AICC cruise control system which operates in accordance with a driver's headway request given in terms of a desired time interval between the controlled vehicle and the preceding (target) vehicle, wherein, upon slowing of the target vehicle towards zero velocity, the calculated station of the controlled vehicle behind the target is changed from being a pure time-based interval into a time interval which is calculated to include a proportion of a desired residual range at standstill, the proportion being dependent upon the velocity of the controlled vehicle. [A3039]

"Spread spectrum localizers"

A network of localizers determines relative locations in three-dimensional space to within 1 cm by cooperatively measuring propagation times of pseudorandom sequences of electromagnetic impulses. Ranging transmissions may include encoded digital information to increase accuracy. The propagation time is determined from a correlator circuit which provides an analog pseudo-autocorrelation function sampled at discrete time bins. The correlator has a number of integrators, each integrator providing a signal proportional to the time integral of the product of the expected pulse sequence delayed by one of the discrete time bins, and the non-delayed received antenna signal. With the impulses organized as doublets the sampled correlator output can vary considerably in shape depending on where the autocorrelation function peak falls in relation to the nearest bin. Using pattern recognition the time of arrival of the received signal can be determined to within a time much smaller than the separation between bins. Because operation of standard CMOS circuitry generates noise over a large frequency range, only low-noise circuitry operates during transmission and reception. To provide the time accuracy necessary for distancing, a high-frequency clock operates during inter-localizer communications. The high-frequency clock uses a phase-lock loop circuit to increase the clock rate and a programmable delay to provide still finer time graduations. A stage in the low-frequency clock uses low-noise circuitry during transmissions and receptions, and standard circuitry at other times. [A3040]

"Vehicle collision control system"

A vehicle collision control system has a distance measuring sensor, a collision predictive device for outputting a collision predictive signal, a deceleration calculating device for calculating a first limit deceleration allowing the vehicle to run while braking without losing its stability and a second limit deceleration for making the collision speed lower than a survival space ensuring speed, an arithmetic processing device for outputting a braking start signal upon comparing the aforementioned limit decelerations which change according to the running of the vehicle after the collision predictive signal is outputted, a braking command device for commanding a predetermined braking force to a braking device upon receiving the braking start signal, an impact sensor for sensing, and a collision signal generating device for outputting a collision occurrence signal to the logic circuit when the impact sensor senses the collision, so that an ignition signal is outputted to the inflator of the air bag device according to a logical product between the collision predictive signal and collision occurrence signal. [A3041]

"Automatic vehicle seat adjuster"

An automatic seat adjustment system for a motor vehicle having a passenger compartment with a seat in which an occupant sits. The seat has power mechanisms for moving the seat relative to the passenger compartment from an initial position to an adjusted position, and control mechanisms connected to the power mechanisms for controlling the power mechanisms. Generally, the system includes measurement devices for measuring at least one morphological characteristic of the occupant and generating a first signal representative of the magnitude of that morphological characteristic, a processor including computational means for determining an adjusted seat position based on that measured morphological characteristic and which generates a second signal corresponding to the adjusted seat position, a first input device coupled to the measurement devices and to the processor for inputting the first signal into the processor, and a second input device coupled to the processor and the control mechanisms for inputting the second signal into the control mechanisms. In this manner, the control mechanism is able to affects the operation of the power mechanisms to move the seat to the adjusted position. [A3042]

"Radar device with reduced power emission"

A radar device secured to a vehicle includes a transmitter for broadcasting continuously frequency-modulated radar signals over a time range. The time range is fixed as a function of a speed of the vehicle and is longer at a higher speed and shorter at a lower speed. A receiver receives the radar signals. An evaluation circuit compares the transmitted and received radar signals to ascertain information about the surroundings and in particular a distance from and a relative speed with respect to an object. [A3043]

"Radar transponder"

A radar transponder for a stable and reliable response transmission upon reception of a weak radar signal having a reflection-conscious circuitry free from damage by a transmit effect, including a reception damage by the leakage of a powerful transmit wave signal and a transmission damage by the reflection of the powerful transmit wave signal. The reflection-conscious circuitry may include a circulator coupled to the transmit/receive antenna for selecting the powerful transmit wave signal or the weak radar signal, a receiving circuit provided after the circulator for receiving the weak radar signal, and an SPDT switch provided between the circulator and the receiving circuit for passing an input of the weak radar signal to the receiving circuit in a receiving period with its ground function dormant and for leading an input of the powerful transmit wave signal to a ground using the ground function in a transmitting period. The SPDT switch includes a reflectionless terminator at the entry of the input signal, a diode having a ground end at the outlet of the input signal, a quarter-wave line between the entry and the outlet and a drive signal input for driving the ground function. [A3044]

"Synchronous identification of friendly targets"

A synchronous communication targeting system for use in battle. The present invention includes a transceiver having a stabilizing oscillator, a synchronous amplifier and an omnidirectional receiver, all in electrical communication with each other. A remotely located beacon is attached to a blackbody radiation source and has an amplitude modulator in electrical communication with a optical source. The beacon's amplitude modulator is set so that the optical source transmits radiation frequency at approximately the same or lower amplitude than that of the blackbody radiation source to which the beacon is attached. The receiver from the transceiver is adapted to receive frequencies approximately at or below blackbody radiation signals and sends such signals to the synchronous amplifier. The synchronous amplifier then rectifies and amplifies those signals which correspond to the predetermined frequency to therefore identify whether the blackbody radiation source is friendly or not. [A3045]

"Device security system"

An object tracking, communication, and management system for a laptop computer or similar device, wherein a beacon or transceiver in the computer implements file integrity or device recovery steps. The beacon protects data, or transmits files or data from computer storage back to the owner or authorized party, either automatically or in response to a request for data recovery, and may broadcast a signal for tracking and recovery of the computer after a theft. Preferably the system also operates in a normal mode to provide or acquire files or data, to or from a remote location, as either requested by the operator or by a third, calling or transmitting party, or automatically, for normal communications or data upkeep. When activated as a security device it implements strategic machine control including enabling, disabling, or modifying functions of the computer and communication of data. The system includes a beacon with preferably both a transmitter and a receiver, internal security logic, and external system elements for locating the beacon via either RF tracking or the communication of its position coordinates back to the owner via the transmitter. A combination of hardware and/or software within the beacon and the host system initiates and coordinates operation of the aforementioned communications or security features. Tamper detection logic implemented in software or hardware responds to tampering or removal of the beacon or other components by alerting via the transmitter and/or disabling functionality of the host. Preferably low level codes operate at the bios level to assure effective operation even when higher level software or plug-in components have been overridden or removed. [A3046]

"Traveling-path prediction apparatus and method for vehicles"

A vehicle traveling-path prediction apparatus that detects a stationary object in front of the vehicle by utilizing an obstacle detection device instead of a yaw rate sensor, and predicts a traveling path based on the detected stationary object. The apparatus comprises control unit having an obstacle detection device which receives a detection signal from a radar head unit to detect an obstacle in front of the vehicle, stationary object detection device which receives an output signal from the obstacle detection device to detect the obstacle as a stationary object, a first traveling-path prediction device which receives an output signal from the stationary object detection device, and if there is a stationary object in front of the vehicle, calculates a radius of curvature R1 of a first traveling path, based on data indicative of running conditions of the vehicle, a second traveling-path prediction device which calculates a radius of curvature R2 of a second traveling path, based on a velocity V0 and a steering angle .theta.H, and a selection device which receives a detection signal from the radar head unit and if there is no stationary object in front of the vehicle, selects the second traveling path R2 calculated by the second traveling-path prediction device. [A3047]

"Method and apparatus for coherent burst ranging"

A high resolution ranging method is described utilizing a novel modulated waveform, hereafter referred to as coherent burst modulation. In the coherent burst method, high frequency modulation of an acoustic or electromagnetic transmitter, such as a laser, is performed at a modulation frequency. This modulation frequency is transmitted quasi-continuously in the form of interrupted bursts of radiation. Energy from the transmitter is directed onto a target, interacts with the target, and the returning energy is collected. The encoded burst pattern contained in the collected return signal is detected coherently by a receiver that is tuned so as to be principally sensitive to the modulation frequency. The receiver signal is processed to determine target range using both time-of-flight of the burst envelope and phase shift of the high frequency modulation. This approach effectively decouples the maximum unambiguous range and range resolution relationship of earlier methods, thereby allowing high precision ranging to be conducted at arbitrarily long distances using at least one burst of encoded energy. The use of a receiver tuned to the high frequency modulation contained within the coherent burst vastly improves both sensitivity in the detection of the target return signal and rejection of background interferences, such as ambient acoustic or electromagnetic noise. Simultaneous transmission at several energies (or wavelengths) is possible by encoding each energy with a separate modulation frequency or pattern, electronic demodulation at the receiver allows the return pattern for each energy to be monitored independently. Radial velocity of a target can also be determined by monitoring change in phase shift of the return signal as a function of time. [A3048]

"Method and apparatus for precise noncoherent doppler tracking of a spacecraft"

A method and apparatus are disclosed for making precise velocity measurements of a spacecraft using a two-way noncoherent Doppler tracking system. By comparing the received uplink and transmitted downlink frequencies on-board the spacecraft, information is generated that is included in the downlink signal and used to cancel spacecraft oscillator drift rate effects in the two-way Doppler measurement made by the ground station. This data can also be used to characterize the drift rate of the spacecraft oscillator, thus permitting periods of accurate one-way Doppler tracking by the ground station. [A3049]

"Method and apparatus for precisely locating a resonant object"

The method and apparatus precisely identifies and locates an object which resonates in response to signals of at least one and, more typically, two resonant frequencies. The locating apparatus includes a transmitter for concurrently transmitting signals having a resonant frequency and signals having a non-resonant frequency toward the resonant object. The locating apparatus also includes at least two receivers for receiving reflected signals having the resonant frequency and the non-resonant frequency. The locating apparatus further includes a signal processor for locating the resonant object based upon the reflected signals detected by the receivers. The signal processor has multiple channels, one of which is associated with each receiver, for separately processing the reflected signals received over time by each of the receivers. Within each channel, the signal processor significantly reduces signal clutter based upon respective differences between the reflected signals having the resonant frequency and the reflected signals having the non-resonant frequency which were received by the respective receiver. By reducing signal clutter in the received signals, the locating apparatus identifies and locates the resonant object with more precision. [A3050]

"Vehicle accurately detect an object in a lane of the radar equipped vehicle moving in a curve"

A scan-type radar apparatus for a vehicle which determines with a high level of accuracy whether an object detected by the radar exists in the lane in which the radar equipped vehicle is moving while the radar equipped vehicle is moving in a curve. A scan-type radar detects objects existing in a detectable range. A center direction is assumed which indicates a center of each of the objects detected by the scan-type radar with respect to the vehicle based on a distance between the vehicle and each of the objects and a turning radius of the vehicle. A vehicle moving lane area is set within the detectable range. The vehicle moving lane area, which corresponds to a vehicle moving lane in which the vehicle is moving, extends on either side of the center direction with a predetermined angle range. An extent of the vehicle moving lane area is corrected so that an inner area of the vehicle moving lane area is increased when the vehicle is moving along a curve, the inner area being a portion of the vehicle moving lane area located on an inner side of the curve with respect to the center direction. [A3051]

"Fast maximum likelihood processor for means wind velocity estimation"

A real time maximum likelihood estimator (MLE) processor employs a table look-up mechanism to eliminate the MLE computation complexity. The real time MLE processor can be implemented with digital signal processing (DSP) chips in a personal computer. Optimally accurate estimates of mean wind velocity are obtained at all signals and noise ratios (SNR) using fast software algorithms. [A3052]

"Method for position determination"

Method which involves determining the position of a number of measured objects by determining a number of directions to the measured objects from at least two measuring stations, of which at least one is mobile, the method being used to decide which of the points of intersection between the directions correspond to measured objects and which ones do not correspond to measured objects. Changes in the mutual movements between the measuring stations and the points of intersection are in this case determined by comparison between the paths in which the points of intersection and the measuring stations are moving. The points of intersection whose movement is not affected by changes in the movement of other points of intersection, or by changes in the movement of at least one measuring station, correspond to positions of measured objects. [A3053]

"On-board unit for transponder operation"

An on-board unit includes at least one receiving and transmitting antenna for a bidirectional transmission of data which works in accordance with the transponder method. To compensate for interference fading, a high-frequency amplifier is connected in an incoming circuit to the demodulator/modulator, through which the transmission range of the transmission distance is improved as well. The same amplifier and the demodulator/modulator can be used in downlink and uplink operation. In uplink operation, the demodulator/modulator can alternatively subject the carrier signal to amplitude shift keying or phase shift keying. [A3054]

"Radar system and method of operating same"

A proximity fuze radar system is described including a transmitter for transmitting a signal modulated by a pseudo-random noise code signal and a receiver for receiving signals including the modulated signal reflected by an object or target. The proximity fuze radar system further includes delay circuitry for delaying in time the pseudo-random noise code signal for providing a delayed noise code signal and circuitry for correlating a near range portion of the received signals with the delayed noise code signal and for providing base band signals. The proximity fuze radar system still further includes suppression circuitry for correlating a longer range portion of the received signals with the delayed noise code signal and for providing a rejection signal for summing the base band signals with the rejection signal to reduce the signal level of undesired signals. With such an arrangement, a radar system is provided having less susceptibility to undesired signals. [A3055]

"Method of an apparatus for detecting the displacement of a target"

A method of detecting the displacement of a target in a given environment includes storing reference data having data representative of the environment, transmitting a transmit signal towards the target, sensing the return signals from the target and the environment, and detecting the displacement of the target by comparing the return signals and the stored reference data. A method of detecting the level of a sample in a container is also disclosed. Analogous apparatus features are also disclosed. [A3056]

"Radar apparatus for detecting a direction of a center of a target"

A radar apparatus of an automotive vehicle includes a radar unit which radiates an electromagnetic wave to a target in a forward direction of the vehicle and receives reflection beams from the target to detect the target. A scanning control unit performs a beam scanning of the radar unit to the target so that the reflection beams during the beam scanning are received. A center direction determining unit detects a distribution pattern of the received reflection beams with respect to respective scanning angles of the radar unit, performs a similarity approximation of the distribution pattern by using an antenna directional gain pattern of the radar unit to produce an approximated distribution pattern, and determines a direction of a center of the target based on a peak of the approximated distribution pattern. [A3057]

"Collision avoidance system"

A system for preventing collisions between a vehicle and other objects, the vehicle having a blind side, an opposite driver side, a from end and an opposite rear end, has side ranging capability that determines the distance from the blind side of the vehicle to an object in a lane immediately adjacent to the blind side while the vehicle is in the process of moving into a traffic lane immediately adjacent to the blind side. Rear ranging capabilities are employed to determine the distance from the rear side to an object behind the vehicle while the vehicle is in the process of backing up. A calculating capability, responsive to the side ranging capability and the rear ranging capability, determines when an object is in a lane immediately adjacent to the blind side while the vehicle is in the process of moving into the lane immediately adjacent to the blind side and also determines when an object is behind the vehicle while the vehicle is in the process of backing up. An indicating capability, responsive to the calculating means, indicates that an object is in the lane immediately adjacent to the blind side while the while the vehicle is in the process of moving into the lane immediately adjacent to the blind side and indicates that an object is behind the vehicle while the vehicle is in the process of backing up. [A3058]

"Proactive exterior airbag system and its deployment method for a motor vehicle"

A proactive vehicle safety device, a proactive exterior airbag system, is disclosed, which consists of a detection subsystem, a control subsystem and a deployment subsystem. The design of each of the subsystems is provided. The detection method, control method and deployment method of the proactive exterior airbag system are also provided. Two types of exterior airbags are disclosed. [A3059]

"Detection range adjusting system of obstacle detection apparatus for vehicle"

A detection range adjusting system of an obstacle detection apparatus for a vehicle having a transmitting-receiving unit mounted on the vehicle for transmitting a detection signal directed over a predetermined range and receiving a reflection signal of the detection signal is provided. This system comprises a detection range setting means for processing the reflection signal and setting a detection range for detecting an obstacle which is included within the predetermined range and narrower than the predetermined range, a standard reflecting body positioned at a predetermined position relative to the vehicle, a standard position storing means for storing a standard position of the standard reflection body in the detection range beforehand, and an adjustment instructing means for instructing transmission of a detection signal for adjustment of the detection range. Setting of the detection range setting means is changed so that a detected position of the standard reflecting body in the detection range detected based on a reflection signal of the detection signal transmitted according to the instruction of the adjustment instructing means coincides with the standard position stored in the standard position storing means. [A3060]

"FM-CW radar apparatus for measuring relative speed of and distance to an object"

An FM-CW radar which is suitable for automotive anti-collision systems, for example, is provided. This radar outputs a radar signal in the form of a triangular wave whose frequency is increased at a given rate and decreased at a given rate. A receiver receives a wave reflected from a target to produce a beat signal and takes the Fourier transform of the beat signal to determine peak frequency components thereof showing peaks in a frequency spectrum. The receiver also determines phases of the peak frequency components and selects at least one from the peak frequency components in a frequency-rising range wherein the frequency of the radar signal is increased and at least one from the peak frequency components in a frequency-falling range wherein the frequency of the radar signal is decreased which show substantially the same phase to pair them for determining the distance to and relative speed of the target based on the frequency of the paired peak frequency components. [A3061]

"Interference canceling receiver"

A receiver used in a system having a transmitter (10) that sends an exciting signal to a remote transponder (18) is configured to receive a relatively weak signal from the transponder and to cancel out relatively high level interference from the transmission itself. A received frequency shift keying signal is fed to a tuned amplifier (22) for preliminary analog signal conditioning, and thence fed to an analog to digital converter (24) . The output of the analog to digital converter is integrated (26) over a selected number of clock pulses and then dumped into a quarter rate quadrature demodulator (60) that multiplies the integrated signal by the same signal delayed by one clock interval. Undesired artifacts generated in the demodulator (60) are removed by a cascade of comb filters (70) , and the demodulated digital output is available as the desired output of the receiver. The several clock signals of the system are all referenced from a basic exciter signal that itself gives rise to the transmitted interference signal so that the interference and all timing signals are approximately synchronous. [A3062]

"Detection of multiple articles"

An identification system comprises an interrogator and a plurality of transponders. The interrogator includes a transmitter which transmits at least two independent interrogation signals to the transponders, and a receiver for receiving response signals from the transponders. The interrogator also includes processor means for identifying the transponders from data in the received response signals. Each transponder comprises receiving means, a code generator, and transmitter means connected to the code generator. On receipt of at least one of the transmitted interrogation signals the transponder transmits a response signal containing data which identifies it. The interrogation signals may be transmitted continuously or intermittently. In a preferred embodiment, the interrogation signals are relatively narrow bandwidth signals at different frequencies. The receiving means of each transponder has a relatively broad reception bandwidth so that the transponder is responsive to one or more of the interrogation signals. [A3063]

"Trenchless underground boring system with boring tool location"

An apparatus and method for locating an underground boring tool using a radar-like probe and detection technique. A boring tool is provided with a device which generates a specific signature signal in response to a probe signal transmitted from above the ground. Cooperative operation between the probe signal transmitter at ground level and a signature signal generator disposed within the boring tool provides for the accurate locating of the boring tool, despite the presence of a large background signal. The signature signal produced by the boring tool may be generated either passively or actively, and in a manner which differs from the probe signal in one or more ways, including timing, frequency content, or polarization. A survey of a boring site, made either prior to or during the boring operation, provides data related to the characteristics of the ground medium subjected to the survey and the identification of underground hazards, such as buried utilities. Knowledge of ground characteristics enables estimates of boring productivity and cost to be made. Accurate surveys of planned boring pathways can be made and compared, either contemporaneously or subsequently, against the accurately measured position of the boring tool during a boring operation. The direction of the boring tool may be adjusted in response to the measured position in order to maintain the boring tool along the planned pathway and at an optimum boring rate. [A3064]

"Radar device for vehicle use"

A radar device for vehicle use which can be manufactured inexpensively while enhancing its monitoring function for an adjacent object as well as a remote object. The radar device includes a radar module for monitoring an adjacent object having a plurality of adjacent object monitoring antennas, a signal transmitting/receiving section for supplying transmitting signals to the adjacent object monitoring antennas and outputting signals by mixing the transmitting signals with received signals supplied from the adjacent monitoring antennas and a delay circuit inserted between the signal transmitting/receiving section and the adjacent object monitoring antennas. The radar device also includes a module for monitoring a remote object having a remote object monitoring antenna and a signal transmitting/receiving section for supplying transmitting signals to the remote object monitoring antenna and generating signals by mixing the transmitting signals with received signals supplied from the remote monitoring antenna. The radar device has a monitoring control section for controlling the operations of both the radar module for monitoring an adjacent object and the radar module for monitoring a remote object and the monitoring control section receives the signals output from the radar modules and detects the range to the object which generates reflected signals based on the beat signals. [A3065]

"Doppler-radar based automatic vehicle-classification system"

A method for automatically categorizing the general variety of motor-vehicle types moving through a given checkpoint, according to their predominant characteristics, basically involving features such as length, height, axle count, existence of a trailer, and specific envelop contour (i.e.--motorcycle, car, truck, bus, limousine, etc.) . Advantageously employing Doppler-based CW-radar for ultimate real-time accuracy, resolving even closely spaced vehicles having differing acceleration/deceleration rates, the system will establish a vehicle's classification during stop-and-go or at speed. Real-time velocity information is read from successively radar targeted vehicles, while combined with real-time information acquired via at least one special electronic profiling-window apparatus employing beam emitters/receptors or lasers in making incremental transverse-slice readings of traversing vehicles. Readings are assembled by data-processor into a longitudinal dot-matrix pattern, and compared to pre-established vehicle profiles, for segregation into particular vehicle-classification types for toll-charge auditing. [A3066]

"Vehicle collision avoidance system"

A collision avoidance system for a vehicle has a vehicle steering sensor for sensing a direction in which the vehicle is being steered, a source of radiation, an articulated reflector for directing radiation from the source in a desired direction, an articulation mechanism for effecting articulation of the articulate reflector, and a close loop control circuit responsive to the vehicle steering sensor for controlling the articulation mechanism so as to cause the articulated reflector to direct radiation in a direction which is generally the same as that direction in which the vehicle is turning. [A3067]

"Method of improving zone of coverage response of automotive radar"

Side detection radar utilized on a host vehicle for covering a blind spot in a vehicle mirror view produces alert commands resulting in signals which have gaps due to poor radar reflectivity of portions of a target. To fill these gaps to produce a steady alert signal when a target vehicle is in radar view and to extend the perceived zone of coverage, a variable sustain time is added to each alert signal which exceeds a threshold value. The sustain time varies as an inverse function of the relative vehicle speed and the threshold value varies as an inverse function of vehicle speed. If the alert signal is shorter than the threshold value, then a minimized hold time can be applied. [A3068]

"Microstrip antenna"

An microstrip antenna for use in a vehicle collision system is described wherein an array of rectangular patch elements are arranged in rows and columns on a substrate. A feed structure is used whereby a high gain highly efficient flat plate antenna is produced. The feed structure includes a pair of main lines to which feed points are connected. A plurality of branch lines connect at right angles to the main lines and extend alongside columns of patch elements. The patch elements are so spaced that they are electrically separated by a whole multiple of the dielectric wavelength. The main lines are connected to the branch lines by coupling traces whose widths are selected to establish a desired power distribution. A plurality of strip transformers are distributed along the main lines and connected to junctions with the branch lines to reduce reflections. [A3069]

"Radar module for radar system on motor vehicle"

A FM radar alarm system for use on a motor vehicle detects a following motor vehicle in an adjacent lane behind the motor vehicle. The FM radar alarm system includes an FM radar module including a near-region monitoring antenna and a far-region monitoring antenna. The near-region monitoring antenna radiates a relatively wide radio-wave beam in a near region positioned behind the motor vehicle and extending over an adjacent lane. The far-region monitoring antenna radiates a relatively narrow radio-wave beam in a far region positioned behind the motor vehicle and extending over the adjacent lane. [A3070]

"Digitally programmable radio modules for transponder systems"

A programmable digital radio is configured to perform transponder functions. A receiver in the programmable digital radio receives analog signals from an interrogator and digitizes the analog signals to produce digital interrogation signals. The digital interrogation signals are processed digitally and valid interrogations are detected. Processing includes detection of pulses, determination of each pulse's threshold, determination of intervals between pulses and whether the intervals meet mode criteria, and determination of priority of output of digital messages encoded in the pulses. At least one message is supplied to a transmit module in the programmable radio. The transmit module performs diversity processing on the received message to determine to which received signal to reply, produces reply data and modulates the reply data to produce intermediate frequency signals. The intermediate frequency signals are then converted to analog signals which are transmitted to the interrogator. [A3071]

"Method and apparatus for adjusting steering feel"

A vehicle steering apparatus (20) includes a steering feel motor (50) . A torque sensor (58) senses steering torque applied by a vehicle driver. A sensor (24) senses a characteristic of a driver and provides a signal indicative thereof. A hazard sensor (44) senses a potential steering hazard. The steering feel motor is controlled in response to the sensed driver characteristic and to any sensed potential steering hazard. Either open-loop or closed-loop control is provided for controlling the feel motor in response to sensed static and dynamic forces. [A3072]

"Excavator data acquisition and control system and process"

A data acquisition system for acquiring geological information from a subsurface includes a geologic imaging system that is used to survey the subsurface of a site or route. A geologic characterization unit may also be employed to enhance the geologic imaging data obtained by the geologic imaging system. The acquired data are processed to provide detailed geologic information for the subsurface. In one embodiment, a memory stores geologic filter data including geologic profile data for numerous types of known geology. A processor, cooperating with the memory and data acquisition unit, uses the geologic filter data to remove content from the acquired geologic imaging data corresponding to known geology, thereby providing for immediate recognition of unknown and suspect subsurface characteristics. In another embodiment, the memory stores excavation difficulty data associated with known types of geology. The processor associates a reflected electromagnetic signal received by the geologic imaging system with the excavation difficulty data to produce estimated excavation difficulty data for the subsurface. The geologic imaging system may include a ground penetrating radar system having a plurality of antennas oriented in an orthogonal relationship to provide three-dimensional imaging of a subsurface. [A3073]

"Broadband CDMA overlay system and method"

A spread-spectrum CDMA communications system for communicating data between a plurality of users to a plurality of spread-spectrum units. The spread-spectrum communications system is located within a same geographical region as occupied by an existing FDMA, proposed TDMA or any other mobile-cellular system. The spread-spectrum CDMA communications system includes a plurality of spread-spectrum-base stations and a plurality of spread-spectrum units. A spread-spectrum-base station has a comb filter for notch filtering predetermined channels of the mobile-cellular system, a device for converting the format of the data into a form for communicating over radio waves, a spread-spectrum modulator for spread-spectrum processing the data, and a transmitter for transmitting the spread-spectrum-processed converted data from the spread-spectrum-base station to a spread-spectrum unit. The spread-spectrum-base station also has an antenna, and spread-spectrum detectors for recovering data communicated from the spread-spectrum units. A spread-spectrum unit has an antenna, and a detector, including a spread-spectrum demodulator, coupled to the antenna for recovering data communicated from the spread-spectrum-base station, and the spread-spectrum unit has a spread-spectrum modulator, a transmitter, and a device for converting the format of the data for communicating over radio waves. [A3074]

"Traffic information system"

Disclosed is a traffic information system high in the ability to collect information. An on-vehicle apparatus is carried on a vehicle, to collect traffic information such as traffic jam information, accident information and weather information. The on-vehicle apparatus comprises a car navigation system, where position information is sensed, and information relating to a traffic jam, an accident and weather are manually entered or are automatically sensed. The on-vehicle apparatus further comprises a laser radar, where the number of vehicles, the speeds of vehicles, and the shapes of vehicles are sensed, and traffic jam information and accident information are created based thereon. Various information collected by the vehicle are transmitted to a center via a repeater. Information processed by the center are transmitted to vehicles again. [A3075]

"Vehicle collision preventing system"

In a vehicle collision preventing system, a possibility of collision of a subject vehicle against an object ahead of the subject vehicle is determined at least based on values measured by a distance measuring unit for measuring longitudinal and lateral distances between the subject vehicle and the object and a value detected by a subject-vehicle speed detecting device, an actuator is operated in accordance with the result of such determination to avoid the collision. A lateral relative distance of the subject vehicle and the object is calculated by a lateral relative distance calculating device based on the values measured in the distance measuring unit. Any of a judge level in the judgment of the collision possibility in a judging device or operation levels of actuators is changed in accordance with the result of the determination in a collision avoidance level determining device based on the lateral relative distance. Thus, the actuators are operated in accordance with a variation in lateral relative distance between the subject vehicle and the object, so that the collision preventing operations of the actuators are more easily accepted by a driver. [A3076]

"Navigational system and method"

A navigational system for determining the relative position of two objects, which comprises projector means for projecting an information field to be at least partially incident on both said objects, receiver means associated with at least one of said objects for detecting the information field incident on said two objects, and means responsive to the receiver means to determine the relative position of said objects. [A3077]

"System and method for determining absolute vehicle height and ground speed"

A system and method for determining absolute vehicle height and ground speed. As disclosed, a millimeter wave radar system for determining selected boundary distances is implemented based upon a generation of a modulated millimeter wave signal which is envelope detected and thereafter phase detected to determine the selected boundary distance on a continuous real-time basis. To similarly determine absolute vehicle speed on a continuous real-time basis, a method is disclosed for use in cooperation with an on-board microcomputer, the height sensing system described above, and a passive speed sensor aperture which is affixed to the chassis and directed toward the ground at some angle theta. In operation, a portion of the RF signal radiated by the height sensor is backscattered toward the passive speed sensor aperture. The Doppler Shift of this signal caused by vehicle motion is determined. Information derived from the height sensor subsystem is then used to correct errors in vehicle speed computation due to vertical chassis motion and road surface aberrations. [A3078]

"Resonant tag and method of manufacturing the same"

A resonant tag has one electrode plate of a capacitor and an electric circuit, which is electrically connected to the capacitor, formed on one surface of the insulating film composing the resonant circuit. On the other surface of the insulating film, the other electrode plate of the capacitor, which is electrically connected to the electric circuit, is formed. Heat pressing is performed on the insulating film existing between the two electrode plates with a predetermined pressure and at a predetermined temperature to shorten a distance between these electrode plates, and a crystal structure of the insulating film is destroyed to form a penetrating hole which penetrates through both the electrode plates. [A3079]

"Cruise controller for vehicles"

A vehicle which can execute both vehicle-speed based auto-cruising control and vehicle-interval distance based auto-cruising control has a single operation knob having a SET switch, a RESUME switch, and a COAST switch. In order to allow the single operation knob to set both a target vehicle speed and a target vehicle-interval distance, when the SET switch is operated during the vehicle-speed based auto-cruising control, a vehicle speed at the time of the operation or at the end of the switch operation is set to be the target vehicle speed, when the SET switch is operated during vehicle-interval distance based auto-cruising control, a vehicle-interval distance at the time of the operation or at the end of the switch operation is set to be the target vehicle-interval distance. [A3080]

"Vehicle-mounted radar system and detection method"

Modulation frequency setting device sets the modulation frequency on the basis of the vehicle speed data from a vehicle speed detector and the detected range data, causing a low frequency oscillator to generate a low frequency signal of the set frequency. A transmitter transmits an electromagnetic wave (e.g., infrared light) which have been modulated with the low frequency signal. A phase comparator detects the phase difference between the low frequency signal and a detector output, and a range operating device produces range data. Relative speed operating unit finds the relative speed based on the range data. In case of a high vehicle speed, the modulation frequency is set low to extend the detection range. If an object in a short distance is detected, the modulation frequency is set high to limit the detection range to a short range, thereby enhancing the range resolution. [A3081]

"Police traffic radar using FFT processing to find fastest target"

A police radar utilizing digital data transmission from the antenna unit to a separately housed counting and display unit. The antenna has a double balanced mixer to suppress even order harmonics. The counting and display unit has a computer programmed to perform digital signal processing on the digital data received from the antenna to improve the quality and accuracy of calculated speeds for patrol speed, strongest target speed and fastest target speed. Fastest target speed can be displayed simultaneously with strongest target speed. Signal processing techniques are used to suppress false signals caused by double and triple bounce, harmonics, intermodulation products, video display terminal interference, etc. [A3082]

"Vehicle location unit"

A Vehicle Location Unit (VLU) device includes in functional relationship an RF receiver, a transmitter, a receive/transmit switch, a microcontroller to control the receiving/transmitting path, a digital Large Scale Integration (LSI) , having a digital signal processing device, a crystal oscillator, and a filtering device for an outcoming signal. [A3083]

"Statistical quality control of wind profiler data"

The quality of wind profiling radar data is evaluated by comparing the probability density function of the power density of sets of returned samples to an exponential function. The standard deviation of individual samples from the exponential function can be evaluated to identify possible sources of contamination of the wind profiler data. [A3084]

"Converter for cruise control system"

A converter for use with a constant speed vehicle cruise control system including a speedometer for generating a self speed signal representative of the self speed of the vehicle and a speed adjustment control responsively coupled to the speedometer for maintaining the self speed of the vehicle at a preset speed. The converter adapts the control system to a constant distance system, and comprises a rangefinder for generating a distance signal corresponding to the distance of the vehicle from a front vehicle, and a distance-dependent speed adjustment device coupled to the rangefinder and to the speedometer for generating a synthetic-speed signal corresponding to the set speed required for maintaining a predetermined distance between the two vehicles. A selector switch allows either the self speed or synthetic-speed signals to be connected to the speedometer of the cruise control system. [A3085]

"Obstacle detecting system for vehicles"

An obstacle detection system for vehicles detects kinetic attributes relative to a vehicle equipped with the system of an object present in a forward path of travel of the vehicle, sets a presumed zone into which the object is expected to have entered at a lapse of a specified period based on the kinetic attributes, and proves an object detected at a lapse of the specified period as the object previously detected if the object of second detection is determined as one having moved into the presumed zone and an obstacle precarious to the vehicle. [A3086]

"Transponder maintenance mode method"

A method and system is provided for communicating permanent or semi-permanent information to a transponder (14) from an interrogator (12) , preferably operated by a toll agency or other authorized entity. This permanent or semi-permanent information is communicated by means of special instructions valid only during a special mode or maintenance mode which is entered by transmitting a special access code to the transponder (14) from the authorized interrogator (12) . The transponder (14) will preferably acknowledge to the authorized interrogator (12) that it is, in fact, operating in the maintenance mode so the interrogator (12) can transmit the special instructions in confidence. [A3087]

"Method and apparatus for constructing an environment map of a self-propelled, mobile unit"

An improved method and apparatus for constructing a cellularly structured environment map of a self-propelled, mobile unit is provided. Examples of such self-propelled, mobile units are household robots, self-propelled vacuum cleaners and industrial transport vehicles. To this end, a higher increment for the occupancy degree of a currently evaluated cell is selected for near objects. Further, the occupancy degree is also incremented dependent on a velocity. As an additional measure given standstill of the unit, all cells of the environment map that are located within the aperture cone of a wavefront that emanates from the sensor of the mobile unit are modified in terms of their occupancy degree values. Additionally, a blind zone in which grid cells of the environment map experience no modification of the occupancy degree is defined around the mobile unit. [A3088]

"Highway vehicle guidance system"

A radar highway motor vehicle guidance apparatus for guiding a land vehicle along a roadway using a forward looking, lateral position sensing, monopulse tracking radar guidance apparatus which transmits radar pulses forward of the vehicle. The pulses are reflected back to the vehicle by a stripe distributed along the roadway. The stripe is a frequency selective surface which generates retro-reflective grating lobes at an operating frequency of the tracking radar. Operating the radar at two frequencies allows the radar to look at regions spaced at two different distances from the front of the vehicle. Highway related information may be encoded in the frequency selective surface by variations in the shape or dimensions of the frequency selective stripe morphology in order to modulate the reflected signal with highway information which is then also detected at the radar receiver. Target discrimination is enhanced by using pseudo random codes and matching antenna polarization with stripe polarization. [A3089]

"Position-finding apparatus for locating a vehicle travelling along means for propagating electromagnetic waves"

The present invention relates to apparatus for locating a vehicle V travelling along propagation means P. An object of the apparatus of the invention is to determine the position of the vehicle V, i.e. to determine the distance D between the vehicle V and a given point along the propagation means P. Application in particular to rail transport. [A3090]

"Collision avoidance detector"

A collision avoidance detector including a transceiver installed in a rear portion of a leading vehicle operative to transmit a signal to and receive a reflected signal from a trailing vehicle, a processor operative to process the signals and derive therefrom information concerning a safe distance criterion between the leading and trailing vehicles and an alarm device, wherein the processor actuates the alarm device if the safe distance criterion is not met. [A3091]

"Measuring apparatus for detecting distance between vehicles and related warning system"

A measuring apparatus for measuring an actual distance between vehicles and comparing the measured distance with a reference distance. The reference distance (SL) is obtained on the basis of: a personal space (VR.multidot.TIMEK) being an uneasy distance peculiar to a driver and obtained in accordance with the own vehicle speed, a free running distance (VRR.multidot.TIMEN) corresponding to a response time of a driver's braking operation and a relative speed between two vehicles, a braking distance (VRR.sup.2 / (2.multidot.GR)) corresponding to a depressing strength of a braking pedal in the driver's braking operation and the relative speed, and an acceleration change distance (.alpha.G.multidot.GA) corresponding to a relative acceleration between the two vehicles, using the following equation: where VR represents the own vehicle speed, TIMEK represents an uneasy factor, VRR represents the relative speed, TIMEN represents a response factor of the driver's braking operation, GR represents a braking deceleration factor, .alpha.G represents a preceding vehicle acceleration, and GA represents a preceding vehicle deceleration factor. [A3092]

"Method for localization of beacons for an autonomous device"

The present invention provides an improved method for determining a coarse direction in an orientation system of a an autonomous device (10) , for instance a dust cleaning robot together with a system of active beacons or transponders. A transmitter (20) for transmitting sensing signals is displaced in relation to the rotational center (25) of the the device (10) . When the device is rotated around a vertical rotational axis in the rotational center, a minimum in the distance to the respective transponder or beacon is obtained when the transmitter of the device is positioned immediate to a point lying on a straight line between the rotational center of the device and a respective transponder, whereby an immediate coarse determination of the direction to each transponder is directly obtained. From such an immediate direction determination direct better starting values are obtained for a position calculation by means of for example Kalman filtering, by which successively from the signals obtained by these transponder responses an orientation basis is achieved for the area where the device should be acting. [A3093]

"Pulse homodyne field disturbance sensor"

A field disturbance sensor operates with relatively low power, provides an adjustable operating range, is not hypersensitive at close range, allows co-location of multiple sensors, and is inexpensive to manufacture. The sensor includes a transmitter that transmits a sequence of transmitted bursts of electromagnetic energy. The transmitter frequency is modulated at an intermediate frequency. The sequence of bursts has a burst repetition rate, and each burst has a burst width and comprises a number of cycles at a transmitter frequency. The sensor includes a receiver which receives electromagnetic energy at the transmitter frequency, and includes a mixer which mixes a transmitted burst with reflections of the same transmitted burst to produce an intermediate frequency signal. Circuitry, responsive to the intermediate frequency signal indicates disturbances in the sensor field. Because the mixer mixes the transmitted burst with reflections of the transmitted burst, the burst width defines the sensor range. The burst repetition rate is randomly or pseudo-randomly modulated so that bursts in the sequence of bursts have a phase which varies. A second range-defining mode transmits two radio frequency bursts, where the time spacing between the bursts defines the maximum range divided by two. [A3094]

"Electromagnetic detection system for parking operation"

A system which provides an alarm indicative of a presence of an obstacle in a vicinity of a vehicle. The system operates by electromagnetic detection, and generates an oscillating radiofrequency signal. A transmitter transmits the generated oscillated radiofrequency signal to create, all around the transmitter, an electromagnetic radiofrequency near field. A receiver receives the electromagnetic radiofrequency near field. A detector is connected to the receiver and detects a perturbation resulting in a reduction of an oscillation amplitude of the electromagnetic radiofrequency near field, and an indicator indicates the detected perturbation of the received electromagnetic radiofrequency near field. Based on this operation, an obstacle in a vicinity of the vehicle can be detected. [A3095]

"Vehicle signal apparatus"

Apparatus provides a signal to an operator of a following vehicle when it is necessary to take appropriate action to avoid coming within a predetermined distance of a lead vehicle proceeding in the same direction. From initial predicted forward velocities and distances of the lead and following vehicles, the signal apparatus (1) derives subsequent predicted velocities and positions of the lead and following vehicles and a subsequent predicted distance D (t) between the lead vehicle and the following vehicle after a projected short time interval while assuming a predetermined braking action of the following vehicle (2) , derives and compares the subsequent predicted distance D (t) between the lead vehicle and the following vehicle with a least distance D.sub.LEAST, and (3) sets the least distance D.sub.LEAST equal to the subsequent predicted distance D (t) between the lead vehicle and the following vehicle if the latter is smaller. The signal apparatus iteratively applies the calculating means, beginning with forward velocities and positions derived from sensor signals as the initial predicted forward velocities and distances in the first iteration and generates a signal if and when the least distance becomes smaller than a minimum allowable distance D.sub.MIN. [A3096]

"Collision judging system for vehicle"

A collision judging system for a vehicle includes a sensor for detecting a relative speed between a subject vehicle and an object, and a judging section for judging a possibility of collision of the subject vehicle with the object based on the relative speed. In the collision judging system, when an output from the differentiating device exceeds a preset value, a signal indicative of a command to prohibit the judgment of the possibility of collision in the judging section is outputted from the prohibiting-signal outputting device, thereby avoiding the unnecessary judgment of the possibility of collision in the judging section. [A3097]

"Vehicle run safety apparatus"

When information of an obstacle is not outputted from a radar device, a presumption device presumes at least a present value of a distance between a vehicle and the obstacle based on information in a memory part obtained until the time, and a contact-possibility judgment device judges a possibility of contact of the vehicle with the obstacle based on the information from the presumption device. A detection device is provided for detecting conditions at the time when the information of the obstacle is not outputted from the radar device, for example, a relation of relative position of the obstacle to the vehicle. Further, a restriction device is provided for restricting the presumption by the presumption device according to the relation of relative position. Thus, a possibility of contact of the vehicle with the obstacle running forward of the vehicle is appropriately judged and mis-operations of an alarm, an automatic braking and the like are prevented, while ensuring running safety. [A3098]

"Mine detecting device having a housing containing metal detector coils and an antenna"

A device detects metallic and non-metallic objects on, flush with, or covered by the ground or other surfaces, or by interfering or obscuring structures or surfaces, using ground penetrating radar, a metal detector and a radiometer. It is specifically designed for detection of non-metallic mines. The coils of the metal detector are mounted in a multi-sensor module with the radar antenna in a co-boresighted and/or co-located arrangement, without degrading the performance of the metal detector or the ground penetrating radar. Preferably, the ground penetrating radar uses a feed and a collimation lens, (such as a Luneberg or Step Dielectric lens) , as an antenna to reduce the change in the loss of signal strength due to changes in distance between the surface and the antenna, (for short distances) . The collimated beam has approximately constant power for distances closer than twice the diameter of the lens. By using the lens with a ground penetrating radar, the antenna can be held somewhat farther from the ground, as well as eliminating "clutter" introduced as the antenna moves closer and farther from the ground. The sensor for the radiometer is co-located in the multi-sensor module. The sensors selected for the multi-sensor module employ different detection phenomena. Therefore, each sensor has its unique source for false alarms. The sensors' independent phenomenologies provide a synergism, which when processed, achieve an increase in probability of detection concurrent with a reduction in the false alarm rate for mines. [A3099]

"Method for producing a cellularly structured environment map of a self-propelled, mobile unit that orients itself in the environment at least with the assistance of sensors based on wave refection"

The method produces an improved cellularly structured environment map of a self-propelled mobile unit which orients itself using sensors based on wave reflection. In detail, the following measures are implemented. First, an error of discrete representation in the positional determination of the self-propelled mobile unit is avoided in that the position of the self-propelled mobile unit within an originating cell of the coordinate system of the environment map is also used for identifying the location of obstacles. Further, a smaller cell size is employed in the proximity of the self-propelled mobile unit in order to facilitate maneuvering between obstacles located close to one another. Further, two separate grid maps are maintained, one containing the unit with a rotational orientation and the other being rotated by a rotational angle relative to the global environment map for a fast occupation of a plurality of cells with values. Examples of such self-propelled mobile units are household robots, self-propelled vacuums and industrial transport vehicles. [A3100]

"Radar apparatus for detecting a distance/velocity"

A radar apparatus for detecting a distance/velocity has a transmitting system for transmitting a signal which is frequency-modulated with a modulating signal having a predetermined recurrence frequency, a receiving system for receiving a reflected wave signal, which is the modulated transmission signal transmitted from the transmitting system and reflected by an object, and which mixes the reflected wave signal and the modulated transmission signal from the transmitting system so as to detect a beat wave signal of the reflected wave signal and the modulated transmission signal. The apparatus also includes a high-pass filter for filtering the beat wave signal detected in the receiving system so as to cut off modulation frequency components of the modulated transmission signal with orders that are equal to or lower than a predetermined order, and a distance/velocity calculating unit which calculates the distance to and the relative velocity with respect to the object based on frequency information in the beat wave signal which has been passed through the high-pass filter. Accordingly, the radar apparatus effectively removes FM/AM conversion (reconversion) noise in a simple structure thereby to accurately detect the distance to and the relative velocity with respect to the object even with low transmitting power. [A3101]

"Inter-vehicle distance measuring apparatus and method for automotive"

An inter-vehicle distance measuring apparatus is composed of an inter-vehicle data measuring and transmitting unit for measuring and transmitting inter-vehicle distance data related to the distance between a vehicle in front and a host vehicle, a communications unit installed by a road for receiving the inter-vehicle distance data transmitted from the inter-vehicle data measuring and transmitting unit, an inter-vehicle distance measuring unit for measuring the distance between the vehicle in front and the host vehicle, a correction amount determining unit for calculating a correction amount for correcting the distance between the vehicle in front and the host vehicle measured by the measuring unit based on the inter-vehicle distance data received by the communications unit, and a correcting unit for correcting the distance between the vehicle in front and the host vehicle measured by the inter-vehicle distance measuring unit based on the correction amount. [A3102]

"Durable, lightweight, radar lens antenna"

A radar lens 14 is made from a conventional Fresnel lens 10, but replaces the conventional curved surface 32 with a stepped approximation thereto 22, 24, 26, preferably of three steps. The thickness of the stepped lens 14, at each step, is a half-wavelength or a multiple half-wavelength of the radar operating frequency in the medium of the lens 14. The half-wavelength or multiple half-wavelength separation of the steps 22, 24, 26 causes reflections from the front 16 and rear 18 surfaces to cancel, thereby minimizing the (undesirable) standing wave between the lens 14 and the feed horn or feed horns 46, 48, 50. This avoids the necessity of reducing the standing wave by presenting the curved or stepped side 18 forward. The planar side 16 of the lens 14 (unlike the stepped side 18) doesn't need to be protected from road debris. The lens 14 can therefore be molded as an integral unit of a radome, desirable in the automotive setting. This lens 14 is also thin enough (and, therefore, light enough) that it can be moved side-to-side very rapidly, preferably by a combination of cams 42, 52 and springs 44, 54. This allows a very fast scan, albeit over a limited field of view. Gimballing 56 the lens 14 and feed horns 46, 48, 50 together provides a slower scan, but gives an unlimited field of regard. Combining the two gives a fast scan and unlimited field of regard, desirable in the missile setting. [A3103]

"Police radar jammer"

A method to confuse a police radar by moving a multiplicity of radar reflector antennas in the field of view of the radar. The moving radar reflector antennas present continuously changing doppler velocities to the police radar. The radar reflectors can be any of several reflective antennas such as dipoles, Yagies, horns, etc. The continuously changing doppler velocities are generated by mounting the radar reflector antennas on a moving disk. The moving disk is driven by an electric motor or by the wind. The radar reflector antennas can also be mounted on the rim or in the tread of a vehicle's tires. [A3104]

"Apparatus for automatic refueling of vehicles"

Apparatus for the automatic fuelling of vehicles. A robot head that carries a fuel filler tube is movable to enable it to be brought into position to engage with a vehicle fuel-tank pipe. The robot head carries an opening device for opening a fuel-tank cover plate of a vehicle. The positioning of the robot head is effected by a positioning system that includes a transceiver unit carried by the robot head and that preferably operates at microwave frequency. A passive transponder is carried by the vehicle and includes a simple code which the transponder is intended to modulate on a signal transmitted by the transceiver and is reflected by the transponder. The signal received by the transceiver from the transponder is decoded and is used to access a robot head movement plan that corresponds with that code, to automatically steer the robot head to the fuel tank pipe and thereby enable the vehicle to be fuelled. [A3105]

"Radar apparatus of automotive vehicle for producing accurate beam axis correction value"

A radar apparatus of an automotive vehicle includes a radar unit which outputs signals at intervals of a predetermined time, each signal indicating data of a position of a target at an output time. A position detecting unit detects data of the position of the target from the signals output by the radar unit when the vehicle operates in a straight line path. A correction value determining unit generates a set of errors of a beam emission axis to the straight line path with respect to a horizontal direction so that an average of the errors with respect to each of the signals is determined from the data detected by the position detecting unit. The correction value determining unit determines a correction value by taking an average of the averages of the errors with respect to all the signals. [A3106]

"Transmit power control for automotive radar system"

A radar system for detecting hazardous objects has a transceiver including a transmitting antenna for transmitting microwave power. for a side detection system, power transmission is available when the vehicle is moving forward. A signal processor receives a pulsed vehicle speed signal and a reverse signal and is programmed to terminate transmission when no speed pulse is received for a preset time or when the reverse signal is present. The transmission is terminated by removing power from the transceiver or by rerouting the microwave power from the antenna to an internal calibration circuit. Radar transmission is re-enabled when the vehicle begins to move forward again. for a rear detection system, radar transmissions are enabled when the reverse signal is present. [A3107]

"Antenna reflector"

An antenna reflector, which can reflect incoming radio waves, is formed as a corner of a cube by orthogonally connecting three reflectors which can reflect incoming radio waves. The reflectors are formed from semiconductor layers, conductive sheets scattered on one surface of the semiconductor layers, insulator films formed on both sides of the semiconductor layers, conductor films provided on the opposite surface of each of the insulator films, and switching elements that are formed on the semiconductor layers and which connect the conductive sheets. As a result, if direct current voltage is applied between the resistor films, the reflectors reflect radio waves while radio waves are absorbed when no direct current voltage is applied, and thus, the reflected radio wave is modulated by the application and non-application of the direct current voltage. [A3108]

"Velocity measurement apparatus of moving object"

A velocity measurement apparatus is disclosed which is composed of a transmitter having a plurality of elements for transmitting a signal wave, a receiver having a plurality of elements for receiving a reflected signal from a target object, and a Fourier transformation processor for two-dimensionally Fourier transforming a two-dimensional received signal in an array direction and a time axial direction of the plurality of elements of the receiver. The two-dimensional received signal is derived by repeating the transmission and reception operations a plurality of times. The velocity measurement apparatus measures a moving velocity of the target object directing to the means for receiving. [A3109]

"System and method for tracking objects using a detection system"

A system and method of tracking objects first receives returns from objects in the field of view of a detector. The sensor generates a current frame of datapoints, where an object in the field of view can be represented by multiple datapoints. The datapoints are converted into global coordinates and mapped into a next frame of datapoints and generated at a next sample time to create a new current frame of datapoints. This new current frame of datapoints is processed to form a list of objects with location and power information that includes information from one or more previous frames. This mapping and processing to form the list of objects allows the system to detect weak signal targets in a ground cluttered environment and minimizes the occurrence of false alarms. [A3110]

"Electric power steering system"

An electric power steering system of this invention can inform the driver of potential danger by providing control by way of safety precaution before a vehicle enters a dangerous situation. The occurrence of dangerous situations is determined based on a signal from an obstacle sensor. If a steering wheel is turned in a dangerous situation, a warning control is performed on a motor. The motor outputs a torque for t1 seconds, for example, which counters against turning of the steering wheel. Then, the motor enters a "non-assist" state wherein no current is applied thereto for t2 seconds. If an intermittent counter torque is applied by the motor, it is hard to turn the steering wheel and the steering wheel is caused to vibrate, thereby preventing the vehicle from being steered to collide with an obstacle and, warning the driver of the danger with vibration caused in the steering wheel. [A3111]

"Method for detecting the location of a mobile terminal"

In location detection of a mobile terminal, a location inquiry signal is transmitted from one or more base stations to the mobile terminal at predetermined intervals. In response to the location inquiry signal, the mobile terminal transmits a location signal including its identification information such as a telephone number. The location signal is received by at least three base stations neighboring to the mobile terminal. The respective distances from that base stations to the mobile terminal are calculated based on the respective field strength values of the location signal received by the base stations, and the location of the mobile terminal is detected based on the calculated distances. More specifically, the location is calculated as an intersection of the respective circles defined by radiuses of the calculated distances from the base stations receiving the location signal. [A3112]

"CDMA communications and geolocation system and method"

A spread-spectrum CDMA communications system for locating remote units, and for communicating message data between a plurality of remote units and a base station. The spread-spectrum CDMA communications system includes a plurality of base stations and a plurality of remote units. A base station has a spread-spectrum modulator for spread-spectrum processing the message data, and a transmitter for transmitting the spread-spectrum processed-message data, combined with a generic-chip-code signal, from the base station to a remote unit. The base station also has an antenna, and spread-spectrum detectors for recovering message-data communicated from the remote-units. A remote-unit has an antenna, and a detector coupled to the antenna for recovering data communicated from the base station. The detector includes a spread spectrum demodulator. Also, the remote unit has a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator and a transmitter. The base station has a range circuit, which comparers the generic-chip-code signal generated at the base station with the generic-chip-code signal received from the remote unit, for determining a range between the remote unit and the base station. [A3113]

"Method and system for regional traffic monitoring"

A method and system is disclosed for remote all-weather monitoring of civilian road traffic over large portions of a metropolitan region, using one or more microwave radar systems situated at elevated locations, such as high towers or pilotless aircraft. Pulse-Doppler waveforms provide, for each position of the radar beam, range-velocity maps of traffic over a number of selectable roadway sections, which maps are used to estimate the speed, density, and volume of traffic flow and to identify discontinuities in the flow which may be indicative of accidents or obstructions. In addition, a high-resolution wideband waveform can be included to provide detailed examinations of selected portions of the monitored roadway sections. [A3114]

"Transponder charging apparatus"

Apparatus for automatically charging a transponder mounted to a go-cart. The transponder charging unit is basically comprised of a housing having a wall which divides its space into first and second compartments wherein a PC board and a transponder are at least partially contained, respectively. A cover plate secures and protects the PC board and transponder within the housing. A wire is spliced into the go-cart's coil grounding wire to extract A/C power therefrom and send it to the PC board. The PC board contains several solid state devices to rectify and regulate the voltage. Wires extend from the PC board's output to charging contacts operatively connected to the transponder's battery, thereby providing a charge thereto. Thus, the transponder's battery, is continually being charged while the go-cart's engine is running. [A3115]

"Layered dual frequency antenna array"

A dual frequency array antenna comprises an upper layer including an array of antennas operating at a first frequency, a first ground layer disposed below the upper layer at a predetermined distance and a dielectric material disposed between the first ground layer and the upper layer. An array of slot radiator apertures are provided in the first ground layer. The apertures are spaced from the array of antennas and radiate at a second frequency. An array of feed lines is disposed at a predetermined distance below the first ground layer with one of the feed lines below each one of the apertures. A second ground plane layer is disposed at a predetermined distance below the array of feed lines. The two frequencies are, for example, from two distinct microwave bands. [A3116]

"System for the identification and automatic detection of vehicles or objects"

A system for the identification and automatic detection of vehicles or objects includes an electronic label installed in each of the vehicles or objects, each of these electronic labels having means for memorizing an identification code assigned to a vehicle or object in which the electronic label is installed and radioelectrical transmission and reception means for transmitting this identification code, and at least one mobile reader disposed exterior to the vehicles or objects and movable within a vicinity of these vehicles or objects. Each mobile reader includes a recording memory for recording a file of identification codes of vehicles or objects to be identified, radioelectrical means for transmitting a signal to at least one of the vehicles or objects which prompts the electronic labels of these vehicles or objects to transmit identification codes assigned to these vehicles or objects to the radioelectrical means, comparison means for comparing the identification codes recorded in the file of the recording memory with each identification code transmitted by the electronic labels, and reporting means for reporting to authorities the presence of any vehicle or object whose identification code appears in the file of the recorded memory, as determined by the comparison means. The invention finds particular utility in the automatic detection of stolen vehicles, the purchase of second hand vehicles, and identity checks on motorists. [A3117]

"Window-closing safety system"

A safety device includes a wire loop embedded in the glass of a passenger car window and routed near the closing leading-edge of the window. The wire loop carries microwave pulses around the loop to and from a transceiver with separate output and input ports. An evanescent field only and inch or two in radius is created along the wire loop by the pulses. Just about any object coming within the evanescent field will dramatically reduce the energy of the microwave pulses received back by the transceiver. Such a loss in energy is interpreted as a closing area blockage, and electrical interlocks are provided to halt or reverse a power window motor that is actively trying to close the window. [A3118]

"Excavator data acquisition and control system and process"

An information acquisition and control system and process acquires geological information from a subsurface and modifies the operation of an excavating machine using the acquired geological information. The system includes a data acquisition system to acquire geological information along an excavation route, a machine controller to control the operation of the excavating machine, and a main controller that produces estimated machine performance parameters for use by the machine controller using the acquired geological information and machine operation information. In another embodiment, geologic characteristics acquired for a first subsurface are associated with excavation performance information for the first subsurface to produce correlation data. Geologic characteristics acquired at a second subsurface are compared with the correlation data to produce estimated excavation performance information for the second subsurface. [A3119]

"Method and apparatus for operating a surface detection surveillance radar using frequency agile pulse transmissions"

In accordance with the principles of the invention, a surveillance radar is provided with a rotating, frequency squinting, end-fed slotted array antenna, which is caused to transmit a plurality of different carrier frequency pulses for successively illuminating specific antenna beam positions during rotation of the antenna. Upon reception of each radar signal return, a signal processor responsive to the frequency of each transmitted pulse and the mechanical pointing angle of the antenna at the time of transmission of each pulse, will determine the frequency dependent squint angle for the transmitted pulse and combine that angle with the instantaneous mechanical pointing angle of the antenna at the time of the pulse transmission, to determine the actual beam pointing angle for each pulse at the time of its transmission. A video signal processor groups together the pulse signal returns from physically adjacent ones of the actual beam pointing angles for common processing, i.e, integration, for improving the target detection performance of the radar system. [A3120]

"Vehicle-surroundings monitoring apparatus"

A plurality of radar devices are provided on and along the periphery of a vehicle for monitoring in different directions. While sequentially switching the radar device to be used for the monitoring operation in response to a transmission-enable signal, a processing device detects, for each direction, presence of and distance to an obstacle or object on the basis of a phase difference (time difference) between signals transmitted and received via the corresponding radar device. Thus, the processing device causes an image display device to show the detected conditions around the vehicle and also causes a sound synthesizer to output a sound message to call the vehicle operator's attention. [A3121]

"Vehicle occupant position and velocity sensor"

An occupant position sensor utilizing either ultrasonic, microwave or optical technologies, or seatbelt spool out and seat position sensors, are used as inputs to the primary vehicle crash sensor circuit to permit the longest possible sensing time before the occupant gets proximate to the airbag and is in danger of being injured by the deploying airbag. The sensor further disables the inflatable restraint system if the occupant is in danger of being injured by the system deployment. Separate systems are used for the driver and passenger to permit the optimum decision to be made for each occupant. [A3122]

"Adjustable zone security system"

Security systems which include an adjustable structure and a motion detector which detects changes in electromagnetic energy from within a zone of protection are described. The structure has a base for mounting the motion detector and wall members which extend away from the base and to form walls around the detector. The wall members are adjusted to positions between the plane of the base and planes perpendicular to the base to alter the shape of the zone of protection and conform it to the area or object of interest. The motion detector is electrically connected to a control unit and alarm module which includes a shock sensor and a current sensor. The motion detector and the control unit and alarm module are connected to a power supply and operated by remote control. [A3123]

"Automotive rear safety detection system"

An automotive rear detection system which assists a driver by informing whether an obstacle is present when the vehicle is in a reverse motion. The alarm is activated by transmitting an audible noise to warn the driver. The signals are monitored by detectors which uses frequency modulation current wave mode to recognize whether objects are present within approximately eight feet regardless if it is in motion or not. The detectors send a signal to a control box mounted inside the vehicle which activates the alarm. [A3124]

"Traveling control system for motor vehicle"

A traveling control system for a motor vehicle includes a detector for detecting an object which exists in front of the motor vehicle to follow a vehicle traveling ahead. The system further includes a first course determination device for estimating a first course on which the motor vehicle will travel hereafter, an identification device for identifying an first target vehicle among the objects existing on the first course, and a second course estimation device for estimating, based on the first target vehicle, a second course on which the motor vehicle will travel hereafter at least while the first target vehicle is outside of the first course. The identification device identifies a second target vehicle among vehicles which travel on the first or second courses while the first target vehicle is outside of the first course. [A3125]

"Microburst detection system"

A radar station utilizes fuzzy logic processing to detect atmospheric microburst events. The detection process accesses radar velocity measurements to calculate wind shear and produce a wind shear likelihood image. Reflectivity measurements are used to create a reflectivity likelihood image as an indicator of storm activity. A clutter image of stationary objects close to the radar is used to create a clutter likelihood image as an indicator of false alarms. A weighting factor is applied to each set of wind shear, reflectivity, and clutter likelihood data, and the values are combined to produce a combined likelihood image. The combined likelihood image is subjected to averaging over a fixed area to eliminate spurious readings, and positions having a sufficient size in combination with a likelihood value exceeding a minimum threshold amount are selected as microburst events. [A3126]

"Transponder detection system and method"

A transponder detection system for detecting the presence at a detection area of a vehicle on which the transponder is mounted. Two antenna arrays are located on opposite sides of the detection area, and have their boresights directed to the detection area. for each array, a sum and difference signal of signals received from the transponder are measured. The sum channel signal is used to establish whether a transmission has occurred, and the difference channel signal is used to isolate any transponder that is at the detection area. [A3127]

"Method and apparatus for controlling a biphase modulation to improve autocorrelation in pseudorandom noise coded systems"

This invention relates to a method and apparatus for controlling a biphase modulator (602, 702) to improve autocorrelation in pseudorandom noise coded systems. The biphase modulator modulates a carrier frequency with one of two phase states responsive to a pseudorandom noise (PN) binary code sequence. The spectrum (610, 710) at the output of the biphase modulator comprises a plurality of spectral lines separated by the code repetition frequency, including a center spectral line (611, 711) and at least one adjacent spectral line (612-615, 712-717) . The magnitude of the center spectral line is measured and compared to a reference to produce a control signal which is responsive to the magnitude of the center spectral line. This control signal is supplied to the biphase modulator for maintaining a predetermined magnitude of the center spectral line thereby achieving a desired spectrum output and improving autocorrelation of the system. [A3128]

"Performance matching of weather avoidance radar"

The invention of this patent is related to unit-to-unit performance matched radar provided by automatic compensation based on software mapping of calibration data over an dynamic operating range of temperature and radar return signals. [A3129]

"Coherent, frequency multiplexed radar"

Coherent, frequency multiplexed radar is a new generic type of continuous wave radar architecture wherein contiguous pulses of discrete frequency segmented signals are serially transmitted from an antenna, and after reflection from radar targets, signals from the same antenna are coherently processed in a parallel manner to provide correlated measurements of target's pulse compressed range and radial velocity. Simultaneously transmitted and received signals are separated by frequency multiplexing. [A3130]

"Method for avoiding collision of vehicle and apparatus for performing the same"

An apparatus which determines a kind of an object to warn a driver based on the kind of the object and properly performs deceleration and braking operations based on a position of the object and a speed of the vehicle is disclosed. An infrared-ray camera is employed to detect a shape and a temperature of the object. A digital signal processing technique is utilized for displaying the temperature distribution of the object. Therefore, using the apparatus, it is able to distinguish the shape and the kind of the object in the night time and the vehicle is suitably decelerated and/or stopped based on conditions. [A3131]

"Portable geophysical system using an inverse collocation-type metehodology"

The invention pertains to a hand-held or vehicle mountable portable procer based high resolution radar system for detecting and identifying an object by using high resolution radar. In particular, the invention concerns using radio waves for identifying a depth and material of an object within a media. This system can perform target and media identification in real-time. This process is achieved by the system's processor where the media identification results can be visually displayed on an output unit. The generated carrier signal used in the radar system is an exponentially decaying superimposed direct and alternating signal. The frequency of the carrier signal can be in the microwave region. The system performs analog to digital (A/D) conversion using integrated circuitry whose sampling rate is in the same as the carrier signal transmission rate. In addition, Fourier and Hilbert transforms of the observed signal is generated for frequency domain analysis of the observed object to be identified and a profile inversion methodology for real time analysis. To achieve high resolution results, digital codes such as Barker, Welti, or Frank codes are used in the processor. The carrier signal is coded using a digitally controlled phase shifter. Power usage by the instant invention's radar system is low. The profile inversion methodology is a real time based analysis. [A3132]

"Backscattering transponder switchable between a modulator/demodulator and ground"

An electronic toll system for monitoring a plurality of lanes including a plurality of lane monitoring devices operative to monitor passage of vehicles through the corresponding plurality of lanes, and a lane monitoring device coordinating system for coordinating operation of the lane monitoring devices such that not all of the lane monitoring devices operate simultaneously. [A3133]

"Target prediction and collision warning system"

A device for target prediction and collision warning for tracking objects in a region proximate to a vehicle includes a signal transmitter which provides first and second detection signals for at least partial reflection by an object located in a spatial region. The device further includes a signal receiver for receiving the deflected first and second detection signals corresponding to first and second parameter signals. A Fourier transform circuit is provided for receiving the first and second object parameter signals and generating first and second Fourier transform object parameter signals corresponding to relative range and velocity data of a target being tracked. The device includes a probabilistic neural network which preferably sorts the first and second Fourier transform object parameter signals corresponding to the relative range and velocity of a target being tracked. Operatively coupled to the probabilistic neural network is a target tracker circuit which receives the sorted first and second Fourier transform object parameter signals after at least three samples of relative range and velocity data have been measured. The target tracker generates an output signal indicative of a prediction of regression parameters of a second order or higher order equation that characterizes the change in relative range and velocity of the target being tracked. [A3134]

"Alarm system for swimming pools"

A sonar, lidar, or radar system generates an alarm signal if a child enters a swimming pool when the system is enabled, and includes multiple safeguards against sounding false alarms due to wind-activated waves in the pool or self interference arising from multi-path propagation of the sonar signals. An acoustic or electromagnetic receiver having a narrow bandwidth is employed to demodulate a composite signal spectrum produced by a target object such as a child and signals generated by wind-activated waves. It also performs an envelope amplitude monitoring function to suppress false alarms that might be generated by low amplitude envelopes of the type created by self interference. In a first embodiment, an alarm signal is generated only if the demodulating function and the envelope amplitude monitoring functions both indicate a legitimate alarm. In additional embodiments, still further redundancies are added to further decrease the probability of a false alarm, but none of the redundancies reduces the probability of recognizing legitimate signals. [A3135]

"Apparatus for and method of preventing car collision utilizing laser"

An apparatus for and a method of preventing a car from coming into collision with an object car running ahead or behind, by monitoring car running conditions in the front and rear of the car by the provision of front and rear sensors to give an alarm to the front and rear object cars when an emergency situation has monitored, sensing a slope of a road surface on which the car runs to remove an error caused by an inclination of the car, sensing a handle rotation of the car to enable the car to follow the front object car on a curved road and to be informed of situations in the front and rear of the car on the curved road, establishing a sufficient safety distance, and sensing an emergency situation occurring in the rear of the car to inform a driver of the rear object car of the emergency situation by the provision of a display. When a rotation of the handle is detected, the front and rear sensors are rotated in a direction corresponding to that of the rotation of the handle by an amount corresponding to a rotation angle of the handle, while when a slope of a road surface on which the car runs is detected, the front and rear sensors are rotated in a direction reverse to that of the road surface slope by an amount corresponding to a gradient of the slope at a point of an estimated slope beginning time. [A3136]

"Sensing apparatus"

An apparatus for determining various physical quantities such as temperature, pressure, stress, strain, distance and the like in a manner such that a change in the physical quantity of interest results in a measurable change in the frequency of oscillation of a signal generated within the apparatus. [A3137]

"Object sensing apparatus using predicting means for Determining if the object is a guardrail"

An obstacle sensing apparatus uses an FM-CW wave as an emitted wave to an object in front of a car. A received wave from the object is mixed with the emitted wave to produce a beat signal which is analyzed in frequency to measure a distance and a relative speed with respect to the object. A distance and a relative speed at the next time is predicted from the measured distance and relative speed. The object is determined to be a car if the relative speed does not have an approaching direction or substantially the same value as a sensed car speed. The object is otherwise determined to be at least one of a guardrail and a sound barrier if a difference between the measured distance and the predicted distance exceeds a preset value and a plurality of the last measured distances are substantially constant. The object is otherwise determined to be a stationary object other than the guardrail. [A3138]

"Radar method and device for carrying out the method"

A radar method and a device for carrying out the method include estimating an azimuth angle of each target object from determined variables of distance or range, relative speed and relative acceleration after Kalman filtering and separating out target objects having a physically impossible behavior (tracking and prediction) . That is used to determine which target objects are located on a roadway occupied by a vehicle and which are the most dangerous thereof. Indication, warning or action thresholds are determined as a function of driving behavior of the driver, road conditions and weather conditions. Indication, warning or action signals (in the brakes, throttle valve or gear shift of the vehicle) result if the thresholds are exceeded or undershot by the range, the relative speed and the relative acceleration. [A3139]

"Cruise control systems for motor vehicles"

A cruise control system for a motor vehicle includes a forward looking distance sensor adapted to sense vehicles moving in the same path as the equipped vehicle or in paths adjacent to the equipped vehicle, the system tracking vehicles in front of or in paths adjacent to the equipped vehicle and controlling braking or acceleration of the equipped vehicle in response to vehicles travelling in front of or on converging paths with the equipped vehicle, in order to maintain a safe distance between the equipped vehicle and vehicles in or entering its path. [A3140]

"Method for simultaneously measuring the positions of more than one surface in metallurgic processes"

A method for measuring the position of at least one surface in a metallurgical process which includes the steps of providing a metallurgical melt, the metallurgical melt including at least a metal portion and a slag layer, providing a signal generator for generating signals at a plurality of frequencies over a frequency band, and providing an antenna for receiving the signals generated by the signal generator and for transmitting circularly polarized radio waves at the plurality of frequencies over the frequency band. The invention further includes the steps of disposing the antenna adjacent the metallurgical melt, transmitting the circularly polarized radio waves from the antenna toward the metallurgical melt, the circularly polarized radio waves being transmitted by the antenna at the plurality of frequencies over the frequency band, receiving reflected images of the transmitted radio waves through the antenna, the received reflected images of the transmitted radio waves having a substantially opposite circular polarization from the transmitted circularly polarized radio waves, determining a phase displacement between the transmitted radio waves and the received reflected images of the transmitted radio waves, transforming the determined phase displacement from a frequency to a time plane, and determining from the time plane transform a position of at least one surface of at least one of the metal portion and the slag layer. [A3141]

"Method and apparatus for alerting pilot to transponder antenna failure in a traffic alert and collision avoidance system"

A system for use with aircraft having a collision avoidance system which employs i) two transponder systems each including two antennas and a selected one of two transponders and ii) a failure warning when a transponder system failure occurs, to permit the aircraft to take off when the failure warning is the result of only one antenna failure. [A3142]

"System and method of installation for locating a hidden sensor externally active on a motor vehicle"

To hide, and protect a transducer (2) , such as an ultrasonic, infrared transducer or the like, located on an outer surface part (1) of a vehicle, for example within a recess in a bumper, from vandalism or other damage, the transducer is located on the outer surface part (1) to be flush with the outer surface thereof, and a cover (4) is located on said outer surface part. The outer surface part (1) , as is customary has a predetermined surface shape or contour, and the outer surface cover (4) matches and engages that predetermined outer surface part of contour. Preferably, the transducer is an ultrasonic transducer terminating in a membrane (3) which is located flush with the outer surface of the outer surface part (1) , and acoustically coupled, for example by an adhesive (5) , with the outer cover (4) to reduce damping of signals from the transducer, and of echo signals from an object received by the transducer, and passing through the outer cover. The material of the cover is preferably so selected that it has sufficient hardness and stiffness for good matching with the transducer. The method and system is suitable for combination with a parking assistance system (10, 11) . The cover location of the transducer (2) prevents visual identification of the transducer, so that there is no interference with the visual aspect of the vehicle, and damage to the transducer, inadvertently or by vandalism, is effectively eliminated. [A3143]

"Tubular sonic displacement sensor"

The displacement sensor of this invention comprises a tube combined with a sonic transmitter and receiver. The tube acts as a waveguide for the sonic waves and a processor determines whether the tube has changed in length or has been constricted which, in either case, changes the pattern of sonic waves traveling from the transmitter to the receiver. In some applications, the transmitter and receiver are at different ends of the tube. In these cases, the attenuation in sound energy reaching the receiver, caused by the tube being squeezed at at least one point, is measured and the amount of cross action area reduction is determined. In other applications, the transmitter and receiver are at the same end of the tube and, in some of these cases, the transmitter and receiver are the same transducer. When the transmitter and receiver are at the same end of the tube, the receiver receives sonic waves reflected from a constriction in the tube and the time between transmission and reception of the waves permits the processor to determine the location along the tube of the constriction. The measuring device of this invention can also be used to measure the change in length of the tube or effective length, such as when the tube is partially filled with a liquid. [A3144]

"Vehicular safety distance alarm system"

A vehicular safety distance alarm system for monitoring a travelling distance between a source vehicle and a target vehicle and activating an alarm when a predetermined safety distance defined between the two for a given speed is compromised comprising a distance measurement mechanism coupled to a source vehicle for determining and transmitting a distance signal representing a travelling distance between the source vehicle and a remote target vehicle, a selection mechanism coupled to the source vehicle for allowing a driver to select a desired range of safety distances expressed as a function of source vehicle velocity and a set time to reach a target vehicle, an alarm signal generation mechanism coupled to the distance measurement mechanism and selection mechanism for comparing the distance signal to a safety distance at a given source vehicle velocity and transmitting an alarm signal when the safety distance is compromised, and an alarm mechanism coupled to the alarm signal generation mechanism for providing an indication upon receipt of an alarm signal. [A3145]

"Wide-angle multiple-doppler radar network"

The sky is scanned with transmitted radar pulse beam of electromagnetic radiation from a high gain antenna with a narrow viewing angle. Weather echos from the radar pulse are monitored with a low gain receiving antenna that has a wide, or moderate, viewing angle of the sky. The source location of echo signals along the direction of the radar pulse beam path are defined by synchronizing the sampling of the echo signal at the receiving station with the transmission of radar pulses at the transmitting station. The receiving station defines the location of an echo signal source by knowing the locations of the transmitting and receiving antennas, the pointing angle of the transmitted beam and the relative time between transmission of the radar pulse and receipt of each echo signal sample along the transmitted beam path. The relative time can be defined by synchronizing the sampling of the echo signal with each transmitted pulse. [A3146]

"Vehicle-ground surface measurement system"

A measurement device (103) and method determines various metrics between a vehicle (101) and a ground surface (105) using a transmitter-antenna (109) for emitting energy including a portion directed down toward the ground surface. A receiving antenna (115) , has a portion oriented facing toward the transmitter-antenna for receiving a portion of the emitting energy along a direct path (117) , and a portion oriented facing downwardly toward the ground surface for receiving a portion of the emitting energy reflected from the ground surface along a reflected path (113) . A decoder provides separate indications of forward (121) and sideward (123) velocity relative to motion of the vehicle along the ground surface. Furthermore, the decoder comprises means for determining vehicle height (125) dependent on a measured difference in path length, vehicle level (127) , or front to rear tilt angle, dependent on polarization elliptical ratio changes, and road surface conditions (129) dependent on amplitude and phase changes that occur versus time. [A3147]

"Multi-stage transponder wake-up, method and structure"

A system and method which conserves energy in the operation of a transponder or tag (14) by providing that the transponder (14) be enabled or awakened in multiple stages. A threshold detector (62) is provided which measures the power level of received RF energy. If the RF energy received by the detector (62) exceeds a pre-determined level, the transponder (14) then employs a modulation detector (64) to ascertain whether it has been awakened by a valid interrogation signal from an interrogator (12) or whether the RF energy received was merely a spurious burst of RF energy from some other source. If a pre-determined modulation is detected by the modulation detector (64) , the transponder (14) is then fully activated to its normal operational state. [A3148]

"Multichannel radar system for motor vehicles"

A multichannel radar system for use on a motor vehicle has a plurality of transmission and reception channels each composed of an AM or FM signal generator for generating an AM or FM signal including a carrier which is amplitude- or frequency-modulated by a modulation signal, transmission and reception antennas for radiating the generated AM signal and receiving a return signal reflected by an obstacle, an amplifier for amplifying the received return signal, and either a detector for detecting the amplified return signal or a mixer for mixing the amplified return signal with the FM signal generated by the FM signal generator thereby to generate a beat signal. A power supply circuit supplies DC voltages respectively to the AM or FM signal generators and the amplifiers of the respective transmission and reception channels in a time-division multiplex manner at successive times. A processor calculates a distance up to the obstacle based on either the phase difference between the detected return signals and the modulation signals or the frequencies of the beat signals in the respective transmission and reception channels. [A3149]

"Low-cost near-surface burst (NSB) capability for proximity fuzes"

System and modifications are presented which allow existing artillery and rtar projectile proximity fuzes to have a near-surface burst (NSB) option enabling low height of bursts ranging between one and three meters. The additional circuitry needed to implement this NSB into an existing fuze is a single operational amplifier. The velocity of the fuze is calculated by the micro-controller counting the number of Doppler cycles over a pre-determined sample period of time. Thereafter, using the fuze velocity, the delay time needed for a NSB detonation is computed. [A3150]

"Radar-based method of level measurement"

In a method of level measurement on a radar basis, microwaves are emitted by means of an antenna to the surface of a material in a container and the echo waves reflected from the surface thereof are received. An actual echo function representing the echo amplitudes as a function of the distance is formed from the echo waves received by the antenna for each measurement, the probable useful echo and the transit time thereof are established from the actual echo function, and the distance of the material surface from the antenna is determined therefrom. To recognize the formation of a deposit and/or other trouble, such as e.g. damage to or loss of the antenna, an undisturbed echo function corresponding to an undisturbed measurement is obtained and stored prior to performing the measurements. In each measurement the actual echo function is compared to the stored undisturbed echo function. When due to the comparison, deviations between the two functions are found in the antenna region and the proximity zone, these deviations are evaluated to recognize the formation of a material deposit and/or other trouble. [A3151]

"Apparatus and method for motion detection and tracking of objects in a region for collision avoidance utilizing a real-time adaptive probabilistic neural network"

Apparatus for motion detection and tracking of objects in a region for collision avoidance includes a signal transmitter which provides first and second detection signals for at least partial reflection by an object located in a spatial region. The apparatus further includes a signal receiver for receiving the deflected first and second detection signals corresponding to first and second object parameter data signals. The apparatus further includes a Fourier transform circuit for receiving the first and second object parameter data signals and providing first and second Fourier transform object parameter data signals. The apparatus further includes a probabilistic neural network for receiving and sorting the first and second Fourier transform object parameter data signals without the use of a priori training data. [A3152]

"Vehicle radar for excluding a vehicle changing a lane from targets to track"

A vehicle radar includes a vehicle in front from being a target when the vehicle shifts to another lane by decreasing certainty of the vehicle as the target. The vehicle radar calculates a relative distance and a relative speed between each of target objects and a vehicle on which the vehicle radar is provided by transmitting forwardly a frequency modulated carrier wave and receiving the carrier wave reflected by each of the target objects. A certainty level represented by probability of existence of the target objects is calculated based on a relationship between a currently detected condition of the target objects and a previously detected condition of the target objects. The certainty level of the target objects is changed when it is determined that the target objects move away from a lane in which the vehicle is moving so that the target objects are excluded from targets to track. [A3153]

"Combined motion detector/transmitter for a traffic information warning system"

A combined motion detector/transmitter device for a traffic information warning system is disclosed. The device includes first and second oscillators for transmitting first and second carrier signals, respectively. The first carrier signal has a first carrier signal frequency and the second carrier signal has a second carrier signal frequency. The carrier signals are used to transmit a message regarding a traffic situation based upon either the magnitude of the frequency difference between the first and second carrier signal frequencies or the specific frequency locations of the carrier signals. The first and second oscillators also set up first and second disturbance fields, respectively. A first reflected signal receiver is associated with the first oscillator and receives a first reflected signal when a target is within the first disturbance field. A second reflected signal receiver is associated with the second oscillator and receives a second reflected signal when a target is within the second disturbance field. First and second detector circuits are provided for detecting the presence or absence of a moving target in the first and second disturbance fields, respectively. Finally, the device includes an indicator for indicating the detected presence of a moving target in either the first or second disturbance fields. [A3154]

"Phase difference microwave densitometer and method which detects a number of phase rotations through a reference point"

A phase difference measuring apparatus obtains a first receive signal by transmitting and receiving a to-be-measured material in a reference state and a second receive signal by transmitting and receiving a signal wave to and from that material in a measured state. The apparatus finds a reference phase difference .theta..sub.1 from the transmit wave and first receive signal and an apparent phase difference .theta..sub.2' from the transmit wave and second receive signal. The apparatus adds the apparent phase difference .theta..sub.2' to a product of the number of rotations, n, the apparent phase difference .theta..sub.2' passes through a given reference point and an angle of 360.degree. to find a true phase difference .theta..sub.2. The apparatus varies the number of rotations, n, to n+1 when the apparent phase difference .theta..sub.2', while being increased, passes through the reference point and that number of rotations, n, to n=n-1 when the apparent phase difference .theta..sub.2', while being decreased, passes through the reference point. [A3155]

"Informational/training video system"

The present invention provides a video-based, combined informational/training system for user activity related applications. In one embodiment, the system (2) includes a video recording assembly (10) and a measuring device (4) located at a user activity site (6) such as a tee box of a golf driving range. A video tape (60) , including activity specific information on a first, pre-recorded portion thereof, is provided to the user for use in the video recording assembly (10) at the user activity site (6) . The video tape (60) is cued for recording user specific information on a second portion of the video tape (60) during a practice session. The sensor (4) determines corresponding parameter information, such as estimated golf ball carry distance, for display on video tape (60) . The video tape (60) and video recording assembly (10) cooperate to provide a mechanism for preventing or discouraging use of unauthorized tapes and to ensure proper usage of the system (2) . [A3156]

"Electronic multi-purpose material level sensor"

The present electronic multi-purpose material level sensor is based on time domain reflectometry (TDR) of very short electrical pulses. Pulses are propagated along a transmission line that is partially immersed in a liquid, powder, or other substance such as grain in a silo. The time difference of the reflections at the start of the transmission line and the air/liquid interface are used to determine levels to better than 0.01 inch. The sensor is essentially independent of circuit element and temperature variations, and can be mass produced at an extremely low price. The transmission line may be a Goubau line, microstrip, coaxial cable, twin lead, CPS or CPW, and may typically be a strip placed along the inside wall of a tank. The reflected pulses also contain information about strata within the liquid such as sludge-build-up at the bottom of an oil tank. [A3157]

"Bistatic angle-cued radar system and processing method"

A radar system and method employing a radar with an electronically scanned antenna array for estimating range and range rate to a target using angle cueing only. The radar transmits radar pulses at the target and searches the projection of the line-of-sight to the target on the ground for ground-bounce returns associated with each transmitted pulse. A processor coupled to the radar and processes the ground-bounce returns to determine an angle corresponding to the maximum reflected multipath ground-bounce return when the antenna array scans the ground. The angle data derived from processing the multipath ground-bounce returns permits computation of the range to and range rate of the target. [A3158]

"Mobile unit identifying system and method of demodulating for the same"

A first mobile unit identification system having a interrogator and responder. The interrogator transmits a given magnitude of a spread spectrum coded signal in standby mode. The responder receives the spread spectrum coded signal and when the magnitude of received signal exceeds a given value, it reflects the transmitted spread spectrum coded signal with ID code when the magnitude of received signal exceeds the given value. The interrogator receives this and then, transmits data to the responder with amplitude modulating the spread spectrum coded signal with the data. The responder detects by amplitude demodulation and stores the detected data. The interrogator may transmit a mode change code. The responder may transmit an end code after transmission of a data train. A second interrogator informs the responder of the standby mode thereof by amplitude-modulated signal having a given cycle. A second responder judges whether or not the second interrogator is in standby mode by detecting the cycle and sends a communication requesting signal Q to the second responder and then, transmits ID code. In response to the signal Q, tile second interrogator transmits a signal having a fixed magnitude. A method of modulating for the mobile unit identifying system is also disclosed. [A3159]

"Detection object searching device"

The invention provides a detection object searching device which makes it possible to immediately know the direction of a mobile detection object such as a car by information presented on a display of a portable unit. The detection object searching device includes a portable operation unit and a body unit. The operation unit includes a transmission section for transmitting a search signal upon operation of a transmission button, a receiving section for receiving a direction indication information signal, an absolute direction detecting section for generating an absolute direction signal, a control section for generating direction indication information indicating the direction of the car based on the direction information signal and absolute direction signal, and a display section for displaying the direction indication information. The body unit includes a direction detection receiving section which searches the incoming direction of the search signal and generates an incoming direction signal, an absolute direction detecting section for generating an absolute direction signal, a control section for generating a direction information signal indicating the direction of the car with respect to the operation unit 1 from the incoming direction signal and absolute direction signal, and transmission section for transmitting a direction information signal. [A3160]

"Radar system"

A radar system having a transmitter for transmitting a series of radio frequency (RF) pulses with sequential, incrementally changing carrier frequencies. A receiver receives energy from multiple scattering points of an object reflecting such transmitted RF pulses. The received energy from each one of such scattering points includes a series of radio frequency (RF) pulses corresponding to the transmitted pulses delayed in time, .tau., from the transmitted pulses an amount proportional to the range to such scattering point and shifted in frequency from the carrier frequency an amount proportional to the velocity of such scattering point. The receiver includes a heterodyning section, responsive to a range tracking error signal, .epsilon..sub.R, and a velocity tracking error signal, .DELTA..sub.VEL, for producing a series of pulsed signals for each one of the scattering points. Each one of the pulsed signals for any given scatterer sequentially changes in phase, .phi., at a rate, .DELTA..phi./.DELTA.T, related to the range to the scattering point producing such one of the pulsed signal series. A processor, responsive to each of the series of pulsed signals produced by the heterodyning section, unambiguously determines from the frequency spectrum thereof the range tracking error signal, .epsilon..sub.R, and velocity tracking error signal, .DELTA..sub.VEL, for each of the scattering points as well as the range centroid. [A3161]

"Ferro-electric frequency selective surface radome"

Ferro-electric frequency selective surface radomes that have dielectric layers that comprise voltage controlled material, and the electrical properties of the dielectric layers are voltage controlled. By varying the dielectric properties, the passband frequency of the radomes can be shifted to optimize frequency and angular response of the frequency selective surface. The radomes comprise grating screens having a plurality of printed radiating elements. Inner and outer voltage controlled dielectric layers are disposed on the grating screens. Relatively high ohms per square resistive films are disposed on exposed surfaces of the voltage controlled dielectric layers. In one embodiment, voltage control circuitry is coupled to the respective resistive films for controlling the voltages applied to the respective voltage controlled dielectric layers by actively varying the dielectric permittivity of the resistive films around a small percentage of its nominal value to provide a ground on outer surfaces of the dielectric layers. In another embodiment, the ferro-electric frequency selective surface radome may comprise voltage controlled dielectric layers disposed on one surface of the grating screens. Voltage control circuitry is coupled to the first and second grating screens for controlling the voltages applied thereto and thus the performance of the radome. [A3162]

"Electromagnetic wave reflective type, low cost, active proximity sensor for harsh environments"

A low power, low cost, millimeter wave (MMW) proximity sensor that provides over a 6: 1 increase in minimum detection range (55 mm minimum) compared to standard 18 mm inductive proximity sensors preferably includes a low cost MMW Gunn oscillator, MMW detector and analog processing/driver circuitry. The sensor is preferably designed for 3-wire operation and will fit in a standard 18 mm tube. [A3163]

"Velocity detecting system"

A velocity detecting radar unit that is easy to operate and to view so as to minimize distraction to the operator, particularly when in use in a moving vehicles includes a spotlight unit having a housing with a lens, a light source within the housing and a control wand pivotally mounting the housing for rotation about an axis and including an elongated tube adapted to extend through the windshield pillar of a vehicle. A radar antenna is mounted in the housing to be movable therewith and has a radar transmitting and receiving end extending from the housing oppositely of the spotlight lens. A display module is adapted to display velocity data and other information and is adjustable mounted to the tube at a location thereon remote from the spotlight housing. Similarly, an input or control module including function switches for providing function commands to a controller for the unit is provided and is adjustable mounted to the tube at a location thereon remote from the housing. [A3164]

"Vehicle obstacle avoidance system"

A system for warning a vehicle driver of obstacles to the front, rear and sides of the vehicle. If the vehicle is stopped and a front or rear obstacle is detected, the vehicle is prevented from moving forward or reverse, respectively. The inhibition of movement can be overridden by the driver once he acknowledges the obstacle. Similarly, the driver is warned of front, rear and side obstacles while the vehicle is moving. In the case of side obstacles, only when it appears that the driver will move the vehicle toward the obstacle is he warned. [A3165]

"Method and system for object detection within an angular zone, and its applications"

A method for detecting fixed or moving objects within an angular zone, as may be used in vehicle anti-collision systems, employs separate and distinct transmission and reception patterns. The transmission pattern successively illuminates consecutive segments of the angular zone. The reception pattern receives echo signals in parallel from illuminated objects in each zone segment. The echo signals are then digitally beam formed into a total field signal. The angular positions of the detected objects are then derived from the total field signal. [A3166]

"Two-way cable TV conversion system for data transmission over a dedicated frequency band"

A bidirectional cable television system provides for transmission of signals from cable subscribers downlink in the same direction as the ensemble of television channels which the cable television system is already constructed to deliver. The subscriber signals may be transmitted over the cable in the blanking intervals of a cable television channel, using the T-NET technique described in U.S. Pat. No. 4,750,036. Alternatively, the signals may be carried over a dedicated channel, or transmitted cochannel along a cable television channel carrying ordinary programming by adding the subscriber information to alternating video frames in alternating polarity to achieve visual cancellation. The subscriber signals are collected after the last distribution line amplifier in the cable downlink. The collected signals are transmitted to a central receiver via wireless or other customary means such as a modem. The collected signals may alternatively be transmitted over the air to the central receiver in the blanking intervals of a broadcast television channel using the T-NET technique. [A3167]

"Electronic baffle and baffle controlled microwave devices"

Microwave devices incorporate at least one photosensitive baffle that is selectively illuminated changing the baffle's electronic characteristic from being transparent to being reflective of microwave energy. The baffle serves as a gate, tuning element, reflector and the like. Various forms of photosensitive baffles and microwave devices are presented. [A3168]

"Cruise controller for vehicles"

In a vehicle which sets a target vehicle-interval distance, and can execute auto-cruise control for controlling the vehicle speed so as to maintain the target vehicle-interval distance, when the auto-cruise control is not executed, a vehicle-interval distance to be set by a driver is detected together with the vehicle speed at that time. A plurality of sets of the vehicle speed and vehicle-interval distance data are accumulated, and the relationship between the vehicle speed and the vehicle-interval distance is calculated. Upon execution of the auto-cruise control, a vehicle-interval distance corresponding to the vehicle speed at that time is obtained from the calculated relationship, and the obtained vehicle-interval distance is set to be the target vehicle-interval distance. [A3169]

"Processing method using an advanced radar waveform for simultaneous matched processing and range profiling of different size targets"

A method of processing radar returns derived from a new radar waveform. The method processes radar returns derived from transmitting the radar waveform to provide simultaneous matched processing and range profiling of different size objects in the presence of clutter. In the present method, radar returns are digitized and processed to produce pulse compressed radar returns having a predetermined (169: 1) pulse compression ratio. A pulse to pulse fast Fourier transform on each RF step is performed on the pulse compressed radar returns. The Fourier transformed radar returns are then simultaneously processed by three processing channels, one each for ships, boats and submarines to provide detection of the different size objects. The waveform permits concurrent detection, discrimination, and high resolution range imaging of detected objects within a single dwell, using a single waveform. Thus, a radar search mode using the waveform integrates several search functions without increasing search frame time. [A3170]

"Moving target identifying system in a base station radar unit for specifying information about moving targets carrying a mobile station radar unit"

A vehicle ID radar system has a simple construction and obtains high identifying performance by making a general identification based on a plurality of responses. There are provided an antenna for obtaining a plurality of question signals from a base station radar unit, a receiver for processing the signals received from the antenna, a question code demodulator for demodulating question codes from the received signals, a question code decoder for decoding the question codes and reading responses respectively corresponding to the plurality of questions from a plurality of data bases, a response code generator for generating response signals, and a transmitter for modulating the response signals and supplying them to the antenna. [A3171]

"Collision probability detection system"

An accident alarm system continuously assesses the potential for a collision between a host vehicle and an object, based solely on input signals representative of the host vehicle velocity and the distance to the object measured at intervals at time t, by first assessing the status of the host vehicle to determine whether it is moving with constant velocity, stationary, accelerating, or decelerating, and then carrying out different signal processing routines to determine, as necessary, whether the object is moving with constant velocity, stationary, accelerating, or decelerating, the magnitude of the host vehicle and object accelerations, and the direction of movement of the object. Warning signals are generated based on these determinations, which assume that the vehicle and object will continue to possess the same acceleration or deceleration until a collision occurs. The system can also be used to activate additional safety devices by performing additional determinations as to whether a severe collision is imminent. [A3172]

"Warning system for vehicles"

A warning system for a vehicle has a warning device for issuing a warning when the vehicle approaches an object. A warning timing parameter section detects a driving operation by the driver of the vehicle, and calculates a reaction time from the time a warning is issued by the warning device to the time the driver starts the driving operation in response to the warning. A warning control section controls the timing at which the warning should be issued by the warning device, based on the calculated reaction time. [A3173]

"Wind profiling radar"

Clutter present in radar return signals as used for wind profiling is substantially removed by carrying out a Daubechies wavelet transformation on a time series of radar return signals. The smoothly varying nature of the return from clutter provides a relatively small number of high amplitude components in the wavelet transformation, which are truncated to remove the clutter. Inverse transformation yields a time series having had a significant amount of clutter removed, without distortion of the radar return from turbulence, which can then be processed to provide useful wind profile data. [A3174]

"Compatible interactive TV and multimedia delivery system two-way cable TV conversion system for data transmission over a dedicated frequency band"

A bidirectional cable television system provides for transmission of signals from cable subscribers downlink in the same direction as the ensemble of television channels which the cable television system is already constructed to deliver. The subscriber signals may be transmitted over the cable in the blanking intervals of a cable television channel, using the T-NET technique described in U.S. Pat. No. 4,750,036. Alternatively, the signals may be carried over a dedicated channel, or transmitted cochannel along a cable television channel carrying ordinary programming by adding the subscriber information to alternating video frames in alternating polarity to achieve visual cancellation. The subscriber signals are collected after the last distribution line amplifier in the cable downlink. The collected signals are transmitted to a central receiver via wireless or other customary means such as a modem. The collected signals may alternatively be transmitted over the air to the central receiver in the blanking intervals of a broadcast television channel using the T-NET technique. [A3175]

"Resonant tag and method of manufacturing the same"

A resonant tag is manufactured in the manner described below: a conductive thin film is formed to a predetermined thickness on two surfaces of an insulating thin film. Thereafter, a conductive pattern, composed of an inductor element and a capacitor element corresponding to a resonant frequency of a resonant circuit, is printed on a surface of one of the conductive thin films, and a conductive pattern, composed of a capacitor element corresponding to the resonant frequency of the resonant circuit, is printed on a surface of the other insulating thin film at a position which faces the capacitor element formed on one of the conductive thin films using an ink which resists etching. A non-printed portion of the conductive thin films is removed by etching to form a resonant circuit pattern. Thereafter, a portion of the insulating thin film, which corresponds to the capacitor element pattern, is thinned to a desired thickness by pressing a heating/pressing member heated to a predetermined temperature against that portion under a predetermined pressure for a predetermined period of time. [A3176]

"Apparatus for defeating radar speed detection signals"

Acquisition and interpretation of reflections from a target in response to a Doppler radar probe signal from a seeker are inhibited by providing at the target a receiver, preferably a high-speed sweeping transceiver, which is operative to injection lock quickly to the probe signal and thereafter to repeat a low-power replica of the probe signal with frequency modulation of the carrier from the repeater with a deviation greater than the locking bandwidth of the local oscillator to generate a random aperiodic signal. The vehicle operator is notified of the presence of seeker signals to prompt the operator to verify compliance with vehicle operating regulations. The carrier frequency modulation is selected to be of a frequency and deviation sufficient to confuse phase locking and limiting circuitry in a seeker receiver and thereby to inhibit acquisition of an echo from the target. [A3177]

"Apparatus and method for imaging with wavefields using inverse scattering techniques"

An apparatus and method for rapid real time imaging with wavefield energy by inverse scattering using a C.P.U programmed to process data derived from wavefield energy that has been transmitted and scattered by an object so as to reconstruct a wavefield image of the object. Electronic signals are propagated and are transduced into wavefield energy waves which in turn are propagated toward the object. Detector means detect the wavefield energy waves scattered by the object. The detected wavefield energy waves are then electronically processed and input into a high-speed digital computer which may comprise a C.P.U. and/or a C.P.U in combination with an array or parallel processor. Data is also prepared and input to the computer representing the incident field and the computer then reconstructs a high-quality image of the object having high spacial resolution and including actual internal viscous and elastic properties of the object through the use of new inverse scattering techniques used in the data processing steps. The media in which the object is embedded may be fluid or solid, homogeneous, or layered (such as stratigraphic layering, or ocean velocity layers, or layering of composites in nondestructive imaging applications) , or may consist of porous material (either sedimentary deposits or composites in nondestructive testing) . [A3178]

"Spread spectrum CDMA communications system"

A spread spectrum CDMA communications system for communicating data and/or digitized voice between a plurality of users to a plurality of PCN units. The spread spectrum communications system is located within a same geographical region as occupied by an existing FDMA, proposed TDMA or any other mobile cellular system. The spread spectrum CDMA communications system includes a plurality of PCN-base stations and a plurality of PCN units. A PCN-base station has a comb filter for notch filtering predetermined channels of the mobile cellular system, a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator for spread spectrum processing the data, and a transmitter for transmitting the spread spectrum processed converted data from the PCN-base station to a PCN unit. The PCN-base station also has an antenna, and spread spectrum detectors for recovering data communicated from the PCN units. A PCN unit has an antenna, and a detector coupled to the antenna for recovering data communicated from the PCN-base station. The detector includes a spread spectrum demodulator. Also, the PCN unit has a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator and a transmitter. [A3179]

"Method and device for maneuvering a motor vehicle out of a parking space"

A method and a device for maneuvering a motor vehicle out of a parking space, in the case of which neither the size nor the clearance of obstacles is known. By means of sensors mounted on the motor vehicle, the clearance between the motor vehicle and surrounding obstacles and the position and steering angle of the motor vehicle are determined, and continuously updated. On the basis of this data, an up-to-date, local map of the surroundings is placed in a computer module. A polyline is used to connect the detected obstacles to form a barrier. From this data, a model of the surroundings is produced, with which a driving strategy for maneuvering the motor vehicle out of the parking space is determined. Driving-direction pointers indicate the appropriate driving direction to the driver of the motor vehicle. [A3180]

"System and method for tracking objects using a detection system"

A system and method of tracking objects first receives returns from objects in the field of view of a detector. The sensor generates a current frame of datapoints, where an object in the field of view can be represented by multiple datapoints. The datapoints are converted into global coordinates and mapped into a next frame of datapoints and generated at a next sample time to cream a new current frame of datapoints. This new current frame of datapoints is processed to form a list of objects with location and power information that includes information from one or more previous frames. This mapping and processing to form the list of objects allows the system to detect weak signal targets in a ground cluttered environment and minimizes the occurrence of false alarms. [A3181]

"Distance measurement device and vehicle velocity control device for maintaining inter-vehicular distance"

The computer (CPU) of a distance measurement device determines the inter-vehicular distance by applying a software filter (weighing means) upon successive values obtained directly from measurement. A vehicle velocity control device for maintaining the inter-vehicular distance include a distance measurement device for measuring the inter-vehicular distance, and the deviation .DELTA.R of the inter-vehicular distance with respect to the target inter-vehicle distance R.sub.S is determined. The vehicle velocity is controlled on the basis of the deviation .DELTA.R in accordance with the PID (proportion plus integral plus differential) control method, and the gains are varied in accordance with the current value of the inter-vehicular distance. [A3182]

"Transponder having microprocessor generated frequency shift signals"

An improved transponder for use in identifying an controlling vehicles wherein transponders mounted on vehicles respond to signals from a fixed location interrogator providing information relative to the vehicle or other data as required. The transponder disclosed in particular utilizes an improved method of providing frequency shift keyed (FSK) signals in response to a trigger or command signal received from a ground mounted loop or antenna. As disclosed, the transponder of the invention generates FSK signals through programming multiple microprocessor loops of predetermined duration, each loop providing microprocessor highs and lows for transmission to the interrogating station. Utilization of the inherently accurate microprocessor cycle time to generate distinct FSK signals avoids problems with ordinarily used analog frequency generating devices. [A3183]

"Microwave doppler radar system for detection and kinematic measurements of river ice"

The present invention pertains to a microwave continuous wave (CW) Doppler adar system for river ice motion detection and real-time kinematic data acquisition using digital signal processing equipment for processing, storing and displaying such data. With less complex electronic signal processing hardware, a Doppler radar ice motion detection and alarming system can be used in conjunction with the system. River ice kinematic measurements are fundamental to analyses of river/ice dynamics. The system herein can be rapidly deployed, requires minimal operator interaction, and can continuously acquire, process, store and display ice kinematic data regardless of visibility conditions. Use of the Doppler radar system is an effective, efficient and precise method and apparatus for obtaining river ice kinematic data. [A3184]

"3-D weather display and weathercast system"

A weathercasting system for displaying dynamic real time photo-realistic three-dimensional pictorial representations of weather conditions created from meteorological data combined with geographical and topographical data. Geographical and topographical data is retrieved, digitized, and processed to produce a simulated three-dimensional volumetric image and stored in memory for later retrieval. Meteorological data including precipitation, cloud cover data, the bottom and top of cloud formations, and reflectivity and velocity of rain droplets in real-time are acquired from C-band and/or K-band Doppler radar, or non-Doppler K-band and Doppler X-band radar installations which ameliorate S-band radar data and the data is digitized and processed to produce a simulated three-dimensional image of the meteorological data. The meteorological data is combined with the geographical and topographical data to produce a digital signal capable of being transmitted to a computer, displayed on a computer display screen, and manipulated by peripheral devices connected with the computer. The combined data is displayed as a photo-realistic three-dimensional pictorial representation of weather conditions from a selective observation point and relative to a selective geographical area. The pictorial representation can be manipulated to give the visual effect of moving through a weather system to allow the viewer to visualize the effects of the weather system at various geographical locations. [A3185]

"Vehicle speed sensor utilizing relationship between vehicle wheel speed and doppler-effect speed"

The apparatus has a signal processor for determining the ground speed of a motor vehicle on the basis of the frequency of a wave transmitted from a transmitter and the frequency of the wave reflected by the ground surface and received by a receiver. The signal processor includes a relationship obtaining device for obtaining a relationship between an estimated vehicle speed obtained on the basis of the speed of a vehicle wheel, and a provisional speed determined on the basis of the frequencies of the transmitted and reflected waves, when the vehicle is in a steady running state in which the estimated vehicle speed accurately represents the actual vehicle speed. The signal processor determines the final vehicle speed on the basis of the obtained relationship. [A3186]

"Passive identification of friend vs. foe apparatus and method"

A method and apparatus for passive identification includes a series of elements preferably in the form of strips, bars or other geometric shapes, or as dipole antennas made of a material having variable EM retro-reflectivity characteristics. By varying the characteristics of individual elements (i.e. spatial, polarization, frequency response and angular extent of retro-reflection) , the elements form an alterable pattern which can be used for identification. The characteristics can be changed remotely, the ability of the device to understand and implement the change being a criterion for identification. [A3187]

"Contact management model assessment system for contact tracking in the presence of model uncertainty and noise"

A system for providing an iterative method of assessing accuracy of selected models of physical phenomena and for determining selection of alternate models in response to a data sequence in the presence of noise. Initially, a residual sequence is generated reflecting difference values between in response to said data sequence and an expected data sequence as would be represented by a selected model. Feature estimate values of a plurality of predetermined data features in the residual sequence are then generated. In response to the feature estimate values, a threshold value is generated for each feature at an estimated ratio of data to noise power. Probability values are generated in response to the threshold value, representing the likelihood that the feature exists in the data sequence, does not exist in the data sequence, and that the existence or non-existence in the data sequence is not determinable, along with an amplitude probability value indicating the belief of the amplitude of the respective feature in the data sequence. Probability values are generated in response to the feature existence and amplitude probability values, representing the likelihood that various modelling hypotheses are represented by the observed features, or are not ruled out by the observed features in the presence of the given noise level. Finally, a model is selected in response to the probability values for use during a subsequent iteration. [A3188]

"Recording of operational events in an automotive vehicle"

An apparatus and method for recording operational events in an automotive radar system. The invention provides an Event Recording Apparatus (ERA) that records selectable vehicle performance, operational status, and/or environment information, including information useful for accident analysis and updated software for use by a system processor capable of reading data from the ERA. The preferred embodiment of the ERA comprises a non-volatile solid-state memory card, a memory card adapter located in a vehicle, and a microprocessor, either as part of the memory card or embedded in a system within the vehicle, for controlling the storage of data within the memory card. The ERA is configured to store such vehicle information as the closing rate between the recording vehicle and targets located by the vehicle's radar system, distance between the recording vehicle and targets, vehicle speed, and such vehicle operational status and environment information as braking pressure, vehicle acceleration or deceleration, rate of turning, steering angle, hazard levels determined from a radar system processor, target direction, cruise control status, vehicle engine RPM, brake temperature, brake line hydraulic pressure, windshield wiper status, fog light status, defroster status, and geographic positioning information. In addition, the ERA can be configured to function as a common trip monitor, recording distance travelled, average speed, miles-per-gallon, fuel remaining, compass direction of travel, etc. The device can also record vehicle maintenance information, such as oil temperature, engine temperature, transmission fluid temperature, and engine timing. [A3189]

"Radio frequency automatic identification system"

A radio frequency automatic identification system detects targets which include a plurality of radio frequency resonators. Information is attributed to the target in accordance with the radio frequency response characteristics of the target, such as the resonant frequencies of resonators present, and/or the spatial locations within the target of the resonators. Preferred resonators include thin dipoles, which may be metallizations on a plastic film substrate. Information may be attributed to a target by fabricating the target with resonators disposed at locations to encode information in accordance with a predetermined encoding system, alternatively, resonators may be randomly disposed, and a translation code applied to convert the radio frequency information to particular information in a particular format. Readers for use in the system read the radio frequency response characteristics of a target in the near field of a radiating aperture which is illuminated by a radio frequency source. Items which may be encoded with radio frequency readable information include documents, credit cards, and computer diskettes. [A3190]

"Speed detecting apparatus"

A speed detecting apparatus mounted on an object moving on the ground detects a Doppler frequency for computing a moving speed thereof by receiving reflection waves of a microwave signal or a millimeter wave transmitted to the ground. The apparatus comprises a plurality of transmitting/receiving systems each having an antenna and a transmitter/receiver, and a signal processing section for computing moving speed according to Doppler frequency detected by the transmitting/receiving systems. Directivity of an antenna provided in each of the plurality of transmitting/receiving systems is set at a different angle respectively. [A3191]

"Intelligent area monitoring system"

An intelligent area monitoring system having a field sensor, a neural network computer, and a communications apparatus is disclosed. The system has the capability of detecting and monitoring the location and identity of people, animals, and objects within an indoor or outdoor area for the purpose of intrusion detection, theft deterrence, and accident prevention. The neural network computer accepts the input signals from the field sensor and forms a virtual model of the monitored area from the input. Any changes that occur within the monitored area are communicated to system users. The sensors can be active or passive, analog or binary, and the system is optimally configured with a mix of different sensor types such as vibration, sound, infrared, optical, microwave, and ultrasonic. Each analog sensor provides an analog output which varies in proportion to the size and distance of its target. After monitoring changes in the space being monitored and identifying various objects within the space, the neural network computer communicates such information to the user. [A3192]

"Narrow field electromagnetic sensor system and method"

A narrow field electromagnetic sensor system and method of sensing a characteristic of an object provide the capability to realize a characteristic of an object such as density, thickness, or presence, for any desired coordinate position on the object. One application is imaging. The sensor can also be used as an obstruction detector or an electronic trip wire with a narrow field without the disadvantages of impaired performance when exposed to dirt, snow, rain, or sunlight. The sensor employs a transmitter for transmitting a sequence of electromagnetic signals in response to a transmit timing signal, a receiver for sampling only the initial direct RF path of the electromagnetic signal while excluding all other electromagnetic signals in response to a receive timing signal, and a signal processor for processing the sampled direct RF path electromagnetic signal and providing an indication of the characteristic of an object. Usually, the electromagnetic signal is a short RF burst and the obstruction must provide a substantially complete eclipse of the direct RF path. By employing time-of-flight techniques, a timing circuit controls the receiver to sample only the initial direct RF path of the electromagnetic signal while not sampling indirect path electromagnetic signals. The sensor system also incorporates circuitry for ultra-wideband spread spectrum operation that reduces interference to and from other RF services while allowing co-location of multiple electronic sensors without the need for frequency assignments. [A3193]

"Automatic brake control system"

An automatic brake control system produces a warning before automatically making the braking action of a driving vehicle according to the velocities of the driving vehicle and the vehicle ahead. The system calculates the desired vehicle distance according to the velocities of the driving vehicle and the vehicle ahead, and sets a warning distance which is longer than the desired vehicle distance. The warning distance is set in accordance with the driver's feeling. According to the present invention, the system is prevented from producing undesirable warning. [A3194]

"Obstacle recognition system for a vehicle"

A radar device emits a wave beam into a given angular range outside a vehicle, and scans the given angular range by the wave beam. The radar device detects a reflected wave beam. A recognizing device is operative for recognizing an obstacle with respect to the vehicle on the basis of the result of detection of the reflected wave beam by the radar device. In the recognizing device, a point recognizing section recognizes obstacles as points, and a uniting section is operative for uniting adjacent points among the points provided by the point recognizing section. The uniting section provides sets each having adjacent points. A line-segment recognizing section is operative for detecting a specific set or specific sets of adjacent points among the adjacent-point sets provided by the uniting section, and for recognizing every detected specific set as a line segment having a length only along a width direction of the vehicle. Every specific set has a length smaller than a given length along a longitudinal direction of the vehicle. A position estimating section estimates the position of a line segment, which will be provided by the line-segment recognizing section, in response to the position of a previously-provided line segment. An identity judging section is operative for comparing the line-segment position estimated by the position estimating section and the position of a line segment currently provided by the line-segment recognizing section to judge whether or not the line segment currently provided by the line-segment recognizing section and the previously-provided line segment are the same. [A3195]

"Proximity detonator"

A proximity detonator which derives its firing criterion from reflected beam measurements and thus obtains information about the radial relative velocity of the detonator with respect to its target object by evaluating the Doppler effect, wherein the firing signal is produced by a circuit including a function generator whose output voltage has a time sequence which corresponds to the decrease in radial relative velocity as the detonator approaches its target object (possibly under consideration of a correction value resulting from the firing law) , a voltage controlled oscillator whose control input is connected to the output of the function generator, and a phase comparator having two signal inputs, one of which receives a Doppler signal which corresponds to the radial relative velocity and the other of which is connected to the output of the oscillator. The phase comparator compares the two input signals and emits the firing signal whenever the frequency of the Doppler signal is equal to the comparison frequency from the oscillator. [A3196]

"Body monitoring and imaging apparatus and method"

A non-acoustic pulse-echo radar monitor is employed in the repetitive mode, whereby a large number of reflected pulses are averaged to produce a voltage that modulates an audio oscillator to produce a tone that corresponds to the heart motion. The antenna used in this monitor generally comprises two flat copper foils, thus permitting the antenna to be housed in a substantially flat housing. The monitor converts the detected voltage to an audible signal with both amplitude modulation and Doppler effect. It further uses a dual time constant to reduce the effect of gross sensor-to-surface movement. The monitor detects the movement of one or more internal body parts, such as the heart, lungs, arteries, and vocal chords, and includes a pulse generator for simultaneously inputting a sequence of pulses to a transmit path and a gating path. The pulses transmitted along the transmit path drive an impulse generator and provide corresponding transmit pulses that are applied to a transmit antenna. The gating path includes a range delay generator which generates timed gating pulses. The timed gating pulses cause the receive path to selectively conduct pulses reflected from the body parts and received by a receive antenna. The monitor output potential can be separated into a cardiac output indicative of the physical movement of the heart, and a pulmonary output indicative of the physical movement of the lung. [A3197]

"Automatic vehicle following system"

An automatic vehicle following system is provided for controlling a following vehicle to maintain at least a predetermined distance behind a preceding vehicle and to substantially follow the path of the preceding vehicle. An on-line measurement system of the preceding vehicle generates signals indicative of the velocity (having speed and directional components) of the preceding vehicle, and a communication system transmits the velocity signals to the following vehicle. The following vehicle likewise has a communication system for receiving the signals from the preceding vehicle, and an on-line measurement system for providing signals indicative of the velocity of the following vehicle and signals indicative of the distance between the two vehicles. A signal processing system of the following vehicle is coupled to the communication system and on-line measurement system for estimating motion trajectory of the preceding vehicle based on the difference in the velocities of the preceding and following vehicles and the following distance. A control system generates control signals and takes action so as to perform speed control and maintain at least a predetermined safe following distance between the two vehicles, and steering control to substantially follow the path of the preceding vehicle. [A3198]

"Anti-collision system for vehicles"

An anti-collision system detects conditions of an object preceding a source vehicle, and parameters indicative of operating conditions of the source vehicle, and controls the source vehicle so as to prevent a collision with the object, based on the detected conditions of the object and the detected operating conditions of the source vehicle. The system estimates a path of travel of the source vehicle, based on the detected parameters, and sets an area of travel of the source vehicle to a first predetermined area lying about the estimated path of travel. Further, the system estimates a path of movement of the object, based on the detected conditions of the object, and sets an area of movement of the object to a second predetermined area lying the estimated path of movement. The system calculates a possibility of collision, based on the set area of travel and area of movement, to thereby control the velocity of the source vehicle. [A3199]

"Police traffic radar using absolute signal strength information to improve target signal processing accuracy"

A police radar utilizing digital data transmission from the antenna unit to a separately housed counting and display unit. The antenna has a double balanced mixer to suppress even order harmonics. The counting and display unit has a computer programmed to perform digital signal processing on the digital data received from the antenna to improve the quality and accuracy of calculated speeds for patrol speed, strongest target speed and fastest target speed. Fastest target speed can be displayed simultaneously with strongest target speed. Signal processing techniques are used to suppress false signals caused by double and triple bounce, harmonics, intermodulation products, video display terminal interference, etc. [A3200]

"Statistical averaging method for wind profiler doppler spectra"

This method for Doppler spectral processing more readily identifies the profiler radar return signals from the atmosphere in the presence of contamination, e.g., from bird echoes, ground clutter, and radio frequency interference. Profiler radars measure winds in the atmosphere by using backscatter (i) from refractive index fluctuations in clear air due to turbulence or (ii) from precipitation such as rain or snow. These radars also receive contaminating radar returns from ground clutter (e.g., from vehicles, power lines, and trees) and from fliers (e.g., aircraft, insects, and birds) . In general, the radar return signals from the atmosphere have statistical and physical properties different from those properties for the contaminating radar returns. This new method uses these differences to eliminate or reduce contamination in radar Doppler spectra for estimation of atmospheric winds. [A3201]

"Method and apparatus for hybrid analog-digital pulse compression"

A method and apparatus for hybrid analog-digital pulse compression, as well as, a method of use and manufacture includes an analog intermediate frequency filter, a converter, and a digital correlator. The analog intermediate frequency filter filters and weights returned echo signals, and the digital correlator compresses the filtered and weighted echo signals. The frequency or impulse response of the digital correlator is set based on the frequency or impulse response of the analog intermediate frequency filter to obtain a pulse compressor with minimal mismatch loss and improved sidelobe suppression. The invention provides for the lowest possible sampling rate of analog-to-digital convertors used with the apparatus, thus, minimizing the cost of this device and all subsequent digital processing. [A3202]

"Police traffic radar for allowing manual rejection of incorrect patrol speed display"

A police radar utilizing digital data transmission from the antenna unit to a separately housed counting and display unit. The antenna has a double balanced mixer to suppress even order harmonics. The counting and display unit has a computer programmed to perform digital signal processing on the digital data received from the antenna to improve the quality and accuracy of calculated speeds for patrol speed, strongest target speed and fastest target speed. Fastest target speed can be displayed simultaneously with strongest target speed. Signal processing techniques are used to suppress false signals caused by double and triple bounce, harmonics, ntermodulation products, video display terminal interference, etc. [A3203]

"Doppler microwave sensor"

A Doppler microwave sensor for a vehicle alarm employs a mixer stage and a signal-processing stage on a printed circuit board, the printed circuit board having a ground plane containing a slot antenna which is coupled to the mixer stage. The ground plane is electrically connected to an electrically conductive enclosure which is disposed behind the slot antenna and encloses the component parts of the mixer and signal-processing stages. A dielectric lens may be placed over the slot antenna to provide a transmission beam pattern which is configured to the vehicle in which the sensor is to be used. In a preferred embodiment, the mixer stage is based arounda self-oscillating mixer arrangement in which the active element is a bipolar transistor and a single antenna is employed both to transmit the oscillator signal and to receive the Doppler-shifted return signal. [A3204]

"Weather radar using spectral gaussian envelope discrimination for clutter rejection"

A method for removing clutter related frequency components from power spectrums generated from weather radar return signals to provide improved windshear detection capability. Weather radar return signals are synchronously detected and digitized to provide i and q time domain sample sequences. The i and q time domain sample sequences are passed through a window function and then transformed to frequency domain sequences by a Fast Fourier Transform. A power spectrum is generated from the frequency domain sequences. The spectrum is subjected to a Spectral Gaussian Envelope Discrimination (SGED) process in which the spectral envelope is scanned to identify any lobe therein having a slope greater than a predetermined minimum. A first pseudo-Gaussian sigma, calculated from the width and maximum amplitude of any such lobe, is compared with a second pseudo-Gaussian sigma, calculated from known conditions. If the first sigma is less than the second sigma, the lobe is deemed to be clutter related and is edited from the spectral envelope. [A3205]

"Police traffic radar using digital data transfer between antenna and counting unit"

A police radar utilizing digital data transmission from the antenna unit to a separately housed counting and display unit. The antenna has a double balanced mixer to suppress even order harmonics. The counting and display unit has a computer programmed to perform digital signal processing on the digital data received from the antenna to improve the quality and accuracy of calculated speeds for patrol speed, strongest target speed and fastest target speed. Fastest target speed can be displayed simultaneously with strongest target speed. Signal processing techniques are used to suppress false signals caused by double and triple bounce, harmonics, intermodulation products, video display terminal interference, etc. [A3206]

"Radar system"

In an FMCW radar system, the velocity of obstacles relative to the radar couples a Doppler frequency shift into the return signal which causes an error in the range measurement. It is known to use a radar signal having a frequency ramp that both increases and decreases to distinguish the range of an obstacle from its velocity but when multiple obstacles are present this is not practical. By using a measure of velocity from a succesion of return signals, which of the radar output signals from the upsweep and downsweep of the radar signal that relate to a particular obstacle can be identified so that the range and velocity can be determined accurately. The FMCW radar system may be provided with a frequency scanned antenna, the beamwidth determined by the processing circuitry is variable according to the size of the obstacle being detected or the range at which the radar is searching for obstacles. Instead of scanning the beam of the radar, the variation in frequency can be made to alter the beamwidth of the radar so that, for example, a car radar will detect only vehicles in the lane ahead of the car, regardless of the range of the vehicles. [A3207]

"Low target velocity interferometric AMTI radar"

An AMTI radar employs a dual cancellation format to cancel the clutter in the radar returns received by the apertures of an interferometric radar antenna. The three-aperture antenna presents the radar returns to three receivers which demodulate the returns to a complex in-phase signal I and a quadrature signal Q which are sampled at a pulse repetition interval at all ranges of interest. After conventional motion compensation four data sets are derived from the returns of the three apertures, L (t) , C (t-.tau.) , C (t) and R (T-.tau.) which represents samples taken over multiple pulse repetition intervals for each range interval or bin of interest. The data is processed by both adjacent array processing and outer array processing, the latter only requiring a minimal amount of additional capacity. Compensation phase is further adjusted in a clutter/clutter-free phase calculator allowing a much reduced phase quantity to be applied to the delayed data sets as the second part of the dual cancellation signal. Following subtraction of doppler filter outputs of the delayed data sets from the undelayed data sets in the cancellation/enhancement unit, maximum clutter cancellation is achieved in the clutter region and optimal moving target response is obtained in the clutter-free region. The two-range maps that result after subtraction of the doppler filter outputs are presented to a detection and validation processor to determine range, doppler, amplitude and angle measurements to the moving targets with a high degree of accuracy. [A3208]

"Height finding antenna apparatus and method of operation"

A ground based radar antenna system and method for determining the elevation angle .phi. of a tracked target having a shaped reflector and a pair of spaced feedhorns for transmitting radiated energy to and receiving returned signals from the tracked target T, the shaped reflector and feedhorns cooperating to increase the range of coverage of the elevation angle .phi. beyond the coverage previously available with a standard parabolic reflector and to increase the gain of the signals returned to the ground based radar antenna system while simultaneously eliminating elevation angle ambiguities over prior systems employing only feedhorns for collecting returned signals. The radar system includes a construction which approximates a cosecant-squared antenna pattern, permits the calculation of the target height and three-dimensional position, and is economical to manufacture. [A3209]

"Device for measuring the velocity of vehicles for traffic monitoring"

A device for measuring the velocity of vehicles for traffic monitoring a doppler signal transmitter and receiver is used which comprises two mixer diodes arranged to deliver two doppler signals which are dephased against each other by 90.degree., the one or the other signal leading the other, depending on whether the picked up vehicle approaches or recedes from the doppler signal transmitter is fed into a frequency measuring device for measuring the signal frequency as a quantitative measure for the relative velocity between vehicle and doppler signal transmitter. for this purpose one signal of the doppler signal transmitter and receiver 10 is fed into a phase control circuit 34, the output frequency of which is converted into a voltage proportional to the relative velocity between doppler signal transmitter 10 and monitored vehicle. Furthermore, the two signals of the doppler signal transmitter and receiver are fed into a phase detector 26. The output signals of the phase detector circuit 26 are fed into a directional logic circuit 28 which has two logic outputs 30, 32 at which logic signals appear indicating as to whether the picked up vehicle approaches or recedes. The logic signals from the directional logic circuit 28 are fed into a frequency voltage converter 56. The frequency voltage converter 56 has two outputs 62, 64. A voltage proportional to the relative velocity of the picked up vehicle appears at output 62 when the picked up vehicle approaches. A voltage proportional the the relative velocity of the picked up vehicle appears at output 64 when the picked up vehicle deviates. [A3210]

"Method for locating leakage of substances from subterranean structures"

A method for imaging substances leaking from underground structures using continuous-wave signals includes translating an antenna array over the ground, transmitting a continuous-wave signal into the ground at an array of points, detecting the amplitude and phase of the reflected signal at each point, transforming the reflectance values into the frequency domain, propagating this reflectance spectrum to a predetermined depth, and transforming the propagated spectrum into an image in the spatial domain at that depth. An image representing the underground structure containing the substance may be overlayed on the calculated image to detect differences that represent leakage. Successive images of the same area may be produced over a period of time and the differences compared to determine the rate of leakage. [A3211]

"Surface wave guideline and object detecting device using surface wave guideline"

An electromagnetic surface wave guideline that is formed by intertwisting dielectrics while providing a periodic structure like a rope and arranging conductors in a period harmonizing with the structure, and is suitable for such a use that entry of various objects including human beings and animals into a specific area for instance, and an object detecting device using the guideline [A3212]

"Excavator data acquisition and control system and method of use"

An excavator data acquisition and control system and process for characterizing the subsurface geology of an excavation site, and for utilizing the acquired data to optimize the production performance of an excavator. A geologic imaging system and a geographic positioning system are employed to initially survey a predetermined excavation site or route. A geologic characterization unit may also be employed to enhance the geologic imaging data. The acquired data are processed to provide detailed geologic and position data for the excavation site and utilized by a main control unit to optimize excavator production performance. In one embodiment, the main control unit accesses a geologic filter database, which includes geologic profile data for numerous types of geology, when analyzing unknown subsurface geology. Removing geological filter data content corresponding to known geology from the acquired geologic imaging data provides for immediate recognition of unknown and suspect subsurface objects. The geologic imaging system preferably includes a ground penetrating radar system having a plurality of antennas oriented in an orthogonal relationship to provide three-dimensional imaging of subsurface geology. Correlation software is employed to correlate acquired geologic image data to historical excavator production performance data to characterize the structural mechanics of subsurface geology. Accurate geographic mapping of an excavation site is provided by the geographic positioning system which preferably includes a mobile transponder mounted to an excavator and a plurality of ground-based transponders and, in one embodiment, Global Positioning System (GPS) signals. [A3213]

"Device for wireless transfer of information"

A device for wireless transfer of information includes a data carrier in the form of a thin card, and a transponder that receives a first microwave signal, modulates it and codes it with data, and reradiates a second microwave signal without adding new energy thereto. The transponder includes at least one antenna device formed using microstrip conductors. The antenna device includes a patch antenna with an antenna layer that acts against a ground plane where the antenna layer and the ground plane are of substantially equal size. The device is characterized in that, it is equipped with a separate card holder with a reflective surface that is larger than said ground plane. The reflective surface increases the range by reradiating the second microwave signal and reducing sensitivity to back lobe reflections. [A3214]

"Two-way cable tv conversion system"

A bidirectional cable television system provides for transmission of signals from cable subscribers downlink in the same direction as the ensemble of television channels which the cable television system is already constructed to deliver. The subscriber signals may be transmitted over the cable in the blanking intervals of a cable television channel, using the T-NET technique described in U.S. Pat. No. 4,750,036. Alternatively, the signals may be carried over a dedicated channel, or transmitted cochannel along a cable television channel carrying ordinary programming by adding the subscriber information to alternating video frames in alternating polarity to achieve visual cancellation. The subscriber signals are collected after the last distribution line amplifier in the cable downlink. The collected signals are transmitted to a central receiver via wireless or other customary means such as a modem. The collected signals may alternatively be transmitted over the air to the central receiver in the blanking intervals of a broadcast television channel using the T-NET technique. [A3215]

"Apparatus and method for measuring mass flow rate of a moving medium"

A mass flow meter is provided for measuring the mass flow rate of a material moving along a flow path. The mass flow meter generates a field of electromagnetic energy through which a material moving along the flow path passes. The mass flow meter includes a receiver that detects an amount of electromagnetic energy reflected from the material which is proportional to the concentration of material moving along the flow path. The amount of electromagnetic energy reflected and an assumed velocity are used to generate a response related to the mass flow rate of the material moving along the flow path. [A3216]

"Optical monopulse chirp processor"

An optical chirp processor for the collection and processing clutter samples is presented that allows the simultaneous estimation of both the clutter mean and variance. The estimated clutter mean and variance allow the actual calculation of both clutter model parameters using a power spectrum analyzer, and a CFAR special purpose processor unit. The power spectrum analyzer is composed of: a spatial frequency demultiplexor, and a four element photodetector array. The special purpose processor is composed of: an A/D converter, a square root calculator, an averaging calculator, a combiner unit, a parameter memory unit, and a threshold calculator unit. The components of the CFAR processor may be implemented in a conventional CFAR processor (when modified by the teachings of the present invention) or in individual electronics components. [A3217]

"System for determining and registering location of mobile terminal for communication system with non-geosynchronous satellites"

The non-geosynchronous orbiting satellites each transmit identification information given to each of spot beams irradiated from them. A mobile terminal, when registering its location, receives the spot beam identification information at some moments in time with the predetermined time interval. Then, the mobile terminal transmits the received spot beam identification information and each of their reception time together with the terminal identification information assigned to the mobile terminal. On the basis of an overlapped area of spot beam coverage areas at time when each of identification information is received by the terminal, a terrestrial network estimates and registers the latest location of the mobile terminal. [A3218]

"Radar system with adaptive clutter suppression"

A method of spectral estimation of a received radar signal wherein an image of the received radar signal is applied to windows of differing prolate spheroidal sequences to calculate multiple eigenspectra. The value of each of said sequences are multiplied with the radar signal, and the Fourier transforms of the products provide a plurality of realizations of orthogonal eigenspectra. The orthogonal eigenspectra are combined into a minimum variance, low bias estimate of the mean power spectrum and an estimate of a variance of said spectrum for each frequency in the spectrum to provide a more accurate estimate of back ground noise and to further improve detection performance. [A3219]

"Pulse doppler proximity sensor"

A pulse Doppler proximity sensor uses a plurality of stepped output radio signals for accurately determining the relative range between the proximity sensor and an object. A dual modulation technique is employed which incorporates a pulse modulation arrangement and a carrier frequency modulation arrangement to detect the necessary range accurately from the plurality of output radio signals. The proximity sensor processes in parallel each of the plurality of output radio signals returned from the object. A binary comparison is made and the comparison is integrated over time to prevent false alarms. The pulse Doppler proximity sensor is particularly useful in fuzing arrangements for a munition in which a number of range settings are desired. [A3220]

"Neural network based data fusion system for source localization"

A method is described for providing an estimate of the state of a moving contact. The method comprises providing a device for estimating the state of the contact, inputting information about a location of an observer platform at particular time intervals and information from at least one sensor about a position of the moving contact relative to the observer platform at each time interval into the device, transforming the inputted information into a series of geographical grids with one grid being formed for each reading of the at least one sensor, combining grids corresponding to similar time intervals into a series of consolidated grid representations, and analyzing the series of consolidated grid representations to produce an estimate of the state of the contact at a final point in time where an observation was made. The device of the present invention includes a grid stimulation block for forming the geographical grids, a fusion block for forming the consolidated grid representations, a correlation block for providing a path likelihood vector, and an estimation block for providing the desired estimate. [A3221]

"Method and system for tracking multiple regional objects by multi-dimensional relaxation"

A method and system for real-time tracking of objects is disclosed. A region is repeatedly scanned providing a plurality of images or data sets having points corresponding to objects in the region to be tracked. Given a previously determined track for each object in the region, an M-dimensional combinatorial optimization assignment problem is formulated using the points from M-1 of the images or data sets, wherein each point is preferably used in extending at most one track. The M-dimensional problem is subsequently solved for an optimal or near-optimal assignment of the points to the tracks, extending the tracking of the objects so that a response to each object can be initiated by the system in real-time. Speed and accuracy is provided by an iterative Lagrangian Relaxation technique wherein a plurality of constraint dimensions are relaxed simultaneously to yield a reduced dimensional optimization problem whose solution is used to formulate an assignment problem of dimensionality less than M. The iterative reducing of dimensions terminates when exact solutions are determined for two-dimensional cases. A recovery procedure is used for determining a higher dimensional assignment problem solution from a problem having one less dimension. The procedure is useful when the reduced dimensional optimizational problem has two constraint dimensions. [A3222]

"Method for tracking moving objects"

The tracking of moving objects on land, in the air or at sea is effected by means of one or more sensors (S.sub.j.sup.1) . The observation space of each sensor is divided into resolution cells (X.sup.1h) forming a grid. The sensors of the same grid are grouped together. A probability estimate (.beta.k) for a moving object being in a cell (Xk) which is an intersection of the resolution cells (X.sup.1h) is produced. for this purpose, the starting points are signals (M.sub.j.sup.1h) delivered by the sensors (S.sub.j.sup.1) and previously selected according to windowing criteria, sets of pairs (F.sub.i (M.sub.j.sup.1h) D.sub.ij.sup.1h) stored in memories (1) and coming from a prior supervised statistical learning, and tracking coefficients (.alpha.k) delivered by an adaptive tracking filter (4) of the PDAF type. After application of this probability (.beta.k) to the adaptive tracking filter (4) , there is obtained on the one hand an estimated status (X*,P*) affording a trajectory prediction (x,S) for at least one moving object and, on the other hand, the windowing criterion is adjusted. [A3223]

"Apparatus for measuring physical quantity related to relative movement between two objects"

A measuring apparatus is provided in one of two objects moving relatively to each other. The apparatus includes a circuit for effecting a direct spread modulation with respect to a transmission carrier signal using modulation codes, an antenna unit for transmitting the modulated carrier signal toward the other of the two objects and for receiving a reflection wave therefrom, a circuit for demodulating the received reflection wave signal using the transmission carrier signal, a circuit for making correlation between the demodulated output signal and a signal having the same code as that of the modulation code and having a phase delayed by a predetermined time, a unit for extracting a Doppler frequency component contained in a signal which has been propagated through a propagation path existing in a specified distance range, and a circuit for properly processing the extracted Doppler frequency component. By the constitution, it is possible to precisely measure a speed and/or direction angle of one object relative to the other of the two objects, without being subject to an influence by a reflection in the close neighborhood, or an influence by interference of a transmission signal or interference signal in a receiving channel of the apparatus. [A3224]

"Anticollision device, notably for motor vehicles"

In an anticollision device, a moving object heading in a given direction along a movement vector and having a relative speed vector directed towards an obstacle is fitted out with at least two antennas sending out a microwave signal liable to be received by the obstacle. The device furthermore comprises reception means and means to analyze the echoes received from the obstacle, the analyzing means determining the variation with respect to time of the angle .theta. between the movement vector and the relative speed vector, a substantially zero variation of the angle .theta. indicating a risk of collision. Application to the equipment of motor vehicles to prevent collisions, notably in the event of poor visibility. [A3225]

"Arrangement for comparing two temporally separated bursts of signal at two different frequencies"

A comparator circuit compares two temporally separated input bursts of signals which occur at two different frequencies. The first burst is an interrogation pulse and the second burst is a reply pulse in a DME system. The comparator circuit includes a first frequency converter (CO1) for receiving at an input thereof the two input bursts, and a comparing device (DC) connected to receive an output of the first frequency converter (CO1) . In order to reduce the measurement errors, the first frequency converter (CO1) receives at the input thereof the two input bursts and converts them into two new bursts of signals that have a common frequency so that the comparing device (DC) can carry out the comparison at the common frequency. [A3226]

"Non-contact speed measuring apparatus for railroad vehicle"

A speed measuring apparatus includes: a modulation circuit for carrying out a direct spread modulation with respect to a transmission carrier signal using coded two-phase random signals, an antenna unit for transmitting the modulated transmission carrier signal as a radio-wave toward an object and for receiving a reflected wave from the object, a demodulation circuit for demodulating a signal corresponding to the received reflected wave using the transmission carrier signal, to thereby generate intermediate frequency signals, a correlation circuit for making correlation between the intermediate frequency signals and signals each having the same code as that of the coded two-phase random signal and having a phase delayed by a predetermined time, a Doppler detecting unit for extracting from an output signal of the correlation circuit a Doppler frequency component contained in a signal which has been propagated by way of a propagation path existing in a specified distance range, and for generating speed information based on the extracted Doppler frequency component, and a computing unit for computing a movement distance and a position of the railroad vehicle over the whole track, on a real-time basis, using the generated speed information and fixed-point position information input from an outside of the apparatus. By the constitution, it is possible to precisely measure a speed of the railroad vehicle without being subject to the influence by a slip or glide of the wheels under any circumstances. It is also possible to specify a movement distance and position of the vehicle on a real-time basis. [A3227]

"Three-pulse MTI without blind speeds"

An MTI with no blind speeds which compensates for antenna scan modulation. his design includes circuitry for generating and transmitting consecutive first, second and third doppler-tolerant FM pulses, wherein the first and third FM pulses have a given dispersion characteristic, and the second FM pulse has a dispersion characteristic which is the complex conjugate of the first and third FM pulses. Circuitry is then provided for receiving and compressing the first, second, and third echos from the first, second, and third pulses, respectively. Finally, a processing circuit is used to effectively add the first and third echo pulses and to subtract twice the second echo pulse from this sum to effect the detection of the moving target. [A3228]

"Blind-zone target discrimination method and system for road vehicle radar"

A method and system for discriminating a target which presents a hazard to a motor vehicle moving in a first lane of traffic from a target moving in a second adjacent lane of traffic which does not present a hazard to the vehicle. The method includes the steps of utilizing an antenna mounted flush to a side of the vehicle to produce a radar beam having a beamwidth greater than 5-10 degrees to illuminate the target. At least a portion of the radar beam is produced along a first axis which is perpendicular to the direction of motion of the vehicle. The reflected signal is received from the illuminated target and a velocity of the illuminated target is estimated with a Kalman filter relative to the velocity of the vehicle in the direction of a second axis which is parallel to the direction of motion of the vehicle based on the reflected signal. The method also includes the steps of measuring the velocity of the vehicle using at least one velocity sensor and determining that the illuminated target is hazardous if the sum of the measured vehicle velocity and the estimated parallel target velocity is greater than a predetermined threshold. The illuminated target is determined not to be hazardous if the sum of the measured vehicle velocity and the estimated parallel target velocity is less than a predetermined threshold. [A3229]

"Vehicle speed control system"

A vehicle speed control system for controlling the speed of a controlled vehicle to follow a preceding vehicle detected at a constant interval is provided. In this system, when a preceding vehicle traveling ahead of the controlled vehicle is detected, it is checked if the preceding vehicle detected meets a given tracking condition. When the tracking condition is encountered, it is reported to a driver. The system is responsive to a manual operation of the driver after the driver has perceived that the preceding vehicle can be tracked to initiate constant inter-vehicle distance control. [A3230]

"Traffic radar with digital signal processing"

A traffic radar processes Doppler return information by analysis of the received frequency spectrum in order to improve target identification and minimize interference and unwanted harmonics. Digital signal processing including transformation of the return information into the frequency domain is employed to provide multiple modes of operation including a stationary mode where either the strongest or the fastest Doppler return signal may be selectively recognized, and moving modes for monitoring traffic moving in both the opposite direction and the same direction as the patrol vehicle. In the moving modes either strongest or fastest signal processing may be elected, and operation when the patrol and target vehicles are moving in the same direction is provided irrespective of whether the patrol vehicle is moving faster or slower than the target vehicle. The speed of the patrol car is determined by recognizing a signature that exhibits an asymmetry due to the cosine effect. Interference and harmonics are detected and suppressed by recognizing unwanted harmonic patterns and eliminating signal magnitudes at the harmonic frequencies. [A3231]

"Police traffic radar using double balanced mixer for even order harmonic suppression"

A police radar utilizing digital data transmission from the antenna unit to a separately housed counting and display unit. The antenna has a double balanced mixer to suppress even order harmonics. The counting and display unit has a computer programmed to perform digital signal processing on the digital data received from the antenna to improve the quality and accuracy of calculated speeds for patrol speed, strongest target speed and fastest target speed. Fastest target speed can be displayed simultaneously with strongest target speed. Signal processing techniques are used to suppress false signals caused by double and triple bounce, harmonics, intermodulation products, video display terminal interference, etc. [A3232]

"Collision avoidance system for vehicles using digital logic circuitry and retro-fitting techniques"

A continuous exterior perimeter monitoring system for collision avoidance by vehicles with exterior objects is provided utilizing microelectronic digital logic circuits and techniques to produce a visual three-digit numerical display, a discrete multi-color display and a multi-level sound warning system, indicating precise and range of distances of exterior objects from vehicles which could collide therewith within pre-selected distances. The time-to-distance circuits of the system are an integral part of the digital logic circuits that are utilized to ascertain distances and such circuits are in a compact electronic package adapted to and is readily installed and integrated into existing vehicles utilizing the existing wiring electrical power systems primarily as a retro-fitting process for vehicles or as an original installation. [A3233]

"Communication system and method for determining the location of a transponder unit"

A multilaterating two-way message delivery system for mobile resource management provides efficient two-way radio data communication for multitudes of portable transponders using a single frequency in half-duplex communication. The system includes at least one transponder device which transmits and receives data using a radio frequency communication link, and an array of at least three base stations which communicate with the transponder device using the radio frequency communication link. The radio frequency communication link employed by each base station and the transponder device is designed to provide muitilateration information and to deliver message data simultaneously. Further, a control arrangement is coupled to the array of base stations to coordinate the communication between the base stations and the transponder devices. Time-division multiplex and spread spectrum technology is employed by the system for communication efficiency and minimizing the effect of multipath interference. [A3234]

"Police traffic radar for calculating and simultaneously displaying fastest target speed"

A police radar utilizing digital data transmission from the antenna unit to a separately housed counting and display unit. The antenna has a double balanced mixer to suppress even order harmonics. The counting and display unit has a computer programmed to perform digital signal processing on the digital data received from the antenna to improve the quality and accuracy of calculated speeds for patrol speed, strongest target speed and fastest target speed. Fastest target speed can be displayed simultaneously with strongest target speed. Signal processing techniques are used to suppress false signals caused by double and triple bounce, harmonics, intermodulation products, video display terminal interference, etc. [A3235]

"Transponder interface circuit"

A transponder interface circuit (172) operates to allow communication between a transponder controller (104) and external circuitry. The interface circuit (172) has a buffer memory (184,186) that allows the transponder controller (104) and the external circuitry each to transmit data at either the transponder's (14) or the external circuitry's clock rate without complicated protocols for direct communication. Each of the transponder controller (104) and the external circuit may be enabled by an interface controller (174) to assume control of the buffer memory (184,186) . By using the buffer memory (184,186) and interface controller (174) , whichever of the transponder controller (104) and the external circuitry is transmitting or receiving data may fill or empty the buffer memory (184,186) at either the transponder controller's (104) or the external circuitry's chosen clock rate. The interface controller (174) will monitor the transfer such that when the buffer memory (184,186) is full or empty, the interface controller (174) will send a command to the appropriate transponder controller (104) or external circuit to either receive data from the full buffer memory (184,186) or transmit data to the empty buffer memory (184,186) . [A3236]

"Method and system for conserving power in a recognition system"

A system and method for avoiding the discharge of a battery or otherwise excessive power consumption by a transponder (14) in the presence of a spurious noise source. In a described embodiment, the transponder (14) renders itself immune to activation by presence of RF energy for some period if the transponder does not receive a proper wake-up message within an activation period. [A3237]

"Mobile object identification system"

The primary object of the invention is to realize a mobile object identification system of simple construction and low cost, in which the responding unit attached to a mobile object writes data only once when it receives write signals repeatedly in communication with antenna units. When a tag unit (responding unit) receives a write signal from a writing antenna unit, it writes data to the data memory when a completion flag is cleared. When the data is first written, a control circuit sets the completion flag. Then, if the tag unit receives additional write signals in the communication area of the same writing antenna unit, the control circuit invalidates the data write command on the ground that the completion flag is set, thereby preventing duplicate data writing. [A3238]

"Ultra-wideband receiver"

An ultra-wideband (UWB) receiver utilizes a strobed input line with a sampler connected to an amplifier. In a differential configuration, .+-.UWB inputs are connected to separate antennas or to two halves of a dipole antenna. The two input lines include samplers which are commonly strobed by a gating pulse with a very low duty cycle. In a single ended configuration, only a single strobed input line and sampler is utilized. The samplers integrate, or average, up to 10,000 pulses to achieve high sensitivity and good rejection of uncorrelated signals. [A3239]

"Range-gated field disturbance sensor with range-sensitivity compensation"

A field disturbance sensor operates with relatively low power, provides an adjustable operating range, is not hypersensitive at close range, allows co-location of multiple sensors, and is inexpensive to manufacture. The sensor includes a transmitter that transmits a sequence of transmitted bursts of electromagnetic energy. The transmitter frequency is modulated at an intermediate frequency. The sequence of bursts has a burst repetition rate, and each burst has a burst width and comprises a number of cycles at a transmitter frequency. The sensor includes a receiver which receives electromagnetic energy at the transmitter frequency, and includes a mixer which mixes a transmitted burst with reflections of the same transmitted burst to produce an intermediate frequency signal. Circuitry, responsive to the intermediate frequency signal indicates disturbances in the sensor field. Because the mixer mixes the transmitted burst with reflections of the transmitted burst, the burst width defines the sensor range. The burst repetition rate is randomly or pseudorandomly modulated so that bursts in the sequence of bursts have a phase which varies. [A3240]

"Method for providing guiding assistance for a vehicle in changing lane"

Method of assisting a motor vehicle in changing from a current lane to an adjacent target lane. The space in front and the space behind the vehicle at least in the adjacent target lane is monitored, the distance of objects (in particular vehicles) detected there, and their speeds are measured, and safety distances calculated therefrom. If all the measured distances are greater than the calculated safety distances, a possible lane change is signalled. [A3241]

"Detection of multiple articles"

An identification system comprises an interrogator and a plurality of transponders. The interrogator includes a transmitter which transmits at least two independent interrogation signals to the transponders, and a receiver for receiving response signals from the transponders. The interrogator also includes processor means for identifying the transponders from data in the received response signals. Each transponder comprises receiving means, a code generator, and transmitter means connected to the code generator. On receipt of at least one of the transmitted interrogation signals the transponder transmits a response signal containing data which identifies it. The interrogation signals may be transmitted continuously or intermittently. In a preferred embodiment, the interrogation signals are relatively narrow bandwidth signals at different frequencies. The receiving means of each transponder has a relatively broad reception bandwidth so that the transponder is responsive to one or more of the interrogation signals. [A3242]

"Vehicle obstacle monitoring system"

A vehicle obstacle monitoring system for alerting a driver to the presence of an obstacle within a predetermined distance from the vehicle. The system includes a signal generator which radiates a signal around the vehicle and a plurality of signal receivers encircling the exterior of the vehicle. A display monitor located in the interior of the vehicle displays a zone image around the car and alerts the driver to the presence of an obstacle within the zone. [A3243]

"Intelligent area monitoring system"

An intelligent area monitoring system having a plurality of sensors (11,12,13,14,15,16) , a neural network computer (20) , a data communications network (28,30,32,42) , and multiple graphic display stations (40) . The neural network computer (20) accepts the input signals from each sensor. Any changes that occur within a monitored area are communicated to system users as symbols which appear in context of a graphic rendering of the monitored area. The sensors can be active or passive. Each sensor provides an analog output (54) . Codes are communicated to graphic display stations (40) via a data communications network (28,30,32,42) . Based on these codes, the graphic display stations (40) select and place symbols on their display screens to accurately represent the identity and location of targets in the monitored area. [A3244]

"Smart blind spot sensor with object ranging"

A radar system for sensing the presence of obstacles in a vehicle's "blind spots" and generating a signal to the vehicle operator indicative of the presence of such an obstacle. The system uses a common radar transceiver that transmits a multi-frequency radio signal directed at a blind spot of the vehicle. The signal is reflected off any obstacles that are present in that blind spot region. Doppler shifts in the received reflected multi-frequency signal generally indicates that an obstacle has moved into the blind spot. Doppler frequencies attributable to objects which are of no interest, such as stationary objects, are filtered out. The system has a signal processor which determines if a potentially hazardous object is within a pre-determined range from the vehicle. Only objects that are traveling at approximately the same speed and direction as the vehicle, and that are within a pre-determined range of the vehicle, are considered to be of interest, and will cause the blind spot sensor to generate an indication that an obstacle is present within the blind spot. The indication is preferably an unobtrusive illuminated indicator which is affixed to one of the vehicle's mirrors. In addition to the illuminated indicator affixed to a mirror, an obtrusive audible indicator is provided in the preferred embodiment of the present invention which creates an audible tone, whistle, or buzz when an obstacle is present and the vehicle's turn signal is active. [A3245]

"Meteorological workstation"

A meteorological workstation provides for editing of raw data at its input by providing intelligent control of extraction of data from one or more data streams of collected weather data. Commands by the operator to the graphics processing of a weather forecasting and numerical modelling application cause the generation of commands to a dedicated processor controlling acceptance or extraction of data. Thus, data to be processed is limited, at any given time, to the data actually needed by the meteorological workstation under user control and has the effect of allowing the workstation user to control the source of the data being collected. Intelligent direction of the selected data also allows the formation of messages and the issuance of advisories and warnings even when the workstation is unattended. [A3246]

"Navigation display apparatus for collison avoidance utilizing polygonal safety regions and predicted danger areas"

A navigation supporting display apparatus makes it easy for an operator of ship to navigate with a safe passing distance between own ship and a target by indicating an exact danger area between own ship and the target ship. The apparatus has a collision point calculator which calculates a possible collision point of each of the vertexes of a polygonal safe passing region set around own ship, and the target ship, from a relative position of the target ship, a velocity vector of the target ship and a velocity of own ship. The apparatus has an own-ship-mapping-position calculator which calculates a position at which own ship would be located when each of the vertexes places on the collision point, and defines the position as a own-ship-mapping-position. The apparatus further has a danger area calculator which determines lines joining own-ship-mapping-positions corresponding to the collision points with each other to define a danger area. The relation between connected own-ship-mapping-positions and the own-ship-mapping-positions are output to a display device, and the display device displays the area defined by the lines joining own-ship-mapping-positions as a danger area together with the position and the vector of own ship and the position of the target ship. [A3247]

"System for processing returns from a target from transmissions containing repeated signals to detect the doppler velocity of the target"

A signal processing system of reduced complexity over conventional banks of matched filters for each Doppler velocity of interest is responsive to a transmission which is in the form of a train of repeated Doppler invariant signals which are preferably phase continuous. The system utilizes a head end zero Doppler correlator and tapped delay line summer with summing nodes in cascade for each Doppler velocity of interest. The summer provides coherent sums indicative of the Doppler velocity of the target. [A3248]

"Built-in radiation structure for a millimeter wave radar sensor"

A compact radar system includes a dielectric substrate having an upper and lower surface. A ground plane is formed on the upper surface of the dielectric substrate and includes a radiating slot formed therein. A radar transceiver is located below the dielectric substrate and generates transmit signals. A frequency selective surface spaced above the dielectric substrate includes a radiating aperture with a plurality of uniformly spaced holes. The frequency selective surface decreases flow of electromagnetic energy from the radiating slot in one direction towards the transceiver and increases the flow of electromagnetic radiation in an opposite direction away from the transceiver. [A3249]

"System for distinguishing a vehicle traveling ahead based on an adjustable probability distribution"

An anticollision radar system for a vehicle is provided. This system includes a distance sensor for measuring distance to an object present in a given forward detectable range, and determines a curvature of a road on which the system vehicle is moving, determines the probability that the object present in a given forward detectable range of the distance sensor is identified as a preceding vehicle traveling on the same lane as the system vehicle in a preselected relation to the distance to the object measured by the distance sensor and the curvature of the road determined, determines a target speed based on the probability determined, and modifies the speed of the system vehicle to the target speed determined. [A3250]

"Apparatus for wind shear compensation in an MTI radar system"

The invention relates to apparatus for reducing the masking effect in the doppler frequency domain of wind sheared clutter upon the radar returns of moving targets. The invention consists in forming two beams from the elements of a radar antenna array by means of adjustable complex weights which are then summed. One of the two beams is then delayed by a predetermined amount and added algebraically to the other beam to form a composite beam containing a narrow trough-like depression in beam angle/doppler frequency space. Means are then provided for adjusting the weights to bring coincidence between the depression and the clutter to cause attenuation of the clutter with a minimum reduction in the usable doppler frequency domain. [A3251]

"Single antenna location and direction finding system"

The invention provides a circuit for analyzing backscatter-modulated RF signals received from a remote transponder to determine whether the transponder is stationary or moving toward the reader or away from it and, if moving, the rate at which the transponder is coming or going. The circuit of the invention can be integrated with existing readers of the type described in U.S. Pat. No. 4,739,328 and requires only a single antenna. In response to the signal received from a transponder, the invention circuit generates three signals, each having a different phase. By analyzing the pattern and frequency of signal state changes in the three signals, the invention can determine the transponder's speed and direction of movement. [A3252]

"Vehicular radar wayside transponder system"

Doppler control circuit for a CW or pulse Doppler radar system for monitoring not only the phase shift between echo signals from several targets but also the amplitude difference between the several targets and to further provide a phase lock loop which tunes the radar to a particular target among one or more targets from which echo signals return. The control circuit can be used in state of the art CW or pulse Doppler type radar systems. In a further system, a continuously generated radar signal is repeatedly transmitted at three different frequencies in time division fashion to define a succession of transmit and receive frames. The receive frames are divided into a plurality of time interval windows with selected windows being used to detect received signals at the different frequencies. The remaining windows can be used for subsystems of the radar system. The rate of phase shift of received signals at a center frequency is used to determine closing rate, while the phase shift difference between received signals at the other two frequencies is used to determine range. A subsystem of the vehicular radar system is provided, in which communications between the vehicle radar system and a wayside transponder take place within one of the remaining windows of the receive frames. The wayside transponders transmit multi-bit words to the vehicle to provide the vehicle with update information and to warn of possible hazards in particular locations. [A3253]

"Combined radar detector, speed measuring device and printer for verifying vehicle speed"

The disclosed device enables the user to verify the speed of their vehicle responsive to sensing that a radar device has been used to measure their speed. The device includes a radar detector designed to sense a radar beam. When the detector senses the beam, it activates a speed measuring device mounted on the vehicle which instantaneously measures the vehicle speed and then stores the measured speed for later display and for printing a permanent record, if desired. [A3254]

"Vehicle identification classification and communication system"

An interrogator-transponder system in which multiple vehicle mounted transponders which may be closely spaced in distance and moving at similar velocities are interrogated by interrogation signals that are identical for all interrogations. Digital coded data blocks consisting of an address code and a message code are transmitted on the interrogation frequency and are interleaved with the interrogation signals. Transponders respond with a coherent identification code and a message data code signal that is displaced in frequency from the interrogation signal by an amount that is identical for each transponder. The transponders decode interrogator data blocks that are associated with an address that is identical to the transponder identification code. The response signal spacings in time are difference for each transponder but are always multiples of the pulse repetition interval of the interrogation signal. Means are provided in the interrogation device to determine the velocity of each transponder, its range with respect to the interrogator, its identity and the contents of the transponder messages. Means are also provided to determine the range and velocity of transponder and nontransponder-equipped vehicles using the vehicle skin reflection of the interrogation signal. [A3255]

"CDMA communications and geolocation system and method"

A spread-spectrum CDMA communications system for locating remote units, and for communicating message data between a plurality of remote units and a base station. The spread-spectrum CDMA communications system includes a plurality of base stations and a plurality of remote units. A base station has a spread-spectrum modulator for spread-spectrum processing the message data, and a transmitter for transmitting the spread-spectrum processed-message data, combined with a generic-chip-code signal, from the base station to a remote unit. The base station also has an antenna, and spread-spectrum detectors for recovering message-data communicated from the remote-units. A remote-unit has an antenna, and a detector coupled to the antenna for recovering data communicated from the base station. The detector includes a spread spectrum demodulator. Also, the remote unit has a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator and a transmitter. The base station has a range circuit, which comparers the generic-chip-code signal generated at the base station with the generic-chip-code signal received from the remote unit, for determining a range between the remote unit and the base station. [A3256]

"Continuous wave radar effective for preventing collision of mobile object"

A continuous wave radar for detecting a relative velocity between a target and a mobile object where the radar is loaded, and for detecting whether the mobile object is relatively approaching to or separating from the target. The radar has a hybrid circuit for branching an oscillation signal of a fixed frequency outputted from an oscillator into two oscillation signals. A transmitting antenna is provided for irradiating one of the oscillation signals branched by the hybrid circuit, and a receiving antenna is provided for receiving radio waves reflected from the target. The continuous wave radar further has an image cancel mixer for detecting, on the basis of the frequency of the other oscillation signal branched by the hybrid circuit, a first signal of an upper sideband frequency and a second signal of a lower sideband frequency of the received signal obtained via the receiving antenna. A signal processing circuit is provided for detecting the relative velocity of the mobile object to the target by processing the first and second signals, and detecting a relative approach of the target by processing the first signal or detecting a relative separation of the target by processing the second signal. [A3257]

"Radar sensor/processor for intelligent vehicle highway systems"

A radar sensor/processor for intelligent vehicle highway systems. The radar sensor/processor provides the range, speed, identity of, and selective communications with, vehicles equipped with a transponder in a first cooperative interrogator/transponder mode, and provides information on the range and speed of vehicles without a, or with an inoperative, transponder in a second noncooperative mode. The interrogator includes a first direct digital synthesizer, with an associated first input binary tune register, for producing a sine wave output, a multiplier for multiplying the sine wave output to produce an X-band signal, and a bi-phase single sideband modulator which modulates the X-band signal with data to be transmitted. The interrogator receiver receives a returned transponder reply signal, and includes a balanced mixer for downconverting the reply signal. A down-converted carrier signal is extracted, and is an input to a control loop which includes a second direct digital synthesizer, its associated second input binary tune register, a phase detector, and an A/D converter. The control loop rapidly adjusts the count in the second binary tune register to bring the output frequency of the second direct digital synthesizer into exact correspondence with the down-converted carrier signal. A subtraction of the respective counts in the input binary tune registers for the first and second direct digital synthesizers is a measure of the vehicle speed. [A3258]

"Traffic radar with digital signal processing"

A traffic radar processes Doppler return information by analysis of the received frequency spectrum in order to improve target identification and minimize interference and unwanted harmonics. Digital signal processing including transformation of the return information into the frequency domain is employed to provide multiple modes of operation including a stationary mode where either the strongest or the fastest Doppler return signal may be selectively recognized, and moving modes for monitoring traffic moving in both the opposite direction and the same direction as the patrol vehicle. In the moving modes either strongest or fastest signal processing may be elected, and operation when the patrol and target vehicles are moving in the same direction is provided irrespective of whether the patrol vehicle is moving faster or slower than the target vehicle. The speed of the patrol car is determined by recognizing a signature that exhibits an asymmetry due to the cosine effect. Interference and harmonics are detected and suppressed by recognizing unwanted harmonic patterns and eliminating signal magnitudes at the harmonic frequencies. The radar has multi-band capability and recognizes the frequency band of a selected antenna to automatically configure the radar for correct processing of Doppler return information. [A3259]

"Automobile navigation guidance, control and safety system"

An automobile is equipped with an inertial measuring unit, an RF GPS satellite navigation unit and a local area digitized street map system for precise electronic positioning and route guidance between departures and arrivals, is equipped with RF receivers to monitor updated traffic condition information for dynamic rerouting guidance with a resulting reduction in travel time, traffic congestion and pollution emissions, is also equipped with vehicular superceding controls substantially activated during unstable vehicular conditions sensed by the inertial measuring unit to improve the safe operation of the automobile so as to reduce vehicular accidents, and is further equipped with telecommunications through which emergency care providers are automatically notified of the precise location of the automobile in the case of an accident so as to improve the response time of road-side emergency care. [A3260]

"Ground unit for the detection, identification, and direction determination of a marker beacon"

A ground unit capable of being carried on the back of a member of the armed orces is used in conjunction with a marker beacon. The ground unit detects and identifies the signals from the marker beacon and is also capable of indicating the direction in which the marker beacon is located. for identification purposes, a received signal at the ground unit from the beacon is checked with a known identification code signal inserted in the ground unit by the user. Upon detection of the signal the user can determine the direction to the marker beacon by scanning with a hand-held antenna system. Visual and audio information is provided to the user. [A3261]

"Method and apparatus for improving the signal-to-clutter ratio of an airborne earth penetrating radar"

The method improves the signal-to-clutter ratio of an airborne earth penetrating radar for distinguishing subsurface objects from surface clutter or above-ground objects. The method relies on the dispersive response of the signals returned from an subsurface object to distinguish these subsurface signals from the non-dispersive response signals returned by surface clutter. The electromagnetic response from a subsurface object is spread out over time in comparison to the response from surface clutter. A correlation coincidence detection methodology discriminates surface clutter based on the temporal persistence of a subsurface object. The correlation procedure produces a sequence of values which are used as the basis for detection. If the radar pulses detect a subsurface object, the sequence of values persists beyond the interval of integration containing the clutter response. [A3262]

"Apparatus and method of warning rear-end collision"

A warning apparatus for warning of possible rear-end collision of a given vehicle having the warning apparatus with another vehicle preceding the given vehicle includes: a computer, a distance sensor for measuring a vehicle-to-vehicle distance to the another preceding vehicle, and a velocity sensor for measuring the velocity of the given vehicle. The computer computes a relative velocity of the given and the another preceding vehicle from a differential of the vehicle-to-vehicle distance and then computes an anticipated rear-end collision time by dividing of the vehicle-to-vehicle distance by the relative velocity of the given vehicle. The computer corrects the anticipated rear-end collision time in response to an acceleration and the relative velocity. The computer produces a warning of signal and an alarm is provided in response to the corrected anticipated rear-end collision time. A method of warning of a possible rear-end collision comprises the step of: detecting a vehicle-to-vehicle distance between a given vehicle and the another vehicle preceding the given vehicle, detecting a velocity of the given vehicle, computing an anticipated rear-end collision time T.sub.a of the given vehicle with the another vehicle, with an equation: ##EQU1## and producing a warning in response to the computed anticipated rear-end collision time T.sub.a. [A3263]

"Method and apparatus for monitoring the thickness of a coal rib during rib formation"

Apparatus for monitoring the position of a mining machine cutting a new entry in a coal seam relative to an adjacent, previously cut entry to determine the distance between a near face of the adjacent previously cut entry and a new face adjacent thereto of a new entry being cut by the mining machine which together define the thickness of a coal rib being formed between the new entry and the adjacent previously cut entry during the new entry-cutting operation. The monitoring apparatus, includes a transmit antenna mounted on the mining machine and spaced inwardly from the new face of the coal rib for transmitting radio energy towards the coal rib so that one portion of the radio energy is reflected by the new face which is defined at an air-coal interface between the new entry and the coal rib and another portion of the radio energy is reflected by the near face of the coal rib which is defined at an air-coal interface between the coal rib and the adjacent previously cut entry. A receive antenna mounted on the mining machine and spaced inwardly of the new face of the coal rib receives the one portion of the radio energy reflected by the new face and also receives the another portion of the radio energy reflected by the near face. A processor determines a first elapsed time period equal to the time required for the one portion of the radio energy reflected by the new face to travel between the transmit antenna and the receive antenna and also determines a second elapsed time period equal to the time required for the another portion of the radio energy reflected by the near face to travel between the transmit antenna and the receive antenna and thereafter calculates the thickness of the coal rib being formed as a function of the difference between the first and second elapsed time periods. [A3264]

"Simultaneous differential polymetric measurements and co-polar correlation coefficient measurement"

A polarimetric Doppler weather radar system which allows measurement of linear orthogonal polarimetric variables without a switch by using simultaneous transmission of horizontally and vertically polarized waves. This is accomplished by splitting the transmitted power into two waveguides and combining them with an orthomode coupler at the antenna feed. Thus, in general the transmitted polarization is elliptical but with equal amount of power in horizontal and vertical polarization. On reception, the power is divided, at the orthomode coupler, into linear horizontal and vertical components. These components are processed and combined to yield Doppler and polarimetric information about storm structure. [A3265]

"Distance measuring system"

A distance measuring system includes a base unit and a remote unit. The remote unit transmits a first radio frequency signal to the base unit. The base unit transmits a second radio frequency signal upon receipt of the first radio frequency signal from the remote unit. The remote unit measures the time between transmission of the first radio frequency signal and receipt of the second radio frequency signal, thereby enabling the distance between the base unit and the remote unit to be ascertained. The accuracy of the measured distance may be improved by averaging additional measurement cycles. [A3266]

"Fine-grained multi-planar clutter rejection processor"

A fine grained multi-planar clutter rejection processor (10) for correlating multiple sets of data. The processor (10) maps each set of data onto a plurality of arrays (28-34) . The data includes target data which is correlated between sets and clutter which is uncorrelated between sets of data. The system also includes a means for shifting (40) the positions of the second and subsequent arrays in a pattern which is larger for each successive array. In addition, a correlation identification unit (78) identifies the coordinate locations in the first array (28) which contain data points and which also contain data points in subsequent arrays in their shifted positions. In this way, data points identified in this manner are correlated and the remaining data points can be discarded as clutter. The processor (10) system is able to handle a very large number of data points per scan (over 100,000) over a high number of scans (such as eight) . Due to its highly parallel approach, the total processing time is completely independent of the number of data points or scans. [A3267]

"Expert system constant false alarm rate (CFAR) processor"

An artificial intelligence system improves radar signal processor performance by increasing target probability of detection and reducing probability of false alarms in a severe radar clutter environment. This utilizes advances in artificial intelligence and expert systems technology for the development of data analysis and information (signal) processors used in conjunction with conventional (deterministic) data analysis algorithms to combine radar measurement data (including observed target tracks and radar clutter returns from terrain, sea, atmospheric effects, etc.) with topographic data, weather information, and similar information to formulate optimum filter coefficients and threshold tests. Present fielded radar systems use one CFAR algorithm for signal processing over the entire surveillance volume. However, radar experiments have shown that certain CFAR algorithms outperform others in different environments. The system intelligently senses the clutter environment, and selects and combines the most appropriate CFAR algorithm (s) to produce detection decisions that will outperform a processor using a single algorithm. The invention provides for improved performance through the application of rule-based and data-based expert system computer software technology to CFAR signal processors, thereby improving target detection by reducing processing losses which result from a mismatch between the single, fixed CFAR processor and dynamically changing environment in which a radar must operate. [A3268]

"Wide band stepped frequency ground penetrating radar"

A wide band ground penetrating radar system (10) embodying a method wherein a series of radio frequency signals (60) is produced by a single radio frequency source (16) and provided to a transmit antenna (26) for transmission to a target (54) and reflection therefrom to a receive antenna (28) . A phase modulator (18) modulates those portion of the radio frequency signals (62) to be transmitted and the reflected modulated signal (62) is combined in a mixer (34) with the original radio frequency signal (60) to produce a resultant signal (53) which is demodulated to produce a series of direct current voltage signals (66) the envelope of which forms a cosine wave shaped plot (68) which is processed by a Fast Fourier Transform unit 44 into frequency domain data (70) wherein the position of a preponderant frequency is indicative of distance to the target (54) and magnitude is indicative of the signature of the target (54) . [A3269]

"Electrically powered postage stamp or mailing or shipping label operative with radio frequency (RF) communication"

The present application describes an electronically powered postage stamp or mailing label and including a radio frequency identification (RFID) device and system mounted between the opposing and facing major surfaces thereof. The RFID device and system includes an integrated circuit transceiver chip which is connected to and powered by a thin flat battery cell and is operated with a thin film RF antenna, all of which are mounted in side-by-side relationship on a thin base or support layer. These thin flat components are mounted in an essentially two dimensional planar configuration well suited for incorporation into the planar structure of a postage stamp or a mailing label. In addition, the RFID transceiver chip may be replaced with an electro-optically operated IC chip using, for example, LEDs or laser diodes for the propagation of light signals to an interrogator. [A3270]

"Detection and calibration of horizontal error in a scanning type radar device"

A method to determine a horizontal error of a radar device mounted on a vehicle along with the mounting error or imbalance in the diameters of wheels based on an echo signal from a reflector provided on a road. A vehicle's traveling locus is stored in advance as a reference locus obtained from the distance L between the vehicle and reflector and the direction .theta..sub.R. A traveling locus when the vehicle is actually traveling in a straight line where the steering handle is kept in a neutral position is compared with the previously stored reference locus. A horizontal error is obtained from the traveling locus on the coordinate axis .theta..sub.R and the shift from the reference locus. [A3271]

"Method of and apparatus for cruise control"

A vehicle cruise controller is provided which monitors the range to and relative speed of a target vehicle ahead of the vehicle being controlled by the cruise controller. A radar provides measurements of range and relative speed. The range measurement is compared by a subtracter with a desired range which is a function of vehicle speed, so as to form a distance error. The relative speed signal represents a speed error. An acceleration demand is formed as a function, for example, a weighted sum, of the distance and speed errors. More significance is given to the distance error when the target is relatively close. This is achieved by varying the gain of a multiplier. The acceleration demand may be supplied to vehicle brake and drive systems, but preferably the acceleration demand is compared with actual vehicle acceleration to provide the advantages of closed loop control. [A3272]

"Monopulse transceiver"

A dual channel monopulse transceiver is described for use at millimeter wavelengths and for the detection of targets for vehicle collision avoidance. A microstrip antenna is located on one side of a plate and a transceiver microstrip circuit coupled to the antenna is located on the other side of the plate. The transceiver includes a reflective balanced mixer, an isolated balanced mixer and a hybrid circuit for connecting the mixers to antenna feed points. Sum and difference signal generating circuits are employed to provide single and split antenna beams for the detection of targets. [A3273]

"Autonomous cruise control"

A cruise control system for a vehicle includes a vehicle borne radar for determining range and closing rate of the vehicle relative to a target, such as another moving vehicle, ahead of the vehicle. The range and closing rate are used to determine a new set speed for the cruise control system which may be less than but is not greater than the speed entered in the cruise control by the driver of the vehicle. The new set speed is selected to prevent the vehicle from overtaking the target, and ideally reduces the closing rate to zero at a predetermined minimum distance from the target. In determining the new set speed, the system also determines incremental movements for the vehicle throttle using a selected gain boost and designed to minimize throttle jerk. If the target moves out of the path of the vehicle or speeds up, the system adjusts accordingly and eventually allows the vehicle to resume the originally entered speed when possible. [A3274]

"Single loop transponder system and method"

An apparatus including an object 10 associated with a contactless, electronic identifier is disclosed herein. In one example, the object 10 is a trash bin. This object 10 is formed from a non-conductive material. A single-loop antenna 14 is disposed adjacent the object 10. An impedance transformer 18 which is matched to the single-loop antenna 14 is used to generate a desired inductance. A transponder 12 is also disposed near to and associated with the object 10. The transponder 12 is coupled to the antenna 14 through the impedance transformer 18. [A3275]

"Transponder interface circuit"

A transponder interface circuit (172) operates to allow communication between a transponder controller (104) and external circuitry. The interface circuit (172) has a buffer memory (184,186) that allows the transponder controller (104) and the external circuitry each to transmit data at either the transponder's (14) or the external circuitry's clock rate without complicated protocols for direct communication. Each of the transponder controller (104) and the external circuit may be enabled by an interface controller (174) to assume control of the buffer memory (184,186) . By using the buffer memory (184,186) and interface controller (174) , whichever of the transponder controller (104) and the external circuitry is transmitting or receiving data may fill or empty the buffer memory (184,186) at either the transponder controller's (104) or the external circuitry's chosen clock rate. The interface controller (174) will monitor the transfer such that when the buffer memory (184,186) is full or empty, the interface controller (174) will send a command to the appropriate transponder controller (104) or external circuit to either receive data from the full buffer memory (184,186) or transmit data to the empty buffer memory (184,186) . [A3276]

"Active signalling systems"

A signalling system in time-frequency space for detecting targets in the presence of clutter and for penetrating media, includes a transmitter antenna system, receiver and processor system. The transmitter antenna system generates and launches into a medium containing the targets an energy pulse (wave packet) having a predetermined duration and frequency characteristic, and which energy pulse matches at least one of the following: 1) the time-frequency reflection characteristics of the target (s) but not the clutter, or 2) the penetration time-frequency dielectric window of the medium, or 3) the time-frequency characteristics of the window of the receiver. Preferably, the time-frequency wave packet is the complex conjugate of the impulse response of the combined medium and target. The processor solves the wave equation for transmissions through the medium, reflectance from the target (s) and transmission back through the medium and causes a match of the generated wave packet signals to both the medium and target for maximum propagation through the medium and reflectance from the target, the wave packet match to the medium and the target being with respect to both time and frequency response characteristics. [A3277]

"Automatic real-time highway toll collection from moving vehicles"

One or more roadside collection stations (RCS) communicate over a short-range, high speed bidirectional microwave communication link with one or more in-vehicle units (IVU) associated with one or more respectively corresponding vehicles in one or more traffic lanes of a highway. At least two up-link (IVU to RCS) communication sessions and at least one downlink (RCS to IVU) communication session are transacted in real time during the limited duration of an RCS communication footprint as the vehicle travels along its lane past a highway toll plaza. Especially efficient data formatting and processing is utilized so as to permit, during this brief interval, computation of the requisite toll amount and a fully verified and cryptographically secured (preferably anonymous) debiting of a smart card containing electronic money. Preferably an untraceable electronic check is communicated in a cryptographically sealed envelope with opener. Transaction linkage data is utilized in each phase of the complete toll payment transaction to facilitate simultaneous multi-lane RCS/IVU operation. A plaza computer local area network and downlink plaza controller is also used to facilitate simultaneous multi-lane transactions. [A3278]

"Complex MTI filter"

Entered complex data is phase-rotated by the corresponding to the moving velocity of the clutter component. Then clutter component information is eliminated by a real type MTI filter assembly. Thereafter, the output data of the real type MTI filter assembly is reversely phase-rotated. [A3279]

"Method and apparatus for determining the location of a vehicle"

Vehicle navigation systems typically include devices for determining the location of the vehicle. In many situations it is advantageous to improve the resolution of such devices or to provide a back-up system for determining vehicle location. Simple and efficient systems are also desirable when used as the primary positioning systems. The subject invention provides a simple and efficient system for determining the location of a vehicle in a base reference frame. One or more targets are located at predefined positions with respect to the base reference frame. A target sensing device determines a position of one of the one or more targets with respect to the vehicle. A device determines an estimated vehicle position. A vehicle locating device determines the location of the vehicle with respect to the base reference frame in response to the position of the target with respect to the vehicle and the estimated vehicle position. [A3280]

"Method for measuring the distance and velocity of objects"

In a method for measuring the distance and the velocity of objects employing electromagnetic waves, the frequency of an emitted signal is modulated. The signals received during one rise and one drop in the frequency of the emitted signal are mixed with the emitted signal. The intermediate-frequency signals resulting from the mixing are then spectrally analyzed. The distance and the velocity of at least one object are calculated from the frequency of the spectral lines of the intermediate-frequency signals during at least one rise and at least one drop in the frequency of the emitted signal. [A3281]

"Radar terrain bounce jamming detection using ground clutter tracking"

A radar jamming detection system is suitable for recognizing and distinguishing the presence of jamming and, particularly, terrain bounce jamming. The radar system includes a transmitter and a receiver. The receiver receives true radar skin return signals, in addition to ground clutter signals and jamming signals. The true radar skin return signals and ground clutter signals are recognizable in accordance with a predetermined receiver passband.

Estimated target location, velocity and frequency data, as provided by a cueing radar, is used to set up the receiver passband for the radar detection system. Ground clutter range and angle measurements are used to determine an estimated ground range at the jammer angle, which is then compared with the cue range to determine if the received signals are terrain bounce jamming signals. [A3282]

"RF imaging of low observable coatings using a wire-over-ground-plane transmission line"

A non-destructive test system that displays time domain amplitude returns from multi-frequency, multi-phase, constant magnitude RF signals, that are reflected by differences in characteristic impedance of a wire over ground plane transmission line. The reflections are used to detect RF discontinuities or faults in conductive areas that form the ground plane which preferably are resolved using a generalized pencil-of-points algorithm. The nondestructive testing system so constructed is especially useful in testing field repairs of radar absorbing material (RAM) and other features of a conductive object or vehicle whose radar return is to be minimized. [A3283]

"Broadcast system for a facility"

A broadcast system for a facility including audio and video signal generators that may also include the audio output of a microphone for forming broadcast signals. The broadcast signals include a program signal, a supervisory program signal and a supervisory alert signal. The power supply for monitoring stations and broadcast signals are combined to form an output signal that is broadcasted throughout the facility. A bus distributes the output signal in the facility to each of a plurality of monitor stations. Each monitor station includes decoders to recover the audio and video signals and form a resident power supply for that monitor station only from the output signal on the bus. The monitor could also includes a video monitor and speaker coupled to the resident amplifier to the resident power supply for responding to any of the broadcast signals. A resident controller controls the resident amplifier when receiving a program signal supplied to the monitor. A resident executive controller disables the resident controller and applies a recovered supervisory alert signal and supervisory program signal to the resident amplifier. [A3284]

"Doppler radar system for automotive vehicles"

A continuous wave Doppler radar system having a transmitter module and a receiver module is provided for automotive vehicles. Each module includes an antenna system, including a horn, a lens, and a waveguide system, which is attached to a monolithic microwave integrated circuit (MMIC) chip that provides all necessary electronic functions. Each MMIC chip may be attached to a metal base heat sink, which may be conveniently connected to a base plate heat sink that holds the entire radar assembly. The transmitter module includes a voltage controlled oscillator (VCO) that generates a VCO frequency signal which is amplified and switched sequentially to three multiplier chains for transmission in three different directions. Each transmit signal is taken off the MMIC chip by a dielectric waveguide and directed to the antenna system. The receiver module includes three receivers that are selected sequentially to provide a beam azimuth scanning function. A reference local oscillator is provided at the VCO frequency by electromagnetic radiative coupling from the VCO of the transmitter module. Information on the location and relative speed of a radar target are obtained by comparing the frequency of the signal reflected by the target with the frequency of the signal radiated by the transmitter module. Quadrature mixers are used for each receiver channel to output low frequency data signals containing amplitude and phase information on the received reflected signal. Radar directional discrimination is achieved by sequential selection of the mixer output signals. [A3285]

"Power supply and power enable circuit for an RF/ID transponder"

A power supply self-contained within a portable RF/ID transponder includes a full wave rectifier having an input for receiving an antenna signal and outputs for providing power supply and ground voltages, wherein the power supply voltage has a time varying voltage waveform corresponding to the electric field generated by a reader/controller. The power supply further includes a clamping circuit for regulating the power supply voltage and a ferroelectric filter/storage capacitor coupled between the power supply and ground outputs of the full wave rectifier. The power supply further includes a power enable circuit for constantly monitoring the supply voltage waveform and for providing a power enable indication after an initial portion of the supply voltage waveform rises above a predetermined power-up threshold level and for removing the power enable indication when a terminal portion of the supply voltage waveform falls below a predetermined power-down level. The power-up and power-down thresholds describe a proper voltage range of operation for the ferroelectric memory in the transponder. The power enable indication is provided to the ferroelectric memory so that the memory is only operated when the power supply voltage is within the proper range so that data is valid during read and write operations. [A3286]

"Vehicle collision judging system for controlling brake actuation"

A collision judging system for a vehicle comprises a subject vehicle position estimating means for estimating the position of the subject vehicle after a lapse of a preset time from a certain braking start time, on the assumption that the braking is starting at such braking start time, an obstacle position estimating means for estimating the position of an objective obstacle after the lapse of the preset time, and the judging means for judging whether or not the position of the subject vehicle estimated by the subject vehicle position estimating means and the position of the obstacle estimated by the obstacle position estimating means coincide with each other. Thus, the judgment of collision can be performed with the avoidance of the collision by the driver's operation being taken into consideration, leading to an improved feeling of driving operation. [A3287]

"Tagging system having resonant frequency shift compensation"

A tagging system (20) compensates for both resonant frequency spatial dependent shifts and resonant frequency dependent shifts for detecting data resonant circuits (DC1-DC6) on an RF tag 10 which is carried by a tagged object (34) . The system includes at least one transmitter (26) and at least one receiver (28) for determining the actual resonant frequencies of reference resonant circuits (SC1-SC5, FC1-FC4) on the tag 10. A microprocessor controller (22) , in response to the frequency difference between the undisturbed resonant frequencies of the reference resonant circuits and the actual resonant frequencies of the reference resonant circuits, provides compensating factors to compensate for the spatial and frequency effects of the resonant frequencies of the resonant circuits on the tag (10) . The transmitter and receiver determine the actual resonant frequency of each data resonant circuit (DC1-DC6) on the tag (10) . The microprocessor controller (22) then determines the undisturbed resonant frequencies of the data resonant circuits on tag (10) from the actual resonant frequencies of the data resonant circuits and the compensation factors. [A3288]

"Electromagnetically propelled high-speed high-capacity transportation system for short-distance travel in urban and suburban areas"

An electromagnetically propelled transportation system designed to provide extremely high capacity at travel speeds between 50 and 150 miles per hour, to serve as a means of transportation within contiguous urban and suburban areas. The transportation system includes centrally controlled vehicles operated on a dedicated guideway, propelled by an embedded linear synchronous motor or other linear motor, which uses coils embedded in the guideway to carry an electric current which provides the propulsion force for vehicles on the guideway. In addition, the transportation system includes other components necessary to the operation of a high-capacity high-speed urban transportation system, such as off-line stations, entry and exit ramps, for acceleration and deceleration, which connect stations to the dedicated guideway, with appropriate branching to permit the same vehicle flow rate on the ramps as on the dedicated guideway, and means of switching or steering vehicles between the ramps and the guideway. Provision is made for passengers to obtain automated entry to the system. Vehicles have dual-use capability, so as to be able to operate on city streets as well as the dedicated guideway. [A3289]

"Collision avoidance and warning system"

A collision avoidance and warning system for land vehicles including radar transmission and receiving apparatus for sensing the presence of objects within a spatial range relative to a vehicle, multiple target tracking apparatus receiving an output from the radar transmission and receiving apparatus for tracking a plurality of targets sensed by the radar transmission and receiving apparatus, auxiliary non-radar target sensing apparatus and alarm decision apparatus receiving an input from the multiple target tracking apparatus and from the auxiliary non-radar target sensing apparatus for indicating the alarm status of a target and providing an output indication to alarm generating apparatus. [A3290]

"Multi-stage transponder wake-up, method and structure"

A system and method which conserves energy in the operation of a transponder or tag (14) by providing that the transponder (14) be enabled or awakened in multiple stages. A threshold detector (62) is provided which measures the power level of received RF energy. If the RF energy received by the detector (62) exceeds a pre-determined level, the transponder (14) then employs a modulation detector (64) to ascertain whether it has been awakened by a valid interrogation signal from an interrogator (12) or whether the RF energy received was merely a spurious burst of RF energy from some other source. If a pre-determined modulation is detected by the modulation detector (64) , the transponder (14) is then fully activated to its normal operational state. [A3291]

"Receiver antenna for bistatic doppler radar network"

A multiple-Doppler radar network can be constructed using only one, traditional, transmitting pencil-beam radar and one or more passive, non-transmitting receiving sites. Radiation scattered from the pencil beam of the transmitting radar as it penetrates weather targets can be detected at the receive-only sites as well as at the transmitter. In a bistatic system, the location of targets in Cartesian space can be calculated from the pointing angle of the transmitting antenna and the time between transmission of a radar pulse from the transmitter and detection at a passive receiver site. [A3292]

"Overlaying spread-spectrum satellite system and method"

A spread-spectrum satellite system for communicating data and paging messages to a plurality of remote units. The spread-spectrum communications system has a satellite with an antenna beamwidth located within a same geographical region as covered by an existing FDMA, TDMA or other mobile-satellite system. The spread-spectrum satellite system has a device for converting the format of the data into a form suitable for communicating over radio waves, a spread-spectrum modulator for spread-spectrum processing the data, and a transmitter for transmitting the spread-spectrum-processed-converted data from the satellite to a remote unit. The remote unit has an antenna and a spread-spectrum receiver for recovering data communicated from the satellite. The remote unit optionally may have a comb filter for notch filtering mobile channels of the mobile-satellite system. [A3293]

"Passive SAW-ID tags using a chirp transducer"

A Passive Surface Acoustic Wave Identification Tag ("SAW-ID tag") device utilizes pulse compression techniques and a large number of coding possibilities for identifying articles at enhanced ranges. The SAW-ID tag device provides a piezoelectric substrate having bus bars, spaced electrode taps between the bus bars and a built-in antenna, with an input chirped SAW transducer having a dispersive, complementary matched filter response to an input expanded chirp signal from an expanded linear FM chirp waveform actively generated by a nearby chirp transmitter. The input expanded chirp signal is fed into the input chirped SAW transducer through the built-in antenna, to compresses the input expanded chirp signal into a narrow, compressed pulse signal propagating toward the electrodes taps. The spacing of the electrode taps establishes the desired unique time-ordered coding. The electrode taps sample the narrow, compressed pulse signal and provide narrow, compressed pulse samples propagating a coded, pulse train output transmitted via the antenna to a nearby interrogation means to identify the tagged article. The preferred embodiment is an SAW-ID tag device with a piezoelectric quartz substrate about 1 inch long, a built-in dipole antenna and five (5) spaced electrode taps, establishing several million coding possibilities. Also disclosed are methods of identifying articles using an SAW-ID tag device, and methods of selectively disconnecting and connecting electrodes to facilitate mass production. [A3294]

"Receiver for bistatic doppler radar network"

A multiple Doppler radar network can be constructed using only one, traditional, transmitting pencil-beam radar and one or more passive, non-transmitting receiving sites. Radiation scattered from the pencil beam of the transmitting radar as it penetrates weather targets can be detected at the receive-only sites as well as at the transmitter. In a bistatic system, the location of targets in Cartesian space can be calculated from the pointing angle of the transmitting antenna and the time between transmission of a radar pulse from the transmitter and detection at a passive receiver site. [A3295]

"Oceanographic and meteorological data"

A method of obtaining oceanographic and meteorological data from high frequency radar spectral information including the steps of transmitting a plurality of signals to a remote geographic location, recording signals backscattered from the said location, generating a family of Doppler clutter spectra from the recorded backscattered signal and analyzing the Doppler clutter spectra in terms of a model or models to generate oceanographic and meteorological data estimates. The Doppler spectra are categorized according to Suitability for Deatiled Analysis (SDA) . The SDA takes account of the clutter-to-noise ratio in the spectrum, the amplitudes of the Bragg-lines, multimode propagation, spectral broadening and other spectral parameters. Spectra with a low SDA are inappropriate for extracting directional wave spectrum estimates of reasonable accuracy but are useful for obtaining wind direction estimates. Spectra with a high SDA are capable of being inverted to provide good quality estimates of the extended directional wave spectrum. [A3296]

"Obstacle detection system for motor vehicle"

An obstacle detection apparatus for a motor vehicle detects another vehicle traveling in front of the vehicle as an obstacle. The apparatus has a first unit, providing a course on which the vehicle is supposed to travel, a second unit, providing a reserve course located outside of the course, an obstacle detector detecting the other vehicle traveling in the course or the reserve course as an obstacle, and an obstacle detection continuation unit continuously detecting the other vehicle until a predetermined condition has been satisfied when the other vehicle moves from the course to the reserve course. [A3297]

"Obstacle sensing apparatus for vehicles"

An obstacle sensing apparatus for vehicles is provided in which detection of obstacles is performed efficiently by predicting the traveling path of the vehicle appropriately when detection of obstacles by a radar unit is limited to a region along the traveling path. The apparatus is provided with a radar unit for transmitting radar waves ahead of the vehicle and sensing obstacles present ahead of the vehicle, a steering angle sensor for sensing the steering angle of the vehicle, and a yaw rate sensor for sensing the yaw rate produced by the vehicle. First traveling-path predicting device predicts a traveling path of the vehicle based upon the steering angle, and second traveling-path predicting device predicts a traveling path of the vehicle based upon the yaw rate. One of these traveling paths is selected in dependence upon the operating state of the vehicle and detection of articles by the radar unit is carried out within a limited region along the traveling path selected. [A3298]

"Phased array based radar system for vehicular collision avoidance"

A phased array based radar and vehicular safety warning system for collision avoidance, including a phased array based radar, a controlling processor, and a warning system that also provides a warning to the driver of the equipped vehicle as well as drivers of other, non-equipped automobiles involved in an unsafe driving condition. The phased array radar includes a flexible antenna array that may be mounted conformally on existing automobiles without detracting from their design curvature. In one embodiment a pair of phased array radar antenna may be oriented towards opposing sides of an equipped automobile to provide warning surveillance of vehicles laterally approaching the equipped auto from the sides. In another embodiment a phased array radar antenna is oriented to the rear of the equipped automobile to provide warning surveillance of vehicles following the equipped auto too closely, and for warning of unsafe lane changes. In still another alternative embodiment a pair of phased array radar antenna having 180.degree. fields of view may be installed in a pod mounted on the roof of the equipped automobile to provide 360.degree. warning surveillance coverage. [A3299]

"Method and apparatus for determining driver fitness in real time"

A method and apparatus for evaluating a driver's performance under actual real-time conditions and for using such evaluations to determine the driver's ability to safely operate a vehicle compares the information gathered by a radar system and other sensors with information previously stored in an event recording device. Conditions monitored are used to make a determination as to whether the driver is performing in conformity with normal driving standards and the driver's own past performance. The driver's performance is constantly monitored and compared to that driver's past performance to determine whether the driver's present performance is impaired, and if so, whether the impairment is detrimental to the driver's ability to safely operate the vehicle. [A3300]

"MTI using a polyphase code"

An improved MTI radar system including a signal expander/compressor for providing palindromic P2 phase-coded upswept and downswept expanded signals that are alternately transmitted by a radar transmitter. The echos from the upswept and downswept signals are received by a receiver, compressed in the signal expander/compressor and inputted to an MTI subtractor. Since the autocorrelation sidelobes of the palindromic phase coded echos are real, the echos from stationary clutter are completely cancelled so that the system is capable of detecting weak echos from moving targets. [A3301]

"Remote controlled guidance system for working vehicle"

A remote control method of guidance for a work vehicle including a handheld control unit, an antenna/transponder placed on the periphery of the worksite, a controlling unit on the work vehicle itself. The control unit compares timing signals to subsequently control of the speed of independently powered wheels. There is a manual and automatic mode of control for the vehicle. The vehicle is positioned at a starting point by the user, and upon activation of the automatic mode, a timing pulse, either ultrasonic or electromagnetic is issued from the control unit on the vehicle. When the pulse is sensed by the transponder on the antenna, a responding pulse is transmitted. This is, in turn, received by the vehicle and thus a base time is set for the interval between the transmission of the pulse and the return signal from the transponder, the interval being indicative of the distance between them. The vehicle moves forward while continuing at intervals to send the pulse and if the secondary timing interval is larger than the base interval, the inner wheel is slowed to bring the vehicle closer. If the interval is shorter, the inner wheel is speeded up to move the vehicle away from the transponder. Thus, the vehicle describes a smooth arc about the transponder until the user sends another signal to the device, indicating that the device is to move a preset distance further away from the transponder, reset the base interval, and continue. [A3302]

"Real-time holographic surveillance system"

A holographic surveillance system including means for generating electromagnetic waves, means for transmitting the electromagnetic waves toward a target at a plurality of predetermined positions in space, means for receiving and converting electromagnetic waves reflected from the target to electrical signals at a plurality of predetermined positions in space, means for processing the electrical signals to obtain signals corresponding to a holographic reconstruction of the target, and means for displaying the processed information to determine nature of the target. The means for processing the electrical signals includes means for converting analog signals to digital signals followed by a computer means to apply a backward wave algorithm. [A3303]

"Method for determining target velocity by measuring phase shift"

A method for determining velocity of a target object comprises transmitting a propagating wave emitted from a wave transmitter and detecting a reflected wave reflected back by the target object by using a wave receiver, and determining of a phase angle difference between two alternating electrical signals respectively representing the transmitted wave departing the wave transmitter and the reflected wave arriving at the wave receiver, wherein the velocity of the target object is determined as a function of the time rate of change of the phase angle difference between the two alternating electrical signals. [A3304]

"Adaptive cruise control"

Adaptive cruise control speed limiting consistent with sensor and system limitations ensures an adaptive cruise control source vehicle operates in adaptively controllable speed ranges including speed ranges corresponding to following distances within the sensor range and excluding speed ranges at which preceding targets are not reliably distinguishable by the sensing system. [A3305]

"Transponder systems for automatic identification purposes"

A method of communicating between an interrogator (10) and at least a first and second transponder (12) . The transponders (12) are separately located within a first and a second vehicle (20) travelling within a first and a second traffic lane, respectively. The method has the steps of providing a first and a second LF antenna (16) associated with and proximity to a first and a second traffic lane, respectively. From each of the first and second LF antennas (16) a continuous LF subcarrier is transmitted to serve as a clock signal for each antenna's associated transponder (12) . Initially, a wake-up signal is sent by each of the LF antennas (16) to its associated transponder (12) . Following the wake-up signal, a unique lane code is sent by each of the LF antennas (16) to its associated transponder (12) . The transponder (12) stores its unique lane code in its memory (70) . The transponder then sends a UHF response in a pre-determined time period depending on the unique lane code stored in each of the transponders (12) . The time period in which the transponder (12) sends its UHF response is unique to that transponder (12) so that interference between responding transponders (12) is avoided. Other devices, systems and methods are also disclosed. [A3306]

"Vehicle collision prevention system using the Doppler effect"

A vehicle collision prevention system for preventing a source vehicle from colliding with an obstruent object comprising detection circuitry adapted for detecting and providing an indication of an impending collision with an obstruent object, the detection circuitry further comprising transmission circuitry adapted to transmit a preselected reference signal with a known frequency, reception circuitry adapted to receive a modulated reference signal reflected from an obstruent object, compensation circuitry adapted to receive environmental inputs external to the source vehicle and provide a measure of source vehicle velocity, processor circuitry coupled to the transmission circuitry, reception circuitry, and compensation circuitry, the processor circuitry adapted to control and monitor the transmission and reception of a reference signal, calculate its propagation time to and from an obstruent object, and determine its reflected strength, determine the approximate propagation velocity of the reference signal and obstruent object with respect to the environmental inputs, determine the frequency of the reflected reference signal based upon the Doppler effect, and determine the approximate distance to the obstruent object based upon the reflected reference signal frequency, signal strength and propagation velocity and generate a distance signal indication, indication circuitry coupled to the detection circuitry and adapted for providing an indication of the distance to the obstruent object based on distance signal indications, and a energizing mechanism for energizing the detection circuitry and indication circuitry. [A3307]

"Automatic starting and stopping apparatus for an engine"

The present invention relates to an automatic starting and stopping apparatus for an engine, which prolongs the lives of mechanical components such as a starter motor and which is applicable also to automatic vehicles. The automatic starting and stopping apparatus for an engine comprises a vehicle-to-vehicle distance sensor 29, which detects whether the distance from the preceding vehicle is less than a preset value, a signal color identifying and detecting device 30, which identifies whether the lit color of the signal is yellow or red, a car speed sensor 15, and a control circuit 31, which performs automatic start and stop of the engine in accordance with the detection results of the vehicle-to-vehicle distance sensor 29 and the signal color identifying and detecting apparatus 30. The control circuit 31 carries out automatic stop by cutting off the electric power to the engine ignition circuit 3 if the vehicle-to-vehicle distance is less than the preset value or the signal indicates a yellow or red light and also the car speed is zero, while it supplies electric currents to the starter 8 and the engine ignition circuit to implement automatic start when the vehicle-to-vehicle distance has reached the preset value or more or the lit signal color has changed from red to green. [A3308]

"Transponder maintenance mode method"

A method and system is provided for communicating permanent or semi-permanent information to a transponder (14) from an interrogator (12) , preferably operated by a toll agency or other authorized entity. This permanent or semi-permanent information is communicated by means of special instructions valid only during a special mode or maintenance mode which is entered by transmitting a special access code to the transponder (14) from the authorized interrogator (12) . The transponder (14) will preferably acknowledge to the authorized interrogator (12) that it is, in fact, operating in the maintenance mode so the interrogator (12) can transmit the special instructions in confidence. [A3309]

"Stereophonic warning apparatus"

A stereophonic warning apparatus for a vehicle is provided with a judging device which judges warning priority level relative to an object around the vehicle according to signals from radars for detecting the object and a vehicle behavior detecting device. A control device controls the output level of a plurality of speakers in a passenger compartment of the vehicle according to the position of the detected object such that the speakers output a warning sound to form a sound image at a position to which the detected object is located, while changing the warning sound according to the warning priority level. [A3310]

"Electronic life detection system"

The invention relates to an electronic life detection system, in particular for the searching for buried persons and the surveillance of buildings, having a microwave transmitting/receiving device for generating and radiating microwaves into an area to be investigated and for registering the microwave signal reflected from the area under surveillance and modulated with the frequencies corresponding to the life functions of any living beings present in the area, which device has a first signal-conditioning device, and a second signal-conditioning device. [A3311]

"Modulation field detection, method and structure"

Disclosed is a system and method which protects a transponder or tag (14) from being enabled or awakened by spurious RF energy. A modulation detector (64) is provided which detects a modulation signal that is superimposed upon an RF modulation from an interrogator (12) . Preferably this superimposed modulation is of a low frequency, below those typically existing as Electro-Magnetic Interference (EMI) , such that the transponder (14) is less likely to be erroneously activated by an unintended RF signal. Upon reception of an RF interrogation having the proper modulation superimposed thereupon, the modulation detector (64) is operable to awaken other circuitry within the transponder (14) such that the transponder (14) is then operable to communicate with the interrogator (12) . [A3312]

"Dual alarm apparatus for monitoring of persons under house arrest"

A monitoring system determines the presence of the person or persons to be monitored within a well-defined area or areas using one or more portable remote devices which are in two-way communication contact with a base unit. The base unit is connected to a telephone line to enable communication with a monitoring service. The base unit and remote unit incorporate spread spectrum communication technology which permits a high transmit power level. The effectiveness of the monitoring system does not depend on radio signal strength, but instead, operates using a radio ranging method that measures the time it takes for a security-coded signal to be transmitted to and returned from the remote device. The remote device also includes a mechanism for sounding an audible out-of-range warning alarm in the event that the person being monitored exceeds the house arrest boundaries. A second audible alarm preferably sounds from the remote device and the base device at predetermined times after the sounding of the out-of-range alarm if the person does not return to the house arrest area. [A3313]

"Enclosed transceiver"

An enclosed transceiver includes an integrated circuit and a battery together laminated between two films. Printed conductors on each film couple operative power to the integrated circuit. Other-printed conductors form an antenna coupled to the transceiver for sending and receiving signals. In a preferred embodiment, the integrated circuit has three terminals. The first terminal is connected to a first side of a thin film battery. The second terminal is connected to a first side of a printed loop antenna. The third terminal serves two purposes being connected to the second side of the battery and to the second side of the loop antenna. The enclosing films are treated with silicon nitride for hermeticity. Enclosed transceivers of the present invention are suitable for mass production in web, sheet, and tape formats. Such transceivers are useful as stamps, labels, and tags in object tracking systems including systems for mail delivery, airline baggage tracking, and inventory control. [A3314]

"Resonant tag and method of manufacturing the same"

A resonant tag is manufactured in the manner described below: a conductive thin film is formed to a predetermined thickness on two surfaces of an insulating thin film. Thereafter, a conductive pattern, composed of an inductor element and a capacitor element corresponding to a resonant frequency of a resonant circuit, is printed on a surface of one of the conductive thin films, and a conductive pattern, composed of a capacitor element corresponding to the resonant frequency of the resonant circuit, is printed on a surface of the other insulating thin film at a position which faces the capacitor element formed on one of the conductive thin films using an ink which resists etching. A non-printed portion of the conductive thin films is removed by etching to form a resonant circuit pattern. Thereafter, a portion of the insulating thin film, which corresponds to the capacitor element pattern, is thinned to a desired thickness by pressing a heating/pressing member heated to a predetermined temperature against that portion under a predetermined pressure for a predetermined period of time. [A3315]

"Low-cost compact microwave antenna for a transmitter and/or receiver system mounted in a vehicle"

The antenna is produced by placing radiating elements (70) in at least one of the spaces occupied by the various vehicle external lights. The radiating elements can be dipoles formed by metallizing the lens (43) which closes the headlight casing (40) and the casing itself can be used to reflect the electromagnetic energy forwards. [A3316]

"Extremely high frequency vehicle identification and communication system"

Apparatus and method for allowing ground vehicle identification and communication utilizing IFF equipment consisting of a multi-channel extremely high frequency transmitter for IFF and data transmissions and a receiver for multi-frequency conversions and multi-channel reception. The apparatus and method has both an IFF mode of operation in which the vehicle is able to identify itself and a communications mode in which the vehicle transmits vehicle status information to other vehicles and a command unit. The transmitter comprises a first and second oscillator means for generating a number of frequency tones and a power combiner for combining the tones prior to transmission. A controller monitors the transmitted signal and operates the first and second oscillation means. The receiver consists of a channelizer for separating a received signal into separate frequency tones and a measuring means for determining the values of the frequency tones. A controller controls the comparison or decoding of received signals. [A3317]

"System for bidirectional data transmission between a plurality of stationary units and a vehicle"

A system is proposed for bidirectional electromagnetic transmission of data signals between at least two stationary units and one vehicle unit. The stationary units in the downlink mode synchronously transmit the data signals to the vehicle unit and have different carrier frequencies. In the uplink mode, the data signals are transmitted from the vehicle unit to the stationary units by the semipassive transponder principle. In the process, the data signals of the vehicle unit are frequency-modulated to the various carrier frequencies of the stationary units. This arrangement improves the reliability of bidirectional data transmission. A preferred application is data exchange for traffic control systems between stationary beacon units and moving vehicles. [A3318]

"Process and device for evaluating the precipitations over an area of terrain"

Automatic rain gauges (P00-P0n) are employed within the area of terrain (ZT) . A meteorological radar (R1) provides, with a given radar periodicity, a radar image representing rain-bearing cells of concern to the area of terrain. By analyzing the succession of radar images, the main rain-bearing cells are tracked dynamically by their shape and motion. Then a radar rainfall measurement chart is compiled by accumulating, in each pixel of the area of terrain, the precipitations due, during a second chosen time interval, to these main rain-bearing cells, with interpolation of their shapes and positions. At least one sub-array (PA, PB) of four rain gauges separated from one another by about 2 to 4 kilometers and affected by at least one main rain-bearing cell is selected. Finally, the rainfall measurement chart is corrected at least partially as a function of the relation between the accumulated true rainfall data and those from the said chart at the locations of the rain gauges of the sub-array. This allows excellent estimation of the precipitations in each square kilometer of the area of terrain. [A3319]

"Rainfall detection"

A method of obtaining oceanographic and meteorological data from high frequency radar spectral information comprising the steps of transmitting a plurality of signals to a remote location, recording signals backscattered from the said location, generating a family of Doppler cluter spectra from the recorded backscattered signals and analysing the Doppler clutter spectra in terms of a model or models to detect the presence of rainfall. The model or models identify the presence of rainfall by detecting a reduced amplitude in some parts of the Doppler spectrum, especially in the "wings" of the spectrum by which is meant the regions where the magnitude of the Doppler shift is greatest. The method may also be used by detecting opportunity signals scattered from a remote location. [A3320]

"Metallic cable-locating apparatus and method having an image capturing means"

A probe (10) for locating a buried cable (12) includes a casing (16) adapted to be driven into the earth (14) . Situated in the casing is an RF receiver (23) for sensing RF energy radiated by the cable to establish the cable's approximate location. The casing also has a viewing window (19) in its lower tip (18) in optical communication with a television camera (30) . The camera allows the cable, once its approximate location is established by the RF receiver, to be visually identified. [A3321]

"System for targeted braking of vehicles"

A system for identifying momentary location and the momentary velocity of, in particular, a rail-bound vehicle, has a transmission/evaluation unit having an antenna for emitting a high-frequency pulse and for receiving a reflected pulse reply signal. Surface wave identification marks having individual coding are arranged at intervals from one another in an area of and along a prescribed travel path of the vehicle. The mutual phase shift of at least two pulse reply signals can be measured as a Doppler shift and the travel velocity can be calculated therefrom via the relative velocity with pulse interrogations of an identification mark following one another at least twice at a predetermined location before/after traversing a specific identification mark. The point in time change in operational sign of the Doppler shift is acquired for this identification mark, and is the point in time of traversal of the location of the specific identification mark. [A3322]

"System and method for initiating communications between a controller and a selected subset of multiple transponders in a common RF field"

A system and method for initiating communication between a controller and a selected one or other subset of multiple transponders in a common RF field in which each transponder has a unique, (or commonly unique) preprogrammed ID number. The controller transmits a series of commands/questions to the transponders and they either respond, or do not respond, to the controller based on their ID number, with the non-responding transponders entering a reset state. The transponders respond to the controller in such a way that, if multiple transponders respond, the controller can recognize that at least one transponder has responded and, for individual responses, the controller is not required to determine how many transponders have responded. Through use of the communications system and method disclosed, a sequence of controller commands and transponder responses single out a selected individual transponder or group of transponders based upon its particular ID number. [A3323]

"Vector neural networks"

A vector neural network (VNN) of interconnected neurons is provided in transition mappings of potential targets wherein the threshold (energy) of a single frame does not provide adequate information (energy) to declare a target position. The VNN enhances the signal-to-noise ratio (SNR) by integrating target energy over multiple frames including the steps of postulating massive numbers of target tracks (the hypotheses) , propagating these target tracks over multiple frames, and accommodating different velocity targets by pixel quantization. The VNN then defers thresholding to subsequent target stages when higher SNR's are prevalent so that the loss of target information is minimized, and the VNN can declare both target location and velocity. The VNN can further include target maneuver detection by a process of energy balancing hypotheses. [A3324]

"Radar obstacle detection system with self test"

A radar system which detects the presence of objects in the proximity of a movable vehicle includes a signal source which generates object detection signals, a first antenna which transmits the object detection signals and receives the object detection signals as reflected signals reflected from an object in the proximity of the movable vehicle. The first antenna is further operable for receiving non-reflected test signals. A second antenna is provided for transmitting test signals which correspond to a delayed portion of the object detection signal generated by the signal source. A control unit is responsive to the reception of the reflected signals for providing an indication of the detection of the object, and is responsive to the reception of the test signals for providing an indication of the operability of the system. [A3325]

"Warning apparatus for a vehicle"

A warning apparatus for a vehicle generates a warning for a driver of the vehicle when the separation between the vehicle and an obstacle located in front of the vehicle falls below a prescribed value. The prescribed value is varied in accordance with changes in the physical or mental state of the driver of the vehicle, environmental conditions, or the driving characteristics of the driver and thereby adjust to changes in the driver's reaction time and the stopping distance of the vehicle. [A3326]

"Cylindrical phased array antenna system to produce wide-open coverage of a wide angular sector with high directive gain and moderate capability to resolve multiple signals"

A cylindrical phased array antenna system capable of scanning at rates faster than the information rate of signals being received so that no information is lost by the scanning process. The array is configured to add the capability to provide multidimensional separation of multiple signals and to eliminate the sensitivity loss due to sampling. The cylindrical phased array is comprised of the means to decompose the distribution of current on the radiator elements caused by wave incidence into component signals which are the Fourier spatial harmonics of the distribution, heterodyne means to differentially phase shift these component signals at rates exceeding 4 .pi. radians per cycle of the highest frequency present in the information content of the incident wave, and means to form multiple complex-weighted sums (beams) of the component signals. The means for beam summation selectively forms a coherent sum at only one of its multiplicity of output ports, the particular port being a periodic function of the signal frequency. The ambiguities which arise in frequency measurement capabilities due to the periodicity are resolved by auxiliary means for coarse frequency measurement. [A3327]

"Method and apparatus for automatically dimming motor vehicle headlights using radar signal"

The intensity of the headlights of a motor vehicle are modulated in response to pulsed Doppler radar signals which are used to distinguish between moving vehicles and other objects. The radar signals scan an area generally in front of the host vehicle. Reflected radar signals are received and radar return signals representative thereof are generated. A time to frequency domain transform, preferably a fast Fourier transform, is performed on the radar return signals to produce radar frequency signals. An adaptive technique is used to identify portions of the radar frequency signals produced by reflections from significant objects. The Doppler effect is used to determine the velocity of detected objects to the host vehicle. Any difference between the relative velocity of a detected object and the velocity of the host vehicle indicates that the object is moving. The velocity of the host vehicle may be determined by a conventional speed sensor or by means of radar signals reflected from a stationary object. Distance between the vehicle and a moving object is determined from the travel time of radar signals reflected from the moving object. The headlights of the host vehicle are modulated when a moving object is a predetermined distance from the host vehicle. [A3328]

"Doppler-effect vehicle speed sensor using different speed determining rules depending upon receiver output"

A Doppler-effect speed detecting apparatus for detecting a ground speed of a motor vehicle, including a transmitter, a receiver for receiving a portion of a wave transmitted by the transmitter and reflected by a road surface, a circuit for detecting an output level of the receiver, and a ground-speed determining device for determining the vehicle ground speed, on the basis of the frequencies of the transmitted and received waves, according to a predetermined first rule when the output level of said receiver is higher than a predetermined threshold value, and according to a predetermined second rule different from the first rule when the output level is not higher than the threshold value. [A3329]

"Apparatus and method for ionospheric mapping"

This invention is a unique single-site method of determining the local total electron content (TEC) of the ionosphere and its space-time variation using a global positioning system (GPS) ionospheric receiver. The TEC of the ionosphere is specified in terms of a space-time map of the local TEC in the vicinity of the receiver. Differential group and phase path data between two L-band frequencies (L1 and L2) for a plurality of the GPS satellites in view of the receiver station are analyzed by a least squares technique to extract both the ten parameters of a full second order space-time polynomial expansion for the vertical TEC (VTEC) and the differential delay biases associated with the space vehicles (SVs) . The method is applicable to day and nighttime data. [A3330]

"Operating delay means for a hydraulic door closer"

A door closure delay system produces a first signal when a person approaches a doorway housing the door. The first signal is applied to a timing system and a voltage comparator so that a second signal is produced to limit closure of an open door. The second signal is maintained for a predetermined and adjustable time period after the first signal has been removed. More patricularly, a voltage regulator provides a base or reference voltage to the comparator. A sensor, monitoring the doorway or portal, provides a signal voltage to the comparator when a physical presence is in, or in proximity to the doorway. The comparator passes on an output voltage which is stretched (i.e., has its time line extended) to circuitry coupled to a door closer, to delay the closure of the door by the closer. [A3331]

"Open loop proximity detector"

An open loop proximity detector is contemplated which receives a Doppler frequency when a target is first detected, and predicts a specific fuzing Doppler frequency. The detector continues to transmit and receive electromagnetic waves and sends a detonating signal to the fuze when the predicted fuzing Doppler frequency is received by the detector. The Doppler frequency of the first, or front surface in a forward moving direction of the target is received and is used to detonate the fuze. Thus the ideal surface of the target, the front surface, detonates the fuze and Doppler frequencies from other surfaces of the target are not allowed to interfere with the detonating process. [A3332]

"Process and system for determining the position and orientation of a vehicle, and applications"

The present invention relates to a process and a system for determining the position and orientation of a mobile, and to applications thereof. In order to ascertain both the position and orientation of a mobile, the invention proposes an interrogation/response process whose particular feature is to supply, to a given interrogation, two responses which are distinguished on the one hand, by different modulating frequencies and, on the other hand, by the fact that they are transmitted according to two patterns which differ in aim relative to one another. It is then possible, simply by measuring the angular deviation of either one of the two responses, and simply by measuring the ratio of the amplitudes of the two responses received, to deduce on the one hand the angular position .phi. and on the other hand the orientation .theta. of the mobile. The applications in the automobile sector are numerous (anticollision, control of road traffic and of compliance with the highway code, automatic toll points, etc.) . [A3333]

"Detection method and system"

The invention provides a method and a system for the detection of an object moving relative to another object. The object possibly being a person, an element, an installation, a tool, a surface, etc. According to the invention, a UHF wave is generated in a slotted antenna and the rays exiting from the slots are directed onto the area to be monitored. The reflected waves are detected and this frequency is compared with the frequency of the transmitted waves. [A3334]

"Sensor arrangement for sensing a threat"

A sensor arrangement for the sensing, through the intermediary of the intermediary of high-frequency of an actual threat against an object which is equipped with a receiver device by an attacker penetrating into a radio link. The arrangement has the receiver device designed for the receiving or pickup of radio reception links from a plurality of satellites operating at the same or different frequencies, and which includes at least one comparator stage for the evaluation of the radio reception link which has been influenced by a penetrating potential attacker in comparison with an uninfluenced radio reception link. [A3335]

"Method, apparatus and system for transmitting and receiving data in a moving linear chain"

A method, apparatus, and system for transmitting and receiving an electromagnetic data signal in a moving, linear chain. Each unit in a chain of units has a processing unit interconnecting a directional receiving element, a directional low power transmitting element, a deceleration detector for the unit, and a deceleration detector for preceding units in the chain. In a simple form, motor vehicles are the units. If the invention detects deceleration of a preceding vehicle, deceleration of itself, or an identifiable signal from a preceding vehicle such as a blue light, it causes a rearward facing blue light to illuminate. This blue light indicates to following motorists that the perceived vehicle is decelerating or that a vehicle somewhere in front from of it is decelerating. The blue light also may be received by another vehicle equipped with the invention and consequently be transmitted rearwardly. In a general form, a data encoded high frequency signal is transmitted rearwardly from a vehicle. This signal contains information relating to deceleration of any preceding vehicles (Chain Brake) and of the transmitting vehicle (Brake) . A receiving vehicle analyzes and displays this data to provide a motorist with information regarding preceding vehicles that may or may not be seen by the motorist. In a complex form, a variety of data is transmitted and received bi-directionally throughout the chain. [A3336]

"Apparatus with a signal receiving unit for locating golf balls"

The invention relates to a device with a signal receiving unit for locating golf balls. Each golf ball is associated with a transmitting unit and the signals emitted by each transmitting unit are detected by the signal receiving unit. The transmitting unit is associated with an energy store as an operating voltage source. The device includes a charging circuit with an energy transmitter for wireless transmission of the electrical energy to an energy receiver connected in front of the energy store. Immediately after the charging phase of the energy store, the transmitting unit starts sending transmission signals and in so doing discharges the energy store. The transmitted signals received by the signal receiving unit are fed to an evaluation circuit which produces an output signal for locating the golf ball. This output signal is then fed to a display unit. After a certain discharge time, the transmitting unit stops transmitting the transmission signals. The golf ball is located only during this limited transmission time. Golf balls which have been mishit can be located rapidly and simply using the device. [A3337]

"Method for tracking a maneuvering target with a slow scan rate sensor"

When the scan interval or time between successive potential detections is long with respect to a potential target's maneuvering capability (say on the order of ten seconds for a radar system) , there is the possibility that the target may be able to deviate far enough away from its last detected position at scan i-1 that correlation of the target with a detection in scan i may not be possible using conventional tracking methods. The present invention uses a maneuvering gate to monitor a volume in space. The volume is bounded by intersecting ellipsoids and is disposed, preferably uniformly about the target's last estimate velocity vector. The surfaces of the ellipsoids which bound the volume may be determined by determining the loci of a combination of a straight and turning maneuver at a predetermined acceleration, which acceleration may be selected to be the maximum acceleration expected to be achievable by a predetermined target. When target correlation is disturbed or lost, the volume is examined. A detection in the volume is correlated to the target. [A3338]

"Closed-loop control for scanning application"

An error-free tracking system is disclosed which can operate with a scanning sensor. Beginning with an initialized trajectory for an object, predictions are made with respect to future object position and the sensor produces an error signal representing an error between sensor position (predicted target position) and actual target position at the measurement time. From a sequence of error signals, trend information is extracted and, on the basis of the trend information, the gain of a trajectory correction algorithm is adjusted. Based on the corrected trajectory, a new position estimate is determined. This further estimate is then used for another measurement to produce a further error signal in order to provide for tracking the object or target. [A3339]

"High frequency MTI radar"

An MTI radar based on a comparison of the Doppler shifts of the original signal and a phase-reversed signal using pulse compression wherein the received signal is phase detected for in-phase and quadrature components relative to the IF. A Doppler-corrected pulse compressor produces a magnitude signal for the Doppler shift of the received signal from the sequence of in-phase and quadrature components. Another Doppler-corrected pulse compressor produces a magnitude signal for the Doppler shift of the received signal from the conjugates of the sequence of in-phase and quadrature components. The magnitude signal of the same Doppler shift of the two compressors are compared and the difference is the output of the MTI. [A3340]

"Microwave object counter and method"

A microwave signal is generated from a fixed source across a fixed path to trigger individual FM transmitters in passing objects such as race vehicles. A vehicle transceiver then sends an omnidirectional specific frequency FM radio carrier signal with a tone imposed to a console and a portable remote receiver. As the FM signal and tone are detected and decoded by the console receiver, data word is sent to a scoring computer which displays the lap of that particular vehicle and the current order of all vehicles. [A3341]

"Automatic brake control system"

An automatic brake control system produces a warning before automatically making the braking action of a driving vehicle according to the velocities of the driving vehicle and the vehicle ahead. The system calculates the desired vehicle distance according to the velocities of the driving vehicle and the vehicle ahead, and sets a warning distance which is longer than the desired vehicle distance. The warning distance is set in accordance with the driver's feeling. According to the present invention, the system is prevented from producing undesirable warning. [A3342]

"Method for the discriminating of obstacles by means of radar, and applications"

Disclosed is a method for the discriminating of obstacles by means of a radar, and its different applications to the measurement of a liquid in a tank or vessel, or again to the elimination of unwanted or parasitic echos coming notably from the ground, for radars mounted on vehicles or controlling vehicle traffic. To implement the method, the obstacle to be discriminated must have a substantially plane surface. The disclosed method then consists in successively transmitting substantially plane waves at slightly different angular frequencies .omega..sub.i, each wave being furthermore sent with two different polarizations p and p' chosen in such a way that these different coefficients of reflection on the obstacles according to the incidence of the waves give a criterion of discrimination. The processing at reception depends on the use (measurement of distance, elimination of parasitic echos etc.) . The main promising feature of the invention lies in the fact that it is possible to make very precise measurements without placing excessive constraints on the transmission pattern of the radar. [A3343]

"System for evaluating the inner medium characteristics of non-metallic materials"

A pulse radar system for determining the subsurface structure of a medium comprising an electronics unit for providing electronic signals and control comprising a utility controller, a sampler controller, and a timing controller such that the timing controller provides a pulser trigger and the sampler controller provides a sampler trigger, a microwave unit comprising all the microwave components within the system including a pulser for generating pulses as directed by the timing controller in the electronics unit, a transmitting antenna for receiving the pulses directly from and being in close proximity to the pulser, a receiving antenna for accepting the pulses emitted from the transmitting antenna, and a receiver in close proximity to and for accepting the pulses from the receiving antenna, and a data unit for receiving signals from the electronics unit and for displaying the data for review and analysis. In accordance with another embodiment of the present invention, a method is provided for determining the characteristics of a medium. Also provided in the present invention is a pulser which utilizes all microwave components and a novel antenna assembly. [A3344]

"Location of missing vehicles"

Method and apparatus for determining the present location of a missing vehicle, such as an automobile or marine vessel, using a Global Positioning System that receives GPS signals from two or more GPS satellites. A GPS antenna, GPS signal receiver/processor, a paging responder, a cellular telephone and associated antenna, and a controller/modem are installed in a vehicle and electrically connected together. When the vehicle is determined to be missing, because the vehicle has been misplaced, lost or stolen, the vehicle owner or operator contacts a vehicle location service center, which broadcasts a paging request that is received by the paging responder on the vehicle. The paging responder causes the controller/modem to interrogate the GPS receiver/processor to determine the present location of the vehicle. The receiver/processor determines the present vehicle location and notifies the controller/modem of such location. The controller/modem then causes the cellular telephone to notify the vehicle location service center of the present location of the missing vehicle so that the vehicle can be recovered. The GPS signal receiver/processor and GPS antenna can be replaced by a receiver/processor and associated antenna that works with a LORAN system, or with a group of gyroscopes or local magnetic field sensors mounted on the vehicle. Optionally, the signal receiver/processor is kept in a "sleeper" mode to conserve power, until the controller/modem receives a paging request for its present location. Optionally, the receiver/processor is periodically activated to determine, and thus update, its present location. Optionally, the presence of the GPS antenna and/or the cellular telephone antenna on the vehicle is concealed. In another embodiment, a sensor is positioned on the vehicle, and the cellular telephone is caused to transmit to the vehicle location center a message containing information on the present location of the vehicle when the sensor senses occurrence of a selected trigger event, such as unauthorized movement of, or breaking into, the vehicle. [A3345]

"Vehicle anti-theft alarm system"

A vehicle anti-theft alarm system comprises a microwave transmitter and receiver for transmitting microwave frequency signals from one location in the vehicle against a target in the vehicle at a given distance from the transmitter-receiver and for receiving the signals reflected back from the target and producing a monitoring signal representative of a time, frequency or distance parameter for sending and receiving the signals. If, for example, an object is interposed in the path of the transmitted signals, the parameter and thus the monitoring signal changes and a control signal is produced for actuating an alarm. A holding circuit provides for the alarm to remain actuated when the article is removed from the path of the transmitted signals. [A3346]

"Device for information transmission"

A device for information transmission, a so-called transponder, for receiving a first microwave signal, modulating and coding, and retransmitting a second microwave signal, having at least one antenna made in microstrip technique is described. The device is characterized primarily in that the antenna has an antenna layer (20) , acting towards a ground plane (21) , the antenna layer and the ground plane essentially equal area, and in that the device further having a reflex position (23) , arranged next to or at a distance of at most 1/6 of the air wave length of the first microwave signal from the edges of the antenna layer and the ground plane, so that an antenna lobe directional from the antenna is obtained, including directly transmitted microwave signal and reflected microwave signal. With this embodiment a device is obtained that is compact, effective, light and inexpensive and gives well defined and directional antenna lobe for communications with good range. [A3347]

"Bistatic multiple-doppler radar network"

A multiple-Doppler radar network can be constructed using only one, traditional, transmitting pencil-beam radar and one or more passive, non-transmitting receiving sites. Radiation scattered from the pencil beam of the transmitting radar as it penetrates weather targets can be detected at the receive-only sites as well as at the transmitter. In a bistatic system, the location of targets in Cartesian space can be calculated from the pointing angle of the transmitting antenna and the time between transmission of a radar pulse from the transmitter and detection at a passive receiver site. [A3348]

"Method and apparatus for displaying the impending danger due to speed associated with the driving situation of a vehicle"

A method for displaying the impending danger due to speed associated with the driving situation of a vehicle and a display appliance for carrying out the method are described. In accordance with the method, a degree of danger is defined and calculated and displayed to the driver of a vehicle and, in fact, independently of whether the vehicle, as following vehicle, is driving too close to a vehicle in front or other obstacle (distance problem) or is driving too fast in fog (visual range problem) . The signals necessary for this purpose are obtained from vehicle environment sensors, for example from a distance warning radar or distance recording radar and an infrared visual range measuring system, and are analyzed, together with vehicle condition signals, by a safety computer. On the basis of its specific programming, this computer determines and/or decides, for the respective current driving condition, which of the two degrees of danger is instantaneously predominant and indicates the condition which is respectively more critical to safety on a display. The display, as an indicating appliance, is produced in such a way that it makes it possible to recognize, in symbolic proportion, both the degree of difference between the instantaneous speed and the speed which is currently still safe and the current measure of the danger or freedom from danger in the manner of an analog display which reproduces trends. [A3349]

"Rainfall, snowfall forecast apparatus and method"

An apparatus is presented for providing a short time range forecast with relative high accuracy from weather radar images of cloud reflection data by incorporating physical properties of cloud in the forecasting method. The method consists of defining a plurality of lattice points on a radar image, and multiplying the reflection data from a group of neighboring lattice points obtained at a specific past point in time with selected coefficients. The products of multiplication are summed, and transformed into image data by specific function based on the properties relating to cloud. Squared errors of the difference between the computational reflection data and the observed reflection data are iterated to a value below a predetermined threshold value to select the coefficients, and these coefficients are used to provide forecasting of reflection data at a specific future point in time. [A3350]

"Method and system for tracking multiple regional objects"

A method for tracking objects is disclosed. First a region containing the objects is scanned to generate a multiplicity of sequential images or data sets of the region. A plurality of points in each of the images or data sets corresponds to a respective plurality of the objects. Next, respective figures of merit are determined for assigning the points to the tracks. Next, a k-dimensional cost function is defined which sums the figures of merit for combinations of assignments from the images or data sets. Next, the complexity of the cost function is reduced by Lagrangian Relaxation by permitting a point to be assigned to more than one track and adding a penalty factor to the cost function when a point is assigned to more than one track. The reducing step is iteratively repeated and the resultant penalized cost function is solved. Next, an auxiliary function at a (k-1) -dimension is defined as a function of lower order penalty factors and a solution at the dimension at which the penalized cost function was solved directly. Next, a gradient of the auxiliary function is determined, a step is made in the direction of the gradient to identify a peak region of the auxiliary function and penalty factors at the peak region are determined. The penalty factors at the peak region are used to determine track assignments for the points in the images or data sets. Then one or more of the following actions are taken based on the track assignments: sending a warning to aircraft or a ground or sea facility, controlling air traffic, controlling anti-aircraft or anti-missile equipment, taking evasive action, working on one of the objects. [A3351]

"Object location process and apparatus"

Methods and apparatus for the determination of the location of a mobile vehicle relative to a radio transceiver. The apparatus incorporates a mobile transceiver that calculates its location relative to at least a first stationary transceiver, and communicates this location back to the stationary transceiver. As a mobile vehicle enters the radio field radiated from at least a first stationary transceiver unit, the mobile vehicle transceiver begins measuring the energy of one or more radiated signals as an analog value, converts the analog value to digital form, from which a microprocessor and software algorithm calculates the specific distance from the stationary transceiver, and then returns a data string that informs the stationary transceiver of its location. This system thus allows both the mobile transceiver and the stationary transceiver unit to gain specific information with regard to the relative distance between mobile and base station units. [A3352]

"Carrier locating system"

A system for locating any mobile body or a plurality thereof within a predetermined environment, wherein each mobile body carries a transmitter (10 to 18) , each transmitter producing a unique identifying signal, and a plurality of receivers (20 to 32) located in a corresponding plurality of defined regions in the environment, each receiver incorporating a FIFO controller for interrogating the receiver means in turn to link the identification data with location data. [A3353]

"System for the calculation of at least one vehicular traffic check parameter"

This invention comprises a system for calculating at least one vehicular traffic check parameter. The system according to the invention includes a pulse modulated radar placed at a high point at the side of the lanes to be monitored. The radar emits pulses having a frequency f.sub.o and width .tau. according to a radiation diagram. The radiation diagram is narrow in plan and sufficiently wide in elevation to cover all lanes to be monitored, and inclined in elevation and plan such that at least one range bin of the radar is included in a lane. Echo signals received by the radar are then processed by a signal processing module and a parameter extraction module. The invention is particularly useful in automobile traffic, for calculation of the number of vehicles travelling in lanes, the vehicles speed and length, etc. The advantage of the this inventive system compared with previous systems is that it enables simultaneous checking of several traffic lanes. [A3354]

"Detection of radar targets using higher-order statistics"

A signal detection system, preferably for use with a coherent radar system elects certain combination of input signal samples in a block of signal samples to derive a test statistic which is unbiased by Gaussian noise. Products of pairs of sample values are stored in a data sample look-up table. An index look-up table is created by scanning through possible combinations of addresses and excluding those combinations of sample values which would be redundant over other combination and would result in a contribution to biasing by noise. Pairs of addresses from the index look-up table are then used in sequence to access first and second products from the data sample look-up table. The first product is multiplied by the complex conjugate of the second product and the (quadruple product) result is averaged to form a test statistic which is insensitive to position and constant velocity. Detection of the signal is determined by testing the real part of the averaged test statistic against a threshold. To allow such detection for an accelerating target, a lag index is derived for each combination of addresses in the index look-up table and the accumulation and averaging is done while sorting in accordance with the lag index. Dynamic adjustment of the test statistic compensates for time-varying clutter such as ocean waves, and allow the signal detector to track a substantially constant false alarm rate. [A3355]

"Monopulse azimuth radar system for automotive vehicle tracking"

A monopulse vehicular radar system for tracking a target about an automotive vehicle senses a transmitted signal reflected back from the target and received at two different locations, determines the sum and the difference of the reflected signals sensed at the two locations, and compares the sum and difference to determine the deviation of the target from a reference azimuth. A source frequency provided by a Gunn diode is applied to and transmitted by a two-lobe monopulse antenna. The antenna lobes detect the reflected signals from the target by sensing them at the two different lobes. A hybrid junction provides sum and difference signals to mixers which homodyne the signals to produce sum and difference Doppler frequency signals using the source frequency. The Doppler frequency signals are amplified and then compared to determine the deviation of the target from the reference azimuth. The comparison process can be done digitally by converting the amplified frequency signals to digital signals which are then processed in a digital signal processor, or the comparison may be done in analog fashion using a phase/quotient detector. The range or distance of the target is determined by shifting the source frequency between two frequencies during transmission and frequency shifting the sum and difference Doppler frequency signals in similar fashion following reception by the antenna. [A3356]

"Method and apparatus for controlling the speed of a vehicle and its spacing from a preceding vehicle"

An automatic speed and distance control apparatus responsive to detected signals and operator induced signals for automatically controlling the speed of an automotive vehicle and its distance with respect to objects in its path of movement. A flexible control scheme is provided, which permits a driver to intervene in the operation of the system when he or she wishes to accelerate in preparation for a passing maneuver. Upon interruption of the operation by a vehicle driver, the control apparatus is interrupted for a predetermined period of time and thereafter resuming automatic control function. [A3357]

"Digital phase lock detector"

A digital phase lock detector for determining the periods of an incoming signal for use in measuring rapidly and accurately the relative speed or velocity of vehicles according to the Doppler-radar principle includes a micro-controller based processor unit operated under a stored program to perform period determination. A bandpass filter is provided for generating a periodic signal which has a frequency which is varied in accordance with the velocity of the target vehicle in response to a difference Doppler signal. A comparator is responsive to the periodic signal for generating a rectangular pulse signal which is a digital representation of the periodic signal. The processor unit includes a microprocessor for determining the period of the pulse signal by integrating a number of consecutive cycles to produce a synthesized Doppler frequency signal having a frequency which is proportional to the velocity of the target vehicle. The bandpass filter is responsive to the synthesized Doppler frequency signal for varying the center frequency thereof to track the difference Doppler signal. [A3358]

"Doppler control channel for a radar"

A Doppler control circuit for a CW or pulse Doppler radar system for monitoring not only the phase shift between echo signals from several targets but also the amplitude difference between the several targets and to further tune the radar to a particular target among one or more targets from which echo signals return. The control circuit can be used in state of the art CW or pulse Doppler type radar systems. In a further system, a special circuit is provided for conditioning selected portions of the Doppler frequency spectrum to attenuate or de-emphasize portions of the echo signal corresponding to selected targets in the radar system environment, such as rain or stationary wayside objects, in order to give such echo signals less weight in determining roadway hazards. [A3359]

"Airport surface vehicle identification system and method"

An airport vehicle identification system for improving airport traffic management and collision avoidance, includes a ground surveillance radar and a plurality of low power frequency translators located in spaced relationship about the surface of the airport. The radar system transmits a conventional radar signal for target detection and a beacon interrogation signal for target detection. Each translator is designed to bandshift the interrogation signal to a frequency value compatible with the vehicle transponder, and transmit the bandshifted interrogation signal to the vehicle transponder. Each frequency translator is bi-directional and receives a transponder reply signal indicative of vehicle identity and bandshifts the reply signal to a frequency value compatible with the ground surveillance radar and transmits the bandshifted reply signal to the ground radar. This invention fills the critical void in airport traffic control of providing ground controllers with electronic airport ground surveillance data which includes both vehicle position and identity. [A3360]

"Detection and mapping of hydrocarbon reservoirs with radar waves"

Radar is used to detect and map near-surface geochemical alteration of rock and soil. The radar waves penetrate a buildup of carbonate and silica on the earth surface above micro-seepage of hydrocarbons dissolved in water. The hydrocarbon source may be an oil or gas reservoir buried many thousands of feet, or it may be from near-surface, man-made features. The thickness and sensitivity of the buildup is related to the size of the underground source or reservoir. Radar echoes from the bottom of the buildup provide a reservoir detection and mapping tool. [A3361]

"Metal recovery device"

A device for electrolytically recovering metal, in particular silver, from a photographic processing solution, said device having an anode located in a recovery chamber and a movably arranged cathode as well as a scraper for removing metal, in particular silver, deposited on said cathode. for the purpose of electrolytically depositing metal (17) , cathode (12, 32, 42) is held stationary in its operating position within the solution (16) . for removal of the metal, the metal-loaded cathode (12,32, 42) is moved out of its operating position within the solution (16) and is brought into engagement with the scraper (14, 20, 34, 44) arranged outside the solution (16) . Subsequently, the cathode (12,32, 42) freed from metal (17) returns to its operating position within the solution (16) for a repeated electrolytic deposition of metal (17) . [A3362]

"Weather radar axonometric display mode implementation"

A horizontal plan view and a vertical side view of a weather disturbance are combined into a single axonometric display to facilitate analysis of the disturbance. Desired azimuth and elevation angles for the center of the axonometric display and which of the four quadrants of the display to be emphasized are user selectable. Either the plan view or the side view can be separately displayed in the axonometric format and the axonometric display is user selectable with the conventional display being readily available. [A3363]

"Multiple target discrimination"

A target tracking system (10) comprises sensors (12) which provide data corresponding to a region of interest, the data being time dependent and consisting of amplitudes, ranges and angles. A window (202) is placed around data of interest, the size of the window being determined based on target size, assumed speed and acceleration characteristic, and the window is thereafter broken down into a plurality of smaller windows (208) , thereby forming a grid having a nodal point (210) at each corner of the smaller windows. The data within the window is stored in a matrix, and background noise is thereafter minimized by filtering the data past a threshold value (215) . The filtered data is analyzed to determine its distance weighted contribution at each nodal point (219) , and the weighted distances are summed for each nodal point resulting in a nodal point magnitude for each of the nodal points (220) . A nodal point having the maximum magnitude is selected (221) and its magnitude is compared to a target threshold value (227) . A first target is determined to be present if the nodal point magnitude is greater than the target threshold value. The weighted contribution of the nodal data corresponding to the first target is removed from the nodal point magnitude for each of the nodal points (230-237) , and thereafter, the procedure is repeated until all targets have been identified and deleted (221-237) . [A3364]

"Electronic car bumper"

A plurality of sensitive high-frequency proximity switches are provided in the bumper of a car and obstacles can be accurately identified. The electronic car bumper includes: a plurality of sensor portions each having sensor plates, first loading coils, and a divided capacitor, and a reference resonance circuit having a reference capacitor, a second loading coil and a divided capacitor. An oscillator drives each of the sensor portions and the reference resonance circuit through switching devices, and a detector detects an output of the oscillator. A discrimination portion discriminates an output of the detector and provides a discriminated signal to an output portion corresponding to the sensors and the reference resonance circuit. A synchronous device switches the switching device and the discriminator portion in synchronization. A direct current amplifier has an output which is adjusted to a point at zero as a reference voltage for the output corresponding to the reference resonance circuit, and a comparator is adjusted to a threshold reference according to the reference voltage. [A3365]

"Apparatus and method for estimating weather spectral moments"

A spectral moment estimator includes a first processor which processes signals representative of the magnitudes of complex autocorrelation functions of a signal at a plurality lags and provides Doppler spectral width representative signals and the autocorrelation function at zero lag independent of noise. A second processor, processes the complex autocorrelation representative signals, the complex autocorrelation functions phase angles representative signals, and the Doppler spectral width representative signals to provide the mean Doppler frequency of the the signal. The autocorrelation function phase angles are disambiguated and the unambiguous phase angles are least mean square error fitted to a third order odd polynomial, the linear term of which is the mean Doppler frequency of the signal. [A3366]

"Device for positioning a first object relative to a second object"

A device for positioning a first object relative to a second object, primarily for positioning an automatic fuelling device relative to vehicles. A transponder using a microstrip antenna design is small in dimension and gives accurate position indication by attachment to a back surface of a body which acts as a close reflection plane. The preferred embodiment of the device is a microstrip patch antenna where the ground plane is of similar size as the antenna element, and where the transponder is mounted on a car body rearward of the fuel filling point, to result in a radiation diagram that is created from the added direct signal from the antenna element and the reflected signal from the car body. A rounded profile of the transponder is a result of placement of its battery adjacent to the radiating element. [A3367]

"Weather radar system including an automatic step scan mode"

A weather radar system is operable in an automatic mode for positioning the radar system antenna beam to scan an elevation axis between upper and lower scan limits in incremental steps as selected by a user while continuously scanning an azimuth axis for enhancing the analysis of weather conditions. [A3368]

"Image processor for target detection and tracking"

An image processor for use in detecting and tracking a plurality of targets is provided including a plurality of memory locations for storing intensity images and a signal processor coupled to the memory locations. The signal processor comprises a closed loop feedback system for producing a plurality of intensity images for updating externally derived reference intensity images in response to at least one externally derived data image incorporating target detection signals. [A3369]

"Automotive navigation system and method"

A navigation system for a vehicle travelling along a highway that has an interrogator mounted on the vehicle and, a retrodirective transponder mounted alongside the highway for updating vehicle location. for collision avoidance systems, interrogators transmit and receive fore and aft, and transponders are mounted to respond to signals fore and aft of the vehicle. The transponder modulates information onto the interrogation signal, and retransmits the encoded interrogation signal back in the direction of arrival of the collected interrogation signal. The responder uses a Van Atta array antenna and is capable of responding to an interrogator signal incident over a wide solid angle of arrival while retrodirectively retransmitting without amplification substantially all of the collected signal within a narrow solid angle. The responder may be implemented using monolithic microwave integrated circuit technology (MMIC) , thus being suitable for high volume production. [A3370]

"Obstacle detecting device for a vehicle"

An obstacle detecting device for a vehicle comprises a pair of image sensors for taking an image of an object surrounding a vehicle, a display image plane for displaying an image data taken by said pair of image sensors as an image, and a plurality of windows designating regions of said image on said display image plane. The device further comprises an optical obstacle detecting device for detecting distances from said vehicle to said object in said regions of the image designated by said plurality of windows for the respective windows to thereby detect an obstacle, a laser radar device mounted on the vehicle for radiating a radar beam to the object surrounding the vehicle to thereby detect said obstacle, and an obstacle selecting device for selecting either the obstacle detected by said optical obstacle detecting device or the obstacle detected by said laser radar device mounted on the vehicle. [A3371]

"Transponder for proximity identification system"

A transponder for use in an object identification system including an interrogator which transmits a continuous interrogation signal and detects a responsive identification signal transmitted by the transponder. The transponder receives and detects the interrogation signal and, in response to receipt of the interrogation signal, produces a repeating identification signal having a fixed number of binary bits consisting of an identification data portion of a specified number of consecutive bits less than one half of the fixed number of bits, and a synchronization pattern of consecutive bits consisting of first, second and third bits of alternating binary values, a consecutive sequence of a plurality of bits which are all of the same binary value as the second bit, and a single bit of the same binary value as the first and third bits. The identification signal is modulated onto a carrier signal and transmitted. Preferably, the first, second and third bits and the sequence of a plurality of bits constitute one half of the fixed number of binary bits of the identification signal, with the binary value of the first bit being a binary 1. [A3372]

"Ice thickness measurement reflectometer"

The disclosure defined by this invention utilizes electromagnetic energy reflected from the top and bottom surfaces of ice, the thickness of which is being measured, to determine a phase difference that indicates the thickness of the ice. Since there will be many wave lengths of the electromagnetic energy in the ice, two measurement frequencies are utilized. Integers of wavelengths of each frequency are added to the readings for each frequency to derive sets of numbers. The one number in the set of readings for each frequency that are the same in each set indicate the actual thickness of the ice. [A3373]

"Radio environment measuring system"

A radio environment measuring system for measuring a propagation state of radio waves includes: a fixed radio apparatus provided in a base station, a mobile radio apparatus operatively connected to the fixed radio apparatus through the radio waves, the mobile radio apparatus having a repeater unit for receiving a transmission signal from the fixed radio apparatus and sending a returned signal to the fixed radio apparatus, and the fixed radio apparatus having a transmission/reception unit for sending the transmission signal to the mobile radio apparatus and receiving the returned signal from the mobile radio apparatus, and a measuring unit for measuring the propagation state of the radio waves, for example, a propagation distance, direction and reception intensity of the radio waves between the fixed radio apparatus and the mobile radio apparatus based on the transmission signal and the returned signal. [A3374]

"Method for creating a 3-D image of terrain and associated weather"

A weather visualization system retrieves a static terrain map which is merged with dynamic weather information. The dynamic weather information may be provided from weather radar, weather satellite or remote weather observation sites. The terrain map is combined with the weather information to provide a three-dimensional weather image relative to the terrain map. The system can generate a sequence of images to provide a "fly by" animation. Path data can also be input so that a fly by of a projected storm path can be displayed. Other dynamic information can be displayed relative to the terrain map such as the locations of fires and accidents. Weather information which can be displayed includes storms, clouds, rain, snow, hail, tornadoes and severe weather. The system includes time and date information to generate appropriate shadows in the three-dimensional image. [A3375]

"Radar target velocity estimator"

A radar target velocity estimator apparatus and method for computing a radial velocity of radar targets from differences in Doppler frequency shift between pulse-returns of multi-pulse waveforms. The velocity estimator uses Doppler frequency shift which is obtained from a finite impulse response (FIR) filter in combination with logarithm tables stored in read-only-memory (ROMs) to calculate the target's velocity. The estimation process requires the calculation of each complex FIR filter value twice during a pulse repetition interval, once for returns of a leading set of radar pulses and then for a trailing set. The estimated velocity is proportional to the phase difference between each corresponding pair of filter values. The estimate is a function of the arctangent of the quotient of the in-phase component of the complex value divided by the quadrature component. [A3376]

"Vehicle guidance control system"

In accordance with the present invention, an automatic lateral guidance control system for motor vehicles is provided which includes a steering servo actuator which steers the vehicle. The steering servo actuator also allows for manual control by the driver. A detector detects when the automatic control is malfunctioning or is not present, and restores manual control to the driver. The system also includes a provision for stability augmentation to compensate for oversteering or understeering. [A3377]

"Doppler-effect vehicle ground speed detecting apparatus having means for sensing abnormality of detected ground speed"

A Doppler-effect speed detecting apparatus for detecting a ground speed of a vehicle, including a transmitter for transmitting a wave towards the ground surface, a receiver for receiving the wave reflected by the ground surface, and an output device for producing an output indicative of the ground speed according to the frequencies of the transmitted and reflected waves. The apparatus further includes a device for determining presence or absence of abnormality relating to the output of the output device, on the basis of an output level of the receiver as well as a speed difference between the ground speed obtained by the output device and an estimated vehicle speed which is obtained on the basis of rotating speeds of the vehicle wheels. [A3378]

"Phase-coded monopulse MTI"

A pulse-compression, MTI, doppler-radar system for determining target velty information from a single target-return pulse is improved by the addition of a pulse-compression filter consisting of at least two pulse compressors and by the addition of a phase-comparison processor. The pulse compressors simultaneously pulse-compress separate portions of the single target-return pulse. The phase-comparison processor then determines the phase difference between the compressed pulses to obtain the target velocity information. [A3379]

"Signal metric estimator"

A performance measure of an ATR is made from ancillary target data and the ATR output. A parameter of the ATR is varied to determine the change an ATR performance due to the parameter variation. Separate performance in the form of a quadratic equation models provide performance as a function of parameter and metrics. The performance model is partially differentiated with respect to the parameter. The partial differentiation allows solution for the estimated metric. [A3380]

"Dynamic capacity allocation CDMA spread spectrum communications"

A dynamic capacity allocation spread spectrum CDMA communications system for overlaying, at least in part, geographically and in frequency a radio-relay system. A first receiver, located near the relay receiver of the radio-relay system, measures a first power level within the relay bandwidth of the radio-relay system. A second receiver, located near the relay receiver, measures a second power level outside the relay bandwidth of the radio-relay system. The first power level is compared to a predetermined threshold. A ratio signal is generated from the first power level and the second power level. When the first power level exceeds the predetermined threshold, the ratio signal is used to regulate the power level and dynamically allocate the capacity transmitted from each spread-spectrum-base station. [A3381]

"CDMA communications and geolocation system and method"

A spread-specttrm CDMA communications system for locating remote units, and for communicating message data between a plurality of remote units and a base station. The spread-spectrum CDMA communications system includes a plurality of base stations and a plurality of remote units. A base station has a spread-spectrummodulator for spread-spectrum processing the message data, and a transmitter for transmitting the spread-spectrum processed-message data, combined with a generic-chip-code signal, from the base station to a remote unit. The base station also has an antenna, and spread-spectrum detectors for recovering message-data communicated from the remote-units. A remote-unit has an antenna, and a detector coupled to the antenna for recovering data communicated from the base station. The detector includes a spread spectrum demodulator. Also, the remote unit has a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator and a transmitter. The base station has a range circuit, which compares the generic-chip-code signal generated at the base station with the generic-chip-code signal received from the remote unit, for determining a range between the remote unit and the base station. [A3382]

"Communication system and method for determining the location of a transponder unit"

A multilaterating two-way message delivery system for mobile resource management provides efficient two-way radio data communication for multitudes of portable transponders using a single frequency in half-duplex communication. The system includes at least one transponder device which transmits and receives data using a radio frequency communication link, and an array of at least three base stations which communicate with the transponder device using the radio frequency communication link. The radio frequency communication link employed by each base station and the transponder device is designed to provide multilateration information and to deliver message data simultaneously. Further, a control arrangement is coupled to the array of base stations to coordinate the communication between the base stations and the transponder devices. Time-division multiplex and spread spectrum technology is employed by the system for communication efficiency and minimizing the effect of multipath interference. [A3383]

"Electrical device for liquid level measurements in industrial tanks and the like"

An electrical device for measuring the liquid level in industrial tanks and the like with a microwave transmitter and receiver and a waveguide provided with an aperture and an antenna. The signal reflected from the liquid surface and the transmitted signal are fed to a frequency conversion stage (8) , whose low-frequency output signal is sent via an A/D converter (12) to a microprocessor calculating the fill level. To reduce the effect of interference frequencies produced by reflection of microwaves in the optical aperture, etc., a band-pass filter (9,10) with a lower limiting frequency selected to attenuate the low-frequency interference frequencies is placed between the frequency conversion stage (8) and the A/D converter (12) . The lower limiting frequency can either be controlled with microprocessor (13) or the band-pass filter (9, 10) has adjustable limiting frequencies. To inhibit overcontrol of the A/D converter, an amplification stage (11) controlled by microprocessor (13) is provided for band-pass filter (9, 10) . [A3384]

"Quantitative dielectric imaging system"

In a microwave imaging system, a three dimensional profile of the dielectric permittivity of a target is obtained. A transmitter transmits microwaves toward a target, and the target scatters the microwaves. The scattered waves are received by an antenna and are converted into suitable data for application to a digital computer. The computer processes the data using either a scattering matrix algorithm or a Fourier transform algorithm. The computer then generates data representative of a three dimensional profile of dielectric permittivity which can be displayed on a suitable display device such as a CRT. [A3385]

"Ultra-wideband radar motion sensor"

A motion sensor is based on ultra-wideband (UWB) radar. UWB radar range is determined by a pulse-echo interval. for motion detection, the sensors operate by staring at a fixed range and then sensing any change in the averaged radar reflectivity at that range. A sampling gate is opened at a fixed delay after the emission of a transmit pulse. The resultant sampling gate output is averaged over repeated pulses. Changes in the averaged sampling gate output represent changes in the radar reflectivity at a particular range, and thus motion. [A3386]

"Microburst precursor detection utilizing microwave radar"

A microburst precursor detector samples radar returns from meteorological radar signal reflectors and processes the signal returns in a statistical manner to determine average radar reflectivity and to extract Doppler signal parameters. The vertical velocity in still air and the vertical velocity of the meteorological radar reflectors are respectively determined from the average reflectivity and the Doppler signal parameters. The difference between the two vertical velocities is taken to determine the vertical wind velocity. The vertical wind velocity and the average reflectivity are processed to predict the occurrence of a microburst. [A3387]

"Bulk wave transponder"

An electronic article surveillance system including a bulk acoustic wave transponder 10 coupled to an antenna 12, an interrogator 14, directional antenna 16 and an output connector 18. The transponder comprises a silicon or glass substrate 20, bus electrodes 22, 24, a launching IDT T0 and a series of "connected" and "unconnected" IDTs T1-T4. The connected/unconnected state of the respective IDTs T1-T4 may be detected and employed to generate an identification code comprising a series of binary digits. A thin copolymer piezoelectric film 26 covers the substrate 20 and electrodes T0-T4. [A3388]

"System and method for earth probing with deep subsurface penetration using low frequency electromagnetic signals"

An earth probing system uses deep penetration of electromagnetic waves into soil and other media. Advantage is taken of the lower attenuation of radar waves in soil by frequencies of about three megahertz or less. Bursts of electromagnetic energy of various frequencies in this range are consecutively transmitted. The transmitting antenna is continuously tuned, so as to maintain resonance during each burst, allowing large circulating currents and high power output. In a receiving antenna system, a dual antenna arrangement is providing for obtaining improved reception. A corresponding dual antenna circuit employs "spatial notch filtering", automatic adjustment of antenna gain-frequency variations, as well as compensation for transmitter gain variation. The system may be implemented in a totally analog, totally digital, or hybrid manner. Preferably, a signal processing method detects and digitally samples signals reflected from subsurface layers and buried objects. The invention provides means for removing system distortions and interfering signals, for compensating for aliasing errors and frequency-dependent antenna gain and phase variations, and for avoiding masking errors introduced by strong reflections. [A3389]

"Vehicle collision alert system"

An apparatus for deciding an excessive approach of a vehicle to an object in front of the vehicle. The excessive approach decision apparatus comprises a normalized time rate of change detector for determining a normalized time rate of change of a visual angle for the object as viewed from the vehicle. An excessive approach is indicated based upon the determined normalized time rate. [A3390]

"Overlaying spread spectrum CDMA personal communications system"

A spread spectrum CDMA communications system for communicating data and/or digitized voice between a plurality of users to a plurality of PCN units. The spread spectrum communications system is located within a same geographical region as occupied by an existing FDMA, proposed TDMA or any other mobile cellular system. The spread spectrum CDMA communications system includes a plurality of PCN-base stations and a plurality of PCN units. A PCN-base station has a comb filter for notch filtering predetermined channels of the mobile cellular system, a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator for spread spectrum processing the data, and transmitter for transmitting the spread spectrum processed converted data from the PCN-base station to a PCN unit. The PCN-base station also has an antenna, and spread spectrum detectors for recovering data communicated from the PCN units. A PCN unit has an antenna, and a detector coupled to the antenna for recovering data communicated from the PCN-base station. The detector includes a spread spectrum demodulator. Also, the PCN unit has a device for converting the format of the data into a form suitable for communicating over radio waves, a spread spectrum modulator and a transmitter. [A3391]

"Transponder systems for automatic identification purposes"

A method of communicating between an interrogator (10) and at least a first and second transponder (12) . The transponders (12) are separately located within a first and a second vehicle (20) travelling within a first and a second traffic lane, respectively. The method has the steps of providing a first and a second LF antenna (16) associated with and proximity to a first and a second traffic lane, respectively. From each of the first and second LF antennas (16) a continuous LF subcarrier is transmitted to serve as a clock signal for each antenna's associated transponder (12) . Initially, a wake-up signal is sent by each of the LF antennas (16) to its associated transponder (12) . Following the wake-up signal, a unique lane code is sent by each of the LF antennas (16) to its associated transponder (12) . The transponder (12) stores its unique lane code in its memory (70) . The transponder then sends a UHF response in a pre-determined time period depending on the unique lane code stored in each of the transponders (12) . The time period in which the transponder (12) sends its UHF response is unique to that transponder (12) so that interference between responding transponders (12) is avoided. Other devices, systems and methods are also disclosed. [A3392]

"Method and device to determine the passing to a pre-selected distance of a reflector point by

means of the time of propagation of a continuous wave"

The wave is modulated in frequency (or in phase) and a measurement is made of the frequency of the beat between the transmitted wave and the received wave which gives the propagation delay and hence the distance. The method provides for the superimposing, on this modulation, of a periodic over-modulation with a period that is equal to or is a multiple of the propagation delay corresponding to a pre-selected expected distance. The device comprises, at transmission, in the case of a linear modulation of frequency, a saw-tooth generator (31) and a generator of over-modulations (32) , for example sinusoidal, controlled by the expected distance given by a distance selector (30) . The modulation signal of the transmitter is obtained by summation (33) of the signals of the two generators (31, 32) . [A3393]

"Simultaneous data transmission and reception system using microwaves"

A system including a first station (1) known as a beacon and at least one second station (2) known as a badge, each station having a transmission channel with an antenna and a reception channel with an antenna. To allow multiplex exchanges, using simultaneous transmission and reception, the two antennas (6, 11) (13, 15) in any given station are decoupled by cross-polarization but antennas which communicate with each other (6, 13) (11, 15) have compatible polarization. Applications to identification systems using microwave transmission. [A3394]

"Frequency-coded monopulse MTI"

A pulse-compression, MTI, doppler-radar system for determining target velty information from a single, frequency-coded uncompressed target-return pulse includes a coded modulator, two pulse compressors, and a phase-comparison processor. The coded modulator generates for transmission an uncompressed pulse with the first and second halves of the pulse coded with the even and odd harmonic sidebands of a pulse repetition frequency, respectively. The first and second halves of the pulse returning from the target are pulse compressed simultaneously by the two pulse compressors. The phase comparison processor then determines the phase difference between the compressed pulses to obtain the target velocity information. [A3395]

"Hazardous waste transport management system"

A hazardous waste shipment system provides monitoring and control to verify the location and condition of each shipment. Two-way base stations receive status and identification signals from vehicle-mounted transponders as the shipments pass by, and the base stations relay the information to a central data bank. The vehicle mounted transponders may receive data from sensors that monitor the load, and may actuate alarms or a message display for operator intervention. The three-tier system also provides notifications, and safety instructions in the event of a mishap, with the base stations relaying instructions or route changes to the vehicle mounted transponders. [A3396]

"Ultra-wideband receiver"

An ultra-wideband (UWB) receiver utilizes a strobed input line with a sampler connected to an amplifier. In a differential configuration, .+-.UWB inputs are connected to separate antennas or to two halves of a dipole antenna. The two input lines include samplers which are commonly strobed by a gating pulse with a very low duty cycle. In a single ended configuration, only a single strobed input line and sampler is utilized. The samplers integrate, or average, up to 10,000 pulses to achieve high sensitivity and good rejection of uncorrelated signals. [A3397]

"Continuous-wave reflection transmissometer with target discrimination using modulated targets"

The attenuation of electromagnetic waves by a transmission medium is detected or measured by directing a continuous periodic electromagnetic wave toward a reflector. The reflector is modulated to modulate the electromagnetic wave as it is reflected. The reflected wave is received and an output signal related monotonically to the power of the modulated reflected wave is detected. The output signal is then compared to the output signal which is or would be obtained under various other transmission conditions. [A3398]

"Method and means for avoiding collision between a motor vehicle and obstacles"

The method for avoiding collision between a motor vehicle and obstacles placed in the path of the vehicle comprises the stages of forming a radar map of the area in front of the vehicle, reconstructing the geometry of the road, identifying its edges, detecting the position and speed of the vehicle with respect to the road, determining the presumed path of the vehicle on the basis of the road geometry and the manoeuvre being carried out by the vehicle at that instant, detecting objects on the radar map found lying in the presumed path of the motor vehicle and displaying the map found in a perspective representation, ignoring objects which are off the road and indicating objects in the path of the vehicle in a different manner according to their hazard and if appropriate generating alarms of an acoustic type. [A3399]

"Obstacle-detection system"

A method and apparatus for detecting objects around a vehicle, comprising a plurality of microwave-transceiver sensors for transmitting microwave signals to reflect off objects around the vehicle. The reflected signals are received and passed to a control unit for comparing the received signal to a transmitted signal to determine whether a detected object constitutes a threat to the moving vehicle. An alarm means is connected to the control unit and activates upon the receipt of an alarm signal when the control unit determines a detected object constitutes a threat to the vehicle. [A3400]

"Vehicular cruise control system and radar system therefor"

A radar system (30) for determining the range at a future time of a target moving relative to the radar system. The system comprises an R.F. source (56) for providing a signal at a frequency which increases over time from a base frequency f (Hz) at a rate r (Hz/s) for a sweep duration d (s) . This signal is transmitted and a signal reflected by the target is mixed (38) with a portion of the transmitted signal to give a signal having a frequency proportional to the range of the target. The R.F. source is arranged to have a sweep rate r equal to the base frequency f divided by a time t (s) which time is the delay until the target will be at the measured range. A predicted range may thus be derived without complex compensation for relative velocity. The system may further provide velocity feedback without requiring extra circuitry. [A3401]

"Transponder system"

A transponder system comprising an interrogating source of HF electromagnetic radiation, and a plurality of transponders which each include a token reader unit to receive a removable token, e.g., a smart card, including onboard data processing capability. The transponders, or a group of transponders, are each arranged when interrogated to transmit a unique HF response modulated by information taken upon the token. [A3402]

"Structure of reception frequency converting portion in a multi-band microwave detector"

A structure of a reception frequency converting portion of a multi-band microwave detector, and including a microwave circuit comprises a horn antenna, two-port cavity integrally formed with the horn antenna and having one port communicated with a throat portion of the horn antenna, one-port cavity integrally formed with the two-port cavity and communicated with the other port of the two-port cavity, a mixer diode located at the throat portion of the horn antenna, a first local oscillator arranged within the two-port cavity, and a second local oscillator arranged within the one-port cavity. [A3403]

"Vehicle detection systems"

In a vehicle presence detection system for controlling traffic signal lights at a road intersection, the vehicle detection is performed by targeting vehicles at the location of interest with an FMCW radar beam. The radar can be switched repeatedly between the FMCW mode, for vehicle presence detection, and a doppler mode, for vehicle movement detection. Signal data representing the background of the scene viewed by the radar beam are stored for use by circuitry that determines whether an apparent vehicle presence detect is a true vehicle detect, the background signal data is repeatedly updated, as necessary, as the system cycles. Temperature compensation is provided and entry into the FMCW mode is inhibited if a voltage-controlled oscillator provided for generating the emissions has not settled down after any such compensation. [A3404]

"Very low frequency tracking system"

Apparatus identifying an instrumentality such as a person's hand or an article of merchandise, wherein the instrumentality carries a tag incorporating a transponder generating and transmitting a radio frequency identification signal in response to a radio frequency transmitted inquiry, a nest comprising an identifying station and incorporating a proximity sensor sensing the presence of the instrumentality at the identifying station and producing an indication of the presence or absence of the instrumentality, the identifying station comprising a radio frequency sensor portion generating a radio frequency transmitted inquiry transmitted to the transponder in response to sensing the presence of the instrumentality and receiving the radio frequency identification signal from the transponder, the proximity sensor terminating generation of the radio frequency transmitted inquiry when a clear and reliable output indication identifying the tag has been produced, and the proximity sensor also preventing, after producing a clear and reliable output indication, generation of a subsequent radio frequency transmitted inquiry until the proximity sensor has subsequently produced indications of the absence of the instrumentality at the identifying station. [A3405]

"Traffic management system"

A method of and apparatus for providing information which may be used in making traffic management decisions for limited access highways is disclosed. The method and apparatus employs microwave radar to obtain information bearing signals which are processed to determine the vehicle direction and speed. The apparatus includes the capability of emulating in-the-road or on-the-road sensors to provide output pulse pairs which appear as if generated by switch closures. The method and apparatus also has the capability of providing "wake-up" signals commensurate with a predetermined number of consecutive vehicles which pass a preselected point traveling at an abnormally low speed. Because the method and apparatus are vehicle direction sensitive, the capability of monitoring traffic flow by looking across lanes is also present. [A3406]

"Terrain referenced navigation--woods data base model"

A terrain referenced navigation system utilizing a woods database model including a method for increasing terrain referenced navigation accuracy by compensating for the existence of deciduous forests. Deciduous forests present increased terrain referenced navigation inaccuracies during months that trees lack leaves. The terrain referenced navigation database is modified to include a woods bit to indicate the existence of a deciduous forest. The terrain referenced navigation algorithm is modified to account for the existence of the deciduous forest. [A3407]

"Azimuth range velocity display and cursor for use therewith"

A method of displaying and determining the velocity of radar returns of frequency modulated continuous wave radars including the steps of determining a velocity for each radar return from a detected beat frequency associated with received radar returns, and displaying (for successive radar dwells) one or more major plots indicating range, azimuth and velocity of any radar returns. Each major plot is characterized by a velocity axis with a maximum and a minimum display velocity. The major plots are composed of minor plots indicating range, azimuth and velocity of any radar return and are characterized by a velocity axis that extends between zero velocity and the magnitude of greatest possible velocity corresponding to the range of the detected beat frequencies. Between successive radar dwells, radar returns on one side of the said zero velocity remain substantially in the same display position whereas associated radar returns displayed on the other side of the zero velocity do not remain substantially in the same position. Furthermore, classification of radar returns is assisted by displaying the radar returns on a display, displaying predicted radar return positions of a radar return on the display where the prediction of the position of the radar returns is in accordance with radar return azimuth from an antenna and estimates of the heights of the E and F layers. [A3408]

"Airport surface vehicle identification"

An airport vehicle identification system includes a ground surveillance radar system which radiates both a conventional radar signal and a beacon interrogation signal. The radar receives i) a backscatter signal from the skin returns of a target and ii) an encoded ID signal indicative of the target identity. The encoded ID signal is transmitted by a vehicle (e.g., an aircraft) mounted transponder in response to receiving the beacon interrogation signal. The transponder can be located within an external vehicle light housing such as an aircraft collision avoidance light. This invention fills the critical void in airport traffic control of providing ground controllers with electronic airport surface surveillance data which includes both vehicle position and identity. [A3409]

"Method for two dimensional doppler imaging of radar targets"

A method for two dimensional imaging of a two or three dimensional target is disclosed. As shown, a radar transmitter transmits a beam on a beam axis originating at a position spaced from the target and a radar receiver receives return signals from the target. The stationary radar observes the precessing target whose normal to the two dimensional target plane (or whose axis through a three dimensional target) intersects the transmitted beam axis at a point, and forms a cone half angle with the beam axis. With the normal (or target axis) moving along a conical surface while precessing 2 Pi around the beam axis, signal returns from the target are processed to develop a two dimensional image of the target. The process is repeated at other cone half angles and a composite, reduced-sidelobe image generated by vectorial superposition of images at multiple cone half angles. [A3410]

"R.F. transparent RF/UV-IR detector apparatus"

A dual-mode, radio frequency, optical-wavelength detector apparatus includes RF-transparent optical elements adapted to focusing optical energy in a wavelength range including ultraviolet through infrared wavelengths, on an optical detector, and an RF antenna located behind the optical elements. One embodiment of the apparatus employs a Cassegrain infrared optical telescope system having a concave primary mirror, the front surface of which has applied thereto multiple layers of dielectric material comprising an interference filter reflective in a band of infrared wavelengths, and transmissive to radio frequency energy. A convex secondary mirror having a similar reflective coating is so located as to reflect infrared energy backwards through a central coaxial perforation through the primary mirror onto an infrared detector. The apparatus includes a planar RF antenna rearward of the primary mirror, which antenna utilizes the full aperture of the infrared optical system for the reception and transmission of RF energy. [A3411]

"ID microwave holographic sensor"

A method and apparatus for measuring both physical and electrical properties of a dielectric object using sequential spatial and spectral microwave data. The apparatus is a step CW microwave transmitter and receiver with a spatially modulated antenna positioned linearly in the Poynting vector direction. The method removes the antenna dispersion, removes the antenna image, transfers the image plane to the surface, removes diffraction and then removes the nuisance multipath by spatially integrating along the Poynting vector. The result is a clean complex surface reflection coefficient that contains only the subsurface or object plane information. This clean complex surface reflection coefficient may be compared to reflection coefficients of known objects in order to ascertain physical characteristics of the object. [A3412]

"Battery package and method using flexible polymer films having a deposited layer of an inorganic material"

A battery package for a thin battery includes a flexible base film that covers and encloses the battery and a flexible layer of an inorganic material such as silicon nitride, aluminum nitride or aluminum oxide deposited on the base film to encapsulate and seal the battery. The base film is formed of a flexible polymer material such as polyester that may be attached to the battery using a heat activated adhesive. The layer of inorganic material is deposited on the base film utilizing a low temperature CVD deposition process either before or after the base film is attached to the battery. [A3413]

"Golf information system"

A golf information system which automatically provides golfers with reference position and distance information from a number of points on a particular golf course hole. In one embodiment, radio frequency identification tags would be positioned along a golf cart path, for example, buried underneath the path, and a reading system carried by the golf cart would output an interrogation signal which would activate the tags causing the tags to output a coded signal which would be received by the reading unit, which would retrieve information about that location from memory and output it to the golfer. The system can further be used to display advertising messages and to provide golf course management features such as monitoring cart usage and speed of play. [A3414]

"Interacting multiple bias model filter system for tracking maneuvering targets"

A filtering system used in the tracking of a maneuvering target is provid A first filter estimates a partial system state at a time k in terms of target position measurements. A plurality of second filters are each provided with an acceleration model hypothesis from a prior time (k-1) free of position and velocity constraints. Each second filter generates an acceleration estimate at time k and a likelihood at time k that the acceleration model hypothesis is correct. The likelihoods from the second filters are summed to generate a probability vector at time k. A third interaction mixing filter generates the acceleration model hypotheses from prior time (k-1) using the probability vector from prior time (k-1) and the acceleration estimates from prior time (k-1) . The third filter also provides an error covariance to the first filter to reflect the uncertainty in the acceleration model hypotheses from prior time (k-1) . A probabilistic acceleration estimate for time k is formed as a sum of each of the acceleration estimates associated with each of the acceleration model hypotheses multiplied by a corresponding probability from the probability vector. The partial system state estimate and the probabilistic acceleration estimate are summed to generate a complete system state estimate at time k in terms of position, velocity and acceleration of the maneuvering target. [A3415]

"Multimode radar for road vehicle blind-zone target discrimination"

A road vehicle radar system for discriminating between hazard and non-hazard targets within a predetermined zone uses a pair of frequency modulated continuous wave radar cycles (FM-CW) and a single continuous wave cycle (CW) in the generation of radar quantities for measuring target range and apparent target velocity. Measured quantities from the FM-CW and CW cycles are compared with predetermined quantities for discriminating between hazard and non-hazard targets. [A3416]

"Smart blind spot sensor"

A radar system for sensing the presence of obstacles in a vehicle's "blind spots" and generating a signal to the vehicle operator indicative of the presence of such an obstacle. The system uses a common radar transceiver that transmits a radio frequency signal directed at a blind spot of the vehicle. The signal is reflected off any obstacles that are present in that blind spot region. A Doppler shift in the received reflected frequency generally indicates that an obstacle has moved into the blind spot. Doppler frequencies attributable to objects which are of no interest, such as stationary objects, are filtered out. Only obstacles that are traveling at approximately the same speed and direction as the vehicle are considered to be of interest, and will cause the blind spot sensor to generate an indication that an obstacle is present in the blind spot. The indication is preferably an unobtrusive illuminated indicator which is affixed to one of the vehicle's mirrors. In addition to the illuminated indicator affixed to a mirror, an obtrusive audible indicator is provided in the preferred embodiment of the present invention which creates an audible tone, whistle, or buzz when an obstacle is present and the vehicle's turn signal is active. [A3417]

"Stepped frequency ground penetrating radar"

A stepped frequency ground penetrating radar system is described comprising an RF signal generating section capable of producing stepped frequency signals in spaced and equal increments of time and frequency over a preselected bandwidth which serves as a common RF signal source for both a transmit portion and a receive portion of the system. In the transmit portion of the system the signal is processed into in-phase and quadrature signals which are then amplified and then transmitted toward a target. The reflected signals from the target are then received by a receive antenna and mixed with a reference signal from the common RF signal source in a mixer whose output is then fed through a low pass filter. The DC output, after amplification and demodulation, is digitized and converted into a frequency domain signal by a Fast Fourier Transform. A plot of the frequency domain signals from all of the stepped frequencies broadcast toward and received from the target yields information concerning the range (distance) and cross section (size) of the target. [A3418]

"Method and apparatus for determining runoff using remote geographic sensing"

Images of a selected geographic region are obtained using remote sensing apparatus and are processed to determine characteristic spectral reflectance patterns associated with different ground covers and soil types in the region. The image processing means compares the spectral reflectance patterns to image pixel values in order to classify each pixel in a ground cover or soil type class, the corresponding spectral reflectance pattern for which matches the pixel value. In a preferred embodiment of the invention, Geographic Information System (GIS) software is utilized to combine a remotely sensed image providing ground cover classifications for a geographic region with a remotely sensed image providing soil type classifications for the same region in order to generate a rainfall loss function. The rainfall loss function can then be used to determine a runoff curve number (RCN) for the region, to determine probable maximum flood (PMF) , or to generate various design flood hydrographs corresponding to different precipitation events using a computer water shed model. [A3419]

"Method and apparatus for obtaining sectional information of the underground by measuring time differences and strength of electromagnetic signals"

An underground radar tomography in which an electromagnetic wave is radiated into the ground, the amplitude and propagation time of a transmitted wave, a reflected wave or a diffracted wave of the electromagnetic wave are measured at a number of points, and signal processing is performed on the result of measurement to thereby obtain the distribution of strata and soil in the ground as section information with a high accuracy. By use of two pseudo random signals which are slightly different in period but the same in code pattern, measurement time which is expanded relative to propagation time is obtained to thereby make the measurement accuracy high. [A3420]

"Data fusion workstation"

A data fusion workstation provides an apparatus and method for realizing the full potential of geophysical and remote sensing by mathematically integrating sensors with each other. Sensor data from each of a plurality of sensor types are related mathematically to each other through a common site model to produce a fused picture with quantified accuracy. Using the concept of pseudo-data, information in sensor data is made equivalent to data in a statistical correlation model, allowing fusion of model information with sensor data during a data inversion step. The process of data fusion comprises several processing steps, which are executed by various microprocessors in a recursire/distributed/parallel-architecture platform. These steps comprise geophysical inversion, geostatistical Kriging, application of statistical information concepts, implementation of a square root information smoother, and application of likelihood techniques. [A3421]

"Interactive television and data transmission system"

A spread spectrum system provides bidirectional digital communication on a vacant television (TV) channel for simultaneous use by more than 75,000 subscribers using time and frequency division multiplex signals locked to horizontal and vertical sync pulses of an adjacent channel Host TV station. The system, whose operation is analogous to a radar system, comprises: (1) the Host TV station to send down-link sync and data pulses to subscribers during the horizontal blanking interval (HBI) , (2) subscriber "transponders" which detect those signals and transmits up-link "echo" data pulses only during the HBI to eliminate interference to TV viewers, and (3) a central receiver which also uses the host TV sync pulses to trigger range gates to detect the up-link data pulses. In a preferred embodiment the central receiver employs directional antennas to determine direction to transponders and to define angular sectors partitioning the service area into pie-like "cells" which permit frequency re-use in non-contiguous sectors (like cellular radio) . The system thus operates like a radar to measure elapsed time between receipt of TV sync pulses and receipt of transponder response pulses and measures bearing to transponders to thereby determine the location of fixed or mobile subscribers as well as provide data links to them. Transponders may share user's existing TV antenna or may operate on cable TV and could be packaged as "RF modems" for personal computers, as transceivers for mobile or portable use, or they may be integrated with a TV receiver to provide "interactive television". [A3422]

"Device for the exchange of data by electromagnetic waves"

In order to increase the sensitivity and range of a system for the exchange of data by microwaves between a fixed station, or reader, and a mobile station, or badge, the modem of the badge includes an oscillator. A single transistor works, under a first bias, as a detector of the wave transmitted by the reader and demodulates this wave, and then, under a second bias, it works as an oscillator and modulates the response transmitted by the badge. Applications to the exchange of data at a distance. [A3423]

"Method and apparatus for determining ship position in a television image"

Apparatus for detecting the position of a vessel in a broadcast image of the radar scan in a radar monitored area includes a television monitor for displaying a broadcast image of a radar scan of the area, and a controllable reflector for varying reflection of the radar waves impinging thereon from the monitoring radar to produce identifiable signal components in the broadcast image of the radar scan received on the television monitor. This controllable reflector may be actuated by the vessel operator to vary the reflection of the radar waves and produce variations in the broadcast image to enable the operator to identify the position of the vessel in the radar scan image appearing on the monitor. The monitoring installation includes a monitoring radar transmitter/receiver, and a television transmitter televising an image of the radar scan. Desirably, it includes a scan converter which receives the signals in polar coordinate form and provides rectangular raster signals with X and Y coordinates. [A3424]

"Situation awareness display device"

A situation awareness display device for providing a graphical display of e relative position of remote units moving along with and in proximity to the local unit utilizing the device. The device is comprised of a tracking means for determining the instantaneous position of the local unit, a communications means for communicating that local position information to cooperating remote units over an external communication link, and receiving the position information of those remote unit over that same external link, a navigation means for deriving course following information, direction and velocity of said display device from said local unit position information, a main processing means for controlling the flow of information within said device and for deriving the relative position of the remote units with respect to the local unit from their respective position information, and a display means for retrieving and graphically displaying said stored relative position information in a uniquely configured display format showing the relative positions of the remote units from the perspective of the local unit. [A3425]

"Method and device for measurement of the velocity of a moving target by making use of the Doppler shift of electromagnetic radiation"

Method and apparatus for measurement of the velocity of a moving target (20) in radio frequencies. From the measurement station (10) and from the target station (20) , radio signals (S.sub.1,S.sub.2) are transmitted that are in different frequency ranges, as compared with each other, so that the receivers at the measurement station (10) and at the target station (20) are not subjected to interference. The radio signals (S.sub.1,S.sub.2) are received at stations (20,10) opposite to their transmission stations (10,20) . The oscillator of the target station (20) is locked with the frequency transmitted by the measurement station (10) by means of a phase-locked loop (PLL) . The frequency of said oscillator is passed to the transmitter part of the target station (20) . The signal (S.sub.2) transmitted by the target station (20) is received at the measurement station (10) . The Doppler shift (fd) of the frequency of the signal (S.sub.1) transmitted from the measurement station (10) and of the signal received at the measurement station is measured, and the velocity (v) of the moving target to be measured is determined on the basis of the Doppler shift. [A3426]

"Radar system and components therefore for transmitting an electromagnetic signal underwater"

A radar system is shown to include a transmitter for transmitting a pulsed electromagnetic signal having a frequency less than 500 Hz and a receiver for receiving a (scattered) reflected signal provided from the pulsed electromagnetic signal (scattered) reflected from an anomaly below the surface of the water. The radar system further includes a switch for inhibiting the receiver from receiving a reflected signal provided from the pulsed electromagnetic signal reflected from the surface of the water and a signal processor for controlling interoperability of the transmitter, the receiver and the switch. With such an arrangement, a radar system is provided for detecting anomalies such as a wake of a moving vessel (if and when this produces a conductivity anomaly) , or a plume of oil beneath the surface of water. [A3427]

"Spray paint monitoring and control using doppler radar techniques"

Systems and methods that use a CW Doppler radar to monitor paint particle velocities as they are sprayed from a paint gun to optimize the application of sprayed paint onto the object, and provide a closed loop spray painting system and paint spraying method that controls the application of paint in real time using data generated by the radar. The Doppler radar and a signal analyzer are used to analyze the Doppler return signals and display data indicative of the velocity of the paint particles. The data may be used by an operator to manually adjust the paint spray system. In addition, the spectrum analyzer may be used to generate and couple control signals to the paint spray system to provide for closed loop feedback control of thereof. One method comprises the following steps. Spraying paint particles toward an object that is to be painted using a paint spray gun. Radiating Doppler radar signals at the paint particles that are moving toward the object. Receiving backscattered Doppler shifted radar returns from the moving paint particles. Processing the received backscattered Doppler shifted radar returns to produce data indicative of the velocity of the paint particles. Displaying the data indicative of the velocity of the paint particles. This method unobtrusively and remotely measures paint particle velocity and velocity distribution. By additionally generating control signals in response to the data, the paint spray system is controlled. [A3428]

"Blindzone signal indicator"

A display apparatus for blindzone signal indication comprises an exterior rear view mirror housing and an exterior rear view mirror disposed in the exterior rear view mirror housing. The exterior rear view mirror defines a portion from which light is reflected and a portion through which light may be transmitted from inside the rear view mirror housing. A light source mounted within the housing is located at the light transmissive portion of the mirror and a directional filter located at the light transmitting portion of the mirror filters light emitted by the light source so that a signal from the light source may be seen from the interior of the vehicle, but may not be seen by drivers of other vehicles. [A3429]

"Track filter bias estimation"

A radar system including a Kalman filter that processes radar return signals to produces position, velocity, acceleration, gain and residual error output signals, and a post-processor that processes these signals in accordance with a track filter bias estimation procedure. The procedure computes bias estimates and revised position, velocity and acceleration output signals that are corrected for bias error. The revised output signals are coupled to the radar system to track a target. The track filter bias estimation method computes bias estimates in accordance with the relationship: ##EQU1## where Res, K.sub.1 /K.sub.2, R and T denote the residual, gains, range, and filter cycle time, respectively, and the tilde indicates a sample averaging. The present invention also provides for improved maneuver detection by implementing an acceleration estimation algorithm used to track a maneuvering target. The present invention is applicable in all fields and areas where estimation using Kalman filters is used. [A3430]

"Portable data processing device capable of transmitting processed data on a radio by reflection of unmodulated carrier signal externally applied"

A detachable IC card applicable to a portable data processing device referred to as an "electronic organizer" is disclosed. The IC card is formed of microstrip lines formed on a dielectric substrate. An antenna receives an externally applied unmodulated carrier signal and guides the received signal to microstrip lines for impedance conversion. Cathode potential of a diode is varied in response to a data signal outputted from a CPU, so that the barrier capacitance of the diode varies. Accordingly, the carrier is reflected according to the data signal and radiated toward the electronic organizer main body through the antenna. An oscillator for data transmission is not required in the IC card, so that an internal battery having a large capacitance is not required, either. As a result, without increasing the size and weight of the device, radio transmission of data from the IC card can be accomplished. [A3431]

"Polarimetric radar signal mapping process"

A process for mapping a region of interest using polarimetric radar signals is disclosed. The process provides for the polarimetric calibration of polarized signal data to account for distortions arising from cross-talk and channel imbalance during signal transmission and/or reception. Moreover, the process also can be used to correct for ionospheric signal distortions of polarized signals with low frequencies prone to Faraday rotations upon encountering the ionosphere. Such calibrations are accomplished with a reduced number of, typically ground-based, signal reflection devices used for calibrating the polarimetric signals to compensate for the above distortions. [A3432]

"Electronically controlled frequency agile impulse device"

An electronically controlled frequency agile impulse source utilizing pulse sharpening techniques to increase its versatility in radiating impulse energy at a variety of center frequencies and bandwidths in the megahertz to the gigahertz range. Such pulse sharpening provides for a radiator having a wider range of applications. [A3433]

"Automatic anechoic chamber calibrator"

A calibration reference target fixture is mounted on a pylon having a motorized spline extending longitudinally therethrough. The body of the fixture is teardrop shaped so as to present a low reflection cross section to a transmitting antenna. The reference target itself is a hinge-mounted plate which is driven by cam means connected to the motorized spline for selectively moving the plate between a deployed exposed position and a stored position, within the recess of the fixture body. [A3434]

"Method for distinguishing between at least two targets"

The present invention relates to a pulse Doppler radar wherein the phase position of the reflected signals is evaluated as the most important component in addition to the amplitude. Thus a very good resolution results in the range direction and in the velocity direction for the detection of multiple target situations. The invention can be employed particularly for a so-called HPRF radar. [A3435]

"Radar apparatus provided with a coherent clutter map"

A radar apparatus provided with transmitter means (1) , rotating antenna means (2) and receiver means (3) for the transmission per burst and the processing in a video processor of radar echo signals. The video processor includes moving target detection unit (4) provided with a doppler filter bank, for instance an FFT processor, and slow moving target detection unit (6) , provided with coherent clutter maps, one map for each radar transmitter frequency used. The coherent clutter maps are also used for reducing the clutter strength of radar echo signals which are applied to the moving target detection unit (4) , by subtracting the coherent clutter strengths stored in the clutter maps from the radar echo signals. [A3436]

"Transponder for vehicle identification device"

The invention relates to a transponder for a vehicle identification device in which a radio wave including vehicle information returned from transponders provided in a vehicle is received by an interrogator. The vehicle transponder receives a query radio wave and uses a detection device to generate a previously memorized coded signal train in response to a received wave. The coded signal train varies an amount of bias voltage of the detection device so that a reflection coefficient of the detection device is varied to modulate the reflection wave of the query radio wave and the modulated wave is transmitted back to the interrogator. [A3437]

"Secure toll collection system for moving vehicles"

A secure toll payment system is realized by transmitting a changeable encryption code from roadside equipment at a toll plaza to a moving vehicle. Thereafter, the moving vehicle uses it to encrypt payment information according to the Data Encryption Standard algorithm. The moving vehicle transmits the encrypted payment information to the roadside equipment which performs a credit or debit transaction. Because the encryption code changes from time to time, so too does the nature of the signal which is transmitted by the vehicle, and fraud, based on electronic eavesdropping, is substantially eliminated. The encryption code comprises an 8-bit random number and a time/date number. Vehicle-mounted apparatus includes a transponder unit and a portable smart card which inserts therein. The roadside equipment includes a pair of spaced-apart antennas that are sequentially located along an express payment lane at a toll plaza and a computer (Plaza Server) which controls them. [A3438]

"Radar with doppler tolerant range sidelobe suppression and time domain signal processing"

A radar system includes a doppler/pulse compressor/range sidelobe suppressor filter bank (40) , which separates received echo signals according to their frequency spectrum into doppler channels, and within each doppler channel performs pulse compression for reducing the duration of the received signals, and also performs range sidelobe suppression, for improving range resolution. It may be advantageous to perform certain types of processing in the time domain, such as determination of spectral moments for estimating velocity spread, mean closing velocity, and reflectivity of a diffuse target such as a weather phenomenon. An inverse (frequency-to-time) transform (50) is performed on the signals produced by the doppler/pulse compressor/range sidelobe suppressor filter bank (40) , to produce a reconstructed version of the received signals. In these reconstructed signals, the pulses are compressed, and range sidelobes are reduced. The time-domain processing (62) is performed on the reconstructed signals. In a particular embodiment of the invention, the range sidelobe suppression and pulse compression filters (34a, 34b . . .) follow the doppler filters (32) , but any ordering of the filters may be used. Interchannel frequency interference attributable to the non-zero bandwidth of the Doppler filters may be reduced by pulse-to-pulse time weighting (30) applied to the received signals over a time window corresponding to a particular dwell, together with inverse weighting (62) following the inverse transformation. [A3439]

"Apparatus for measuring speed"

An apparatus for measuring speed with respect to an object comprises first to Nth sensors sensitive to energy received from first to Nth consecutive regions, respectively, of the object. Signal delay means are provided to delay the signals from the second to Nth sensors, the delay increasing with sensor number. A subtractor is provided to form the difference between the sum of the signals of the even-numbered sensors and the sum of the signals of the odd-numbered sensors. [A3440]

"Modem for telecommunication system with a reflection amplifier function"

A modem which is to be included in a badge or mobile station, in a system for the exchange of data by microwaves with a fixed station or beacon. The modem has at least one transistor that works as a detector in reception or as an amplifier for the transmission of a reflection signal, according to gate bias voltages (V.sub.gs0, V.sub.gs1) that are applied to it, and drain currents (I.sub.ds) that result therefrom. The transmission-reception switching is done by transistors that switch over loads, and hence currents, on an amplifier transistor, with amplitude or phase modulation. Such a modem may find particular application in short-distance telecommunication systems. [A3441]

"Unwanted signal suppression device"

An unwanted signal suppression device is disclosed for suppressing unwanted signals in input signals containing desired and unwanted signals. The input signals are divided into segments in the time domain. The device includes a unit for detecting the segment having maximum power, a unit for computing reflection coefficients on the basis of the segments except the detected power segment, and a lattice filter for suppressing the unwanted signals by using the computed reflection coefficients. A second device includes a reflection coefficient computing unit, a median filter and a lattice filter. A third device includes a unit for estimating unwanted signals frequency, a filter for computing filter weights on the basis of the estimated frequency and filter coefficients and for applying the computed weights to the input signals so as to suppress the unwanted signals. [A3442]

"Multi-frequency, multi-target vehicular radar system using digital signal processing"

A vehicular collision avoidance radar system using digital signal processing techniques including a transmit section that generates a two channel transmit frequency. An antenna both transmits the transmit signal and receives a reflected receive signal. A Schottky diode mixer generates a difference signal having a frequency equal to the transmit frequency minus the receive frequency. A signal switch in a front end electronics section time demultiplexes and samples the channel 1 and channel 2 signals. The samples are coupled to a two-channel analog to digital (A/D) converter. A digital electronics section receives the digital information and performs a Fast Fourier Transform (FFT) on each channel of digital data to determine relative speed and range of a target based upon the frequency and the difference in phase of the two channels. The digital electronics section also receives information regarding the status of vehicle operation and/or controls to determine the degree of danger presented by an identified target. [A3443]

"Apparatus for combining data produced from multiple radars illuminating a common target area"

An apparatus for combining signals from a plurality of radar installations is described. A methodology for combining signals from a pluraltiy of radar installations/sensors has been developed. This methodology provides enhanced target detection performance by properly fusing together the commensurate range-Doppler filter bins of each sensor. In this methodology, the processing of each of the individual radars in the Doppler frequency domain is provided such that a common velocity domain is obtained from each of the radars. Using a zero fill discrete Fourier transform, the velocity domain obtained from each radar is further normalized to have a common bin size. Additionally, for the higher frequency radars, the normalized velocity bins are unfolded so that each radar signal produces the same number of velocity bins in its respective velocity domain. Once the common velocity coordinate has been obtained a vector addition of the resulting velocity bins produces a common radar velocity signal which can be detected and processed. Combining radar signals before detection results in a gain in sensitivity over systems which combine signals after detection. [A3444]

"Distance measuring system"

A distance measuring system which may be used on a golf course in order for a golfer to accurately measure the distance between the present lie of his golf ball and the hole toward which he is currently advancing the golf ball. A master transceiver station is portably carried by the golfer to be disposed proximate the lie of his ball for measurement purposes, and a remote transceiver system is located in or on each hole's flag marker pole. The present system uses, as the basic measurement frequency, only the frequency of the remote carrier itself. Two separate and distinct phase measurements are made in rapid succession. The first measurement is made with the master RF carrier displaced above the remote carrier frequency by amount equal to the IF frequency, and the second measurement is made with the master carrier frequency displaced below the remote carrier frequency by the same amount. With these two phase measurements, range or distance can be measured unambiguously and accurately over a required distance of at least 300 yards for golf purposes. The phase information from the remote location is communicated to the master location by phase-locking the carriers together. This avoids the necessity of using modulated subcarriers to transmit this information. This, in turn, reduces the occupied bandwidth, simplifies the modulation-demodulation required, and reduces errors normally introduced by the subcarrier filtering processes of the prior art. [A3445]

"Proximity alert system"

A proximity alert system including a pair of portable electronic, coded transmitter/receiver units designed to operate in a specific signal band. Each unit transmits a coded signal that is picked up by the other unit. The strength of the received coded signal controls the rate of an audible beeper. The rate of the beeper indicates the approximate distance between companion units. A direction-finder antenna is used to indicate the direction of the received coded signal. [A3446]

"Method for estimating position of objective obstacle for vehicle"

In a vehicle equipped with a distance measuring unit capable of measuring a distance between the subject vehicle and an objective obstacle, the objective obstacle is detected along a widthwise direction of the vehicle by the distance measuring unit. Detection data detected by the distance measuring unit are developed on X and Y coordinates in which the widthwise direction of the subject vehicle is represented by an X axis, the longitudinal direction of the subject vehicle is represented by a Y axis, and the position of the subject vehicle is defined as an origin. Each of obstacle data is labeled in such a manner that the same labels are affixed to obstacle data which are in proximity to one another on the coordinates. The amount and direction of movement are calculated for every label on the basis of the last data and the current data, and a relative speed for every label relative to the subject vehicle is calculated by dividing the amount of movement by a sampling time. The position of the objective obstacle after a lapse of a predetermined time is estimated on the basis of a relative speed vector determined from the relative speed and the direction of movement. Thus, the accuracy of estimating of the position of the objective obstacle is improved. [A3447]

"Radio frequency automatic identification system"

A radio frequency automatic identification system detects targets which include solid resonators resonating at several frequencies, attributing information to the frequencies at which the target resonates. Preferred resonators are quartz crystals, which may be made by a process of heating quartz to soften it and cutting crystals to approximate size and resonant frequency. Resonators produced by such a process are measured to determine their actual resonant frequency, and preferably the crystals are sorted into predetermined frequency windows in accordance with their measured resonant frequency. A set of resonators having frequencies corresponding to predetermined data is selected from the sorted groups of resonators and incorporated into a target. The preferred target is an ink-like material having a plurality of resonators disposed in a matrix which is radio frequency transparent at the frequency of interest. Targets are preferably detected by repetitively sweeping the frequency of the interrogating signal through a range which includes the information-bearing range of the system. [A3448]

"Traffic monitoring and management method and apparatus"

Methods and apparatus for the automatic and management of traffic, utilizing a microprocessor-based, read-write vehicle borne transponder device. The system includes plurality of transceivers spaced along and positioned adjacent to a roadway, a plurality of vehicle borne transponders, and an independent network management computer. As vehicles traverse the roadway the transponders communicate with the transceivers and one or both of those units collect information such as, vehicle entrance point, vehicle exit point, vehicle speed, number of passengers in each vehicle, and vehicle class. Some of the collected information is processed by the transceivers and transponders, while other information is transmitted to the network management computer for processing. [A3449]

"Method for locating and examining cavities under paved roads"

The present invention provides a cavity examination method of a paved road which can examine cavities which are present under the paved road such as the asphalt-paved road in a reduced length of time. By collecting data of the structural conditions of areas under the paved road while traveling on the road by a pavement structure examination vehicle mounted with underground radar means, and scrutinizing according to the above results around the place which may contain a cavity by a pushcart type underground radar means, the cavity examination method of the present invention specifies presence and a planar extent of the cavity. If a cavity is actually detected, a hole with a small diameter is bored in the place and its inner circumferential wall is photographed by a camera to confirm the conditions of the cavity and the area under the pavement by a visual inspection in order to grasp the three dimensional conditions of the cavity. [A3450]

"Multi-frequency automatic radar system"

A Doppler control circuit for a CW or pulse Doppler radar system for monitoring not only the phase shift between echo signals from several targets but also the amplitude difference between several targets and to further tune the radar to a particular target among one or more targets from which echo signals return. The control circuit can be used in state of the art CW or pulse Doppler type radar systems. In a further system, a continuously generated radar signal is repeatedly transmitted at different frequencies in time division fashion to define a succession of transmit and receive frames. The receive frames are divided into a plurality of time interval windows with selected windows being used to detect received signals at the different frequencies. The remaining windows can be used for subsystems of the radar system. The rate of phase shift of received signals at a reference frequency is used to determine closing rate, (positive or negative) while the phase shift difference between received signals at two frequencies is used to determine range and target direction. In yet a further system, a special circuit is provided for conditioning selected portions of the Doppler frequency spectrum to attenuate or de-emphasize portions of the echo signal corresponding to selected targets in the radar system environment, such as rain or stationary wayside objects, in order to give such echo signals less weight in determining roadway hazards. [A3451]

"High power photon triggered ultra-wideband RF radiator with opposite apertures"

A photoconductive switch coupled to an energy storage device wherein the tch is comprised of photoconductive semiconductor material while the energy storage device comprises two discrete dielectric mediums. Each medium having a conductive electrode on the top and bottom surfaces to essentially form parallel capacitors wherein the parallel capacitors are separated by a predetermined gap distance. A photoconductive switch electrically connected to each medium such that the switches are located on the opposite sides of their respective mediums. The predetermined gap distance (between the electrodes) and the photoconductive switches (on opposite sides of the storage devices) provide suppression of surface flashover between very high voltage, charged electrodes.

Such flashover suppression allowing for very high power pulse generation. [A3452]

"Truck/trailer control system"

Automatic Trailer Control System--containing four principle inventions. One part of the invention provides automatic trailer steering control to the trailer to cause a delayed turn of the trailer steering mechanism while maneuvering a turn. A second part of the invention provides an electro-magnetic braking system, to the trailer, which is controlled by the same Microcomputer system that controls the trailer turning. The third part of the invention utilizes the electro-magnetic braking system as an alternator/generator to be used as an auxiliary battery charging system. A fourth part of the invention uses the electro-magnetic braking system as a motor to drive the trailer wheels as an assist during trucking operations. All operational functions are controlled by the Microcontroller based control system mounted on the trailer rear wheel platform. Sensors are placed on the truck/trailer operating system to obtain operational information needed for the control of the system. [A3453]

"Integrated circuit device including means for facilitating connection of antenna lead wires to an integrated circuit die"

A method and apparatus for facilitating interconnection of lead wires to an integrated circuit including the provision of an additional protective layer of insulation to the top of an integrated circuit chip or die and the provision of enlarged plated electrodes to the surface of the additional insulation to form enhanced bonding pads, such pads being electrically connected through the protective layers to the normal bonding pads of the integrated circuit device. The enhanced bonding pads are made of a soft conductive metal such that external wires to be attached thereto can be bonded to the pads using a thermal compression bonding technique. [A3454]

"Active antenna for two-way transmission"

This active antenna is incorporated in the terminal station of a system for data exchange with a central station, by the modulation of a microwave carrier. The terminal station is of the chip card type. The modem of the active antenna is constituted by a transistor, the bias current of which is switched over from a low value at demodulation to a high value at modulation. The switch-over is obtained by a circuit with three resistors (R.sub.d, R.sub.gd, R.sub.g) , which themselves have their values switched over by two transistors parallel connected with the resistors, these transistors being controlled by two signals emitted by the control circuit of the terminal station. The active antenna can be applied to long-distance data exchange, for example in the remote management of toll-charge systems, remote cash dispensing, localization of moving bodies etc. [A3455]

"Interference avoidance system for vehicular radar system"

An interference avoidance system used in conjunction with a vehicular target detection system. The microwave transceiver section of the vehicular target detection system, in which the present invention is incorporated, transmits and receives time-multiplexed microwave signals having at least two channels (frequencies) spaced about 250 kHz apart. The time-multiplexed transmit signal is transmitted and strikes objects (targets) in the environment, and a portion of the transmit signal is reflected back the antenna. A difference signal having a frequency equal to the difference between the frequency of the transmit and the received signal is generated, digitized, and a Fast Fourier Transform (FFT) is performed on the digitized difference signal. A microcontroller analyzes the energy spectrum to determine whether there is interference present. If such interference is present, the microcontroller causes the transmit frequency to change until a frequency is found which is relatively free of the interference. [A3456]

"Method of determining the electrical properties of the earth by processing electromagnetic signals propagated through the earth from a capacitor"

A method of processing electromagnetic signals which are injected into the earth from a capacitor and subsequently detected after reflection from subsurface layers, in order to determine the physical and electrical properties of those layers. The method is based on an iterative process which models the earth as a series of vertically stacked horizontal layers, each characterized by its physical properties of depth beneath the surface and thickness, and its electrical properties of resistivity (or conductivity) and relative dielectric constant. An initial propagation model which specifies the electrical properties of a particular layer or set of layers is constructed and applied to a model input pulse to produce a predicted return pulse which results from the reflection and/or transmission of the input pulse at the boundaries of the layer (s) . The predicted return pulse is then compared to actual return pulse data which is selected so as to roughly correspond to a return pulse produced at the location of the modeled layer (s) . The result of the comparison forms the basis for adaptively varying the parameters of the propagation model in a manner which is intended to increase the correlation between the predicted return pulse and the actual data. Repetition of the method for different layers or additional locations permits the electrical characteristics of the earth beneath a specified region to be determined. Knowledge of these characteristics can be used to infer the type of geologic formation responsible for transforming the input pulse into the received pulse. [A3457]

"Post detection integration method and apparatus for pulse compression radar utilizing surface acoustic wave (SAW) matched filters"

Received expanded radar pulses pass through a surface acoustic wave (SAW) weighted filter (64) for sidelobe suppression, and then into a SAW tapped delay line (66) . The pulses appear at the taps (66a,66b,66c) of the delay line (66) coarsely aligned in time, pass through individual SAW matched filters (68,84,86,88) for compression and envelope detectors (70,90,92,94) for demodulation, and then into a summer (74) for post detection integration. Individual frequency shifters (78,80,82) are provided between the delay line taps (66a,66b,66c) and the matched filters (84,86,88) for shifting the center frequencies of the pulses and thereby the propagation delays through the matched filters (84,86,88) to provide fine alignment of the pulses in time. The delays through the individual delay line taps (66a,66b,66c) and the frequency shifts of the frequency shifters (78,80,82) are adjustable "on the fly" to compensate for variation of pulse repetition rate (PRF) and interpulse jitter. [A3458]

"Vehicle identification and classification systems"

An interrogator-transponder system in which multiple vehicle mounted transponders which may be closely spaced in distance and moving at similar velocities, respond with a coherent identification code signal that is displaced in frequency from the interrogation signal by an amount that is identical for each transponder. The response signal spacings in time (Pulse repetition intervals) are different for each transponder but are always multiples of the pulse repetition interval of the interrogation signal. A coherent reference for the received transponder codes is obtained by combining the coherent interrogation signal with a coherent reference that is substantially identical in frequency to the displacement frequency of the transponder response signal. Means are provided in the interrogation device to determine the velocity of each transponder and its range with respect to the interrogator and to identify vehicles with inoperative transponders. The resulting data stream of identification codes and associated velocities and ranges may be used for traffic speed enforcement, wanted vehicle search, interactive traffic signal control, automated toll collection, traffic surveys, and identification of friendly forces. [A3459]

"Method for ambiguity resolution in range-Doppler measurements"

A method for resolving range and doppler target ambiguities when the target has substantial range or has a high relative velocity in which a first signal is generated and a second signal is also generated which is coherent with the first signal but at a slightly different frequency such that there exists a difference in frequency between these two signals of .DELTA.f.sub.t. The first and second signals are converted into a dual-frequency pulsed signal, amplified, and the dual-frequency pulsed signal is transmitted towards a target. A reflected dual-frequency signal is received from the target, amplified, and changed to an intermediate dual-frequency signal. The intermediate dual-frequency signal is amplified, with extracting of a shifted difference frequency .DELTA.f.sub.r from the amplified intermediate dual-frequency signal done by a non-linear detector. The final step is generating two quadrature signals from the difference frequency .DELTA.f.sub.t and the shifted difference frequency .DELTA.f.sub.r and processing the two quadrature signals to determine range and doppler information of the target. [A3460]

"FM-CW radar"

A switching type FM-CW radar, the type of FM-CW radar improved to reduce FM-AM conversion noise, is further improved to reduce interference by radar waves from other vehicles and echo waves returned from them. A switching circuit is provided at the transmitter side, and its switching frequency is set at a different value for each individual vehicle. Furthermore, the switching frequency of an interfering wave is measured, in accordance with which the switching frequency of the switching circuit is changed. [A3461]

"Docking velocity indicator system"

A relative velocity indicator system for assistance in the docking of vessels uses a radar sensor providing a relative velocity signal indicative of the relative velocity between a ship and a reference, such as a dock. A wireless transmitter associated with the radar sensor receives said relative velocity signal and transmits a signal indicative of said relative velocity signal. A portable receiver and indicator unit carried by the captain of the vessel has a receiver for receiving the transmitted signal and an indicator arranged to receive, from said receiver, a receiver signal indicative of the transmitted signal and, thereby, of the relative velocity signal for indicating the relative velocity between ship and reference. [A3462]

"Safe stopping distance detector, antenna and method"

An FM/CW radar system is disclosed for determining a safe stopping distance between a moving vehicle and a potential obstacle. The radar signal is modulated linearly over several slopes. A microstrip phased array transmit/receive antenna is also disclosed having a hybrid tap, corporate feed structure. Signals from the antenna are amplified and filtered, and passed through an analog to digital converter to a signal processor, which performs a Fast Fourier Transform on the signals to convert them from time domain data to frequency domain data. The frequency domain data is then used to solve target range and doppler equations, determine safe stopping distances, and sound or display alarms if the safe stopping distance has been violated. A sensitivity control adjusts for road conditions or operator reaction time variations. [A3463]

"Microwave vehicle detector"

The present invention provides a microwave vehicle detector which includes a transceiver for transmitting microwave energy into a desired target area and for receiving reflections of this microwave energy from vehicle movement in this target area. The transceiver includes first and second diodes for enabling the microwave vehicle detector to determine the direction of vehicle movement relative to the position of the microwave vehicle detector. In this regard, these diodes are balanced, such that a predetermined phase difference will be produced between the doppler shift signals generated by these diodes. This phase difference is analyzed by a microprocessor to determine the speed and direction of the vehicle being detected. [A3464]

"System and method for detecting radiant energy reflected by a length of wire"

A method and system for detecting wire in a terrain avoidance, terrain following, or a terrain obstacle system. Radiant energy pulses orthogonally polarized are alternately transmitted. Selected dimensions of a full scattering matrix of adjacent reflected pulses for a particular range are collected and combined to form a null matrix. A null matrix with the two reflected pulses being within a predetermined distance from one another is detected as a wire. [A3465]

"Multiple vehicle identification and classification system"

An interrogator-transponder system in which multiple vehicle mounted transponders, which may be closely spaced in distance and moving at similar velocities, respond to an interrogation signal in a sequential or random sequential manner so as to reduce response signal interleaving to an acceptable level. The response signals include a vehicle identification code and are processed by the interrogator to yield data, for example, on specific vehicle speed, distance from the interrogator, vehicle wanted for investigation, and vehicle with an inoperative transponder. [A3466]

"Spread spectrum conference call system and method"

A spread spectrum communications system for use over a communications channel, including a transmitter-generic-chip-code generator, a transmitter-message-chip-code generator, an EXCLUSIVE-OR gate, a combiner, a transmitter, a receiver-generic-chip-code generator, a generic mixer, a generic-bandpass filter, a receiver-message-chip-code generator, a message mixer, a message-bandpass filter, and a synchronous detector. The transmitter-generic-chip-code generator generates a generic-chip-code signal and the transmitter-message-chip-code generator generates a message-chip-code signal. The EXCLUSIVE-OR gate spread-spectrum processes message data with the message-chip-code signal to generate a spread-spectrum signal. The combiner combines the generic-chip-code signal with the spread-spectrum signal. The transmitter transmits the combined generic-chip-code signal and spread-spectrum signal, on a carrier signal over the communications channel as a spread-spectrum-communications signal. The receiver-generic-chip-code generator generates a replica of the generic-chip-code signal. The generic mixer recovers the carrier signal from the spread-spectrum-communications signal. The receiver-message-chip-code generator generates a replica of the message-chip-code signal. The message mixer despreads the spread-spectrum-communications signal as a modulated-data signal. The tracking and acquisition circuit uses the recovered carrier signal for synchronizing the replicas of the generic-chip-code signal to the recovered carrier signal. The synchronous detector synchronously demodulates the modulated-data signal as received data. [A3467]

"Microburst precursor detector"

A microburst precursor detector utilizes a multiplicity of radar beams and samples radar returns, in each beam, from meteorological radar signal reflectors and processes the signal returns in a statistical manner to determine average radar reflectivity and to extract doppler signal parameters. These parameters are utilized to determine a second set of parameters, average doppler frequency within each radar beam, doppler spectral spread within each radar beam, and the skewness of the doppler spectrum in each beam. The second set of parameters is processed to establish the existence of a microburst, predicted surface impact, time to impact, wind shear surface location and track, and the magnitude of the wind shear. [A3468]

"Identification system using hertzian waves, consisting of an interrogation station and a responder unit"

Identification system constituted by an interrogation station or interrogator 1 itself formed by a radio frequency wave transceiver and preferably on an ultra frequency wave length 5, and, on the other hand, by a responder unit 2 adapted to receive the wave and to re-emit (echo) it following the given coded modulation to the responder unit. The interrogator is adapted to receive this echoing wave 11 and to demodulate it in order to derive the identification code therefrom. The interrogator has an emission antenna adapted to emit an inquiry signal constituted by a radio wave emitted in plane polarization. The responder unit has two adjacent antennas, respectively, for the reception of the inquiry wave and for its re-emission (echo) after modulation. The two antennas are of the circular polarization type and each functioning in a direction of rotation of the polarization opposite with respect to each other. This allows a differentiation between the emission inquiry signal and the response signal, since the inquiry signal wave is received by a circular polarization-type antenna of the responder unit according to a first rotation direction of the polarization. The responder unit is adapted to re-emit a modulated response signal constituted by a radio wave of the same kind as the inquiry wave of circular polarization-type according to a second rotation direction of the polarization in the opposite direction to the first rotation direction. [A3469]

"Method of extracting phase errors caused by the atmosphere in the backscatter signal of a coherent imaging radar system carried by a carrier from radar raw data and apparatus for carrying out the method"

In a method of extracting phase errors caused by the atmosphere in the backscatter signal of an on-board coherent imaging radar system from radar raw data, firstly to image areas with different backscatter ratios over a predetermined period of time consecutive azimuth spectra are continuously formed. Thereupon, a frequency offset (.DELTA.F (t)) of the backscatter ratio component is obtained by determining the location of the maximum of the correlations between two respective immediately consecutively formed azimuth spectra. Then, a double integration for the difference of the frequency offset (.DELTA.F (t)) and a desired value (.DELTA.F.sub.soll) of the frequency offset is carried out, the frequency offset desired value (.DELTA.F.sub.soll) being determined either from the carrier forward velocity (V.sub.v) or by a low-pass filtering of the frequency offset (.DELTA.F (t)) , and finally for standardization the result of the double integration is multiplied by a constant (2.pi./.DELTA.t) to obtain thereby the phase error (.phi..sub.e (t)) . [A3470]

"Collision-preventing apparatus for electric motor vehicle"

A collision-preventing apparatus for an electric motor vehicle in which wheels are driven by electric motors and the electric motors are subjected to braking such as regenerative braking or dynamic braking. The apparatus includes an obstacle sensor and a control unit for processing detected information supplied from the obstacle sensor and for outputting a brake actuation signal when the result of processing indicates a set of conditions predetermined to be dangerous, so as to apply brakes to the electric motors. [A3471]

"Dual function satellite imaging and communication system using solid state mass data storage"

The present invention discloses a dual function satellite imaging and communication system (10, 40, 50, 60) using a solid state mass data storage device (30) which generates and stores image data at a relatively low data rate and subsequently transmits the data at a significantly higher data rate. The dual function imaging and communication system (10, 40, 50, 60) , which may be incorporated as a body mounted payload of an imaging satellite, provides a single antenna or aperture (28, 54, 62) to perform both the imaging and communication functions and simplify the imaging and communication systems of the imaging satellite by eliminating the requirement for a separately gimballed antenna and/or aperture for each system. Further, the present invention is designed to operate in a low duty cycle mode to minimize its power supply requirements. In short, the present invention combines and simplifies the imaging and communication systems of an imaging satellite to reduce the weight of the payload and, at the same time, improve the reliability. [A3472]

"One-dimensional electronic image scanner"

A microwave image scanning apparatus which utilizes a dispersive waveguide wedge in front of a microwave sensor. Similar to an optical prism, the waveguide wedge resolves multi-spectral microwave energy from various directions into the same direction for detection by the microwave sensor and subsequent formation of a refined high quality video image. The waveguide wedge consists of a collection of waveguide channels having their longitudinal axes aligned substantially in parallel. [A3473]

"Loro antenna and pulse pattern detection system"

A passive surveillance method and system, capable of operation in conjunction with both non synchronous and synchronous pulse pattern rotating ground radars. Received signal scan modulated pulses are deinterleaved and correlated with a previously selected repetitive portion of an interrogation signal source base pulse pattern. A single receiver channel, sequential lobe on receive only (LORO) direction finding antenna is employed in the system to modulate received signals to extract target object relative bearings for the correlated signals. The system makes use of all available data to determine the best estimate of the target object position. [A3474]

"Millimetric wave radar system for the guidance of mobile ground robot"

The disclosure relates to guidance devices on board autonomous vehicles or robots which have to move about notably in environments that are inaccessible or dangerous to human beings. Disclosed is a device for the detection of the environment, and the positioning and/or the guidance of a mobile vehicle on the ground, of the type comprising, firstly, means for the generation and transmission of a signal that can be reflected by a fixed obstacle and, secondly, means for the reception and processing of the signal reflected by said fixed obstacle, said processing means enabling the recognition of the environment and/or the guidance of said autonomous mobile vehicle, said transmitted signal being a millimetric wave radar signal and said transmission and reception means cooperating with a rotary antenna having a 360.degree. rotation in azimuth. [A3475]

"Data quality and ambiguity resolution in a doppler radar system"

The pulsed Doppler weather radar system reduces ambiguities in measured parameters by staggering at least one pulse of each frame of n pulses transmitted by the radar system. The staggered pulse creates an isolated pulse doublet pair to provide three or more independent and auxiliary Doppler parameter estimates. The parameter estimates are combined optimally in a neuromorphic processor matched to the phenomena of interest, particularly capitalizing on multiparameter volumetric correlations to improve data quality. [A3476]

"Device for determination of distances between close-range objects"

Device for determining distances in the close range (under 100 m) , hereby characterized in that both light pulses and high-frequency pulses are transmitted and received and the correct distance is determined in an evaluating device in a simple way and with reliability under nearly all atmospheric conditions. [A3477]

"Interrogator/transponder system and mobile transponder device"

An interrogation responder system composed of a transmitter stationarily mounted in a certain fixed place and a receiver mounted on a mobile object. The receiver on the mobile side starts the operation when a power is supplied to the entire circuit in accordance with a wake-up signal from the transmitter on the fixed side so as to modulate the electromagnetic signal emitted from the transmitter on the fixed side in accordance with a predetermined code and reflect a response. This enables continuing bilateral communication of a command, data and so forth. By starting communication between the transmitter and the receiver by a direct wave of a carrier signal in a microwave band after sensing that the receiver on the mobile side has entered a good communication zone, secure communication is enabled at a sufficient electric field strength. [A3478]

"Doppler-effect vehicle ground-speed detecting apparatus having means for detecting vehicle body inclination"

A Doppler-effect vehicle ground-speed detecting apparatus having a transmitter fixed to a vehicle body and transmitting a wave toward a road surface on which the vehicle is running, a receiver fixed to the body and receiving a portion of the wave reflected by the road surface, and a ground-speed determining device for determining a ground-speed of the vehicle relative to the road surface, on the basis of a transmitting frequency of the wave as transmitted by the transmitter and a receiving frequency of the wave as received by the receiver. The ground-speed determining device determines the ground-speed of the vehicle, on the basis of a parameter which changes with an angle of the vehicle body relative to the road surface in a plane parallel to a running direction of the vehicle and perpendicular to the road surface, as well as on the basis of a difference between the transmitting and receiving frequencies. [A3479]

"Moving target detection through range cell migration radar"

Radar signal processor for the detection of fast moving targets having small radar cross-sections. A method and apparatus is used to analyze a target that may travel through many range cells during coherent integration time. By transforming the pulse return data into the spatial frequency domain, range bin migration problems have been solved. The signal to noise ratio is also improved thereby permitting the detection of small targets. The processing consists of three major steps: performing an FFT for each pulse to yield spatial frequency components for each return, performing a special DFT for each spatial frequency yielding constant velocity output for each spatial frequency, and finally performing an inverse FFT to obtain target velocity and position. [A3480]

"System for measuring the distance between two stations mobile with regard to one another"

An emitted wave is transmitted from a central station to a passive end. A phase modulation circuit in the passive end modulates a signal resulting from the emitted wave for retransmitting it in the form of a two-phase-state modulated signal at the rhythm of a clock signal. In the central station, the modulated signal is demodulated into two quadrature signals. On the basis of the product of the two quadrature signals and the sign of the difference between the moduli of the rectified quadrature signals, the count of an up-down counter in a digital processing circuit is incremented or decremented in order for said count to be representative of the distance separating the passive end and the central station. [A3481]

"Moving target indicator using higher order statistics"

While the computation of high resolution radar images based on higher order tatistics is position insensitive, velocity estimation may be based on the ratios of values of a trispectral slice and a cross-trispectral slice computed as quadruple products of complex valued signals developed by coherent radar. Signal-to-noise ratio is improved by either averaging over a plurality of bursts during computation of both the trispectral slice and the cross-trispectral slice or averaging of values of ratios of trispectral slice and cross-trispectral slice values at particular frequencies or wavenumbers, or both. [A3482]

"Mobile speed awareness device"

A speed awareness device for allowing passing traffic to perceive from a source other than their own speedometers their true speed. A trailer supports a container within which a radar source is contained operatively connected to a display panel. A suitable source of power operates the radar and display and includes a battery, an optional photo voltaic source to power the battery and a plurality of instrumentalities to preclude or render less likely that the trailer will be moved by unauthorized personnel. These instrumentalities include a removeable trailer hitch, an axle lock, support stands for elevating the trailer and an internal alarm system. [A3483]

"High resolution radar profiling using higher-order statistics"

A coherent radar is used for achieving high resolution radar imaging of a moving object in sea clutter and noise. A stored replica of the transmitted waveform is combined with the returned signal in a synchronous detector to produce in-phase and quadrature (I and Q or complex) samples. High resolution is achieved by transmitting a series of pulses, each at a different frequency, and then processing these complex samples to produce a synthetic down-range profile. To enhance the radar target or object from system noise and sea clutter, the complex I and Q (in-phase and quadrature component) samples from the radar are coherently averaged in a special two-dimensional slice of the trispectrum (e.g. quadruple product or fourth-order moment) . This formulation of the fourth moment retains all important target information and suppresses Gaussian noise. Once averaged, a new set of I and Q samples are reconstructed that produce the same trispectral slice as this average. These reconstructed samples are then transformed using conventional Fourier transform methods to produce the average, or enhanced, down-range profile. [A3484]

"Road void search radar system"

A road void search radar system includes a rotary encoder, a radar controller, an analyzer, and a recording unit. The rotary encoder generates a pulse signal having a period corresponding to a predetermined distance interval traveled by a vehicle. The radar controller outputs a wave every time the pulse signal is supplied from the rotary encoder. The analyzer analyzes an underground state by processing the output signal received from the radar controller. The recording unit records digital data signals and analyzes results. [A3485]

"Passive transmitting sensor"

The disclosed system comprises a receiver that is inductively coupled to one or more passive transmitters by means of a receiving inductor. The receiver comprises a sweep signal source which is coupled equally to the receiving inductor and a reference inductor. The receiving inductor is coupled to a passive transmitter which includes an L-R-C circuit comprised of a transmitting inductor, a temperature-dependent capacitor, and a resistor that may be variable or fixed, depending upon the application. As the sweep signal source passes through the resonant frequency of the passive transmitter, the passive transmitter forms a low impedance load magnetically coupled to the receiving inductor by means of the near or induction electromagnetic field produced by the inductor. Changes in the resonant frequency are used to determine temperature variation. Changes in the peak voltages are a determinant of resistor variation resulting from changes in pressure or strain, or they are a determinant of changes in proximity of the passive transmitter to the receiver, or the resistor variation resulting from changes in pressure or strain. [A3486]

"Apparatus for facilitating interconnection of antenna lead wires to an integrated circuit and encapsulating the assembly to form an improved miniature transponder device"

A method and apparatus for facilitating interconnection of antenna lead wires to an integrated circuit and encapsulating the assembly to form an improved miniature transponder device including the provision of an additional protective layer of insulation to the top of an integrated circuit chip or die and the provision of enlarged plated electrodes to the surface of the additional insulation to form enhanced bonding pads, such pads being electrically connected through the protective layers to the normal bonding pads of the integrated circuit device. The enhanced bonding pads are made of a soft conductive metal such that external wires to be attached thereto can be bonded to the pads using a thermal compression bonding technique, This invention also extends to a method of encapsulating a transponder in heat shrunk plastics material. [A3487]

"Lidar-acoustic sounding of the atmosphere"

A method of remote sensing of atmospheric conditions based on the detection of acoustic modulation of lidar returns in the atmosphere. The measured modulation is caused by density changes of the lidar scattering elements induced by an acoustic wave launched collinearly with the lidar. Applications are disclosed for measuring atmospheric humidity, cloud particle size, and temperature profiling. [A3488]

"Flap-type portal reader"

Apparatus for selectively reading or writing data on a magnetic data stripe on a data card which is thin and flexible and for selectively returning or capturing the card. The apparatus includes a card guide arrangement comprising a cylindrical card guide path section, an entrance card path section with an entrance slit for admitting the data card, and an exit path section with an exit slit for discharging the data card for capture. A drive arrangement drives the data card through the entrance slit, throughout the cylindrical card guide path section, and through the exit slit. A transducer with a read head and write head is mounted relative to the cylindrical card guide path section. A position tracking arrangement determines the position of the data card within the cylindrical card guide and a card-in sensor senses the presence of a data card in the entrance path section. A microprocessor based control circuit is used to operate the system and control operational features. [A3489]

"System for controlling a driving device of a vehicle"

A system for controlling running of a vehicle comprises a switch for setting a slow-run mode, a sensor for detecting that the brake is being applied, a driving force control device mechanically separated from the accelerator for controlling a driving force of the vehicle, a sensor for detecting the running speed of the vehicle, a switch for setting a slow-run speed command signal. A target speed is generated on the basis of information concerning the brake activation and, the running speed of the vehicle and the slow-run speed command signal value. In the slow-run mode, when the brake is not applied, the driving force control device is driven to cause the vehicle to run at the target slow-run speed, and when the brake is applied, the driving force control device is driven so that no driving force is produced at least in the direction of travel of the vehicle. [A3490]

"Two-stage target tracking system and method"

An apparatus and method for tracking maneuvering and non-maneuvering targ in the presence of stochastic acceleration are provided. The apparatus and method utilize a two-stage Kalman estimator, the first stage of which is a bias-free filter providing target position and velocity estimates, and the second stage of which is a bias filter providing estimates of target acceleration. These two filters act together to provide parallel processing calculations thereby achieving high speed target state determination. During target maneuvers, the output of the second stage is used to correct the output of the first stage. In the absence of maneuver, the second stage is turned off and the first stage provides the target position and velocity estimates. [A3491]

"Echo ranging system for detecting velocity and range of targets using composite doppler invariant-like transmissions with suppression of false targets"

False target (reverberation, clutter, etc.) detection is suppressed in an echo ranging system (sonar or radar) in which target velocity and range are measured using a composite Doppler invariant-like signal having at least two segments, such as are present in a "rooftop" or "vee" HFM signal, such composite signal having an ambiguity function with two or more ridge lines of different slopes that intersect along the zero-velocity time axis. A bank of matched filters provides a distribution of outputs which has an ambiguity function-like character with intersecting pairs of ridge lines, the intersecting points of said pairs characterizing the range and velocity of the echo returns. This distribution is adjusted so that the intersecting ridge lines of each pair have equal and opposite slopes with respect to the time axis. In particular, fixed reverberators, which would have ridge lines intersecting on the zero-velocity time axis, would be symmetrical about this axis. A target with velocity v would present ridge lines intersecting along the v-velocity time axis and be symmetrical about that axis. Thus, the reverberation and the moving target would each have crossed ridge lines whose characteristic intersecting patterns would each exhibit symmetries, but about separate and distinct axes. False targets, including clutter and reverberation, are suppressed by subtracting from the adjusted output distribution, a replica thereof, folded (rotated) 180.degree. about a time axis containing the intersection of the ridge line pair corresponding to the false target which is to be suppressed. The rotation and subtraction of the replica from the adjusted distribution provides a set of outputs from which the real target velocity and range can be determined. The rotation-subtraction process can be implemented on an on-going basis to suppress a plurality or continuum of false targets and to achieve a desired width of a Doppler notch covering an arbitrary range of velocities. [A3492]

"Echo ranging system for detecting velocity of targets using composite doppler invariant transmissions"

Target velocity and range are measured with high resolution in an echo ranging system (sonar or radar) using composite Doppler invariant signals consisting of at least two segments, such as "rooftop" or "vee" HFM signals, such composite signals having ambiguity functions that intersect along the zero-velocity time axis with ridge lines slanted in different directions. A single correlator is used for each segment wherein returns from the target are correlated with replicas of each segment of the composite signal to separately transform the Doppler frequency shifts of the target return into outputs whose time relationship provides a frame of reference for high resolution measurement of the velocity of the target. The time relationship measurement is implemented by a set of tapped delay lines and coherent summers which output a coherent correlation-like detection peak in a bin which corresponds to the target's velocity. Thus, one correlator for each transmission segment together with a tapped delay line and summer network may be used for velocity detection, with high precision range detection, based upon the timing of the detection peak with respect to the transmitted signal, also being implemented at the same time, thereby avoiding the classical need for an expensive bank of correlators (one for each velocity bin) and yielding significant economies for the simultaneous high resolution measurement of range and velocity for a target by means of echo ranging. [A3493]

"Vector neural network for low signal-to-noise ratio detection of a target"

A vector neural network (VNN) of interconnected neurons is provided in transition mappings of potential targets wherein the threshold (energy) of a single frame does not provide adequate information (energy) to declare a target position. The VNN enhances the signal-to-noise ratio (SNR) by integrating target energy over multiple frames including the steps of postulating massive numbers of target tracks (the hypotheses) , propagating these target tracks over multiple frames, and accommodating different velocity target by pixel quantization. The VNN then defers thresholding to subsequent target stages when higher SNR's are prevalent so that the loss of target information is minimized, and the VNN can declare both target location and velocity. The VNN can further include target maneuver detection by a process of energy balancing hypotheses. [A3494]

"Radio frequency automatic identification system"

A radio frequency automatic identification system detects targets which include solid resonators resonating at several frequencies, attributing information to the frequencies at which the target resonates. Preferred resonators are quartz crystals, which may be made by a process of heating quartz to soften it and cutting crystals to approximate size and resonant frequency. Resonators produced by such a process are measured to determine their actual resonant frequency, and preferably the crystals are sorted into predetermined frequency windows in accordance with their measured resonant frequency. A set of resonators having frequencies corresponding to predetermined data is selected from the sorted groups of resonators and incorporated into a target. The preferred target is an ink-like material having a plurality of resonators disposed in a matrix which is radio frequency transparent at the frequency of interest. Targets are preferably detected by repetitively sweeping the frequency of the interrogating signal through a range which includes the information-bearing range of the system. [A3495]

"Hick's probabilistic data association method"

A process, known as the Hick's Probabilistic Data Association Algorithm, correlates sensor measurement to target tracks under condition in which there are numerous false measurements. It accomplishes this by forming multiple hypotheses and computing a probabilistic score for each. The hypothesis with the high score is then used as a probability vector to update each target's track. The result is accomplished by combining the attributes of Joint Probabilistic Data Association (JPDA) and Nearest Neighbor Standard Filter (NNSF) . This combination provides an improved algorithm which yields improved performance ever both prior art methods under high clutter conditions with crossing targets. [A3496]

"Weather radar display system"

A weather radar display system and method for obtaining and storing radar return data for a plurality of horizontal and vertical sweeps, each horizontal sweep occurring at a different tilt angle and each vertical sweep occurring at a different azimuth angle. The radar return data is displayed as plan views in a plurality of separate display sections, each corresponding to a plurality of separate horizontal sweeps in one embodiment and to a plurality of separate vertical sweeps in a second embodiment. Radar return data in one display section (horizontal or vertical) is displayed with a variety of colors to represent precipitation intensity. Radar return data in remaining display section (horizontal or vertical) is displayed as a first color with edge returns displayed in second color to differentiate the remaining sections. Display sections partially overlap such that each subsequently displayed plan view is at least partially superimposed on the preceding view to give a three-dimensional image of the weather system. [A3497]

"Inflight weather and ground mapping radar"

The present invention is a radar system that corrects for changes in apparent reflectivity and two-way precipitation attenuation using a correction curve that includes a segment for low rain rates, a segment for high rain rates and, if desired, a transition segment for medium rain rates. The signal to noise ratio is further improved by using a sliding azimuth window during post detection integration processing. [A3498]

"Sensor for detecting the passage of a person or an animal in a field of view"

Both a motion detector and a presence detector receive doppler shifted reflected microwave radiation to detect the passage of a person or an animal in a field of view. The motion sensor is adapted to detect the passage of a person or an animal near a doorway and to actuate the doorway in response thereto, to permit the passage of the person or animal thereto. The presence detector detects "swaying motion" of a person or an animal in a field of view much closer to the location of the sensor as its gain is much lower than that of the motion detection channel. In addition the presence detector is activated only in the event the motion sensor is deactivated. The output signals from the motion sensor and presence sensor are gated through an OR gate and to a timer to activate the door opener. [A3499]

"Method and apparatus for transmitting electromagnetic signals into the earth from a capacitor"

A method and apparatus in which a capacitor is disposed in direct contact with the earth, and a short voltage pulse is applied to the capacitor to transmit a pulse of electromagnetic radiation having a broad frequency band into the earth. In a preferred embodiment, a portion of the electromagnetic radiation that has propagated through the subsurface is detected and processed to image the subsurface. The size, L, of the transmitting capacitor should be sufficiently small to satisfy the relation Re[kL]< 1, where k is the wavenumber in the earth formation of each frequency component of radiation transmitted into the earth. In a preferred embodiment, the voltage pulse applied to the transmitting capacitor has frequency components in a broad band from below 1 MHz to above 100 MHz, and the only frequency components of the detected electromagnetic radiation that are processed to image the subsurface have frequency in the range from about 500 KHz to 25 MHz. [A3500]

"Circuit to increase the information bit rate in a system for the exchange of data"

In a system for the exchange of data by microwaves between a fixed station and a mobile station or portable badge, the information bit rate is limited, in the standby state, by the low power consumption of the badge and the high output impedance of the modem. To increase the information bit rate of the modem of a badge, the information processing circuit associated with the modem sends the modem an activation signal to reduce its output impedance. The means implemented are transistors that switch over the load of the detector transistor or of the amplifier transistor. [A3501]

"System for sea navigation or traffic control/assistance"

A system to control sea navigation or traffic of a plurality of ships or moving bodies is disclosed. The system comprises a radio navigation reference system comprising at least two reference beacon sources and a navigation central station M. Said central station M, the reference beacon sources and the ships or moving bodies are provided with a first intercommunication means from said central station M to each reference beacon source, said first intercommunication means being synchronized by said central station M, and a second intercommunication means from said central station and each reference beacon source to each ship or moving body. The system further comprises a third intercommunication means from each ship or moving body to a control station PC, said control station PC having means making it possible, through the computation of the distances from each ship or moving body to said central station M and to each reference beacon source, provided by said third intercommunication means, to compute the position of each ship or moving body with respect to the reference radio navigation system. Said third intercommunication means being tuned on the radio navigation carrier wave. There is provided means for the real-time display of the geographical position of each ship or moving body. [A3502]

"Ranging, detection and resolving in a multislope frequency modulated waveform radar system"

A maximum likelihood estimator and range-only-initialization target detection method employed to detect and resolve targets in a multislope linear frequency modulated waveform radar. The method resolves a large number of target returns without a large amount of signal processing and without creating a significant number of false alarms, or ghosts. The method simultaneously estimates range and doppler for each target. The method rejects undesired long-range targets that fold into target regions, and processes target regions of interest around a nearest target to reduce signal processing throughput requirements. Using a K out of N detection rule, the method detects targets that compete with mainlobe rain clutter, mainlobe ground clutter, and receiver leakage. The method simultaneously estimates target parameters and optimally resolves any number of targets. The method is limited only by the number of frequency modulation ranging slopes, the slope values, and the doppler filter resolution set by the radar waveform design. The method has the ability to process and detect extended targets. [A3503]

"Doppler frequency spectrum de-emphasis for automotive collision avoidance radar system"

A Doppler control circuit for a CW or pulse Doppler radar system for monitoring not only the phase shift between echo signals from several targets but also the amplitude difference between the several targets and to further tune the radar to a particular target among one or more targets from which echo signals return. The control circuit can be used in state of the art CW or pulse Doppler type radar systems. In a further system, a special circuit is provided for conditioning selected portions of the Doppler frequency spectrum to attenuate or de-emphasize portions of the echo signal corresponding to selected targets in the radar system environment, such as rain or stationary wayside objects, in order to give such echo signals less weight in determining roadway hazards. [A3504]

"Forward looking radar"

In a forward looking radar in which from flying or stationary carriers land or marine surfaces in a forward lying sector region are imaged two-dimensionally, an antenna mounted rigidly on a carrier is made up of a plurality of individual elements preferably in the form of horn antennas arranged rectilinearly adjacent each other and in two rows above each other in such a manner that for a predetermined aperture length l of each individual element and for a predetermined spacing of the individual elements the antenna has an antenna length L=n.l/2. By means of the individual elements in each case a transmitting and subsequently a receiving takes place consecutively from the first to the last of the plurality of individual elements. To implement a digital coupling of the individual elements each said element is evaluated separately digitally and by correlation of a specific predetermined reference function a digital processing is carried out for each angular region. [A3505]

"Interactive television and data transmission system"

A spread spectrum system provides bidirectional digital communication on a vacant television (TV) channel for simultaneous use by more than 75,000 subscribers using time and frequency division multiplex signals locked to horizontal and vertical sync pulses of an adjacent channel Host TV station. The system, whose operation is analogous to a radar system, comprises (1) the Host TV station to send down-link sync and data pulses to subscribers during the horizontal blanking interval (HBI) , (2) subscriber "transponders" which detect those signals and transmits up-link "echo" data pulses only during the HBI to eliminate interference to TV viewers, and (3) a central receiver which also uses the host TV sync pulses to trigger range gates to detect the up-link data pulses. In a preferred embodiment the central receiver employs directional antennas to determine direction to transponders and to define angular sectors partitioning the service area into pie-link "cells" which permit frequency re-use in non-contiguous sectors (like cellular radio) . The system thus operates like a radar to measure elasped time between receipt of TV sync pulses and receipt of transponder response pulses and measures bearing to transponders to thereby determine the location of fixed or mobile subscribers as well as provide data links to them. Transponders may share user's existing TV antenna or may operate on cable TV and could be packaged as "RF modems" for personal computers, as transceivers for mobile or portable use, or they may be integrated with a TV receiver to provide "interactive television". [A3506]

"Sea velocity evaluator"

Sea clutter can be removed from radar signals by accurately determining sea velocity in a coverage area of a radar scan, updating a median value for the coverage area, and selecting a clutter rejection filter for the coverage area biased on the median value for the coverage area. Preferably, a median sea velocity is stored for each coverage area, as the median value. When processing begins for a coverage area, a previously stored median sea velocity is retrieved and updated. The median sea velocity is updated by converting the median sea velocity into a median phase difference between two echo signals, based upon carrier frequency and the time between receipt of two echo signals, which is preferably more than one interpulse period. The difference in phase between the two echo signals is compared with the median phase difference and the median sea velocity is increased if the median phase difference is smaller and decreased if the median phase difference is larger. A rejection filter is selected based upon the previously stored median sea velocity (preferably after adjustment based on the carrier frequency) to remove the echoes from the sea from the radar echo signals. [A3507]

"Telemetric process for measuring short distances"

A telemetric process for measuring short distances comprises emitting an electromagnetic signal modulated by a pseudo-random sequence having a number (n) of bits delivered at a clock frequency (fH) , correlating the echo detected with the modulated signal time-delayed by known means, and varying the clock frequency, as a function of the correlation measurement, within an operational field divided into a plurality of operating ranges, the number of bits inthe pseudo-random sequence being modified accoridng to the operating range of the clock frequency. The process is particlualry useful for proximity measurement close to a reflecting surface. [A3508]

"Downdraft velocity estimator for a microburst precursor detection system"

A weather surveillance apparatus utilizes a set of beams in an elevation angular sector, one beam being offset from the other by a predetermined offset angle. Radar signal returns in each beam are processed to establish an average doppler frequency shift for the signals in the respective beams. An average of the averages and a difference of the averages are determined which are utilized to establish horizontal and vertical wind velocities. These velocities are further processed to determine whether a microburst precursor exists and the location, magnitude, time to impact, and track of any resulting windshear. [A3509]

"Automatic vehicle deceleration"

An unobtrusive vehicular adaptive speed control system controls vehicle traveling speed in response to sensed obstacles preceding the vehicle, to driver influenced control parameters, and to a desired travelling speed set by the vehicle driver. [A3510]

"System for automatic identification of rail cars"

A system is provided for automatic identification of objects, such as rail cars and the like, utilizing two transponders, each attached to the rail car by a bracket. The bracket, which is welded along its ends to the rail car, has a lower planar surface which is placed against the side of the rail car when the bracket is welded thereto. A bottom planar surface of the transponder mates with an upper planar surface of the bracket, thus ensuring a good conduction heat flow path to the rail car and preventing over heating of the transponder when the rail car is placed in a thaw shed. The transponder is attached to the bracket by inserting a flange formed one end of the transponder under a clip projecting from the upper surface of the bracket. A threaded stud projecting upward from the bracket upper surface extends through a hole in a second flange formed at the other end of the transponder. The controlled length of the stud, and the use of an acorn nut and conical washer threaded onto the stud to clamp the transponder to the bracket, prevents generating excessive clamping force. [A3511]

"Radar tracking system having target position dead reckoning"

A vehicle mounted radar tracking system monitors vehicle heading rate, vehicle heading acceleration, vehicle roll rate and vehicle pitch rate, and provides a turn detect signal in response to heading rate, heading acceleration, roll rate or pitch rate being in excess of corresponding enable threshold magnitudes. In response to the turn detect signal, the tracking system dead reckons the positions of targets being tacked, and tracking system parameters are varied to make it more responsive to target motion. The turn detect signal is removed in response to heading rate, heading acceleration, roll rate and pitch rate being less than corresponding disable threshold magnitudes, and the tracking system is returned to normal operation. [A3512]

"Azimuth correction for radar antenna roll and pitch"

A vehicle mounted radar system has an antenna (12) which rotates about a reference axis (19) . During angular movement of the antenna with respect to the reference axis, a radar indicated target azimuth (.phi.') is modified to provide a corrected target azimuth (.phi.) which is substantially indicative of the actual or true target azimuth. A tracking system (25) uses a predicted radar indicated target position (P.sub.n+1 (x,y)) for target tracking and correlation. The tracking system uses a smoothed target position (STP (x,y)) , indicative of actual target position, for providing a visual display (39) of target track. [A3513]

"Method for extracting motion errors of a platform carrying a coherent imaging radar system from the raw radar data and device for executing the method"

For the imaging of terrains with varied ground reflectivity, azimuth spectra continuously following each other in time are formed over a set period of time in a method for extracting motion errors of a platform carrying a coherent imaging radar system from raw radar data. By determining the position of the maximum of the correlation between two azimuth spectra formed immediately following each other in time, the frequency shift of the ground reflectivity part is obtained. Then a separation of a velocity V.sub.v (t) in the forward direction from an acceleration V.sub.b (t) in the direction of LOS of the antenna is performed by filtering and the acceleration V.sub.b (t) obtained is subjected to normalization after two-fold integration, by means of which the displacement in LOS, i.e. the motion errors in the line of sight direction of the antenna, is obtained. In contrast to GPS systems, all information is taken from the raw radar data and no ground station is required, so that the present method can be used much more flexibly and is more self-sufficient. Furthermore, in comparison with the autofocus method, the present method has a much greater band width and can be performed in real time, which cannot be realized with the autofocus method. [A3514]

"Automatic safety driving distance control device for a vehicle"

Disclosed is an automatic safety driving distance control device for vehicle. The device includes a microcomputer which, within the range of 0-120 km/hr, can adjust the safety distance between the vehicle and the front vehicle according to the speed data transmitted from the speedometer and can automatically control the speed of the vehicle to maintain a safety distance from the front vehicle so as to avoid collision. When the vehicle is moving, the microcomputer calculates the safety distance between both vehicles according to the speed of the vehicle and the actual distance from the front vehicle according to the data from the distance detector. If the distance is too short, it will automatically motivate the brake motor to cause the vehicle to decelerate and the brake lights to turn on, if the distance is too great, it will automatically motivate the accelertion/deceleration motor to cause the vehicle to accelerate so that a safety distance is kept between both vehicles. If the front vehicle stops, then the brake motor and acceleration/deceleration motor will be motivated to stop the vehicle. If the front vehicle moves forward, the acceleration/deceleration motor will also be motivated, and the vehicle moves forward, keeping a safety distance from the front vehicle and maintaining a safety speed according to the value set by the speed limit device. [A3515]

"Turbulence radar system"

The present invention is a radar system that detects turbulence by breaking a range cell return down into spectral segments using an FFT processor. The standard deviation of the spectrum is determined and the system compares that standard deviation to a reference threshold of a non-turbulent return if the signal is above noise. If the threshold is exceeded, the range cell is marked for turbulence display. Once the turbulence display is completed it is overlayed on the weather display. To improve matching of the feature size to the variance calculation the invention performs both range and azimuth post detection integration subsequent to the FFT but before variance calculation. [A3516]

"Display system for a head mounted viewing transparency"

A display system for conventional eyewear having a transparency that defines a field of view and a frame for supporting the transparency on a user's head is shown. The display system includes a light transmissive display mounted on the frame of the eyewear and optics for collimating light to project an image of the displayed information at a distance from the user in the periphery of the field of view defined by the transparency. The optics may include a single mirror that receives the information directly from the display wherein the mirror is toroidal or the like so as to project an enlarged image at an apparent optical distance from the user that is greater than the actual optical path. Alternatively, a planar mirror may be employed with a collimating lens to project the image at a desired distance from the user. The mirror may be fully reflective or partially reflective so as to superimpose the image of the displayed information on the scene viewed by the user through the transparency of the eyewear. Further, means are provided for automatically adjusting the optical path defined by the relative position of the mirror, the display and the user's eye to accommodate heads of various sizes. [A3517]

"Safe trailing distance warning for vehicles"

A device and method to avoid collisions is described herein. The invention is primarily directed to preventing tail-gating by motorists. The method and device may also be utilized to detect stationary objects and to alert the driver of a vehicle of an imminent collision. [A3518]

"Movable storage system with aisle monitoring apparatus"

A detection system is disclosed for a mobile storage system which causes the storage system to prevent movement of a storage element whenever a person is detected in an aisle between storage elements. The detection system uses a presence or motion detector for detecting the presence of a person in an open aisle without direct contact between the person and the detection system. Preferably, a radar transceiver operating in X-band is positioned to overlie each open aisle to detect presence of movement of a person in an open aisle, even slight movement such as breathing. The storage system in which the detection system is connected prevents any closing movement of a storage element adjacent an aisle in which a person is detected so as to avoid frightening the person in the aisle. [A3519]

"Traffic speed radar unit"

An improved traffic speed radar unit, operating on the conventional doppler system, is disclosed wherein the unit includes means to verify that the internal time base frequency used to calculate vehicle speeds has not changed. Also, electronic memory is added both to facilitate an officer's work in taking notes and to allow for a more complete unit history to be maintained. [A3520]

"Proximity identification system with flux concentration in operating region"

A proximity identification system incorporating ferrite rods. The rods are used in both the reader and the tag and additional rods may be used to strengthen and concentrate the flux field in the regions near the reader to obtain better performance in such regions. A coding system requiring minimum power for the tag is also described. [A3521]

"Method and apparatus for calculating motional characteristics"

For calculating motional characteristics, particularly of a projectile moving in a barrel of weapon, a microwave directed onto the projectile by a measuring structure is superimposed with the reflected wave and a a calculation of location-dependent velocity and acceleration is carried out based on the chronological curve of the phase difference by a one-time or, respectively, two-time differentiation. In order to reduce measured errors, the operating phase difference and, therefore, the location of the projectile is first assigned to each amplitude value in a registered interferometer signal. A compensation function for the time-dependent location of the projectile is then placed through the arc-cosine-transformed individual action points and the location-dependent projectile velocity is calculated by one-time differentiation and the acceleration is calculated by a further differentiation. [A3522]

"Field disturbance monitor system"

A field disturbance monitor system which senses changes in a reflected signal caused by animate objects compared to inanimate objects in the same zone. The system employs a microprocessor which controls the system. A transmitter transmits a pulses microwave signal in response to a control signal from the microprocessor. A receiver receives a return signal which represents a reflection of the transmitted signal. A sample and hold circuit senses and holds the magnitude of the pulsed signal. Analog to digital conversion is obtained, whereby a ramp generator generates a ramp voltage which is compared with the magnitude of the received signal by a comparator. The microprocessor measures the time it takes the ramp voltage to rise to the magnitude of the detected signal. The microprocessor continuously computes a recursive short term average and compares this average value with a recursive long-term average. Deviations between the two time periods are the result of a disturbance within the monitoring field. Furthermore, the system is continuously self-adjusted to allow the conversion process to occur within the bounds of the measurement circuit, by changing the gain applied to the detected signal. [A3523]

"Precision ranging system"

The range (R) to a target (12) is precisely determined by controlling the amplitude of the carrier before modulation using a feedback signal derived from the detected return. The amplitude of the carrier is adjusted (40) so that all return pulses have a constant amplitude. Hence, for any given range, all return pulses cross threshold at the same time, thereby eliminating ranging errors due to phase distortion. The return pulses are threshold detected (54) and converted to a CW signal, which is then down converted. The phase information, which is indicative of target range, is preserved in the down conversion process and is extracted by phase comparison (72) with a reference signal to determine the target range. [A3524]

"In-furnace level meter and antenna therefore"

An in-furnace level meter for measuring a slag level, or the like, in a convertor, and an antenna used therefore. An antenna position is controlled so that the distance between the antenna inserted in the convertor and the slag level can be established to be constant or within a predetermined range. A water-cooled structure antenna is used as the antenna. [A3525]

"Measuring device"

The invention relates to a device and process which utilize the Doppler effect for measurement of the performance of blasting operations, in particular to the measurement of face velocity. The measuring device comprises radiation generating and receiving means and a signal analyzing means. [A3526]

"Electronic vehicle toll collection system and method"

A system for automatic collection of tolls includes a toll facility, an in-vehicle toll processor having memory for storing a toll-money-available quantity purchased by the user, and a toll-facility-identification site that transmits a toll-facility-identifier signal indicating the identity of the upcoming toll facility and the toll to be collected. As the vehicle approaches the identification site, the in-vehicle processor receives the identifier signal and calculates the toll to be debited. When the vehicle passes through the toll facility, the facility transmits a toll-collect signal instructing the in-vehicle toll processor to debit the calculated toll from memory. The in-vehicle processor debits the calculated amount and transmits an acknowledgement signal to the toll facility. [A3527]

"Vehicle mounting apparatus of an automatic vehicle location system"

A vehicle mounting apparatus for an automatic vehicle location system having a omni-directional antenna, a transmitting and receiving switch, an oscillator frequency converters, a frequency-shift keying demodulator, post office committe standard associate group decoder, a pseudorandom noise signal generator, a phase-shift keying modulator, a transmitting signal generator, a power amplifier, and a power supplier. The vehicle mounting apparatus receives a referencing signal from a control center and transmits an answer signal relating to location of a vehicle to be located. [A3528]

"Oblique spaced antenna method and system for measuring atmospheric wind fields"

Oblique spaced antenna method and system for measuring atmospheric wind fields within a predetermined volume, wherein a pulsed beam of high frequency radar waves is transmitted in predetermined transmitting directions into the volume of the atmosphere to be investigated, parts of the radar waves which return from the volume to be investigated are received from predetermined receiving directions at a plurality of spaced receiving locations, and the received waves are processed to derive information about the wind velocity within the volume to be investigated, to allow direct determination of parameters of the wind field, such as divergence, vorticity etc. The transmitting and receiving directions are oblique with respect to the vertical direction. [A3529]

"Near range obstacle detection and ranging aid"

A range detection apparatus comprising means for generating high frequency energy over a finite frequency range and for frequency modulating over a limited range of bandwidth the generated signal. A first path provides a phase reference while a second path provides for transmitting and receiving the signal. Along one of the two paths, the frequency modulated signal is phase shifted at a plurality of predetermined frequency values over a finite frequency range of bandwidth and at a predetermined plurality of phase-shifting values (greater than two) and at combinations of phase-shifting and frequency values to improve the relative range resolution. The signal in one path is phase compared to the signal in the second path to produce range measurement signals related to the combined phase shifts of the two paths, the results of the phase comparison, and the combinations of phase states of the phase shifts and frequencies of the frequency modulated signal. [A3530]

"Forward looking radar"

In a forward looking radar in which from flying or stationary carriers land or marine surfaces in a forward lying sector region are imaged two-dimensionally, an antenna mounted rigidly on a carrier is made up of a plurality of individual elements preferably in the form of horn antennas arranged rectilinearly in a row adjacent each other in such a manner that for a predetermined aperture length l of each individual element and for a predetermined spacing of the individual elements the antenna has an antenna length L=n.multidot.l. The transmission is incoherent from a single element and thereafter simultaneous reception is effected with the remaining individual elements. To implement a digital coupling of the individual elements each said element is evaluated separately digitally and by correlation of a specific predetermined reference function a digital processing is carried out for each angular region. [A3531]

"Ultrasonic level detector"

An ultrasonic level detector includes a transducer for generating and receiving bursts of sonic energy at a surface to locate the position of the surface. In response to receiving a burst of energy reflected from the surface, the transducer generates an electrical signal, which is then supplied to a variable gain amplifier. After amplification, the electrical signal is supplied to a comparator and a peak detector. The comparator generates a timing signal upon the electrical signal exceeding a threshold. A window generator circuit generates a receive window that controls whether the electrical signal is supplied to the comparator and the magnitude of the threshold on the comparator. The peak detector determines the maximum amplitude of the electrical signal, which may be used to vary the amplifier gain and the number of pulses included in an excitation signal which drives the transducer. Upon receipt of the timing signal, a microprocessor determines the distance between the transducer and the detected surface. [A3532]

"Microburst precursor detector utilizing microwave radar"

A microburst precursor detector utilizes a multiplicity of radar beams and samples radar returns, in each beam, from meterological radar signal reflectors and processes the signal returns in a statistical manner to determine average radar reflectivity and to extract doppler signal parameters. These parameters are utilized to determine a second set of parameters, average doppler frequency within each radar beam, doppler spectral spread within each radar beam, and the skewness of the doppler spectrum in each beam. The second set of parameters is processed to establish the existence of a microburst, predicted surface impact, time to impact, wind shear surface location and track, and the magnitude of the wind shear. [A3533]

"Subsurface target identification radar"

Subsurface target identification radar includes an antenna array, a rotary encoder, a radar controller, a polarization switching circuit, and transmitter and receiver circuits. The antenna array is constituted by dipole antennas having plane triangle elements. The antennas are disposed at angular intervals of 120.degree. with respect to a rotated symmetric point of the array. The rotary encoder generates a distance pulse every time the radar travels a presetted distance. The radar controller sequentially generates three switching pulses within one period on the basis of the distance pulse from the rotary encoder. The polarization switching circuit selects an arbitrary dipole antenna as a transmitting antenna from the antenna array, selects an arbitrary dipole antenna, other than the selected antenna, as a receiving antenna, and changes a combination of selected antennas every time the switching pulse is generated by the radar controller. The transmitter and receiver circuits transmit/receive electromagnetic waves through the selected antennas. [A3534]

"Communicating information by radio"

Information is communicated by microwave radio between transponders (9,10) carried by vehicles (7,8) travelling on a road (1) and a station (22) adjacent the road. The communications from the transponders are effected by the transponders suitably modulating their reflections of beams of microwave energy transmitted by the station from aerials (B) mounted on a gantry (11) above the road, these aerials irradiating respective communication areas (28,29,30) . In order to prevent communications from different transponders overlapping and hence interfering with each other the transponders are enabled for their communications by microwave energy from further aerials (A) , which energy has a higher frequency to enable it to be beamed at relatively small respective activation areas (23-27) the sizes of which are such that they can each only contain one vehicle and hence one transponder at any given time. The further aerials are activated, one at a time, successively and cyclically, so that the transponders are necessarily enabled in succession, the activation rate being, moreover, sufficient to ensure that all transponders passing through the relevant stretch of road are in fact enabled. During each interval between the activation of each further aerial and the next the station transmits a command from the aerial (s) (B) associated with the further aerial (A) which has just been activated ordering any transponder which has just been enabled to communicate its presence. If it receives such a communication the station transmits an address code from the relevant aerial (s) (B) which is stored in the relevant transponder and used subsequently to selectively address that transponder for further communication. [A3535]

"Method and apparatus for detecting fire, explosion, and/or projectile penetration"

A method and apparatus for detecting the occurrence of a fire or an explosion in a monitored space, or the penetration of a projectile through a barrier, by: transmitting to the monitored space an electromagnetic signal of at least one radio frequency, receiving the transmitted signal as scattered by the monitored space, and analyzing at least one parameter of the received signal to produce an indication whether a fire or explosion has occurred, or a projectile has penetrated through a barrier, in the monitored space. [A3536]

"Method and apparatus for ground radar information display system"

Disclosed herein is a method and apparatus for a ground radar and information display system for commercial and general aviation. The method includes processing raw data from the presently existing ATCRBS system, duplicating the raw data and sending it to an auxiliary computer, filtering out non-positional messages of the raw data, encoding the raw data into a data block and transmitting the data block to a display facility, where it is decoded and displayed. The apparatus of the invention includes and auxiliary ground computer and a smaller on-board computer for processing the data block. [A3537]

"Vehicle air bag protection system"

A vehicle air bag passenger protection system that includes switches in the vehicle bumpers. Control signals are generated by the switches to produce rapid inflation of air bags in the passenger compartment of the vehicle. As a further protective feature, a distance measuring system is provided for generating an alarm signal when the vehicle is moving at a significant speed, and another vehicle is so close as to present the possibility of a collision situation. [A3538]

"Method of and apparatus for obtaining vehicle heading information"

When fewer than three of the satellites of a satellite global positioning system (GPS) such as NAVSTAR are visible to a user (15) , the user cannot obtain independent positional information from the system. Since a satellite (11) in such a system is moving with respect to a user (15) , its signals are received with a Doppler offset from their normal centre frequency and the frequency offset due to the satellite motion alone is calculable for a user at an approximate location from a given satellite. An additional Doppler frequency offset will result from any movement of the user. The magnitude of the additional frequency shift, in conjunction with the known speed (m) of the user, can be used to calculate the angle between the satellite motion (V.sub.1) and the user's motion and since the direction of the former is known, the user's heading from local North (N) can be calculated in instances where only one or two GPS satellites (11,12) are visible to a user. [A3539]

"Microwave responder"

A microwave responder resonates or does not resonate with a microwave transmitted from a radio transmitter, and radiates the resonated microwave as a response signal wave. Two microstrip lines are linearly arranged to be separated from each other at a predetermined interval. A diode which is switched between ON and OFF states in response to the response signal is interposed between two end portions of the microstrip lines separated by the predetermined interval, and a distance, between distal ends of the two linearly arranged microstrip lines, which includes an impedance defined by the ON or OFF state of the diode is determined to be 1/2 a wavelength of the microwave. [A3540]

"Method and apparatus for protecting motor vehicle occupants"

In a process for protecting motor vehicle occupants, the acceleration of the motor vehicle is determined and safety means which protect the motor vehicle occupant are activated when a specified limiting acceleration value is exceeded. To optimally release the safety means, the sitting position of the motor vehicle occupant and/or the relative velocity of the occupant with respect to the passenger cabin of the motor vehicle are determined by position sensor using measuring techniques. The safety means are activated when the sitting position of the occupant deviates from a nominal position and/or the relative velocity of the occupant exceeds a specified limiting value. [A3541]

"Single substrate microwave radar transceiver including flip-chip integrated circuits"

A microwave radar transceiver assembly (30) includes a monolithic microwave integrated circuit (MMIC) chip (58) having a coplanar waveguide transmssion lines (100, 102, 104) formed on the same surface (58a) as the electronic elements thereof. Coplanar waveguide transmission lines (68, 70, 72) are also formed on a surface (62a) of a substrate (62) . The transceiver chip (58) , in addition to other chips (56, 60) , are mounted on the substrate (62) in a flip-chip arrangement, with the respective surfaces (58a, 62a) on which the transmission lines (100, 102, 104, 68, 70, 72) are formed facing each other. Electrically conductive bumps (106, 108, 110) are formed on portions of the transmission lines (100, 102, 104) of the chips (56, 58, 60) which are to be interconneced with the transmission lines (68, 70, 72) of the substrate (62) , and solder (114) is formed on the portions of the transmission line (68, 70, 72) of the substrate (62) which are to be interconnected with the transmission lines (100, 102, 104) of the chips (56, 68, 60) . The bumps (106, 108, 110) provide spacing between the mating surfaces (58a, 62a) of the substrate (62) and chips (56, 68, 60) , and isolation between electronic elements on the chips (56, 58, 60) . [A3542]

"Easily encodable surface acoustic wave (SAW) security devices"

This invention features a method for encoding surface acousting wave (SAW) delay lines. The method uses a split-electrode transducer as a programmable reflector. When shorted out, it does not reflect surface waves. When open-circuited, it partially reflects incident surface waves. As manufactured by conventional photolithographic methods, each of several such transducers is shorted out by a fusible link. In the as-manufactured state, the array of shorted transducers produces no reflection of surface waves. If a fusible link is destroyed by passage of electric current or other means, the corresponding transducer becomes a partial reflector. The status of these switchable reflectors may be read by exciting a separate launch transducer with a burst of electromagnetic energy containing substantial energy at the basis operating frequency of the SAW transducers or at suitable harmonics. SAW energy reflected by the switchable reflectors appears at the same transducer at delay times determined by the spacing of the elements. The presence of a pulse at a given delay time indicates that the corresponding fusible link has been destroyed, conversely, absence of the pulse indicates that the fusible link is intact. Thus, destruction of fusible links provides a method for encoding SAW devices for security and other applications, in situ. [A3543]

"Method for using seismic data acquisition technology for acquisition of ground penetrating radar data"

A method and apparatus are used in the acquisition of data by ground-penetrating radar, wherein the signals thus obtained are input to a pre-amplifier which contains filtering component such as an anti-aliasing filter. The base gain of the system is switch selectable and electronically adjusted to bring the input signal to between one half and full scale on an analog to digital converter input. The converted digital value has a resolution of fifteen bits for processing. [A3544]

"Satellite-based position determining system"

Disclosed herein is a transmission system for determining a position of a mobile station by using communication satellites. The determination of the position of the mobile station is effected by one-line signal transmission from the mobile station through one satellite to a fixed station and by two-line signal transmission from the fixed station through two satellites to the mobile station. Thus, the construction of the transmission system can be made simple such that a transmitter for the one-line signal transmission needs to be mounted on the mobile station. [A3545]

"Resonant tag and method of manufacturing the same"

A resonant tag is manufactured in the manner described below: a conductive thin film is formed to a predetermined thickness on two surfaces of an insulating thin film. Thereafter, a conductive pattern, composed of an inductor element and a capacitor element corresponding to a resonant frequency of a resonant circuit, is printed on a surface of one of the conductive thin films, and a conductive pattern, composed of a capacitor element corresponding to the resonant frequency of the resonant circuit, is printed on a surface of the other insulating thin film at a position which faces the capacitor element formed on one of the conductive thin films using an ink which resists etching. A non-printed portion of the conductive thin films is removed by etching to form a resonant circuit pattern. Thereafter, a portion of the insulating thin film, which corresonds to the capacitor element pattern, is thinned to a desired thickness by pressing a heating/pressing member heated to a predetermined temperature against that portion under a predetermined pressure for a predetermined period of time. [A3546]

"Method and apparatus for increasing a radar's range with improved scan-to-scan integration of doppler filtered signals"

Method and apparatus for improving detection ranges of a pulsed radar sys wherein electromagnetic return signal data in range cell order is doppler filtered, digitized and stored in doppler memory channels over multiple scans of an azimuth. The digital doppler data in each doppler memory channel is scan-to-scan integrated over a predetermined number of scans to produce target displays for each possible velocity. The target displays are stored in a velocity memory, which is partitioned into velocity channels, each velocity channel corresponding to one possible velocity. A selector selects the target display having the largest total magnitude as a display signal. The scan-to-scan integrated target displays are not subject to collapsing losses since only target signals plus noise signals will be stored in the doppler memory channel corresponding to the target's velocity. [A3547]

"Lobing system"

The radar system includes a sum and difference network coupled to a conventional monopulse type antenna. The difference signals or error signals are applied into a modulator in space quadrature with electrical vectors in a direction transverse to the direction of propagation polarized at right angles to each other. A rotating magnetic field in the modulator causes any energy that is in line with this field to be continually rotated and applied to a coupler that is sensitive. During search the shutter is closed so that only unmodulated sum energy is passed through the circulator to the receiving unit. for tracking the shutter is opened and the reflecting post is positioned to reflect a selected portion of the error signal energy and pass a selected portion of the sum signal energy, both of which are absorbed in the isolator. The system provides a simplified selection of the lobing frequency by controlling the velocity of the rotating magnetic field at the modulator. The system also operates in a terrain avoidance mode by properly controlling the modulator. [A3548]

"FMCW/2FD implementation for vehicle near obstacle detection system"

A vehicle near obstacle detection system includes a plurality of radio frequency heads that can transmit and receive both frequency-modulated, continuous wave and two-frequency Doppler radar signals, such that the system operates in frequency-modulated, continuous wave radar mode and in two-frequency Doppler radar mode. The radio frequency heads used for transmitting the radar signals transmit their radar signals in accordance with commands from a system controller. The radio frequency heads are provided at various locations on the vehicle, directed at points around the vehicle which cannot easily be seen by the vehicle operator. The system controller switches between the two radar modes depending on which one is more appropriate to make use of one mode's strengths while avoiding the other mode's weaknesses. When there is no relative movement between objects and the vehicle, the frequency-modulated, continuous wave mode is used. When there is relative movement and the accuracy warrants it, the two-frequency Doppler mode is used. [A3549]

"Vehicle with plastic suspension"

Four wheeled vehicle supporting a ground probing radar antenna 52 has an aluminium alloy square plate 10 and four wheel mountings 14 supported by four pairs of equal-length arms 18,20. The arms as seen in plan are arranged in a square. One arm 18 in any pair extends lengthwise of the vehicle from an anchorage 30 on the vehicle to a mounting 14 and the other 20 extends transversely of the vehicle from an anchorage 32 on the vehicle to the mounting 14. Each mounting carries a buffer 36 which on upward movement presses against one of two spring arms 38 carried by mountings 42, one arm being locked in its mounting. The vehicle has an overcover 70 and an undercover 72. In a modification pneumatic spring units instead of arms 38 control vertical wheel motion. [A3550]

"Distance measuring method and apparatus therefor"

A distance measuring method and apparatus in which first and second pseudo random signals which are the same in pattern but slightly different in period are generated to obtain a correlation output of the first and second pseudo random signals before transmission thereof as a reference correlation output, and the first pseudo random signal is directly transmitted toward a target or alternatively a carrier wave is modulated by the first pseudo random signal and transmitted toward the target. A correlation output of the signal reflected and received from the target and the second pseudo random signal is detected and the distance to the target is measured from the time interval between the reference correlation output and the received correlation output. Alternatively, the modulated carrier wave reflected and received from the target and the second pseudo random signal are subjected to correlation processing to detect a correlative modulated carrier wave and the correlative modulated carrier wave is subjected to orthogonal detection by a reference carrier wave thereby obtaining a target detection output. Then, the distance to the target is measured from the time interval between the reference correlation output and the target detection output. [A3551]

"Radiometer system incorporating a cylindrical parabolic reflector and minimum redundancy array feed"

A radiometer system is disclosed, the system incorporating a cylindrical parabolic reflector and a plurality of radiation sensors disposed along the focal line of the reflector in a minimum redundancy array. Digital processing circuitry is connected to the output of the sensors for digitally processing signals using a cross-correlation signal processing and fast Fourier transform circuitry to generate image signals, the system providing reduced weight and increased signal integration time. Several embodiments of the system are disclosed including analog and digital versions having a multiplicity of antenna configurations. [A3552]

"Electromagnetic identification and location system"

An electromagnetic identification and location system is described. The system comprises at least one interrogator which, in operation, generates an electromagnetic interrogation field by at least one antenna coil, and at least one responder which, in response to the electromagnetic interrogation field, generates a code signal in accordance with a binary code stored in a code circuit of the responder. The code signal can be recognized by an identifier. According to the invention, the responder is provided with a generator which, in response to the interrogation field, generates and transmits a pilot signal. The system further includes a position-sensitive antenna arrangement for receiving the pilot signal. [A3553]

"Method and device for assisting terrestrial vehicle traffic"

A method for assisting terrestrial vehicle traffic involves equipping at least some vehicles with a radar system and a transponder capable of re-transmitting with selected frequency transposition any radar wave received within a predetermined frequency band. The radar system semi-continuously transmits the waves capable of measuring a distance over a range of several hundreds of meter, and the radar system receives the transposed echoes in order to carry out distance measurement thereon. It is also possible to provide certain bodies, not equipped with radar, with individual transponders which are different from those provided on vehicles. [A3554]

"Radar"

To provide stationary or mobile radar with the capability of measuring the true range profile, a radar system includes a voltage oscillator coupled to a duplexer via a pulse modulation circuit. A digital control circuit provides a sweeping 500 Mhz frequency (F) of 6N successive batches of pulses being incremented in steps of F/6N. Returns received in response to each transmitted pulse are then combined in a mixing circuit with the signal from the local oscillator to generate a signal IF, each signal is summed with signals for the same range cell derived from earlier pulses transmitted at the same frequency, thereafter the signals pass through a FFT circuit. To maintain the "dissected" spectrum centered at the 2N.sup.th cell, respective summations are carried out in two circuits, and then differenced in and normalized by the total signal energy present in the true profile range obtained from a summing circuit, the output therefrom providing an error signal whose magnitude and sign are used to estimate any change required in the value of prf, fr, thereby to achieve the value of T which will maintain the dissected spectrum centered on the 2N.sup.th range cell. [A3555]

"Collision avoidance system"

A collision avoidance system providing to each properly equipped vehicle an indication of the locational direction, heading, and relative velocity of other similarly equipped vehicles or stationary objects. Each vehicle in the system is equipped with a transponder module which transmits information data relating to that vehicle, and receives information data relating to the other similarly equipped vehicles. A central reference time signal transmitter is provided for transmitting a reference timing signal which effectively synchronizes each of the transponder modules. Upon receiving the reference timing signal, the transponder module subsequently transmits information data relating to that particular vehicle. Each of the transponder modules is allocated a unique time period for transmission of its information data. Thus, the system can accommodate a great number of transponder modules within the system, each transmitting their respective information data during unique time slots during a relatively small time frame. [A3556]

"Azimuth-stacked radar method and apparatus"

An azimuth-stacked radar method and apparatus of the type typically used for surveillance employs a mechanically-rotating antenna comprising horizontal end-fed rows of antenna radiating elements with phase shifter control on each row together with a monopulse elevation manifold to generate an elevation sum and difference beam pair. Additionally, this radar employs a waveform comprising multiple subpulses at different frequencies with sufficient separation between the subpulses at each frequency to spread them in azimuth to form a beam cluster and employs mechanical antenna rotation and phase-responsive elevation scanning. The scanning is accomplished in a way that will permit advantageous avoidance of ground clutter and other uninteresting radar reflectors. [A3557]

"Hybrid clutter cancellation method and system for improved radar performance"

A system is disclosed for use with radar systems so as to reduce the dynamic range requirement of the analog to digital converter through analog clutter cancellation prior to digitization. Clutter return estimates are formulated via modern digital signal processing techniques, converted to analog representation, and subtracted from the received waveform. Typically, the MTI cancellation is performed on the quadrature components of the received signal. The complex residue is then processed for target detection. This quadrature processing is not illustrated in the figures. In practice, sampling the received waveform prior to baseband down conversion, at an intermediate frequency, is also feasible. Digital synchronous detection and coherent MTI processing are then implemented in the digital signal processor. Rather than employ a radar signal processor which is either all analog or all digital it is beneficial to utilize hybrid schemes which capitalize on the advantages of both. A hybrid system is disclosed in which the acoustic delay line, which fundamentally limits analog MTI canceller performance, is replaced by a digital delay line. In effect, the transmitter crystal, delay medium, and receiver crystal are replaced by the analog to digital converter, digital delay, and digital to analog converter. The hybrid clutter canceller with digital processor and analog waveform synthesizer utilizes modern signal processing techniques to estimate the clutter return which is subtracted from the incoming analog signal. The full dynamic range of the received signal is not presented to the analog to digital converter, reducing the number of bits required for target detection in clutter. In effect, application of the hybrid clutter canceller reduces the A/D converter probability of saturation for a given A/D converter. [A3558]

"Road surface sensing system for a vehicle"

A system for sensing road irregularities from a vehicle modifies an operational system of the vehicle, such as a suspension system, according to the type and severity of the sensed irregularity. The system employs a Doppler Microwave radar sensor arranged to project radiation at a road surface ahead of the vehicle and includes means for detecting radiation reflections of which the carrier frequency is amplitude modulated according to the surface irregularities. An electronic circuit differentiates the modulated signal to produce a control signal representative of said surface condition and a controller receives said signal and modifies the operation of the vehicle system in response thereto. [A3559]

"High speed system for reading and writing data from and into remote tags"

A system for reading from and for writing data into electronic tags which may be associated with objects which are moving with respect to an interrogator, or may be located in fixed positions in the path of a moving interrogator. The interrogator, which is stationary if the tag is moving, sends a continuous RF signal to the remote tag. The tag backscatter-modulates the received RF signal with data temporarily or permanently stored in the tag, including, for example, data associated with the object to which the tag is attached, for example, its identity or contents. The system of this invention uses a very efficient encoding technique for the data which is backscatter-modulated by the tag and received by the interrogator. The backscatter-modulated signals are made up of signals of first and second frequencies f.sub.1 and 2f.sub.1, respectively, where the second frequency 2f.sub.1 is twice the first frequency f.sub.1, and where one of the two binary bits ONE and ZERO is represented by one-half period of a signal of the first frequency followed by one period of the second frequency, and the other of the two binary bits is represented by one period of a signal of the second frequency followed by one-half period of a signal of the first frequency. The signals also contain FRAME MARKERS made up of five periods of frequency 2f.sub.1 followed by one-half period of frequency f.sub.1. [A3560]

"Method of Kalman filtering for estimating the position and velocity of a tracked object"

A method of Kalman filtering for estimating the position and velocity of a racked object is provided. A Kalman filter is initialized with at least position and velocity error states in an inertial computational frame. Sensor measurements are used to develop a measured line-of-sight vector to the object. Matrix transformations are used to analytically rotate the sensor measurements into a measurement frame. The measurement frame is defined as having one axis pointing towards the estimated relative position of the object. The use of the measurement frame allows the method to be adaptable to any line-of-sight/computational frame geometry. Since statistical correlation of the measurements is not present in the measurement frame, the number of computations at each filter update is reduced. [A3561]

"Moving target indication unit"

Moving target indication unit provided with a doppler filter bank (1) with n output channels A.sub.i (i=0, 1, 2, . . ., n-1) , several threshold circuits (24.i) connected to the output channels, a detection and registration unit (7, 14, 18, 23) provided with means (7, 14, 18) for the determination and registration, per azimuth cell, of a parameter for the amount of clutter in an azimuth cell. The said means are further suitable for determining, based on the output signals of the filter bank (1) , k (k.gtoreq.2) parameters per azimuth cell and processing per azimuth cell the combination of k parameters to obtain n threshold values, used to set the n threshold circuits. [A3562]

"Target range detector with moving target indication"

An apparatus for determining a target position within a selected range segment includes a range gate generator which provides a range gate signal that enables a detector for a time interval corresponding to the range segment and a signal generator, responsive to the range gate signal, which provides a signal having an amplitude which varies with time. The output signal of the signal generator is sampled by a sample and hold circuit. A control signal generator enabled during the range gate interval couples a switching signal to the sample and hold circuit which, upon the reception of a target reflected signal, causes the sample and hold circuit to switch from the sampling mode to the hold mode. The signal amplitude in the hold mode is a representation of the target position within the range gate. Range rate is determined from a knowledge of the elapsed time between range gates corresponding to the same range segment and the difference in positions within the range gates established by the sample and hold circuit when switched to the hold mode upon receptions of the target reflected signals. [A3563]

"Weather radar system with improved display characteristics"

A weather radar system having improved display characteristics for rotation and translation of weather data where the rotations and translations are accomplished by converting data in a dedicated polar coordinate memory to display memories. The translation and rotation of the data between data updates is accomplished by referring to the data stored in the dedicated polar coordinate memory and thereby generating new rotated or translated data without requiring a manipulation plate of the data in the display memories. [A3564]

"FMCW radar range tracker and method"

A range tracking technique for producing a ground return signal in an FMCW radar system. The radar system produces an IF signal having frequencies within a range extent band, the IF signal including a ground return component having frequencies in a narrower ground return band. The range tracker includes a tracking system, a search system, and a controller. The tracking system receives the IF signal and a track control signal, and bandpass filters the IF signal to produce the ground return signal. The search system also receives the IF signal, together with a search control signal from the controller. The search system includes a second bandpass filter for bandpass filtering the IF signal to produce a band power signal. The controller receives and stores samples of the band power signal, and identifies the ground return component. The location of the ground return is used to adjust the track control signal, to keep the first passband centered on the ground return. [A3565]

"Automatic range adjustable weather radar system"

The range of a weather radar systems (60) is automatically extended by incrementally increasing the pulse width (17) from transmitter (12) in response to detecion of excessive path attenuation determined by a comparator (32) comparing the level of actual attenuated return pulses (19) from a range correction accumulator (34) with a path attenuation compensation level selected by a computer (26) . The bandwidth of the receiver (14) , the value in an initial sensitivity time control value circuit (54) , the value in a path attenuation compensation correction value circuit (62) and the path attenuation correction alert threshold are also selectively varied automatically in accordance with the incremental changes in the width of transmitted pulses (17) . [A3566]

"Vehicular anticollision radar system for driving in the fog"

The space ahead of a moving vehicle is irradiated in sectors (A-G) by a plurality of CW solid state radar devices mounted as an array across the front of the vehicle, such that adjacent lobes of each beam may overlap. The radar signal comprises a CW beam modulated intermittently by a slightly offset frequency to produce `pulses` which when reflected from obstacles within respective sectors (A-G) are detected by mixer diodes in one, or two adjacent radar devices after a time delay which, measured, yields a distance to the obstacle. Obstacles so detected may be displayed in two dimensions within their respective sector (A-G) on a display projected onto the windscreen. [A3567]

"Method for extracting motion errors of a platform carrying a coherent imaging radar system from the raw radar data and device for executing the method"

In a method for extracting motion errors of a platform carrying a coherent imaging radar system from raw radar data, azimuth spectra continuously following each other in time are formed over a set period of time for the imaging of terrains with mainly homogeneous ground reflectivities. An estimate of the ground reflectivity part is performed with a Kalman filter and with the aid of the azimuth spectra represented and system parameters entered. Then the antenna pattern part is obtained by dividing the azimuth spectrum by the estimated ground reflectivity part. By frequency filtering a separation of the drift angle .phi. (t) from the velocity V.sub.b (t) in the LOS- direction of the antenna is subsequently performed and then the velocity obtained is subjected to normalization after having been integrated, from which results the displacement in the line of sight direction of the antenna. [A3568]

"Golf information system"

A golf information system which automatically provides golfers with reference position and distance information from a number of points on a particular golf course hole. In one embodiment, radio frequency identification tags would be positioned along a golf cart path, for example, buried underneath the path, and a reading system carried by the golf cart would output an interrogation signal which would activate the tags causing the tags to output a coded signal which would be received by the reading unit, which would retrieve information about that location from memory and output it to the golfer. The system can further be used to display advertising messages and to provide golf course management features such as monitoring cart usage and speed of play. [A3569]

"Doppler determination system for MTI radars"

A doppler determination system uses an amplitude comparison of odd and even MTI functions derived from the same signal returns in an MTI radar system to determine the doppler frequency of a target return. The system determines the ratio of the amplitudes of the return of a single canceller circuit with a delay of 2/PRF and the amplitude of the return of a double canceller with two delays of 1/PRF. The ratio is then employed to estimate the doppler frequency of the return. The respective amplitudes of the two MTI circuits are also processed in a 3-dimensional radar application to provide estimates of the target radar cross-section and elevation angle, and with PRF switching to determine the target unambiguous range rate. [A3570]

"Method and apparatus for ground radar information display system"

Disclosed herein is a method and apparatus for a ground radar and information display system for commercial and general aviation. The method includes processing raw data from the presently existing ATCRBS system, duplicating the raw data and sending it to an auxiliary computer, filtering out non-positional messages of the raw data, encoding the raw data into a data block transmitting the data block to a display facility, where it is decoded and displayed. The apparatus of the invention includes and auxiliary ground computer and a smaller on-board computer for processing the data block. [A3571]

"Driver alerting device"

A driver alerting device includes a transceiver adapted for mounting at the rearward end of a vehicle for directing its wave output rearwardly of the vehicle. Return wave signals for many objects within the transceiver range are picked up and supplied to the transceiver by an antenna. Any resultant doppler shift signal is amplified for driving an audio alarm adapted for placement within the passenger compartment of the vehicle. The circuit is adapted for electrical connection to the back-up light circuit of the vehicle for activation only when the vehicle transmission is engaged in reverse gear. [A3572]

"Method and apparatus for doppler velocity de-aliasing"

A method and apparatus for real time de-aliasing of the Doppler velocity data in a weather radar system by using a Process Radials routine which processes every valid range gate along a radar dwell by determining if each range gate is within the Nyquist velocity of either the average of four preceding range gates or data from a Windfield Model. To further enhance the de-aliasing process a Process Dual Scans routine is used prior to the Process Radial routine to de-alias velocity data by comparing velocity data from two scans of different pulse repetition frequencies. Subsequent to the Process Radials routine, a Minimize Azimuthal Shear routine checks velocity discontinuities from azimuth to azimuth. The de-aliased data is transferred to an Update Windfield Model routine for quality checks of the de-aliased velocity data and updating of the Windfield Model. This complete method of de-aliasing the velocity data is performed during the real time operation of the radar system. [A3573]

"Measuring system"

The invention relates to a measuring system having a measuring array comprising a transmission and reception section and an electronic evaluation unit. In accordance with the invention, the distance between a first point and a second point is determined by moving the measuring array between the two points using the Doppler effect, with an intermediate frequency being formed in the transmission and reception section from the transmission frequency of the signal emitted by the transmission section and from the reception frequency of the signal reflected off a fixed object and picked up in the reception section, and the number of periods of intermediate frequency generated during the measuring operation being counted in the electronic evaluation unit to derive the distance. [A3574]

"Vehicle forward sensor antenna steering system"

A transmitted and received beam of a forward looking sensor of a source vehicle is steered as the source vehicle travels through a curvilinear path so that the steering angle is controlled to prevent the loss of detection of a target vehicle resulting from the effective lateral shaft of the beam relative to the path as the beam is steered into the curvilinear path. The beam is steered at an angle that limits the effective lateral shift of the beam relative to the curvilinear path such that a predetermined minimum target vehicle detection criteria is achieved. [A3575]

"Marine object detector"

A system is disclosed for detecting and locating the occurrence of anomal to radio frequency electromagnetic transmission in conductive liquids. Applications are described for use in swimmer detection and for process monitoring. [A3576]

"Dual satellite navigation system"

A method and system for determining the position of an object using a fixed station and a plurality of earth orbit satellites whose positions are known. Separate periodic signals are transmitted from the fixed station via first and second satellites to the object whose postion is to be determined. The phase offset in periodic characteristics of the periodic signals as received from the first and second satellites is measured at the object. The phase offset corresponds to a relative time difference in propagation of the signals traveling two different paths to the object. The object transmits via the first satellite a return signal indicative of the measured relative time difference. This return signal is activated some time in the future according to the object local time, which is slaved to receipt of the periodic signal sent through the first satellite. This future time is the start of the particular time period as decided by the fixed station's schedule. At the fixed station, an instantaneous round trip delay, determined by the time offset of the current transmission clock time relative to the receive clock time of reception of the return signal, along with the measured relative time difference sent back on the return signal, is used to calculate the distances between the first and second satellites to the object. From these distances the position of the object is calculated. [A3577]

"Top mounted buoy signaling device"

A top mounted buoy signaling device for marine navigation which is selectively activated in response to a coded address signal. The buoy signaling device includes a buoy having a top mounted receiver assembly which is activated by a transmitter assembly. The receiver circuit, transmitter circuit and antennas therefor are printed on circuit boards. The transmitter circuit includes an encoder chip which is preset to provide a coded address. The coded address is utilized to modulate a carrier signal to provide a coded address signal to activate the receiver circuit. The receiver circuit includes a decoder chip which is preset to the coded address of the corresponding transmitter. A lamp driver subcircuit is enabled in response to the coded address signal. The lamp driver subcircuit includes a master timer subcircuit which maintains the driver subcircuit in an operative condition for a predetermined period of time and a flash timer subcircuit which periodically energizes a lamp to provide a flashed output. The receiver circuit may also include a power timer subcircuit to periodically energize the receiver circuit for short-interval operation and a sweep circuit to allow the receiver circuit to receive coded address signals within a predetermined bandwidth. [A3578]

"Aperture synthesized radiometer using digital beamforming techniques"

A digital aperture synthesized radiometer for synthesizing the imaging an image scene. A plurality of antenna arrays receive radiation emitted or reflected from an scene, and an analog to digital coverter converts received radiation into digitized signals. A digital beamformer synthesizes the digitized signals to provide an image corresponding to the scene. The digital beamformer comprises individual digital beamformers which generate a set of fanbeam signals for each array. The beamformers provide for cross track imaging of the scene. A digital interferometer correlates corresponding pairs of fanbeam signals from the two sets of fanbeam signals to produce a chirp signal for each pair. A matched filter processes the chirp signals to transform each chirp signal into a corresponding image point of the scene. This provides for along track imaging of the scene. The beamformers include an amplitude weighting and data turning circuit to reduce fanbeam signal sidelobe levels and eliminate alternate mainlobes from the digitized radiation signals to reduce mainlobe widening. A fast Fourier transform circuit in the beamformers generally comprises a decimation-in-time algorithm implemented by means of a plurality of parallel and cascaded butterfly computation circuits. Image processing methods for achieving digital radiometry are also disclosed. [A3579]

"Adaptive cruise system"

An adaptive cruise system for a vehicle maintains a desired selected operator-set speed in the absence of a detected preceding target vehicle and adjusts the vehicle speed when a target vehicle is detected to maintain a following distance that is set by the vehicle operator. An alert distance is computed that is a predetermined function of a distance based on driver reaction time. To provide for the driver selectable trailing distance, the driver reaction term of the alert distance is adjusted by the vehicle operator to achieve a desired distance to the target vehicle. [A3580]

"Adaptive multifrequency signal combining system"

Apparatus and methods for combining incoherent signals having different carrier frequencies but a common modulation to obtain a coherent summation of the modulations of such signals are described. The apparatus comprises adaptive means of changing the carrier frequencies and corresponding phases of various signals to a common carrier frequency and a common phase, thus enabling the coherent summation of the common modulation and enhancing, thereby, the level of received information content. When the incoherent signals are transponder-signals, radiated from an object or platform in response to a modulated interrogating signal, and are obtained by different frequency offsets from the interrogating signal carrier frequency, the particular offset frequencies being unique to that object or platform, the ability combining of modulations coherently provides a means of unique identification of the object or platform. [A3581]

"Electronically scanning vehicle radar sensor"

A plurality of transmitting (14, 16, 18, 20) and receiving antenna elements (22, 24, 26, 28) are formed on a support member (12) which may be mounted on a corner of a vehicle for scanning a pattern including areas on opposite sides of the vehicle corner. In an automotive application, the pattern may include a rear area, and a blind spot on the side of the vehicle adjacent to the rear area. A transmitter (50) is connected to the transmitting antenna elements (14, 16, 18, 20) by a passive phased array (30) such as a planar microstrip Butler matrix, and an electronic switch (52) which sequentially connects the transmitter (50) to inputs of the transmitting array (30) . A receiver (62) is similarly connected to the receiving antenna elements (22, 24, 26, 28) by a planar microstrip passive phased array (40) , and an electronic switch (64) which sequentially connects the receiver (62) to outputs of the receiving array (40) . The support member (12) may be formed into a non-planar shape, or be flexible enough to be bent into a non-planar shape, to conform to a non-planar surface of the vehicle on which the sensor is to be mounted. [A3582]

"Method and apparatus for sensor fusion"

Methods and apparatus for fusion of data from optical and radar sensors by error minimization procedure. The method has been applied to the problem of shape reconstruction of an unknown surface at a distance. The method involves deriving an incomplete surface model from an optical sensor. The unknown characteristics of the surface are represented by some parameter. The correct value of the parameter is computed by iteratively generating theoretical predictions of the Radar cross-sections (RCS) of the surface, comparing the predicted and the observed values for the RCS, and improving the surface model from results of the comparison. Theoretical RCS may be computed from the surface model in several ways. One RCS prediction technique is the method of moments. The method of moments can be applied to an unknown surface only if some shape information is available from an independent source. The optical image provides the independent information. [A3583]

"Stolen vehicle recovery system"

A stolen vehicle recovery system (20) in which a vehicle transceiver (30) is disposed on each vehicle (28) for cyclically transmitting a pulsed signal which is modulated by a data stream comprising a verification code, a unique identity code associated with the vehicle (28) , and a code which corresponds to whether the detected vehicle (28) is moving or stationary. The vehicle transceiver (30) is automatically activated if a proper authorization signal is not provided to the transceiver (30) by a verification unit. A scanning receiver (42) decodes the pulsed signal and provides the information to a control processor (40) which, in turn, sets remote direction finding receivers (44, 46, 48) , set up in a triangulation antenna array, to the appropriate channel. The D.F. receivers (44, 46, 48) measure the bearing, signal strength and time variation, as well as the vehicle identity code, and pass it back to the control processor (40) which, after verification of the identity code, passes this positional information on to a mapping and display computer (50) at the central station (22) which, thereafter, provides a digitized street or terrain map display with the vehicle position and identity code being dynamically displayed thereon. The map may be zoomed through a hierarchical geographical display. The system (20) may be used with multiple vehicles in the same detection area with the channel being divided into a plurality of sub-channels and a composite map display dynamically showing all stolen vehicles (28) in the detection area. Mobile tracking (110, 112, 114, 116, 118, 120, 122) may al be used. In addition, the transceiver (30) can be remotely activated or deactivated, and overlapping detection areas can be provided to cover a larger area. When the transceiver (30) is initially activated, the verification code is set to an unverified state and is changed to a verified state, after confirmation of stolen status, by a command sent from the command transmitter (52) . [A3584]

"Mode 4 reply decoder"

A reply decoder (30) for declaring mode 4 replies when used with a KIR cryptograph computer (25) is described including timing logic (114) , memory (112) for storing mode 4 replies and logic circuitry for analyzing replies stored in the memory (112) . The invention further provides logic circuitry for detecting railing (117) i.e., successive replies, for detecting garbled or overlapping replies (123) , for providing a floating density value window (114, 120) for summing the replies in nonselected reply positions and for target start/stop determination (215) based on selected criteria. The invention overcomes the problem of declaring excessive mode 4 replies which over burden the subsequent reply processing in a reply processor (50) . [A3585]

"Battlefield IFF method and system for its application"

An IFF system interrogating station comprises an IFF interrogator which has its transmission antenna joined to the infra-red camera of a field observation device. Each friendly vehicle is fitted with an IFF receiver antenna and an infra-red laser transmitter transmitting a laser pulse at each IFF interrogation. [A3586]

"Single station radar ocean surface current mapper"

A method and system for mapping ocean currents with a single radar. The radar is a pulsed monostatic radar operating in the HF/VHF range using a single transmitting antenna with a wide beam width. There is a linear array of antennas, each with its own receiver/digitizer system to sample the complex signal. The summing and phasing of the signals is done in software. The correlation functions are calculated using two successive complex Fourier transforms. The current vectors are measured as a function of range and angle from the radar site, thereby generating the current map. [A3587]

"Polystatic correlating radar"

The polystatic correlating radar includes a plurality of radar receivers which receive a signal reflected from an object from one or more radar signal transmitters. Signals received from the plurality of receivers are cross correlated to provide high resolution of the angular location, range, and radial velocity measurements, as well as tangential velocity measurements for close targets. [A3588]

"Computed-interferometry radar system with coherent integration"

In a radio-frequency radar system, a radar antenna (12) irradiates a region to be monitored, and antenna elements (14a-p) arrayed irregularly about a mobile platform (10) receive the resultant echo signal, which mixers (18 and 21) translate in frequency, coherently with the transmitted signal, to a lower frequency, at which a sample-and-hold circuit (24) can sample it. A beam-forming operation is performed on the sample signals by employing coefficients that have been computed from calibration readings taken by the elements mounted on the platform. The beam signals resulting from numerous successive transmitted pulses are then integrated coherently to produce an output. [A3589]

"Traffic monitoring device"

A traffic monitoring device mounted in a moving monitoring vehicle comprises a radar device for measuring the relative speed of a vehicle to be detected with respect to the speed of the monitoring vehicle. A speedometer measures the speed of the monitoring vehicle. By means of a releasing mechanism automatically triggered at adjustable limit speeds, a camera is released and the vehicle to be detected is photographed. The relative speed of the vehicle to be detected and the speed of the monitoring device are added in summing means. The sum then corresponds to the absolute speed of the vehicle to be detected. The camera is not released dependent on the relative speed but on the absolute speed of the vehicle to be detected. Thereby, all vehicles exceeding an allowed speed are detected without taking an unnecessary number of pictures. [A3590]

"Method and apparatus for compiling and evaluating local traffic data"

A method for compiling and evaluating local traffic data based on a real time evaluation of Doppler echoes on a digital basis, wherein initially the frequency spectrum of the Doppler echo is formed, then the frequency of the maximum amplitude in this spectrum is identified, and the speed of the vehicle is determined from this frequency. The length of the vehicle can also be determined from the speed of the vehicle and from the Doppler echo signal duration. An apparatus for implementing the method includes a millimeter wavelength radar sensor, a transmission unit, and an evaluation unit operating with digital signal processing. [A3591]

"Signal transmission system and method"

A data transmission system includes a data carrier which has a memory for storing therein data including an identification code and which is attached to an object and a main apparatus having a microwave oscillator so as to conduct communications with the data carrier by use of a microwave, thereby writing data in or reading data from the memory of the data carrier. The main apparatus transmits a microwave modulated by a command or data and thereafter transmits a nonmodulated carrier for a predetermined period of time. On receiving a command, the data carrier executes a read/write operation on the memory and then generates a response. The data carrier receives the nonmodulated carrier sent from the main apparatus so as to conduct a modulation of quadrature phase-shift keying thereon by use of response data, thereby reflectively transmitting the modulated carrier with a plane of polarization shifted from a plane of polarization of the received wave by 90.degree.. [A3592]

"Servo control with self calibrating preset"

A frequency input for receiving a frequency signal and digital storing for storing the received frequency signal. A controller has a first and second input and an output. The first input is connected to the digital storage for providing a reference signal and the output provides a frequency control signal. The second input is connected to circuitry for changing the operation mode of the controller to either an amplifier or an integratory. As an amplifier, a digitally set offset and gain is applied to the amplifier for providing an output generating approximately the frequency of a prior signal. A switch connects the frequency output to the second input when operating in the integrating mode to control the output for generating a desired frequency. [A3593]

"Non-contact control"

Control means is provided for non-contact equipment such as a solenoid valve (2) controlling water flow from a faucet (6) . The control means comprises a motion detector based on strip antennae (14, 15) which transmit and receive microwave frequency electromagnetic radiation into and out of a preselected detection volume (18) . A receiving circuit (16) of the control means may be adjusted so as to vary the detection volume (18) , and is provided with a timing means (24) which insure sustained operation of the equipment even when the motion detected in the detection volume (18) is sporadic. The means finds particular application to faucets such as those used to supply water to sinks or basins. [A3594]

"Method and apparatus for measuring a vehicle's own speed by the Doppler radar principle"

A method for measuring a vehicle's own speed by the Doppler radar principle, in accordance with which microwaves of a transmission frequency are sent out by the vehicle, a part thereof being reflected back and mixed with the microwave signal at transmission frequency. In this way Doppler signals are produced which, after pulse formation, are evaluated as Doppler pulse signals by a frequency measurement in the time range plus direction-of-travel evaluation, so as to form digital Doppler signal values. for the determination of a mean Doppler period in each case, a median M (n-3) is continuously determined from a predetermined number of the last generated digital Doppler signal values of the sequence M (n-1) , M (n-2) , M (n-3) , M (n-4) , M (n-5) . [A3595]

"Method and system for real aperture radar ground mapping"

A system for real beam radar ground mapping using a monopulse antennae to determine off-boresight angle of target returns. Off-boresight angle is converted to azimuth bins. After processing, return energy for each contiguous azimuth bin of an illuminated area is dumped during a respective "look" of the antenna. [A3596]

"Method and apparatus for processing sampled data signals by utilizing preconvolved quantized vectors"

An electronic system for processing sampled data input signals includes an electronic memory which stores a set of preprocessed vectors V.sub.1 f (m, . . .) thru V.sub.N *f (m, . . .) where f (m, . . .) is a sampled data function, having any number of dimensions m, ... * is a convolution operator, and V.sub.1 thru V.sub.N are a finite set of N unprocessed vectors each of which represents an anticipated group of input signal samples. After these preprocessed vectors are stored, input signals are processed in real time by (a) a circuit which samples the input signal, (b) a circuit which compresses the sequence of samples that is taken into a smaller sequence of index signals that correspond to the indexes 1 thru N of the unprocessed vectors, (c) a circuit which receives the smaller sequence of index signals and reads from the memory those preprocessed vectors whose indexes match the received index signals, and (d) a circuit which adds together the read preprocessed vectors while maintaining a predetermined offset between them as they are added. [A3597]

"Brackish-water wire detector"

A detector of electrical wires which aer partially submerged in water and rtially extend out thereof having a means for broadcasting electromagnetic energy to the underwater portion thereof and means for receiving electromagnetic energy from the out of the water portion thereof. [A3598]

"Enhanced pulse time-of-arrival detector"

A detector for detecting a communication pulse in the presence of noise is disclosed having a transmitter for transmitting a communication pulse of carrier frequency having a main pulse portion and a pre-pulse portion, the pre-pulse portion being of substantially opposite phase to the main pulse portion, a receiver for receiving the communication pulse, a correlation signal circuit connected to the receiver for providing a correlation signal, the correlation signal having first and second slopes in response to the communication pulse, the second slope being steeper than the first slope, and a comparator connected to the correlation signal circuit for providing a pulse detection output signal when the correlation signal reaches a predetermined threshold, the threshold being set at level to detect the correlation signal at a point on the second slope. [A3599]

"Electronic proximity fuse responsive to two signals"

An electronic proximity fuse of the FM radar type having a detonating circuit with two inputs. One input is derived from a signal representing the amount by which the frequency of the received signal differs from the frequency of the transmitted signal at the instant of reception averaged over the frequency-modulation period. The second input is derived from a signal proportional to the amount of the frequency fluctuations of the frequency deviation about the averaged amount. [A3600]

"Ground probing radar method and apparatus"

A wheeled support assembly 10 is manually pushed over the ground and has a motor 22 rotating an antenna assembly 60 about a vertical axis 24. Encoders 28 on the antenna shaft 20 and on a wheel axle encode antenna angular position and position over the ground. Transmitted pulses and received data pass through a rotary microwave connector 26. for example, 400 sets of pulses are emitted at equal angular intervals in each revolution of the antenna assembly. The interval between pulses is e.g. 12 microseconds, with 256 pulses per set. Noise reduction is achieved by processing the received data accordingly. In a modification the rotary connector 26 is single channel with some electronic stages mounted on the rotating antenna assembly. Power is coupled to them via the microwave cable. An umbilical connects the assembly 10 to a support facility including a computer. Alternatively, battery power is used with data transferred radiatively. [A3601]

"Collision avoidance system for automatically controlled vehicles moving at short headways"

Safe separation distances between automatically controlled vehicles moving at short headways on a guideway are maintained through the cooperative action of a block control system and reflectometer (radar) and transponder (beacon) intervehicle distance measuring equipment installed in vehicles. A reflectometer determines distance to a leading vehicle through measurement of the delay between a transmitted signal and a received signal relayed by a transponder in the leading vehicle. A transmission line acts as the medium of transmission. Problems associated with non-transponder-equipped reflectometers are obviated. In the event of transponder malfunction, the block control system maintains backup safety regardless of transponder activity in other vehicles. Exessively short block lengths generally required for short-headway maintenance by block control systems are not required. Merge protection is effected through the cooperative action of the block control system and stationary reflectometers, installed at the wayside, which measure distances to merging vehicles through interaction with transponders located in the vehicles. [A3602]

"Single-scan editor of bird echoes"

A single-scan editor of bird echoes uses range rate to aid in identifying bird echoes. The range rate is preferably calculated from change in phase between one interpulse period to the next interpulse period and both unfiltered and MTI filtered signals are used for the calculation of change in phase. The unfiltered phase difference is used if the logarithm of the total power of the phase difference exceeds a predetermined threshold during at least one of the interpulse periods and if not, the MTI filtered phase difference is used if the total power of the MTI filtered signal exceeds a corresponding predetermined threshold. If neither threshold exceeds the corresponding threshold, no calculation is made. Due to the relationship between phase difference and range rate, several possible range rates correspond to most phase differences. Therefore, an occurrence of each of the possible range rates is counted over the course of a cycle. The cycle covered is shifted one interpulse period at a time and the largest number of occurrences of sets of range rates for all such cycles are stored during the detection of a target. These largest number of occurrences are totaled to produce a total count which is used to produce a ratio of the largest number of occurrence of each of the sets of range rates to the total count. These ratios are individually compared with a threshold. If the threshold is exceeded an indication is produced that the target has a range rate within the set of range rates corresponding to bird speeds. In this case, the radar target data is edited to prevent display. [A3603]

"Non-contact vital signs monitor"

An apparatus for measuring simultaneous physiological parameters such as heart rate and respiration without physically connecting electrodes or other sensors to the body. A beam of frequency modulated continuous wave radio frequency energy is directed towards the body of a subject. The reflected signal contains phase information representing the movement of the surface of the body, from which respiration and heartbeat information can be obtained. The reflected phase modulated energy is received and demodulated by the apparatus using synchronous quadrature detection. The quadrature signals so obtained are then signal processed to obtain the heartbeat and respiratory information of interest. [A3604]

"Inductive input/output coupling for a surface acoustic wave device"

A transponder for use in an interrogator/transponder system includes a piezoelectric substrate for coupling electrical energy into and/or out of a surface acoustic wave (SAW) device, a first inductive loop inductively coupled to a conductive loop on the substrate, a second inductive loop inductively coupled to the first inductive loop for transmitting and/or receiving electrical signals to and/or from the SAW device. The first inductive loop forms an intermediate inductive coupling path between the second inductive loop of the transmitter/receiver and the conductive loop on the substrate. [A3605]

"Apparatus for detecting materials buried under the ground"

If electromagnetic waves are emitted from a plurality of points on the ground surface above a material (TG) buried under the ground, an echo image (EP) formed from the data of propagation times of reflected waves at each of the points describes a hyperbola as a result of expansion of the transmitted electromagnetic waves. An operation is carried out to overlap on the echo image (EP) a false echo image (DM) which lies on the same coordinate system and which consists of a similar hyperbolic image. If the two echo images (DM, EP) are overlapped upon each other as the result, the vertex position and the expansion of the opening of the echo image (EP) can be determined from the data of the false echo image (DM) . The propagation velocity of electromagnetic waves under the ground is then calculated from the data that represents the vertex position and the expansion of the opening. After the propagation velocity of the electromagnetic waves are calculated, the position of the material (TG) under the ground is then calculated in relation to the data of propagation time at any position. [A3606]

"ATCRBS/SIF/TCAS reply decoder"

A decoder for separating pulse code modulated messages of the type used in ATCRBS where the messages are identified by two framing pulses separated by 20.3 us. and contain information pulses between the framing pulses separated from the framing pulses and from one another by 1.45 us. The decoder receives an input stream of pulses of uniform width from a Leading Edge Detector which has created the stream from video pulses received from the transmitter of another station. The decoder input pulse stream may contain interleaved pulses from more than one message. The decoder includes an input shift register, an analysis shift register, a plurality of buffer storage devices and additional registers to which selected pulses are fed from the input register for use in determining whether a received message is clear of interfering pulses or whether the message is potentially or actually garbled. The input pulse stream is passed through the input register into the analysis register where the framing pulses enable the loading into buffer storage of the information pulses associated with the framing pulses. Pulses in the analysis register at the time a message is loaded into buffer storage and not included in the message loaded may be included in a message later loaded in a second retained in buffer storage with messages currently being loaded into messages. [A3607]

"Signal-transmission type production supervising system including IC card and wireless type interface unit"

In a production supervising system of a work, a wireless type production supervising data processing apparatus is mounted on the work. The wireless type production supervising data processing apparatus includes a wireless type interface unit, and an IC card. The IC card includes CPU, EEPROM for storing the production supervising data, ROM for storing the program data, and RAM capable of storing other data than the production supervising data. The wireless type interface unit includes antennas, a receiver, a transmitter, a demodulator connected to the receiver, and a modulator connected to the transmitter. During the production of the work, the production supervising data previously stored in EEPROM are read from the IC card and processed in the interface unit and thereafter transmitted from the interface unit toward the external data controlling apparatus. [A3608]

"Radar receiving device and radar including such a device"

Radar apparatus for processing a received signal having a carrier frequency f.sub.0 includes means for directing the received signal in parallel into first and second channels. A first filter in the first channel bandpass filters the received signal and is centered at a frequency f.sub.1 equal to f.sub.0 +.DELTA..sub.1 f. The first filter provides an output signal having a central frequency f.sub.0 +.DELTA..sub.1 f/2. A second filter coupled in the second channel bandpass filters the received signal and is centered at f.sub.2 =f.sub.0 +.DELTA..sub.2 f. The second filter thus provides an output signal having a central frequency f.sub.0 +.DELTA..sub.2 f/2. A first mixer in the first channel mixes the first filter output with a signal f.sub.1 =f.sub.0 +.DELTA..sub.1 f/2 to extract the carrier frequency of the first channel. Likewise, a second mixer in the second channel mixes the second filter output signal with a signal f.sub.2 =f.sub.0 +.DELTA..sub.2 f/2 to also extract the carrier frequency in the second channel. The ouputs of both mixers are then passed to a processing and exploitation device to manipulate the signals to arrive at the appropriate range and/or velocity information. [A3609]

"Geophysical radar apparatus and method"

A ground probing radar is described for detecting radar reflections from underground objects. The radar is of the pulse compression type. A transmitter generates a biph Government Support The U.S. Government has rights to this invention pursuant to Contract No. 536115 (DACA 89-81-K-0004) awarded by U.S. the Army Cold Regions Research and Engineering Laboratory. [A3610]

"Method of detecting oil spills at sea using a shipborne navigational radar"

A method is provided wherein standard shipborne navigational radar is used for the purpose of detecting oil-spills on the sea. A homogenous sea-return image is obtained by selectively reducing the sea-clutter, rain, and haze filters of the radar while selectively increasing the gain of the radar. Because oil-spills on the surface of the water minimize the backscatter of radar waves, the location of an oil-spill may be determined by identifying characteristic distortions in the form of zones of diminished sea-return in the homogenous sea-return image. A moving oil spill may be tracked with repeated observations. [A3611]

"Automatic parking device for automobile"

A device to be mounted on a car for assisting a driver to make a parallel parking or a perpendicular parking, comprises displacement-sensing devices to measure specific distance that the car moves, obstacle-sensing devices for sensing the position of obstacles around a car, and a microcomputer that can, in accordance with the driver's instructions and the data received from aforesaid displacement-sensing devices and obstacle-sensing devices, generate various signals to tell the driver to drive the car forwards, to stop the car, to turn the car left or right, or to back the car so as to park the car along a specific path, further more, the microcomputer may generate an output signal to control the steering mechanism the transmission, the accelerator, and the brake system for backing the car into a parking space automatically. [A3612]

"Apparatus and method for transform space scanning imaging"

An image of a target (11) is produced by illumination of the target (11) with overlapping fields (18, 20) of wave energy, such as coherent light, producing an interference pattern (22) moving across the target. At least one pair (12) of sources (14, 16) wave energy provide the moving interference pattern (22) . The scattered illumination reflected from the target is detected by a non-imaging receiver (24) , a two dimensional spatial frequency map is recorded (30, 62) , based upon the amplitude, frequency and phase of the illumination received, and a two dimensional image of the target is formed (32, 72) by applying a Fourier transform to the two dimensional frequency map. [A3613]

"Collision predicting and avoidance device for moving vehicles"

Apparatus for avoiding collision between a vehicle and an object that moves in a trajectory relative to the vehicle. The apparatus includes at least one microwave pulsed transmitter and receiver for transmitting a scanning beam of pulsed energy which scans a sector of space, at least forward of the vehicle, a check for producing timing pulses, a ranging device connected to the clock and the receiver for measuring the time difference between the transmitted pulses and any echoes received by the receiver. The antenna is pivotally coupled to the vehicle and a scanning motor serves to set the antenna in a scanning motion. A direction device is coupled to the scanning antenna for sensing the direction of the antenna. A computer is connected to ranging device, the clock, the direction device and computes continuously the last three coordinated for vector to the object, and is connected to an anunciator which can speak and/or display a message to the vehicle operator. [A3614]

"Navigation, communication, and surveillance system based on DME"

The distance measuring Equipment (DME) is a well-approved means for short nge navigation in international civil aviation. It utilizes the inherent capacity of the system in most applications to a relatively small degree. Therefore, additional functions can be integrated into the system such as data links, ground derived slant range measurement equipment and direction finders (growth potential) . Thus, the DME can be extended to an Integrated Navigation, Communication, and Surveillance System. This system may be superior by technical, as well as by economical and operational reasons, to conventional solutions, which use separate systems for the different functions. The integrated system can be composed in different ways using different sets of the DME growth elements. A promising set is described and applied to a scenario of helicopter operations with oil rigs. [A3615]

"Secondary radar transponder"

A secondary radar transponder on a mobile target has an antenna arrangement which can receive interrogation signals from all directions and radiate reply signals. The antenna arrangement includes several individual antennas, each of which, with its primary lobe, covers a specific sector of the entire 360.degree. range and is connected to a receiver, so that through receiving level comparison, that particular sector from which the interrogation signal incides can be ascertained. The reply signal is then radiated only by the individual antenna covering that particular sector. The transponder is particularly suited for identification friend-foe (IFF) purposes. [A3616]

"Process for range measurement with a pulse radar of high pulse repetition frequency"

With a frequency-agile pulsed doppler radar with high pulse repetition frequency (HPRF) in the unambiguous velocity region, in order to measure the range of a target the complex time signal derived from the echo signals of a coherent processing interval (CPI) is transformed into the frequency domain, the transformed spectrum is multiplied by a bandpass function with a mean frequency coinciding with the doppler frequency of the target, and the product is transformed back into a time signal. The real envelope of this re-transformed time signal displays a definite leading edge and a steady state region, from which the echo travel time can be estimated. Particular advantages may be derived for the pulsed doppler radar set from a plurality of frequency agile transmitter/receivers operated at the same time at different frequencies, and whose frequency switching times are time-staggered. [A3617]

"Radar system for headway control of a vehicle"

A radar system for monitoring the headway control distance between a vehicle equipped with a radar system of the present invention and a fixed or moving object of immediate concern in front thereof. The system employs an antenna positioned in front of the vehicle, transmitter and receiver circuits and signal processing circuits. A transmitted signal from the transmitter circuit when reflected back from an object of immediate concern is received by the receiver circuit and fed into conditioning circuits which separate the received signal into controlling signals that include the range or distance (R) to a detected object of concern, the closing rate (CR) to that object and the vehicle speed of movement (VS) . Driving condition modifiers (.+-.DM) such as traffic conditions and weather conditions, the level of which are manually chosen by the operator of the vehicle are combined with the received signals to constantly provide changing signals to dynamically determine a hazard level (HZL) which is compared to a preset reference level to 2 according to the mathematical formula or algorithm HZL=R+CR+VS.+-.DM. The DMs, which combined collectively with define or replicate the operator's perceived safe drive conditions. [A3618]

"Intensity area correlation addition to terrain radiometric area correlation"

A system which combines intensity area correlation is disclosed for use with terrain height radar and infrared emissivity systems to give a simultaneous three-mode map matching navigation system. The infrared system senses passive terrain emissions while the height finding radar measures the time between transmission of a radar signal to the ground and receipt of a radar return. The intensity correlator uses the radar returns to sense changes in the reflection coefficient of the terrain. Map matching all three modes simulanteously provides an accurate, highly jam resistant position determination for navigation update. [A3619]

"Sonar doppler system with a digital adaptive filter"

A doppler sonar speed measuring system incorporating a digital adaptive filter responsive to the difference in newly received raw speed data and previously received speed data to determine the amount and sign of change of the previously received data. The allowable amount of change increases to a maximum allowed value if the sign of the change remains the same on successive received data as under acceleration conditions and reduces to a minimum value when the sign changes on successive received data. [A3620]

"Adaptive MTI target preservation"

A method of preserving targets in the clear in an adaptive baseband MTI radar system with pulse compression is disclosed. The angle of the weighting signal is determined from the inverse tangent of the inphase and quadrature components of the weighting signal. This angle is then compared to a threshold angle in order to generate a modified weighting signal. [A3621]

"Interrogator-responder communication system"

An interrogator-responder communication system in which responders are carried by vehicles (such as railroad vehicles) travelling along a route and in which an interrogating station situated along the route operates each passing responder to recall data from a memory in the passing responder. In one embodiment, the responder is equipped to receive data transmitted from a transmit station and to store the received data, for later recall, in a non-volatile, electrically erasable read/write memory. [A3622]

"Apparatus for locating and/or tracking stolen or missing vehicles and the like"

An improved vehicle or other object-tracking and location system, preferably, though not essentially, of national scope, wherein transponder or transceiver-equipped stolen or missing vehicles or other objects may be located and/or tracked, as by appropriately-equipped police direction-finding tracking vehicles, through homing-in on periodic transponder reply radio transmissions automatically activated by command activation signals broadcast on the same carrier frequency as the transponder reply signals and with encoded vehicle identification information that causes the intended vehicle transponder so to reply, and with provision for modifying the command signals to require an increased rate of periodic transponder reply signal transmission to assist homing-in on the selected vehicle. In a preferred mode of operation, the verification of whether the reportedly missing vehicle is thus transponder-equipped is preferably established by querying the FBI-NCIC computer system, which will provide the said coded vehicle identification information and automatically cause the appropriate sector or area to broadcast said command activation signals. [A3623]

"Communication system for radar ground systems"

A first plurality of spaced radar ground systems and a second plurality of radar ground systems positioned in between adjacent pairs of the first systems. The first systems, when employed in an early warning radar chain, preferably have antennas which are mechanically rotatable. The second systems are then provided with phased arrays to enable two-way communication without it being necessary to stop any scanning movement of a corresponding first system antenna. [A3624]

"Traffic light control system and method"

Preferred embodiments include a radar traffic light control system with a transmitter/receiver module including an array (103) of interconnected microstrip patch antennas (38) which also act as the resonators for oscillators powered by IMPATT diodes (34, 36) , varactors (158) on the interconnections permit beam steering for scanning roadways. [A3625]

"Distance measuring device"

A distance measuring device transmits a continuous alternating wave from a wave source to a target which reflects it back toward the device. The wave source is activated until such time that a detector associated with the device senses the beginning of the reflected wave at which time the wave source is deactivated. The wave source is deactivated during the time that the reflected wave is sensed by the detector and upon the sensing of the end of the reflected wave, the wave source is again activated. The frequency at which the wave source is alternately activated and deactivated is a measure of the distance between the measuring device and the target. [A3626]

"Radar type underground searching apparatus"

This radar type underground searching apparatus is a system for detecting the presence and location of buried objects such as gas pipes buried in the ground. This apparatus includes a pulse generating unit which periodically generates pulse, and a transmitting antenna through which the pulse is sent into the ground. Pulses reflected from an object in the ground and reaching the ground surface are detected by a receiving antenna, and a reflected wave corresponding to each pulse wave received by the receiving antenna is amplified in a radio-frequency amplifier where in the amplification is increasing each time a group of pulses are transmitted. By sampling the output of the radio-frequency amplifier with a sampler at a series of reflex time, each being succeedingly delayed by a fixed period from the transmitting timing of each pulse wave, as the reference, a low-frequency signal which is formed by extending one reflected wave in time base is obtained, and the waveform thereof is displayed on a waveform display unit. On the screen of the display unit, the presence of objects will be detected by the presence of peaks in the low-frequency signal caused by the reflection from the objects and the depths of the objects will be detected by the time at which the peaks appear on the screen. By this construction, the attenuation of radio waves in the ground can be compensated without arising waveform distortion. [A3627]

"Marine transponder system"

A marine transponder system which is selectively activated to produce a predetermined signal pattern of light/sound/radio transmissions for maritime devices and structures such as navigational aids, mooring, docking or slip facilities and/or EPIRBs and other emergency signalling devices. A remote transmitter is used to broadcast an uncoded or coded signal at a predetermined frequency to activate the marine transponder system. The transponder system includes an RF receiver tuned to the predetermined frequency, and optionally a decoder unit for verifying the coded signal. Upon receipt of the transmitted frequency signal, the transponder system causes an omni-directional light/sound/radio source to be energized to produce the predetermined signal pattern. The marine transponder system may be an add-on adapted for integration with existing navigational buoys, a standalone buoy, a package configured for mounting on a dock, pier or boat, or a package adapted to be mounted on a life vest/preserver. This system permits quick and positive user identification and location of a desired, unknown locus and avoids continuous power usage. [A3628]

"Object detection and location system"

A millimeter wave object detection and location system is disclosed comprising a source generating a millimeter wave signal which is divided into an illumination beam, directed onto a field of view, and a local oscillator portion, mixed with radiation reflected from objects in the field of view. The mixing is performed in a staring array of mixer/detector elements which need not be mechanically or electronically scanned to generate signals responsive to the entire field of view. The detected signal from each element is directly responsive to a portion of the field of view. The oscillator signal is preferably linearly polarized, and a polarizing grid is used to separate the local oscillator signal and illumination beam and direct them in a simple and efficient manner. A twist reflector may also be used to rotate the polarization of a portion of the beam to direct it onto the mixer/detector array for mixing with the received signal from the field of view. Improved constructions of millimeter wave source and mixer/detector elements are also disclosed, which greatly simplify construction of the device. [A3629]

"Microwave plate antenna in particular for Doppler radar"

The antenna constituted by a plurality of identical parallel and symmetrical linear sub-networks (a7, a6, . . . a1, a'1, a'2, . . ., a'7) . The centres of symmetry (b7, b.notident.b, . . ., b1, b'1, b'2 . . ., b'7) of the sub-networks (a7 to a'7) are aligned on a line (c) perpendicular to their diameter and are fed in phase. Each sub-network is constituted by a plurality of radiating elements in even numbers disposed at regular intervals and which radiate from fields displaced from 180.degree. from one radiating element to the following. The pitch of the sub-network is approximately equal to a wave-length guided on the substrate of the printed circuit. Each radiating element is a conducting square surface the side of which is approximately equal to half the guided wavelength with one corner connected galvanically to the feed line. The direction of the surfaces change from one element to the following element. [A3630]

"Method and apparatus for determining the position of a vehicle"

There is provided a system in which a transponder is carried by each vehicle traveling on or above the earth's surface which transmits a signal which is responsive to an interrogation signal to a ground station through two or more satellites and in the ground station, the position of the vehicle is determined from the propagation time differences of the response signals received via the satellites. In this system, the information indicative of the time lag which is required for the transponder to receive the interrogation signal and to transmit the response signal responsive to the interrogation signal is included in the response signal and then such response signal is transmitted. Thus, the time lag which is peculiar to each transponder and corresponds to the time required from the reception of the interrogation signal to the transmission of the response signal can be corrected. With this system, the positioning accuracy of each vehicle can be improved. [A3631]

"Communication receiver"

Disclosed is a communication receiver for use in a burst communication system. A typical system is composed of a transponder and an interrogator. The transponder receiver and interrogator receiver operate in an asynchronous communication mode. The incoming coded signal is down converted to an i.f. frequency compatible with surface acoustic wave (SAW) convolvers. The i.f. signal is then divided between two SAW convolvers, each having a convolution interval of two times the message symbol length (2T) . Reference signals having a bit length of T provided to each of the two convolvers are time reversed to the coded spread sequences and applied to each of the convolvers at a 50% duty cycle. Each of the convolver outputs are processed through log video detection circuits to reduce the dynamic range followed by peak detecting and stretching to reduce the pulse bandwidth. The outputs from each peak detection and stretching circuitry are coupled to a sample-and-hold circuit which are in turn divided such that one path is to synchronization and interrogation sidelobe suppression (also referred to as sidelobe inhibit, ISLI or control signal) matched filters designed to look for the particular symbol sequences between the two convolver channels characteristic of the preamble and ISLI signals. The synchronization signal and the sidelobe suppression signal are used in order to determine if valid synchronization has been detected by the receiver and if the receiver is in a desired portion of the interrogator radiation pattern, if so, then a timing or address signal clocks into a memory the remaining portion of the message which contains the data. [A3632]

"Pulse radar method and apparatus for detecting an object"

An object detection method and apparatus in which, in order to distinguish only an echo wave which is returned back from an object of interest, such as an underground buried object, from those echo waves returned back from another object of objects, the observation signal is divided (an electromagnetic wave as an echo wave) into portions, and the signal portion is converted into a corresponding frequency region to evaluate that spectral distribution and computes frequency parameter values from the spectrum distribution. The object of interest is detected by comparing the reference data of various fields with the parameters of the object of interest, extracting only an echo wave returned back from the object of interest and displaying a corresponding image. [A3633]

"Fish school detecting method or apparatus"

A fish school detecting method or apparatus radiates radio search signals with their carrier frequency in the S-band frequency range, successively in different azimuthal directions through a wide angular range, receives echo signals, and displays the echo signals on the screen of an indicator in such a manner that the echo signal reflected by a bird is clearly distinguished from the other objects, thereby locating the bird and detecting a fish school under the bird. [A3634]

"Radar navigation system"

A low cost electronic navigation system including a Loran receiver and a marine radar unit adapted to receive vessel position information from the Loran. A computer within the radar unit uses successive Loran outputs to display vessel heading and the bearing of objects of interest such as other vessels or waypoints in graphic and numeric form. The navigator may accurately determine the bearing of such objects of interest in magnetic or true form. Other modes are of particular use when the navigator is interested in using the system to maintain a desired course, to avoid obstacles, or to determine if and by how much he must change his present course to return to the desired course. [A3635]

"Vehicle diplex doppler near-obstacle detection system"

A vehicle near-obstacle detector in the form of a diplex Doppler radar system provides range information between a vehicle and an object based on the phase shift between a pair of Doppler signals derived from two transmitted radar signals at slightly different frequencies. A speed dependent error introduced by the time constant of a filter circuit converting duty cycle range information based on the phase shift to an analog signal is compensated by introducing a small time shift in the signal path of one of the Doppler signals to effect a shift in the duty cycle range information. [A3636]

"Signal discrimination system"

The invention provides a system for discriminating between modulated backscattered signals based upon transmission-to-reception time delay. The system employs a carrier, phase-modulated with a modulating signal, having characteristics which provide unity output when correlated with itself with zero time shift and a substantially lower output level when correlated with itself with a significant time shift. The system works with a backscatter-modulator located a finite distance from the transmitter for receiving and modulating the backscatter of the carrier. A receiver/detector receives and detects the modulated backscattered phase-modulated signal, the detector being phase-sensitive and having as a reference signal the transmitted phase-modulating carrier signal, and having as an input signal the phase modulated backscattered carrier. The detector provides an output signal whose averaged amplitude is substantially dependent upon the degree of phase correlation between the phase of the modulation returned input signal and the reference signal. Finally, the output signal from the detector is selectively processed only when its averaged amplitude is above a threshold level. In a preferred embodiment, the transmitted signal is a spread spectrum signal. [A3637]

"Method and apparatus for monitoring ice masses"

A method and apparatus is disclosed for monitoring ice masses wherein a signal transmitter is attached to an ice mass and receivers are used to detect the location of the transmitter. [A3638]

"Blind speed elimination for dual displaced phase center antenna radar processor mounted on a moving platform"

A radar system mounted on a moving vehicle uses a displaced phase center antenna (DPCA) and associated processing for taking the difference between the two signals received by the displaced antennas to provide moving target indication (MTI) by cancellation of the returns from stationary targets. The presence of moving targets is identified by threshold processing within discrete frequency bands. DPCA processing ordinarily results in amplitude nulls or "blind speeds" for targets moving at particular radial velocities. According to the invention, the two signals received by the displaced antennas are summed, weighted and divided into frequency bands which extend through the expected null region in a form of Doppler processing. Threshold processing is performed on DPCA processed signals within certain frequency bands outside of the null regions and on Doppler processed signals within other frequency bands, thereby substantially eliminating the blind speeds. [A3639]

"Method for locating a radio frequency emitter"

A radio frequency emitter transmits pulses in a regular swept beam pattern. As a result of this regular pattern, the angles of transmission of the pulses can be inferred. Intervisibility data of terrain points in a region around an observation point are stored in computer memory. At the observation point, measurements are made of the times of arrival of a plurality of terrain point reflections of a single pulse transmitted by the emitter. These measurements are repeated for a plurality of pulses transmitted by the emitter. In a computer, a comparison is made of the terrain points of reflection calculated from the measured times of arrival for assumed emitter locations with the stored intervisibility data of terrain points. [A3640]

"Aperture radar"

An improved radar is disclosed wherein an array of digital numbers describing a target area is produced. The numbers have values representing differences in ranges between the radar and reflecting points in an area on the ground illuminated by the radar. The values also represent the differences in angles between the radar and the reflecting points. [A3641]

"Radar arrangement"

A radar arrangement which is particularly useful for the terrain following radar of an aircraft avoids disturbances from rain echoes by utilizing an antenna arrangement with a transmitting/receving directional antenna which is circularly polarized. A supplementary receiving antenna of orthogonally-circularly polarized type is used in conjunction with the directional antenna. From a comparison of the signal level distinctions is made between a target and a rain echo. The rain echo can thus be suppressed to give a truer target signal. [A3642]

"Ridge regression signal processing for position-fix navigation systems"

A position estimator for determining the position and velocity of a moving platform in cooperation with radio navigation aids is described incorporating an unbiased estimator, such as a least means square estimator, a biased estimator for determining the angle of inner section of the lines of position from the radio naviation aids for determining the liklihood of geometric dilution of precision (GDOP) and a switch for selecting the estimate of position and velocity from said biased estimator at first times and the unbiased estimator at second times. The invention overcomes the problem of accuracy degredation associated with a nearly collinear measurement geometry which causes the variance of the position estimates to be higly inflated. [A3643]

"M.T.I. radar system"

A moving target indication (MTI) radar which includes TACCAR circuitry or similar means for shifting the frequency of the transmitter/local oscillator, includes a main directional antenna, and subordinate antenna elements for detecting returns from sidelobe directions. The signals from the subordinate antenna elements are modulated, and modulated return pulses are identified and employed to eliminate false pseudo moving target signals which would otherwise be received from the side lobes of the main antenna. [A3644]

"Combined radar and data link"

A first plurality of spaced radar ground systems and a second plurality of radar ground systems positioned in between adjacent pairs of the first systems. The first systems, when employed in an early warning radar chain, preferably have antennas which are mechanically rotatable. The second systems are then provided with phased arrays to enable two-way communication without it being necessary to stop any scanning movement of a corresponding first system antenna. [A3645]

"Traffic monitoring device"

With a traffic monitoring device for photographic recording of vehicles exceeding a predetermined speed, the speed of the approaching traffic is measured substantially against the travelling direction. The vehicles (12) are photographed frontally when they exceed the predetermined speed. Two speed measurements are effected: A first measuring value is obtained in a relatively short part of the available measuring section (22) on the entrance side and serves to release a camera (18) . A second measuring value evaluates all speed measuring values occuring in the measuring section (22) , in which the vehicle (12) is detected by the radar beam (20) . This second measuring value is recorded. [A3646]

"Driver alerting device"

A driver alerting device includes a transceiver adapted for mounting at the rearward end of a vehicle for directing its wave output rearwardly of the vehicle. Return wave signals for many objects within the transceiver range are picked up and supplied to the transceiver by an antenna. Any resultant doppler shift signal is amplified for driving an audio alarm adapted for placement within the passenger compartment of the vehicle. The doppler shift signal also activates a solenoid which applies the air brakes of the vehicle. The circuit is adapted for operative electrical connection to the vehicle transmission or the like for activation only when the vehicle transmission is engaged in reverse gear. [A3647]

"Rapid signal validity checking apparatus"

This invention relates to an improved signal reader for reading signals from transponders placed on moveable objects such as ship containers, automobiles or railroad cars. The reader sends out a continuous signal, which is modified by the information contained in the transponder attached to the moveable object. Multiple antennas, each of which receive separate signals, may be multiplexed at the reader. The improved circuit of the invention provides quick recognition of the receipt of a valid signal from a transponder or, in the alternative, the absence of such a valid signal. [A3648]

"Item identification tag for rapid inventory data acquisition system"

A computerized transceiver repeatedly sweeps through a set of transmit/receive frequencies to interrogate collectively a plurality of groups of items in a stocking area. Items in each group are tagged with a printed circuit transponder tuned to frequencies uniquely assigned to each group. Data returned is stored and combined mathematically by the computer to arrive at the total number of items in each group. The system is particularly adapted for taking inventory of a large number of retail shelf goods using a mobile transceiver. [A3649]

"Communication adaptive multi-sensor system"

A multi-sensor system adaptively utilizes communications or data bus facilities for multi-sensor signal fusion. for each source of sensor signals, a local signal processor compares each signal against a pre-determined set of hypotheses, and generates a ranking value corresponding to each hypothesis. An adaptive interface unit then selects the highest ranking values and transmits them, together with an identification of the hypothesis to which they correspond, through the multi-sensor system communication network or data bus, to the system signal processor. The system signal processor then multiplies the ranking from the various sensors, or adds their logarithms and selects the hypothesis whose product (or logarithmic sum) is greatest. This provides for transmission of the highest ranking hypothesis, or of a selection of hypotheses, to identify the target detected by multiple snsors. [A3650]

"Single chip transponder device"

A transponder device receives a carrier signal from an interrogator unit. This carrier signal, of frequeny F, is rectified by a rectifying circuit in order to generate operating power. Logic/timing circuits derive a clock signal and second carrier signal of frequency F/n from the received carrier signal. This clock signal reads a unique identifying data word from a programmable read only memory (PROM) . The data word is encoded and mixed with the carrier signal in a balanced modulator circuit. The output of the balanced modulator is transmitted to the interrogator unit where it is decoded and used as an identifying signal. The identifying signal identifies the particular transponder device from which it originated. The rectifier and balanced modulator circuits are realized from the same diode elements. All electrical circuits of the transponder device are realized on the same monolithic semiconductor chip. In one embodiment, an antenna receiving/transmitting coil is also part of the chip, being placed around the periphery thereof. In alternative embodiments, various hybrid elements may be connected to the monolithic elements in order to realize additional functions, such as adjustable tuning of the receiving circuit, independent crystal frequency control, and battery-powered operation. [A3651]

"Method and system for locating and correcting the orientation of an autonomous mobile object and a non-autonomous mobile object"

In a method of locating and orienting a first direction linked to the position and to the orientation of an autonomous first mobile object (M) , such as a ship towing a marine geophysical prospecting cable, and a second direction formed by a non-autonomous second mobile object (Bj) , such as a buoy at the trailing end of the towed cable, and at least one reference point on the first mobile object relative to a fixed reference radionavigation system comprising at least two reference beacons (Si, Si+1) the first mobile object (M) and the second mobile object (Bj) are respectively provided with a first communication device (MI) providing communications between the first mobile object (M) and the reference beacons (Si, Si+1) and a second communication device (MJ) providing communications between the first mobile object (M) and the second mobile object (Bj) . They are further provided with a communication device (BIJ) providing communications between each reference beacon (Si, Si+1) and the second mobile object (Bj) . Firstly, the position of the first mobile object (M) relative to the reference radionavigation system and the orientation of the first direction relative to the first mobile object (M) are determined. Then the position of the second mobile object (Bj) relative to the reference radionavigation system is determined. Finally, the angular offset between the first and second directions is determined, with a view to correcting the orientation of the first direction relative to the second direction. [A3652]

"Three-dimensional electro-optical tracker"

Improved performance in an electro-optical tracker is achieved by incorporating range measurements. Further, the tracker uses a Kalman filter in which the target is modeled as the superposition of two Gaussian ellipsoids in space and projected onto an image plane. [A3653]

"Antenna position tracking apparatus and methods"

Apparatus and methods for tracking a positioning system for antennas and other devices. Hardware of the invention contains circuitry which when given velocity information, changes its output position information at a specified rate. The hardware may also be triggered to capture a sample of such output position information to provide feedback to the firmware of the invention, which implements a position tracking algorithm. The algorithm utilizes two consecutive input position samples, the time between those samples and the feedback information corresponding to the last position input sample to calculate the velocity to be applied to the position tracking hardware until a new position input sample is available. When the new sample is available, a new velocity is calculated and applied to the hardware and the process is repeated. Between position input samples, the hardware updates the output position to correspond to the motion of the positioning system. The invention minimizes group delay and allows for more convenient sampling from a remote positioner. [A3654]

"Method for measuring the distance and/or the relative velocity between two objects"

A method of measuring the distance between two objects and/or the speed of one object in relation to the other, the objects incorporating respectively a transmitter-receiver unit and a transponder or reflector, in which method a phase comparison is made between a signal transmitted by the transmitter-receiver unit and a signal received in the transmitter-receiver unit and transmitted from the transponder or reflector. In accordance with the invention the transmitter-receiver unit is caused to transmit signals of microwave frequency, preferably about 2450 MHz, this transmission comprising the transmission of a first signal having a first frequency, the transmission of at least one second signal having a higher or lower frequency, and the transmission of a third signal having the same frequency as the first mentioned signal, wherewith the phase differences .phi. between the transmitted signals are formed, these phase differences corresponding to the distance between the transmitter-receiver unit and the transponder. [A3655]

"Surface acoustic wave doppler detector"

A surface acoustic wave (SAW) radar doppler shift detection system is provided by transmitting a modulation signal having an up-chirp component followed by a downchirp component from a dispersive array SAW assembly to a target, and then receiving the radar return from the target by a receiver which also employs a similar dispersive array assembly. Dispersive array assemblies are constructed with two in line dispersive arrays. The dispersive arrays of the transmitter is positioned relative to two input SAW transducers and two output SAW transducers such that a pulse signal supplied to the two input transducers results in an expanded signal of the output transducers. The expanded signal acts as a modulation signal which is multiplied by an RF and transmitted. The receiving array assembly detects the radar return signal, and, after it is multiplied down to the SAW frequency, compresses it. When the target is stationary relative to the transmitter and receiver platform, a single envelope will be detected which indicates that no doppler shift has occurred. When there is relative motion between the target and the platform, the spacing between two detected envelopes, and their relative shifts, is measured and utilized to provide an indication of the magnitude and direction of the doppler shift. The transducers of the array assembly are formed of hyperbolically shaped fingers to provide a wideband range of frequencies. [A3656]

"Coherent pulse radars"

A coherent pulse radar is activated successively according to at least two pulse repetition frequencies. These frequencies are of values such that (a) the received signal is ambiguous both with regard to distance and with regard to velocity, and (b) their ratio is reducible to the quotient of two integers which are preferably adjacent and have no common factors. for the frequency analysis, a number of samples is taken which depends upon the pulse repetition frequency, the numbers of samples associated with the two pulse repetition frequencies being, in relation to one another, in the ratio of the two integers. The distance/velocity resolution cell is then invariant with respect to the pulse repetition frequency, this permits removal of the ambiguity concerning mean information items appertaining to a long integration time. [A3657]

"Antenna system"

A side-looking array antenna system is disclosed in which the inclination angle of the antenna main beam is determined depending on the intervals of a plurality of antenna elements forming an array. A switch is provided to selectively connect one of the ports of an antenna feeder to a signal source or the like. The switch is used to select one of the ports of the antenna feeder as an excitation port, thereby reversing the direction of inclination of the antenna main beam. The antenna main beam can thus be directed in either of the two directions by the operation of the switch. Also, by using this antenna system, a Doppler radar vehicle speedometer with small calculation error, automotive radar and the like may be simply configured. [A3658]

"Tracking radar system"

In a tracking radar system target glint and multipath sometimes produce signals which falsely indicate high acceleration rates of the target. These signals cause the boresight of the antenna to be driven away from the direction in which the target actually lies. To avoid this problem, received signals from a receiver are fed through a switch which is opened whenever the target appears to have an acceleration or velocity above a threshold value. The threshold value is varied so that the proportion of the time during which the switch is open is kept approximately constant. Thus, if there is a period during which a large number of high acceleration or high velocity signals appear from the receiver (for example is there is a very high noise level) the switch still remains closed for a certain proportion of the time period. This ensures that the tracking system never loses the target while also ensuring that false tracking due to target glint and multipath is minimized. A circuit is included so that, when the switch is open the antenna is not brought to a complete halt but rather is allowed to continue to move in the direction that it was moving before the switch was operated. [A3659]

"Method of imaging an object by ultrasonic or electromagnetic waves"

A method of imaging an object by the ultrasonic or electromagnetic wave by mechanically or electronically scanning the ultrasonic or electromagnetic wave transmitting/receiving system to transmit the ultrasonic or electromagnetic wave beam spreading in space of the object and using the trace (TOF locus) from the transmission to the reception while receiving the reflected wave from the object, and sequentially reproducing the line image at the central line of the synthetic aperture range using the received signal group from the scanning points in the synthetic aperture range to sequentially image the area to be imaged while scanning the ultrasonic or electromagnetic wave transmitting/receiving system. An imaging apparatus applied with the method has a relatively simple hardware structure for reproducing the image and is also able to perform the operation in real time. [A3660]

"System for detecting underground objects"

A system for detecting underground objects which uses reflected wave profile data collected for obtaining a detected image output and subjects the data to a sequence of synthetic aperture processing, in which set values of the dielectric constant are successively varied, and obtains the actual dielectric constant of the soil in which the targets are buried by evaluating the results of the synthetic aperture processing, whereby the need for special data collecting work only for obtaining the actual dielectric constant is eliminated. [A3661]

"Doppler radar method and apparatus for measuring a projectile's muzzle velocity"

A muzzle velocity chronograph method and apparatus for providing an accurate and precise measurement of the muzzle velocity of a projectile ejected from a gun. A conventional radar Doppler signal is sampled and digitized and arranged in a succession of groups, each group representing a separate time period. A fast-Fourier transform is then computed for each group of samples, and peak frequency measurements in the transformed data are tracked from one time period to the next. These peaks indicate the velocities of the projectile of interest and any other nearby moving objects. Finally, a least mean square error curve fit and standard regression algorithm are used to deduce the projectile's initial, muzzle velocity. The invention provides accurate muzzle velocity determinations even in circumstances where the Doppler signal contains substantial interference caused, for example, by random noise and the presence of moving fragments in the direction of the projectile. [A3662]

"Near-field monostatic intrusion detection system"

The invention comprises a plurality of monostatic devices for radiating and receiving signals. The monostatic devices are disposed in a vertical spaced relationship such that signals from each device follow a direct path to an object to be detected and a reflected path to the object to be detected. The reflected path includes a path to a surface below the object and a path from the surface to the object. The signals are then reflected from the object and return through both the direct and reflected path. The monostatic devices may be radar antennas or acoustic transmitters. [A3663]

"Weather radar with turbulence detection"

A weather radar turbulence detector using a magnetron for transmission and having pulse pair processing. The invention is a high-power, low cost turbulence detector incorporating ground clutter rejection and sea clutter rejection. Autocorrelation among echoes, to note their amplitude variations, which are detected video, rather than RF, from a simple and low-cost receiver, from pulse to pulse of the transmitter, is accomplished by the pulse pair processing. [A3664]

"Short range ranging system"

An accurate ranging system for position determination of a mobile unit using trilateralization. A pair of active reflectors return signals transmitted by the mobile unit in phase at the reflectors, after compensating for interval circuit delay. The mobile unit compares the phases and determines mutual distances and thus its position. The invention includes a two frequency technique for compensating for inaccuracies introduced at distances in excess of one wavelength and for inaccuracies observed at a large multiple of wavelengths, and also includes means for dynamically compensating for drift. [A3665]

"Obstacle proximity detector for moving vehicles and method for use thereof"

A proximity sensing and indicating system for use in automobiles for instance to provide a warning signal to both the car driver and possibly other drivers that the car so equipped is approaching an obstacle at an unsafe speed and/or is getting too close thereto. The system operation is autonomous and is not monitored by the driver once the system is turned on, it responds only to the presence of an obstacle located ahead of the vehicle. The system detects the differential velocity between the car and the obstacle and determines the distance separating the car from the obstacle which may be fixed or moving in a general direction substantially oriented in the same direction as that followed by the system-equipped vehicle. A signal is generated whenever the combination of differential velocity and separation distance reaches an unsafe level. This signal may be processed so as to emit various types of signals that can be seen, heard and/or be used for taking emergency action such as causing the vehicle brakes to be applied automatically if the driver does not heed the passive signals already emitted. Provisions are built-in to prevent the driver from turning off the system after the emission of a signal has been initiated. [A3666]

"System for detecting underground objects"

A system for detecting underground objects is disclosed wherein image data obtained through a deep range-migration correction and image data obtained through a shallow range-migration correction are combined so that data at the corresponding positions on both the image data at high level may mutually intensify, whereas other data may mutually weaken. The target spot on the thus combined image data is made sharp and provides sufficently high resolution. [A3667]

"Recursive radar clutter filter"

A recursive radar filter arranged to provide filtering of ground clutter signals from radar echoes in the form of short batches of pulses. The filter includes a feed-forward section with delay, adder, and fixed amplifier elements. The filter also includes a feedback section which includes similar elements. Two time-varying amplifiers are included in the filter which change gain as the pulses are applied to the input of the filter. In a three delay version of the filter, the gain of one of the time-varying amplifiers is such that the feed-forward section of the filter does not pass any pulses until the fourth pulse has been applied to the filter. After the third pulse, the gain of this time-varying amplifier increases on each successive input pulse. In another embodiment, the two time-varying amplifiers are eliminated by making all of the fixed gain amplifiers time-varying in relationship with the interpulse period of the pulse input signal. Both arrangements allow recursive filtering without the need for extra pulses or pulse tapering to control transients in the filter. [A3668]

"System for detection of objects with given, known characteristics against a background"

The invention is primarily addressed to the problems relating to the detection and identification of vessels against the sea area. A radar sensor connected to powerful data processing equipment can give a monitoring capability having been impossible hitherto, by employing optimal radar structures and signal processing algorithms. There is described which functions which may be operated independently on the transmitter side and the receiver side. Depending upon the purpose such a radar may be applicable for: searching for vessels, searching for wake traces, simultaneous searching for vessels and accompanying wake traces, tracking vessels and wake traces, identifying vessels based upon various filters. As a consequence of the data control such a radar or possibly a corresponding sonar system may be able to reconfigurate as needed, which involves that the requirement for signal processing is reduced and the utilization of the resources improved. In order to form an interference pattern corresponding to the object or objects to be detected, transmitter means and/or receiver means in the system comprise two or more apertures (7A, 7B, 8A, 8B) for the coherent transmission and reception respectively of waves, the mutual distance between these apertures being larger than one wavelength of the waves transmitted. [A3669]

"Medium distance measurement system and method"

A system and method are disclosed for measuring medium range distances, of about 1-10 meters, to a target. A transmission signal is reflected off the target, with the phase difference between the transmitted and received signals taken as an indication of the target distance. The transmitter and receiver are part of a phase-locked loop, with a VCO adjusting the transmission frequency until a predetermined transmission-reception phase difference is reached. A coarse distance measurement is first obtained by comparing the transmitted signal with the received signal, followed by a fine distance measurement in which a multiple of the transmission signal frequency is compared with the received signal. The frequency multiplication in the preferred embodiment is obtained by dividing the VCO output frequency to obtain the transmission frequency. The transmission signal is initialy set at a low frequency prior to the coarse adjustment to avoid phase ambiguities. Numerous different types of transmission signals can be used, although optical signals are preferred. The invention is particularly adapted for robotics applications. [A3670]

"Apparatus for controlling the opening and closing of doors"

An arrangement for controlling operation of a motor operated door is provided with doppler radar sensors facing the approach to the door from both sides. The doppler signals from the sensors are analyzed to determine the presence of motion toward or away from the door and the door is controlled to open upon motion toward the door and close upon motion away from the door. [A3671]

"Multiple-fixed-frequencies navigation system"

A radio navigation system is disclosed which uses multiple fixed frequencies for calculating the bearing and distance of a local station from a central station. The central station has a receiver and an array of fixed, directional antennas all transmitting signals at different frequencies. The local station has a transmitter for transmitting a query signal to the central station, a plurality of local receivers to receive signals from the antenna array, and a stored-program processor. Each of the local receivers operates at a fixed frequency substantially equal to the frequency at which its respective central transmitter and central antenna is operating. A stored-program processor measures the elapsed time between receipt of the query signal from the local station and receipt of a navigational signal from the central transmitters and, using this data, calculates the distance between the local station and the central station. The stored-program processor also compares the relative signal strengths of the signals received by the local station from the various antennas in the antenna array of the central station and, using this data, calculates the bearing of the local station from the central station. [A3672]

"Method of and system and apparatus for locating and/or tracking stolen or missing vehicles and the like"

An improved vehicle or other object-tracking and location system, preferably, though not essentially, of national scope, wherein transponder or transceiver-equipped stolen or missing vehicles or other objects may be located and/or tracked, as by appropriately-equipped police direction/finding tracking vehicles, through homing-in on periodic transponder reply radio transmissions automatically activated by command activation signals broadcast on the same carrier frequency as the transponder reply signals and with encoded vehicle identification information that causes the intended vehicle transponder so to reply, and with provision for modifying the command signals to require an increased rate of periodic transponder reply signal transmission to assist homing-in on the selected vehicle. In a preferred mode of operation, the verification of whether the reportedly missing vehicle is thus transponder-equipped is preferably established by querying the FBI-NCIC computer system, which will provide the said coded vehicle identification information and automatically cause the appropriate sector or area to broadcast said command activation signals. [A3673]

"Friend-foe interrogation method and a system using this method"

For carrying out an interrogation a position modulated laser light wave is used. A key word is displayed in an interrogator and coded in accordance with a cyclic code, for example Golay's code. This coded key word is used for modulating the laser wave. In the responder the same key word is displayed and coded in the same way. After reception and demodulation each message is compared in a correlation circuit with the local reference word. The correlation method used allows parasite pulses to be taken into account and the word received to be validated with a given security threshold. [A3674]

"Method and apparatus for combining waveforms"

A method and apparatus for producing data indicative of the presence of buried objects, wherein two waveforms I (t) Q (t) are combined with two reference waveforms Ir (t) Qr (t) using filters 10, 12, 14, 16 of two types A, B. Type A has time response Ir (-t) and type B has time response Qr (-t) . The products {I (t) @Ir (t) }.multidot.{Q (t) @Qr (t) } and {I (t) @Qr (t) }.multidot.{Q (t) @Ir (t) } from multipliers 18, 20 are subtracted to give V1 and added to give V2 in the combiner 30. A list of object distances (36) is derived from V1. A list of object orientations (46) is derived from V2. Object times (34) are used to section V2 at (40) on a time basis. A correlation operation is represented by @. The invention is particularly applicable to location of buried pipes using ground probing radar, but is also useful in locating planar objects and in other systems. The waveform combination suppresses noise and clutter. I (t) and Ir (t) are quadrature versions of Q (t) and Qr (t) . The emitted radiation is circularly polarized. [A3675]

"Crystal controlled magnetron"

The invention comprises a weather radar system in which a magnetron transmitter is controlled in frequency by injecting therein a low power locking signal from a stable frequency source. Frequency lock between the source and the magnetron is maintained without requiring injection signals of excessive power by an automatic frequency control (AFC) . The AFC determines the frequency and phase error between the injection signal and the magnetron output and adjusts the frequency of the source so as always to be within a narrow band of frequencies centered about the natural frequency of the magnetron. Over the long term, therefore, the frequency of the source will vary by an amount equal to the change in the natural frequency of the magnetron occurring during that time. Over the short term, however, the difference in frequency between the injection signal and the magnetron output is zero, while the phase difference is less than 90.degree.. The frequency source controlling the magnetron also serves as a frequency source for generating the several local oscillator frequencies required by the system receiver. Thus, the pulse to pulse transmitted signals, return signals and receiver i.f. signals all possess a high degree of phase coherence, readily permitting detection and determination of the doppler frequencies contained in the return signals. [A3676]

"Tracking circuit for following objects through antenna nulls"

A circuit for removing abrupt phase changes in a received signal, such as those caused when an object tracking system's directional receiving antenna becomes misaligned with the tracked object. The circuit uses a phase detector to determine when an abrupt phase change has occurred, such as when a signal returned from the tracked object aligns with an antenna null and reverses the phase of a control signal fed to a phase locked oscillator. A delaying low pass filter insures the control signal is stable before it is fed to the phase locked oscillator. [A3677]

"Method and apparatus for measuring distances"

A method for measuring the distance between a first object, which incorporates a transmitter-receiver unit, and a second object, which incorporates a transponder. In accordance with the invention there is transmitted from the transmitter-receiver unit (19) a first microwave signal (S1) , which is received in the transponder (18) . A second signal (S3) of much lower frequency F.sub.m is generated in the transponder and is modulated on a signal (S6) of microwave frequency in the transponder to form a modulated signal (S7) . The modulated signal (S7) is transmitted from the transponder to the transmitter-receiver unit (19) , where it is received and mixed down with the first signal (S1) and thereafter is (a) low-pass filtered to form a first measuring signal (S10) having the frequency F.sub.m, the phase of which corresponds to the phase difference between the first microwave signal (S1) and the microwave signal (S8) received in the transmitter-receiver unit (19) and (b) de-modulated, thereby to form a second measuring signal (S12) having the frequency F.sub.m, the phase of which corresponds to the phase of the second signal (S3) generated in the transponder (18) . The phases of the two measuring signals (S10, S12) are compared in a phase comparison circuit (27) to form a difference therebetween, this difference being proportional to the distance between the objects. [A3678]

"Driver alerting device"

A driver alerting device includes a transceiver adapted for mounting at the rearward end of a vehicle for directing its wave output rearwardly of the vehicle. Return wave signals for many objects within the transceiver range are picked up and supplied to the transceiver by an antenna. Any resultant doppler shift signal is amplified for driving an audio alarm adapted for placement within the passenger compartment of the vehicle. The circuit is adapted for electrical connection to the back-up light circuit of the vehicle for activation only when the vehicle transmission is engaged in reverse gear. [A3679]

"Driver alerting device"

An alarm device for a construction vehicle including a transceiver adapted for mounting at the rearward end of a vehicle for directing its wave output rearwardly of the vehicle. Return wave signals for many objects within the transceiver range are picked up and supplied to the transceiver by an antenna. Any resultant doppler shift signal is amplified for driving an audio alarm positioned on the vehicle. The circuit is adapted for electrical connection to the reverse gear of the vehicle for activation only when the vehicle transmission is engaged in reverse gear. [A3680]

"Motor vehicle locator system"

A system is disclosed for identifying the location of a parked and unattended motor vehicle. When user actuated, the sought-after vehicle will emit a distinctive, user programmable audible and/or visual attention getting signal. Such a signal is preferably produced by standardly furnished vehicular equipment (e.g., horn and headlights) . The system utilizes a radio frequency operated communications link between the operator and the vehicle which is also user programmable. Such programmability allows the user to select one of a plurality of possible link operating frequencies thus greatly reducing the likelihood that his system will inadvertently actuate similar nearby systems. [A3681]

"Radar system"

Where reflection coefficient k of the surface of the sea is in a relatively wide range and as the ratio of the antenna height to the wavelength is larger, a radar system can eliminate ambiguities in measuring a target height of a low elevation angle on the sea surface. An antenna receives two beams, one beam having slightly different elevation angle from the other. An antenna direction adjusting mechanism adjusts, on the basis of tan.sup.-1 (ha/R) , a direction in which receiving sensitivity of one of the beams is equal to receiving sensitivity of the other beam, so that this direction aims at mid point between the target and the image of the target. The phase difference between the two beams is obtained with respect to two different frequencies. Two series of data of the target height are obtained each on the basis of the respective phase difference. These series of data are compared on term-to-term basis for two terms nearly equal to each other for extracting one of the two terms as the true height of the target. [A3682]

"Doppler radar kinemometer"

The invention concerns a Doppler radar kinemometer intended to measure the speed of a railway vehicle. According to the invention, it includes two antennas (1,2) mechanically connected to one another such that their axes form a determined angle between them. This angle is preferably between 60.degree. and 120.degree.. for safety operation, the antennas are each supplied with ultrahigh frequency waves (F1,F2) by their own wave generators (4,5) , and each furnishes corresponding Doppler frequencies (Fd1,Fd2) to a distinct processing unit (11,12) , with the signals coming from these two processing units then processed within a computing assembly (15) which supplies the value of the measured velocity. [A3683]

"Collision avoidance system"

The operation of a positive finding collision avoidance system at an Own station that determines Own's and Others' positions from SSR interrogations and replies thereto is initialized by briefly transmitting interrogations from Own station and receiving non-garbled replies thereto from Other stations to determine their direct ranges from Own. The range data is used in a trigonometric computation to obtain Own's and such Others' initial positions. Interference with the normal operation of the standard ATCRBS is limited to a minimum by transmitting from Own very briefly and only when necessary. The distance between pairs of SSRs is also computed. [A3684]

"Doppler radar velocity measurement apparatus"

Doppler radar apparatus for use in a velocity measuring system for farm tractors and the like. The apparatus includes a dual mode conical horn having a flare angle substantially in excess of 12.5.degree., and a dielectric lens formed of a glass filled polymer. The doppler output signal provided by the RF transceiver associated with the dual mode horn is high pass filtered to remove low frequency signals therefrom. The horn is mounted in such a way that it is isolated from mechanical vibrations which would induce doppler signal frequencies in excess of the cutoff frequency of the high pass filter. Moreover, the horn assembly (which is aluminum) and a steel housing assembly are coupled together in such a way that thermal expansion and contraction will not loosen the friction fit between the two assemblies. The two assemblies are held together by a single, large diameter annular locking ring. [A3685]

"System and method for detecting intervehicle distance of two vehicles moving in the same traffic lane"

The system and method for detecting an intervehicle distance to a preceding vehicle which is moving on the same lane as the vehicle, means for radiating and sweeping an electromagnetic wave such as a laser beam toward the moving direction of the vehicle is provided, with the confirmation of a lane on which the vehicle moves on the basis of a comparison of their sweep angles to reflectors located on both ends of a road on which the vehicle moves from a center axis of the vehicle's movement direction, the traffic lane on which a vehicle moving in front of the vehicle moves is determined on the basis of their sweep angles of the electromagnetic wave with respect to the vehicle from the other vehicle moving in front of the vehicle to the reflectors located on both ends of the road and having the same distance to the vehicle as the other vehicle, and the intervehicle distance data is outputted upon determination that both vehicles move on the same traffic lane, a correct intervehicle distance from the vehicle to the preceding vehicle can thus be measured. In addition, the center axis is corrected according to a steering angle of the vehicle's steering wheel. [A3686]

"Process and device for limiting traffic to be used with an interrogation/response system such as a secondary radar or IFF system"

The process for limiting traffic according to the invention comprises an and input gate receiving the incident pulses representative of the interrogations of the system, its output being connected to an authorization output as well as to a counter which is itself connected to an adder and to a counter, the adder receiving from a memory criteria values, and its output being connected via a reference values memory to the comparator, the output of which is connected via a memory to the said and gate. [A3687]

"Shield tunneling system capable of electromagnetically detecting and displaying conditions of ground therearound"

In a shield machine, there are provided an electromagnetic wave transmitting and receiving unit mounted on the top of the shield machine for radiating electromagnetic impulse wave toward an underground and for receiving the electromagnetic wave reflected from the underground, and a position sensor for collecting an information regarding the position of the electromagnetic wave transmitter and receiver unit. Data processing unit is provided for processing the signals from transmitter/receiver and the position sensor and sent through a transmission line. The data processing unit continuously displays the condition of the underground at the cutting face. [A3688]

"Radar device for measuring the distance of the device to a surface"

This radar device for measuring the distance h of the device to a surface (2) includes transmission means (5) for transmitting to the surface a frequency-modulated wave E (t) provided by an oscillator (14) having a frequency control, receiving means (7) for receiving this wave R (t) reflected from the surface, a mixer circuit (10) for producing a beat wave between the transmitted and received waves and a processing circuit (20) including a beat-wave-digitizing circuit (25) and a time-frequency transform operator (27) for supplying frequency components from which the distance h is determined. This processing circuit (20) further includes an auto-correlation operator for effecting an auto-correlation of the beat wave digitized by the circuit (25) and also spectrum processing means (32) for finally determining the distance h. [A3689]

"System for measuring height distributions of atmospheric temperature, wind direction and wind speed"

A system for measuring height distributions of atmospheric temperature and wind velocity (wind direction and wind speed) utilizes the facts that a sound wavefront in the atmosphere constitutes part of an ellipsoidal surface and that there always exists a normal which passes through an interior point of the ellipsoid. The Doppler radar is capable of measuring a height distribution of wind velocity on the basis of Doppler frequencies of scattered waves produced by the atmospheric turbulence. The radar and generator are arranged on a straight line in the wind direction so that a radio wave from the radar is directed to the wavefront of a sound wave from the generator. The radar antenna beam is scanned so that it perpendicularly intersects the sound wavefront. The speed of the sound wavefront is measured from the Doppler frequencies of reflected waves. The sound speed is obtained by removing the wind speed component from the measured speed of the sound wavefront. The sound speed obtained is calculated in terms of atmospheric temperature, thereby obtaining the height distribution of the atmospheric temperature. [A3690]

"Terrain profile radar system"

Stable measurement of terrain-height variations is provided by this radar system which employs a very low power spread spectrum transmitted signal which, after reception, is processed digitally for extremely stable and predictable performance. The system also includes an automatic power control circuit to maintain the transmitted power at the minimum required level. [A3691]

"Speed sensor and head-mounted data display"

A transmitter is mounted for movement with a skier or other self-propelled sportsman and transmits ultrasonic or electromagnetic waves toward the stationary medium over which the skier or sportsman is moving. An element of the same transmitter or a separate transducer detects waves reflected from the stationary medium. A computer calculates the speed of the skier or sportsman from the Doppler shift of the reflected waves and actuates a readout unit to indicate the speed to the skier or sportsman. The readout system has a head-mounted display including a character generator and a semitransparent reflector in which the character generator is viewed so that the speed indication appears superposed over the normal background in the viewing direction. [A3692]

"Method and system for automatically detecting a preceding vehicle"

A method and system for detecting a presence of a preceding vehicle moving in a front detection area of a controlled vehicle. In the method and system thereof, a plurality of laser or other kinds of beams are transmitted to any object present in the front detection area and the plurality of reflected beams are received so that the respective distances to the reflecting objects are measured on the basis of the propagation delay times between the transmission and reception of the beams. In the method and system thereof, each absolute difference between the current value of distance measured by any one of the beams and any one of previous value of distance measured by the corresponding or another one of the beams before a predetermined time (corresponds to an interruption time of a processing routine) is calculated and compared to a predetermined distance value which is relatively small in order to determine that the preceding vehicle which has been detected by any one of the beams within the predetermined time is the same as that which is currently detected by any one of the beams. Therefore, the presence of the preceding vehicle can accurately be detected without mistaking the preceding vehicle for another vehicle moving on a different traffic lane or as a stationary object located at either side of a traffic lane. This is true even when the controlled vehicle and preceding vehicle move on a curve road. Vehicle speed can be controlled to track the real preceding vehicle. [A3693]

"Method and apparatus for measuring distance"

A signal is transmitted from a first location to a remote second location where a target carrying a transponder is positioned. The transponder re-radiates the signal to the first location where it is received. A phase comparator generates from the transmitted and received signals a measurement of their phase difference which is functionally related to the distance between the first and second locations. In one embodiment, the transponder is a passive parametric oscillator, being powered by energy received from the transmitted signal, which generates and transmits a subharmonic of the transmitted signal. [A3694]

"Method for the in-line measurement of background noise for MTI radar with suppression of samples not originating from noise, and digital device embodying said method"

Apparatus is provided for the automatic in-line measurement of background noise for MTI radar with automatic suppression of samples not originating from noise. The background noise level is determined by making use of summing and shifting operations only, and the suppression of samples not originating from noise is obtained by utilizing the information derived from a normal radar detector so that samples identified as true targets shall not contribute to the calculation of background noise level. The apparatus comprises a multiplexer circuit (22) , a first shifting circuit (23) , a storage element (24) , a second shifting circuit (25) , an inverter (21) , and a counter (26) . [A3695]

"Interactive television and data transmission system"

A spread spectrum system provides bidirectional digital communication on a vacant television (TV) channel for simultaneous use by more than 75,000 subscribers using time and frequency division multiplex signals locked to horizontal and vertical sync pulses of an adjacent channel Host TV station. The system, whose operation is analogous to a radar system, comprises: (1) the Host TV station to send down-link sync and data pulses to subscribers during the horizontal blanking interval (HBI) , (2) subscriber "transponders" which detect those signals and transmits up-link "echo" data pulses only during the HBI to eliminate interference to TV viewers, and (3) a central receiver which also uses the host TV sync pulses to trigger range gates to detect the up-link data pulses. In a preferred embodiment the central receiver employs directional antennas to determine direction to transponders and to define angular sectors partitioning the service area into pie-link "cells" which permit frequency re-use in non-contiguous sectors (like cellular radio) . The system thus operates like a radar to measure elapsed time between receipt of TV sync pulses and receipt of transponder response pulses and measures bearing to transponders to thereby determine the location of fixed or mobile subscribers as well as provide data links to them. Transponders may share user's existing TV antenna or may operate on cable TV and could be packaged and "RF modems" for personal computers, as transceivers for mobile or portable use, or they may be integrated with a TV receiver to provide "interactive television". [A3696]

"Remote sensing apparatus for satellites"

The invention relates to remote sensing from a satellite of a parameter in one or more regions on the ground adjacent the satellite ground track by radar transmission. The purpose of the invention is to reduce energy consumption and optimize measurement accuracy. A transmitter antenna generates a plurality of pencil radar beams which illuminate respective cells of the region. A control means successively energizes the antenna at respective frequencies for respective pulse durations and for respective number of pulses. The invention is particularly appliable to scatterometer apparatus for responding to wind speed and direction by sensing radar backscatter from sea. [A3697]

"Antenna assembly for microwave reflection survey equipment"

An antenna assembly is provided for use in locating buried objects, particularly long thin objects such as pipes can be located, determining the position, and ascertaining the pipe direction by taking measurements from a single point, without mechanical movement of the antenna, and allowing a better suppression of spurious signals and reduction in false indications, which assembly has a plurality of antenna arms adapted and arranged to transmit and receive radiation into the ground and is characterized in that the arms have, on at least the surface nearest the ground, a cladding of a substantially lossless dielectric material, the relative permitivity of said dielectric being at least 3.5 and the thickness of said coating being at least .lambda..sub.d /20 where .lambda..sub.d is the wavelength of lowest frequency of the radiation to be transmitted from the antenna. [A3698]

"Electronic surveillance and identification"

An electronic article surveillance and identification system employing a transceiver (10,11) for broadcasting an interrogation signal into a zone to track the location and movement therein of inventory, merchandise, vehicles, animals, people and objects carrying passive (unpowered) transponder tags (12) adapted to receive the interrogation signal, process the signal in an encoded surface acoustic wave device (15) having a predetermined pattern of reflection groove or grating transducers (30-39, 40-72) and echo an encoded response signal to the transceiver. [A3699]

"Reflective array surface acoustic wave device"

A reflective array surface acoustic wave signal compressor or expander (RAC) has a piezoelectric substrate (LiNbO.sub.3) upon which is deposited an input transducer and an output transducer and etched therein a reflective grating. The RAC grating comprises reflective elements which includes a plurality of grooves having either uniform depths and lengths and preselected widths or uniform depths, lengths and widths for producing a flat pass band or a desired frequency characteristic. Yields are increased owing to the simplified fabrication process and costs decreased owing to batch fabrication made possible by the resulting simplified fabrication-process. [A3700]

"Satellite-based position determining and message transfer system with monitoring of link quality"

A radio position determination and message transfer system is implemented using a number of satellites in geostationary orbit for relaying interrogation and reply signals between a ground station and a user-carried transceiver. Message information can be exchanged between a given user transceiver and the ground station, as well as between different user transceivers. The user transceiver is provided with means for monitoring the quality of the radio communication link between the transceiver and one or more of the satelites, based on errors detected in the received interrogation signals. The transmission of a reply signal by the transceiver is enabled only when the link quality is found to be acceptable. The reply signal may contain message information or may constitute a request for a position fix. In the latter case, the transceiver may be configured to await favorable link quality to more than one satellite before the reply signal is transmitted. [A3701]

"Target position radar"

A traffic radar unit capable of looking past the lead vehicle of oncoming traffic and discovering and identifying a violator employs master and slave antennas having diverging boresights that provide overlapping relative power density radiation patterns. The radar return signal from a target of interest is received by each antenna to produce two independent Doppler signals of the same frequency which are processed by respective master and slave signal processing channels. In the illustrated embodiment, a reference boresight is established in the overlapped patterns such that a target position along the reference boresight occurs at the time that the amplitudes of the two Doppler signals are equal. Controllable high pass filters whose passbands are shifted upwardly in response to return signals of increasing amplitude attenuate stronger, lower frequency interfering signals. The presence of a second Doppler signal in either channel having a frequency near the signal of interest causes the receiver to abort the tracking mode. [A3702]

"Stolen object location system"

A stolen object location system having a base station, a location network and an object unit which is associated with the object to be located. The location system is capable of operating in a plurality of different location modes ranging from simple triangulation to LORAN. The base station, upon being notified that the object has been stolen, will transmit a locate request message to the object unit specifying the location mode to be used and the transmission frequency of the object unit's transmitter. An electronic control in the object unit will control the operation of the object unit's receiver and transmitter in accordance with the location mode and transmission frequency specified in the locate request message. The electronic control will also initiate the transmission of an alarm message if the object unit loses communication with the base station, and is capable of transmitting a tattle-tale message, effectively relaying the alarm message of another object unit if the base station does not respond to the other object unit's alarm message. [A3703]

"Method and arrangement for the suppression of rain echos in a terrain following radar"

To suppress rain echos in a terrain tracking radar with elevation monopulse devices, the signal in the difference channel is amplified by a predetermined factor. By comparing the level of the sum signal with the amplified difference signal, conclusion is reached about the presence of a ground echo or a rain echo. The factor should preferably be automatically adjustable according to the level in the sum channel. [A3704]

"Passive interrogator label system with a surface acoustic wave transponder operating at its third harmonic and having increased bandwidth"

A "passive interrogator label system" (PILS) is disclosed with passive, SAW transponders which are capable of receiving an interrogation signal, processing this signal and transmitting a reply signal that is derived from the interrogation signal and contains encoded information. The SAW transducers employed in the transponders are operated at their third harmonic and comprise split fingers which reduce SAW reflections. These transducers are also shaped to increase their bandwidth and to reduce their capacitance. The bus bars connecting the transducers are formed of double thickness to reduce ohmic resistance losses and these bus bars as well as the transponder phase delay pads have two levels of serrations on their edges to substantially cancel reflections. SAW reflectors in the transponder are provided with shorts between successive fingers to reduce ohmic resistance losses and to render them less susceptible to fabrication errors. [A3705]

"Inductive antenna coupling for a surface acoustic wave transponder"

An arrangement is disclosed for coupling electrical energy into and/or out of a surface acoustic wave (SAW) device, such as a transponder. The SAW device has two input/output terminals electrically connected to at least one transducer for converting between electrical energy and SAW energy. Such transducer presents to the terminals a prescribed capacitance in the frequency range of operation. An inductive loop, formed by at least one turn of an electrical conductor, is connected to the two input/output terminals of the SAW device. The inductance of the loop is made substantially equal to the prescribed capacitance at the frequency range of operation, thus forming a resonant circuit with the SAW device. The loop also forms a protective DC short circuit across the two terminals, preventing build-up of static electricity. The inductive loop is inductively coupled to an antenna capable of receiving and/or transmitting radiation in the frequency range of operation. [A3706]

"Position finding and collision avoidance system"

A position finding and collision avoidance system derives, at an Own station within the service area of an identified SSr at a known location, differential azimuth (A) , differential time of arrival (T) , identity and altitude data regarding any transponder-equipped Other station or stations within a predeterminable region surrounding Own station, from standard ATCRBS interrogations and replies. These data are used to compute the positions of Other stations for display at Own station. [A3707]

"Method for position-finding and apparatus herefor"

A method for determining a mutual position between two objects, comprising transmitting a microwave signal from the first object towards the second object, causing the second object to receive the transmittal signal and re-transmit a signal, which is caused to be received by the first object. According to the invention the first object includes a transmitter/receiver unit (S/M-unit) , which transmits the aforesaid signal (f.sub.o) from a transmitter antenna. The second object (T) is caused to re-transmit the aforesaid signal modulated with a signal (f.sub.m) , the first object being caused to receive the transmitted signal through at least two antennae (M.sub.1, M.sub.2) placed symmetrically on a respective side of the transmitter antenna (S) and in an antenna plane common with the transmitter antenna (S) . The angle (.theta.) between the antenna plane and the second object, at least in one dimension, is determined by a phase comparison or an amplitude comparison of received signals, in dependance on whether or not the second object (T) is located in the so-called proximity zone of the first object. The invention also relates to apparatus for carrying out the method. [A3708]

"Radar echo discriminating device"

A radar echo discriminating device for separating in the video signal of a pulse-type meteorological radar the rain echoes from the echoes due to the ground comprises fluctuation calculating means for subtracting the amplitude of the incident video signal corresponding to a given pulse emitted by the radar from the amplitude of a stored video signal corresponding to a pulse previously emitted by the radar, whereby the signal obtained after this processing represents only the rain echoes, whereas the ground echoes are attenuated. [A3709]

"Microwave reflection survey technique for determining depth and orientation of buried objects"

A method and antenna assembly for transmitting into the ground polarizeable radiation whereby buried objects, and particularly long thin objects such as pipes can be located, the position determined, and the pipe direction ascertained, by taking measurements from a signle point, without mechanical movement of the antenna, and thereby allowing for good suppression of spurious signals and a reduction in false indications. The method includes the steps of transmitting into the ground polarizeable radiation, receiving reflected signals, indicative of the objects, incident upon at least two co-located angularly disposed transducers and comparing the signals thus received, wherein the radiation is transmitted from a transducer source which is co-located but angularly disposed with respect to each receiver transducer. An antenna assembly suitable for use in the method of the invention includes a substantially planar arrangement of at least three, co-located, two-terminal antennas wherein the antennas are angularly disposed with respect to each other around a common point and each antenna is adapted to be capable of selectively transmitting polarizeable radiation into the ground and receiving reflected radiation from out of the ground. [A3710]

"System for interrogating a passive transponder carrying phase-encoded information"

A "passive interrogator label system" (PILS) comprises an interrogator for transmitting an interrogation signal, one or more "labels" or passive transponders which produce a reply signal containing coded information in response to the interrogation signal, and a receiver and decoder for receiving the reply signal and decoding the information contained in it. The frequency of the interrogation signal assumes a plurality of frequency values within a prescribed frequency range. The decoder includes a mixer (4 quadrant multiplexer) for mixing together the interrogation and reply signals (or signals derived therefrom) to produce a further signal containing frequencies which are the sum and difference of the interrogation and reply signals. A signal processor, responsive to this further signal produced by the mixer, detects at least some of the frequencies contained in this further signal and determines the informational code associted with the transponder. [A3711]

"Transponder device"

A transponder device receives a carrier signal from an interrogator unit. This carrier signal, of frequency F, is rectified by a rectifying circuit in order to generate operating power. Logic/timing circuits derive a clock signal and second carrier signal of frequency F/n from the received carrier signal. This clock signal reads a unique identifying data word from a programmable read only memory (PROM) . The data word is encoded and mixed with the carrier signal in a balanced modulator circuit. The output of the balanced modulator is transmitted to the interrogator unit, where it is decoded and used as an identifying signal. The identifying signal identifies the particular transponder device from which it originated. The rectifier and balanced modulator circuits are realized from the same diode elements. All electrical circuits of the transponder device are realized on the same monolithic semiconductor chip. In one embodiment, and antenna receiving/transmitting coil is also part of the chip, being placed around the periphery thereof. In alternative embodiments, various hybrid elements may be connected to the monolithic elements in order to realize additional functions, such as adjustable tuning of the receiving circuit, independent crystal frequency control, and battery-powered operation. [A3712]

"Radar system"

A radar system comprising an RF transmitter and receiver means for mounting in a moving carrier for transmitting

RF energy and receiving RF energy returns and a non-rotating modulating radar reflector which has a lens means for focusing incident impinging RF energy onto a spot opposite the incident side and a plurality of solid state modulating radar reflectors positioned at the spot locations for selectively reflecting the RF energy and dissipating the RF energy for providing RF energy returns modulated with a lens identification code and frequencies for determining true ground speed, range, glide slope, and azimuth position. The solid state modulating radar reflector including a microwave section having open back and front ends, a load resistive means at the back end, a PIN diode adjacent to the load resistive means and a modulating power source for modulating the PIN diode to provide at preselected intervals virtual shorts at the open end of the wave guide for reflecting modulated RF energy returns directly to the source of RF energy. [A3713]

"Ski speedometer"

A transducer is mounted on a ski and transmits ultrasonic waves toward the stationary medium over which the ski is moving. The same transducer or a separate transducer detects waves reflected from the stationary medium. A computer calculates the speed of the ski from the Doppler shift of the reflected waves and actuates a readout unit to indicate the speed to the skier. [A3714]

"Radar system with reduced distance error"

In a radar system comprising equipment for transmitting frequency modulated pulses and compressing the received signals in a filter for frequency-dependent weighting, the weighting is asymmetrical in a manner such that the leading sidelobes of the pulse compression signal are reduced and the lagging sidelobes are raised. The reduced leading sidelobes can easily be reduced below an amplitude threshold so that the main echo lobe within the pulse compression signal is reliably acquired for determining the closest target distance. The invention may advantageously be applied to ground tracking radars. [A3715]

"Alien radar suppression circuit"

Disclosed is an alien radio ranging transmitter rejection technique utilizing random PRF to eliminate the possibility of lock-on between two coherent R/T units in close proximity. If one, or both, are utilizing the random PRF technique taught herein, the alien signal is rejected utilizing standard noise suppression techniques. The random PRF is selected utilizing noise or angle data computed from the received return signal and is thereafter utilized to designate which one of a set number of PRF delays is utilized on a substantially random basis. [A3716]

"Method and apparatus for the graphic registration of moving vehicles"

Vehicles are measured and photographed from the direction in which they are travelling by a Doppler radar speed measuring device equipped with a camera. During a measuring stage after the vehicle enters the radar beam, a measured speed value is determined and when this exceeds a specific limit value, the camera is triggered. The Doppler signal for checking the measured speed value is then further evaluated over a verification distance. If the measured speed value is confirmed then it is printed on the photograph at the end of the verification distance, if it has not been confirmed, then a cancellation indicator is printed. The film is then advanced and the detection of the entry of another vehicle is awaited. As a result of this checking of the measured speed value, the measuring reliability when registering oncoming vehicles is substantially increased and overtaking in particular can be detected in the range of the radar beam. [A3717]

"Super resolution imaging system"

A super resolution imaging system employing coherent radiation comprises transmitting, receiving and processing means to provide complex amplitude image data. The image data is processed by a weight function generator to provide a weight function. The weight function has values at individual image pixels consisting of a background or clutter intensity term added to a pixel intensity dependent term. The latter term is non-zero for pixel intensities exceeding a threshold level well above background. A computer generates singular functions from the weight function and system impulse response, and employs the singular functions to decompose the image data and subsequent object reconstruction. This provides enhanced resolution compared to that available from the image data alone. An iteration controller employs the reconstructed object data to iterate resolution enhancement until no significant improvement is obtained. [A3718]

"Ground speed sensor"

An ultrasonic ground speed sensor has a vehicle-mounted transmitter and a receiver for receiving signals reflected from the transmitter to the receiver by terrain over which the vehicle travels. An attenuated and phase-shifted transmit frequency is superimposed upon an output of the receiver to cancel cross talk, thus providing a substantially pure reflected frequency. A phase-locked loop converts the reflected frequency to a voltage which represents the direction and speed of the vehicle. [A3719]

"Point clutter threshold determination for radar systems"

An adaptive detection threshold system for moving target detector and moving target indicator radar systems. The threshold system uses data from the echo input signal to reconstruct a threshold level closely resembling the output clutter residue in doppler filters due to point clutter sources. At least three azimuth data values are used, with the values being from adjacent coherent processing intervals and separated in azimuth a distance approximately equal to the beamwidth of the antenna system. The data at the same range from the three azimuths is combined to form an estimate of the residue at the output of a doppler filter, assuming that the echo is caused by point clutter. Compensation for radar instability and changes in scan rate or interpulse period is included. Data from conventional constant false alarm rate processing designed to control alarms from distributed interference, such as weather echoes, is also used to compensate the residue estimate. [A3720]

"Method and apparatus for detecting microbursts"

The invention provides a method and apparatus for detecting specialized meteorological conditions, in particular a microburst. The detector is localized so as to process radar return signals from regions in which aircraft are particularly vulnerable to microbursts. The detector includes a Doppler radar and an intelligent processor. Doppler radar returns are stored in an array wherein the contents of each cell identify the wind velocity parallel to propagation path. A pattern matching process identifies the existence of a microburst, maximum wind velocity associated with the microburst, and the location of the center. By tracking the microburst center as a function of time, the microburst velocity and direction can be determined, allowing prediction for microburst location in the future. Based on observed microburst lifetimes, the expected duration of the microburst can also be predicted. Although the apparatus of the invention can be configured as a stand alone or dedicated unit, it can also be configured as an add-on to an existing ASDE-3. [A3721]

"Device for eliminating low frequency noise from a transmission system, in particular 1/f noise in a homodyne radar receiver"

Device for eliminating the noise in 1/f from a Doppler radar comprising in the HF emitting system, a phase coder introducing, at frequency PRF/2 a phase shift of 0 and .pi. alternately, and in the receiving system, after the receiver, a decoder, or gain inverter progrmmable between -1 and +1, acting, in the same manner as the coder, upon the receiving signal and comprising a low-pass filter downstream from the decoder for eliminating the noise in 1/f, that appears at PRF/2, the device being applied to a ground surveying radar. [A3722]

"Selectable doppler filter for radar systems"

An arrangement for selecting between different doppler filter pairs having response characteristics optimized for ground clutter or moving rain clutter rejection. The selecting process detects the amplitude and mean doppler of the received radar echoes. The filter which is optimized for rain clutter rejection is normally used until clutter amplitude is detected above a predetermined value and the mean doppler is detected as being equal to or near zero. When such a detection is made, the filter optimized for ground clutter rejection is selected. Portions of the selecting device allow for the selection to be determined over several samples rather than switching the filters in each sample or coherent processing interval. Another portion of the circuitry changes the predetermined values which must be exceeded for a selection of the ground clutter filter, thereby preventing another filter change with only a small change in detected amplitude or mean doppler. [A3723]

"Method of controlling the mode of driving electric vehicles"

A method of controlling the mode of driving an electric vehicle so that the electric vehicle is accelerated at a maximum acceleration and is decelerated at a maximum deceleration. The mode of variation of the running speed of the electric vehicle is estimated on the basis of the variation of the running speed of the electric vehicle calculated from the revolving speeds of the axles of the electric vehicle detected by revolving speed detectors associated with the axles, respectively. The axles are controlled for minute idle rotation or minute slip on the basis of the estimated mode of variation of the running speed of the electric vehicle to produce a maximum effective adhesion between the wheels attached to the axles and the rail so that the acceleration of the electric vehicle at a maximum acceleration and the deceleration of the same at a maximum deceleration are achieved. The torque of the axle carrying the greatest axle load among the driving axles of the electric vehicle is reduced intermittently or continuously so that the wheel attached to this axle is brought into steady rolling contact with the rail to calculate the estimated mode of variation of the running speed on the basis of a time interval between two successive torque reducing operations by means of a microprocessor or the like. Thus, the mode of driving an electric vehicle can be accurately controlled to produce a maximum effective adhesion through calculation based on the revolving speed of the axle. [A3724]

"Coordinate measurement and radar device using image scanner"

A system for measuring angles, including a lens or antenna for focusing the radiation from an object scene onto an image sensor which is shifted by a clock, thereby producing the real time imaging of the object scene wherein each element of the object scene is detected as a pulse, representing the element angular displacement from the lens, at the output of the image sensor. A system for measuring angles of objects relative to the centerline of a lens or antenna. A goniometer for measuring the bearing of objects. A system for measuring the vector speed of objects. A velocity meter for measuring the speed of objects. A system for tracking objects. A system for motion compensation. A search, track or track-while-scan detection system. Without the lens or antenna, a system for recording and reproducing halograms. [A3725]

"Arrangement for measuring velocity with respect to a surface"

This arrangement comprises a fixed frequency emitter circuit (10) for directing a wave (12) to a surface (2) by means of a transmission antenna (11) , a receiver circuit (25) for receiving by means of at least one receiving antenna (23) the wave (12) returned by the surface, and a processing circuit (30) for processing the return wave and enabling production of an indication of the velocity. The processing circuit has two branches (50 and 54) , a direct branch for applying the received signal to one input of a multiplying member (52) , and a delaying branch for applying the received signal to the other input of the multiplying member after having produced a delay t.sub.0 relative to the direct branch. A frequency estimating element (60) receives the multiplying member output signal and a calculation member (62) produces the indication of the velocity from the estimating member output signal and of the distance "h". [A3726]

"Ship collision preventive aid apparatus"

The present application discloses a ship collision preventive aid apparatus in which a radar picture and a key picture are selected from all pictures displayed on a display means as transmitted through a touch panel, and the operator touches the surface of the touch panel, so that a program for an operation key name selected is executed. Predetermined collision preventive aid data required for collision avoidance are then displayed on a display screen. With operation simplified, appropriate information concerning collision avoidance may be supplied and the entire construction is simplified. [A3727]

"Method and system for detecting an object with a radio wave"

Method and apparatus for detecting an object by using a radio wave which is radiated by an antenna toward the object to be detected. An echo wave of the radio wave reflected from the object is received by the antenna. On the basis of phase difference between the transmitted waveform and the received waveform, material of the object is discriminatively identified. The object is displayed as an image on a display unit. [A3728]

"Radar ranging system"

A system for determining the range R of a stationary emitter on the ground from an airborne bistatic radar as a function of velocity V, direction .beta., antenna spacing d, wavelength .lambda. and rate of change of phase with respect to time .theta. is discussed herein: ##EQU1## [A3729]

"Systems for determining distances to and locations of features on a golf course"

A golfer wishing to know the distance to a specified feature on a golf course, operates a portable interrogation unit, to enter a request for the distance to the location of the feature. Transmitters located to define a triangle encompassing a substantial portion of the course transmit ranging signals, which are received by the portable interrogation unit. The portable interrogation unit includes a memory which stores the locations of the transmitters and the locations of predetermined features on the course and a CPU which processes the ranging signals received from the transmitters to determine the location of the portable interrogation unit and further to determine the distance from the portable unit to the specified feature. The portable interrogation unit then displays the determined distance. To survey the locations of the various predetermined features on the course, a portable survey unit is substituted for the portable interrogation unit. Feature identification data is entered and a CPU in the portable survey unit determines the location of the unit by processing the ranging signals and causes such location to be stored in an area of a memory therein that is addressed by the entered feature identification data. The stored feature locations then are transferred to the respective memories of a plurality of portable interrogation units. [A3730]

"System and method for controlling a vehicle speed of an automotive vehicle"

A system and method for controlling a vehicle speed to follow a preceding vehicle moving on the same traffic lane of a road as the vehicle. The system comprises: means for transmitting electromagnetic waves toward a vehicle movement direction, receiving the reflected waves from a reflecting object, measuring a distance to the reflecting object on the basis of a propagation delay time on the transmitted and reflected wave, and outputting respective Doppler signals derived from a relative movement of the reflecting object to the vehicle, means for calculating a change rate of the phase difference between the Doppler signals with respect to the measured distance, means for determining whether the reflecting object is the preceding vehicle on the basis of a magnitude of the differentiated phase difference with respect to a reference value associated with the distance and set according a radius of curvature of the traffic lane on which the vehicle moves, and means for controlling the vehicle speed so as to follow the preceding vehicle at a safe intervehicle distance on the basis of the vehicle speed and measured distance. [A3731]

"System for the visualization of the movements of marine vessels by television display"

Arrangement for visualizing the movements of marine vessels by television display. The arrangement comprises a position determination unit which is arranged to continuously provide position determinations in the form of coordinate values in a certain coordinate system for a number of vessels together with a data processing equipment which is arranged to feed the coordinate values with predetermined control signals each in the form of a television signal arranged to bring about a stylized image on a television screen of the respective floating units. The control signals are integrated in such a way with the respective coordinate values that a number of images are produced on a television screen of the vessel in positions which correspond to the mutual position between them in the system of coordinates. These images are moved on the television screen in accordance with the change in the continuously output coordinate values. [A3732]

"Systems for determining distances to and locations of features on a golf course"

A golfer wishing to know the distance to a specified feature on a golf course, such as the pin on the next green, operates a portable interrogation unit, which transmits an interrogation signal including a request for the distance to the location of the specified feature. Three remote stations located to define a triangle encompassing a substantial portion of the course receive the interrogation signal and communicate interrogation information signals to a central station. The interrogation information signals include the interrogation signal data, remote station identification data, and pertaining to the location of the source of the interrogation signal relative to the remote station. The central station includes a memory which stores the locations of various predetermined features on the course and a CPU which processes the interrogation information signals from the remote stations to determine the location of the portable interrogation unit and further processes the determined unit locations with the location of the specified feature to determine the distance from the portable unit to the specified feature. The central station transmits a response signal to the portable unit indicating the determined distance, which the portable unit then displays. To survey the locations of the various predetermined features on the course, a portable survey unit is substituted for the portable interrogation unit and transmits a survey signal including feature identification data. The CPU determines the location of the portable survey unit and causes such location to be stored in an area of the memory addressed by the feature identification data in the survey signal. [A3733]

"Subsurface inspection radar"

A radar system for subsurface inspection comprising a short pulse transmitter, an antenna for radiating signals to and receiving external reflections from the surface and from below the surface being inspected, a receiver connected to the antenna for generating an output signal in response to the external reflections, and a clutter cancellation circuit for eliminating internal reflections developed in the system to prevent interference by such internal reflections with the desired external reflections to enhance the system detection capability and reliability of evaluation of such external reflections. Clutter cancellation is accomplished by storing the internally generated clutter and subsequently subtracting it from each incoming radar range sweep consisting of surface and subsurface signals plus unwanted clutter. An internal signal recognition circuit rejects all return signals except that generated internally to the radar by the antenna structure, and this internal antenna echo is used as an internal reference signal whereby the radar system is relatively insensitive to wide variations in external reflection characteristics caused by wide variations in the nature of materials present in the surface being inspected. This in turn provides for a reliable control of the receiver sampling process which is indpendent of external signals and of their amplitude variations. A circuit for compensating for thermal drift permits long term cancellation of the internally generated clutter. The drift compensation circuit, the internal signal recognition circuit and the receiver provide a closed loop stabilization to allow the internal clutter to remain correlated on a range sweep by range sweep basis. [A3734]

"Surface acoustic wave pipe identification system"

A drill pipe identification system automatically provides an identification number for each drill pipe as the drill pipe is being lowered into or withdrawn from the well. The system has a SAW identification device which is mounted in a cylindrical cavity which is formed within a tool joint of each section of drill pipe. The cavity has an aperture leading to the exterior of the tool joint to allow radio frequency signals to be received and reradiated. The SAW device receives signals from a transmitter and receiver, modulates the signals and reradiates them in a manner that corresponds to an encoded number in the SAW device. [A3735]

"Velocity discrimination radar"

A radar method and apparatus which utilizes a first frequency signal modued by a first modulating signal and a second frequency signal modulated by a second modulating signal, the first and second frequencies being different and the first and second modulating waveforms having different periods of repetition. The radar receiver separates the return radar signal into the component due to the first frequency signal and the component due to the second frequency signal. Both components are then heterodyned with their respective frequency signals. Each modulating waveform is subjected to a plurality of delays and each component is subsequently correlated with each of its respective delayed modulating waveforms. A target is recognized when the correlated first frequency component exceeds a predetermined threshold and simultaneously the correlated second frequency component exceeds a predetermined threshold. [A3736]

"Narrow range gate baseband receiver"

A baseband receiver with a range gate interval in the order of nanoseconds. A tunnel diode, set to the low level state, is coupled across the output terminals of a bridge that is balanced in the absence of a received signal, during the range gate interval. Signals received by an antenna are coupled to a tunnel diode in an arm of the bridge causing it to change from its low level state to its high level state thereby unbalancing the bridge and establishing a voltage at the output terminals of the bridge that fires the tunnel diode coupled thereacross. [A3737]

"Automatic range finder and remote controller braking system"

An automatic range finder and remote controlled braking system is provided. When mounted to a vehicle, this system senses the distance between the equipped vehicle and any other vehicle or object in front of it and sets off a warning alarm when the separating distance is less than some preset value. As the distance continues to close, when the distance closes to some preset braking distance, a braking alarm is activated, and controlled breaking, proportional to the rate of change of distance with respect to time commences. The actual distance is always displayed. Additional braking is accomplished by applying increased breaking force to the conventional brake pedal while a panic button can be used to disable the automatic braking entirely. The beamwidth of the corner reflector type antenna is controlled for calibration purposes by adjusting the lateral placement of the radiating dipole using a motor and worm drive system. [A3738]

"Vehicle speedometer"

A vehicle speedometer is disclosed which accurately measures vehicle velocity despite significant vehicle vibration, which causes variation of the angle of incidence of the measuring wave. Two transceivers are mounted on the vehicle, along with means to determine a frequency difference and an angle variation, both being used in an accurate velocity determination. [A3739]

"Multiple range interval clutter cancellation circuit"

A multiple range interval clutter cancellation circuit for MTI radars is disclosed, for assuring cancellation of narrow band clutter in the second or further range interval, while preserving wideband cancellation in the nearer range intervals and economizing on the number of fill pulses. The circuit includes two clutter cancellers. One canceller has a relatively narrow band clutter rejection bandwidth, and effectively a higher number of fill pulses in relation to the clutter rejection bandwidth and effective number of fill pulses for the second canceller. The outputs of the two cancellers are subjected to an and gate function, such that only targets which pass through the clutter rejection bandwidth of both cancellers are reported as a target. The circuit obtains the elimination of returns from ambiguous range interval clutter with less transmitted energy and time than conventional canceller circuits. [A3740]

"Accurate location sonar and radar"

A sonar or radar permits primary distributed scatterers that are close to the sonar or radar relative to the array dimension to be rapidly and accurately located and pertinent characteristics to be estimated, such as Doppler and complex scattering strength. The region viewed is partitioned in annuli instead of in angular pie shaped slices as is normally the case for conventional sonar. This avoids the difficulty with conventional sonar or radar of distinguishing whether a scatterer is in a side lobe or the main beam an dis preferable to conventional sonars or radars in the important case of approaching multiple scatterers, e.g. robotic vehicle sensors or torpedo terminal homing on a target, because near regions may be examined in all directions prior to further regions. Computational speed is achieved by utilizing precomputation and leaving only part of the computation to be performed in real time. [A3741]

"Methods of and circuits for suppressing doppler radar clutter"

Clutter suppressors and methods of clutter suppression for radars which employ the doppler effect for enhancing signals due to moving targets relative to signals due to clutter caused by land, sea or rain. Specifically, the disclosure concerns suppressors and methods of clutter suppression for cw doppler, pulse doppler and MTI (moving target indication) radars. The suppressors reduce the occurrence of radar output due to clutter by permitting and prohibiting radar output on the basis of the strength of signals that contain doppler frequency components of the radar echo. [A3742]

"Survivable ground base sensor"

The survivable ground base sensor is the basic element of a land-based distributed radar that consists of 60 or more individual subarrays, which are located in either a straight line or on the perimeter of a 200 nmi diameter circle in the north central U.S. At least 10 nmi separation is provided between individual subarrays. Each subarray is self-contained with emergency power and is operated unattended. There is no need for any interconnection between subarrays so that the survivability is improved, and there is no limit to the number of subarrays used except that imposed by cost and the desire for greater survivability. Since the spacing between subarrays is 10 nmi, a direct hit on one subarray will not damage an adjacent one so that a separate re-entry vehicles must be targeted to each subarray. [A3743]

"Moving target indicator using a surface acoustic wave device"

A surface acoustic wave (SAW) device in a pseudo-coherent moving target indicator uses a common input transducer to delay both reference and signal inputs to a mixer by varying amounts. The mixer produces a Doppler signal which is processed within a single range cell. The SAW device may contain additional delay paths which drive other range cells. Power splitting and amplification sections of the moving target indicator are minimized through use of the SAW device. [A3744]

"Pseudo-raster weather display apparatus"

A display system employing a stigmator coil disposed on the neck of a cathode-ray tube to widen an electron beam primarily in a direction normal to the electron beam scanning direction to produce a continuous shading effect for displaying weather information. A bidirectional pseudo-raster scan writing pattern is used to obtain maximum fill effect between scan lines and illumination uniformity with far fewer raster lines than in a conventional raster display. [A3745]

"Delay device and the use thereof in the decoding device of distance measuring equipment"

A device for delaying an electric signal comprising means for acquiring the signal, sampling it at a frequency f.sub.e and delivering it in parallel in the form of binary words of M bits, at a frequency f.sub.m such that f.sub.m = (f.sub.e /M) , means for storing said binary words for a given period of time and operating at the frequency f.sub.m and means for restoring at frequency f.sub.e the signal from the binary words. [A3746]

"Doppler-inertial data loop for navigation system"

Accurate vehicle pitch and roll can be computed from a corresponding signal loop which receives inertial data input contaminated by the effects of gravity on a vehicle. Data from Doppler radar is compared to the inertial data and an error signal dependent on pitch or roll angle is substracted from the input inertial data resulting in the generation of accurate navigational parameters. [A3747]

"Out-of-range personnel monitor and alarm"

An out-of-range monitor and alarm system that may be used by a convalescent home or the like to alert an attendant in the home that a supervised person has walked beyond a predetermined prescribed distance. The system includes a base unit that transmits a first signal to a receiver in a mobile unit carried by the supervised person. The receiver includes a threshold circuit that is adjustable to correspond to the prescribed distance and produces a threshold output signal whenever the first signal detected by the receiver drops below the threshold level. In response to the threshold output signal, a transmitter in the mobile unit produces a second signal to a receiver in the base unit, which in turn sounds an alarm indicating that the mobile unit has lost adequate signal strength, as determined by the threshold adjustment, by exceeding the range prescribed for the supervised person. The first and second signals may have equal frequencies if the mobile unit produces an output signal having an identification code. The base unit has decoder for identifying the responsible mobile unit. [A3748]

"Detection of vibrating target signatures"

This radar system can be used as an independent entity or as an addition to n operating radar system for acquiring additional data from a radar target's returned signal that is not currently being utilized. The system is to separate the amplitude modulation and frequency modulation sidebands created by the target's surface motion or vibration into independently useable entities. The system measures near carrier AM and FM noises, together with techniques for integrating these elements into a working radar system. [A3749]

"Instrusion detection system"

An intrusion detection system that comprises a transmission line for RF energy, a transmitter coupled to one end of the transmission line to supply pulses of RF energy into the line, and a range gated doppler receiver for receiving RF energy from the other end of the transmission line. The receiver includes means for producing a detection signal indicating the presence of doppler components in a range gated portion of the RF energy received from the transmission line. [A3750]

"Rapid inventory data acquistion system"

A computerized transceiver repeatedly sweeps through a set of transmit/receive frequencies to interrogate collectively a plurality of groups of items in a stocking area. Items in each group are tagged with a printed circuit transponder tuned to frequencies uniquely assigned to each group. Data turned is stored and combined mathematically by the computer to arrive at the total number of items in each group. The system is particularly adapted for taking inventory of a large number of retail shelf goods using a mobile transceiver. [A3751]

"Golf playing field with ball detecting radar units"

A golf playing arrangement which includes a fairway, a tee area at one end of the fairway, a plurality of radar ground surveillance units located on the fairway at successively greater distance from the tee area, a central processing unit and a video display terminal and putting green adjacent the tee area. Each of the ground surveillance units detects golf balls moving on the ground in a predetermined circular area containing the unit. The central processing unit calculates and the computer terminal visually displays the distance of the unit furthest from the tee area which detects a golf ball moving therethrough, and the sum of a succession of such distances. This arrangement permits a golfer to play a golf-like game without the need to follow a ball from tee to green. [A3752]

"System and method for automatically controlling vehicle speed"

A system and method for detecting a distance from a vehicle to an obstacle in front of the vehicle and controlling the vehicle according to changes in the distance thereof holds the vehicle speed constant upon recognition of the fact that the detected obstacle is a plurality of regularly spaced, stationary objects disposed along a side of a curved road and otherwise the vehicle speed is controlled on the basis of the distance between the vehicle and detected obstacles such as other vehicles moving in front of the vehicle or obstacles resting on the road as the vehicle moves through a curve. [A3753]

"Rear monitor system triggered by occupant leaving the vehicle"

A rear monitor system for an automotive vehicle comprises a sensor secured to a vehicle door located on one side of the vehicle and adapted to be operated by a vehicle occupant when leaving the vehicle, the sensor generating a signal indicating that the occupant is going to leave the vehicle. A control unit is responsive to the signal from the sensor for transmitting radiant energy in a rearward direction to detect a reflection from an object approaching the vehicle from behind at a speed higher than a predetermined value. Further provided is a safety device which is responsive to the detected reflection for preventing the vehicle occupant from opening the door. [A3754]

"Millimeter wave length guidance system"

A high frequency target seeking device, using a stabilized reflector antenna, performs range search and tracking functions and target angle search and tracking functions. A technique is provided for target range discrimination using several narrow band i.f. filters, also thereby improving signal-to-clutter ratio and signal-to-receiver noise ratio. Target search is accomplished with simultaneous range and antenna azimuth scanning, with the range bins and the antenna beam swept across the target. A multiplexer selects the range bin having signals indicative of the target. Target range tracking is accomplished by the multiplexer additionally automatically selecting range bins adjacent to the target's range bin and comparing their output signals. Antenna stabilization is accomplished utilizing signals from vehicle pitch, roll, and yaw rate sensors, and antenna elevation and azimuth rate and angle sensors. These signals are processed in the antenna control circuit according to predetermined relationships to provide the desired antenna stabilization. [A3755]

"Doppler radar velocity measurement horn"

Doppler radar apparatus for use in a velocity measuring system for farm tractors and the like. The apparatus includes a dual mode conical horn having a flare angle substantially in excess of 12.5.degree., and a dielectric lens formed of a glass filled polymer. The doppler output signal provided by the RF transceiver associated with the dual mode horn is high pass filtered to remove low frequency signals therefrom. The horn is mounted in such a way that it is isolated from mechanical vibrations which would induce doppler signal frequencies in excess of the cutoff frequency of the high pass filter. Moreover, the horn assembly (which is aluminum) and a steel housing assembly are coupled together in such a way that thermal expansion and contraction will not loosen the friction fit between the two assemblies. The two assemblies are held together by a single, large diameter annular locking ring. [A3756]

"Doppler distrometer for the measurement of hydrometer size distribution"

An apparatus and method are disclosed which employ the Doppler principle to measure the terminal velocity and, hence, the size distribution of hydrometeors such as raindrops and hailstones. The apparatus of the present invention employs a ground-based, upwardly directed, low power, 10.525 GHz homodyne continuous wave radar module to transmit microwave signals to falling hydrometeors within the size range of 0.5 mm through 4.0 cm, to record the frequency distribution and power spectrum of the reflected signals, and to process these data with "terminal velocity"-to-"hydrometeor diameter" calibration data to generate information on the hydrometeor size distribution in the precipitation under observation. The disclosed method permits a user of the apparatus to select the Doppler velocity threshold above which data are recorded for processing with a Fast Fourier Transform technique to determine hydrometer velocity values. [A3757]

"Passive transponder for locating avalanche victims"

This transponder includes a dielectric support, an antenna and a covering layer. The central portion of the antenna forms a self induction loop which, together with the junction capacity of a non-linear component serving to close the loop, provides a circuit resonating at the frequency at which the transponder receives its energy. The antenna radiates energy at double this frequency which energy may be detected by a receiver. [A3758]

"Radar system"

A radar system comprises means for forming a transmission pulse signal as m sets of n pulses, the individual sets having respective PRPs Ti (i=1, 2, . . ., m) moving target detection means, and angle measurement means utilizing beam-to-beam amplitude comparison and interpolation for a given moving target. Beam-to-beam amplitude comparison and interpolation is carried out at least twice for one target by making use of a pair of video signals with the same PRP processed by the moving target detection means. The angle measurement is achieved through a predetermined correlation processing over thus obtained interpolated angle values for a target. [A3759]

"Efficient adaptive filter bank"

An N-point Fourier transform circuit for a moving target indicator system including a delay circuit with 2N-2 delays, N frequency filters, a processor for forming a main signal and N-1 auxiliary signals via time sample manipulation, a Gram-Schmidt adaptive canceller circuit for decorrelating the N-1 auxiliary signals from the main signal, and a first and second commutating switches. The first switch tracks a given set of N time samples through the delay circuit. The second switch switches the given set of N time samples through a different successive frequency filters of the N frequency filters every transmission. The first switch tracks in synchronism with the second switch and switches to obtain a new given set of N time samples every NT seconds. [A3760]

"Radar detection of hazardous small scale weather disturbances"

The detection and warning of microbursts, low level wind shear, and other weather disturbances, which are hazardous to aircraft operations and to the public at large, are accomplished with either an airport surveillance radar (ASR) or a multi-beam Doppler radar. ASR Doppler systems normally operate to receive one of two relatively large vertical fan beams having different elevation angles but which overlap one another so that they have equal gains at an elevation angle, called the null, at a relatively low angle, for example 5.degree.. Below this null, the low beam antenna gain exceeds that of the high beam, and conversely above it. Accordingly, by subtracting the high beam Doppler spectrum from that on the low beam, a Difference Doppler Spectrum (DDS) is produced which is positive below the null and negative above. The velocity bounds of the positive portion of the DDS provide the wind speed components at the null and at heights near the surface. These wind speed components are then utilized to measure and map radial and horizontal shear, the boundaries of the disturbance and other signatures such as vertical shear and turbulence and the rate of change of all the parameters, thereby permitting the detection of the location and track of the disturbance. A multi-beam Doppler radar can be utilized to perform similar functions of measuring the mean Doppler velocity, Doppler spectral breadth, and reflectivity simultaneously at all elevations. Both systems provide effective enhancements in signal to clutter ratio through pattern recognition and motion detection. [A3761]

"Phased antenna array for wind profiling applications"

A diagonal phased antenna array for use as a wind profiler by means of Doer shift measurements comprises a plurality of Yagi-Uda antennas which are oriented in a predetermined direction such that Yagi-Uda antennas have a polarization 45.degree. offset from the principal planes of operation of the antenna array resulting in similar radiation patterns subject to a geometric taper in the array aperture with respect to the principal planes. [A3762]

"Bistatic coherent radar receiving system"

A coherent-on-receive MTI radar receiver system for use with cooperative or non-cooperative radar transmitters of either the coherent or noncoherent, simple magnatron type and scanning antennas. The receiver includes coherent digital signal processing with provision for normalizing or compensating phase variations in the transmitter carrier pulses. [A3763]

"Method and apparatus for microwave determination of liquid rate-of-rise using Doppler detection"

A method and apparatus provide for the determination of the rate-of-rise of the level of a liquid, such as molten metal in a mold, in a reliable, accurate, and flexible manner. Molten metal passes from a container through an adjustable valve in an orifice to a mold. A microwave generator is connected to a microwave antenna located above the mold for transmitting microwaves to the surface of the molten metal in the mold. A mixer/detector is operatively connected to the antenna, and a computer is operatively connected to the mixer/detector. The computer processes the mixed signal received from the mixer/detector after it is converted to a digital signal. This digital signal is responsive to the Doppler signal caused by change in the level of the metal in the mold. The rate-of-rise of the surface of the molten metal is calculated in response to the digital signal, and is displayed on a monitor. The slide gate is controlled to adjust the amount of molten metal flowing from the container to the mold to achieve a desired rate-of-rise. The computer uses various techniques, such as calculating rolling averages and optimizing maxima-to-maxima and minima-to-minima time interval calculations, to improve reliability in the presence of noise, spurious multiple reflections, and disturbances in the molten metal surface. [A3764]

"Signal receptor-reradiator and surveillance tag using the same"

An improved receptor-reradiator, for use in a surveillance system employing a carrier frequency of UHF or higher in combination with a low frequency electrostatic field signal to be modulated on the carrier signal by the reradiator, is provided by an antenna frame wherein the metallic foil of which it is made is divided into three parts. The first part is U-shape of substantially one width and joins to a central portion of substantially reduced width which is predominantly inductive at the carrier frequency. A semiconductor diode, preferably a Schottky barrier diode or PIN switching diode, is connected in said central portion in series therewith. The opposite end of the central portion joins to an enlarged rectangular portion. At the low frequency the component has effectively two capacitive arms, one on each side of the diode, of different surface area to ensure bias signal for the diode. However, at the carrier frequency, the central portion has a high inductive reactance which, in conjunction with the inductive reactance of the U-shape portion, tunes to resonance the total capacitance of the component including that of the diode. The parts are proportioned such that the diode sees at the carrier frequency an inductance on one side and a capacitance on the other side. [A3765]

"Medical diagnostic microwave scanning apparatus"

Microwave apparatus for diagnosis of cancer of the breast includes a microwave transmitter and a microwave antenna for directing a microwave signal to the breast under examination, and a microwave receiver having amplitude and phase shift detectors for receiving of reflected microwave signals. A processor is connected to the receiver for processing the amplitude and phase information to detect and locate cancer in the breast. A matching plate having a dielectric constant substantially the same as normal breast tissue is located between and in engagement with the breast and antenna. The antenna engages and sweeps over the plane surface of the matching plate to eliminate any air gap in the transmission path. A display unit is connected to the processor to create a microwave image of cancer growth, if any. [A3766]

"Security eyes for prevention of car accidents"

This invention allows for the use of safety apparatus at the front and rear of the automobile, which serve as an addditional pair of "eyes" for the driver. The apparatus comprises a security system for the prevention of automobile collisions. The apparatus at the front of the automobile is connected to the front wheel system or to the steering mechanism by an appropriate rotary device which revolves so that the beams or waves do not encounter vehicles in oncoming lanes going in the opposite direction. The electronic safety apparatus emits beams or waves whose length is automatically regulated to correspond to weather conditions and to the speed of the vehicle so as to ensure safe braking distance. [A3767]

"Adaptive MTD digital processor for surveillance radar"

A digital MTD processor interposed between a coherent video detector and a signal extractor of a surveillance radar comprises a plurality of Doppler filters connected in parallel to the video-detector output, including a zero filter, working into respective modulus extractors connected by way of respective threshold circuits to a common OR gate. Each threshold circuit includes a fixed-threshold comparator and an adaptive-threshold comparator with inputs connected in parallel to the output of the associated modulus extractor, either of these comparators being connectable to the OR gate via a switch controlled with the aid of a rain-clutter map so that the adaptive threshold is used only during exploration of regions with heavy rain. A ground-clutter map, which can be updated on the basis of level measurements performed on the output of the zero filter, controls the selective loading of each Doppler filter with one of three preselected sets of weights depending on the intensity of the ground clutter in the region being explored. Where ground clutter is heavy, the threshold circuit of the zero filter may be cut off from the OR gate. Both the fixed and the adaptive thresholds can be incremented in response to a command from the signal extractor generated upon the occurrence of an excessive number of false alarms. [A3768]

"Vehicle mounted Doppler radar system"

A Doppler radar system for mounting on a vehicle to sense the speed of movement of the vehicle and to provide an output proportional to the speed of the vehicle. The output is substantially free from errors due to the vibration and of the vehicle. A Janus configuration is also provided which also eliminates errors due to the angle of tilt of the vehicle. [A3769]

"Vehicle identification system using radar and acoustic information"

A vehicle identification system includes a doppler radar producing a doppler frequency signal having noise components and having a value f.sub.D corresponding to the speed of the vehicle to be identified and a doppler frequency having a value X.multidot.f.sub.D corresponding to the speed of the vehicle propelling means, each doppler frequency being modulated by signals corresponding to the movements made by individual elements of the vehicle propelling means. The doppler signal is passed through first and second adjustable filters adjusted to pass f.sub.D and x.multidot.f.sub.D respectively and sidebands relating to the modulating signal. Amplitude detectors coupled to the outputs of the two filters remove the doppler frequencies leaving the modulating signals relating to the movement of the vehicle elements. The modulating signals are applied to an adjustable commutating filter adjusted to frequency by a signal corresponding to frequency f.sub.D. The output signal from the commutating filter represents sounds made by the vehicle individual elements by which one can identify the vehicle as to type. [A3770]

"Method for sea surface high frequency radar cross-section estimation using Dopler spectral properties"

A method for estimating the high frequency radar cross-section of the sea surface. A Doppler spectrum of the sea surface is obtained by correlating returns from high frequency radar signals. Approach and recede Bragg spectral lines and a zero Doppler frequency continuum level are identified in the Doppler spectrum. The amplitude ratio .rho. between the Bragg spectral lines and an amplitude ratio .zeta..sub.M between the maximum amplitude Bragg spectral line and the zero Doppler frequency continuum are measured from the Doppler spectrum. The radar cross-section is then determined from the ratios .rho. and .zeta..sub.M. In a further method embodiment, the estimated radar cross-section is used to estimate the radar cross-sections of targets appearing in the Doppler spectrum. [A3771]

"Radar velocity sensor"

A tracking, variable Q bandpass filtering method and apparatus are provided for processing an IF signal from a radar transceiver or the like. The method comprises developing a digital period signal corresponding to the period of each of selected cycles of the IF signal, subjecting the digital period signal to low pass filtering, and controlling the effective corner frequency of the low pass filtering in accordance with the amount of variation in the digital period signal from one selected cycle to a successive selected cycle for producing a filtered signal which substantially follows the digital period signal, thereby substantially simultaneously tracking and filtering the IF signal. The apparatus comprises apparatus for carrying out the foregoing method. Preferably, the apparatus also includes an output switching control for selectively delivering or withholding the filtered signal from an output utilization device. This control is responsive to a predetermined control signal for withholding the filtered signal from the output utilization device. Preferably, the apparatus also includes a switchable power supply for the radar transceiver and a control circuit responsive to a predetermined control signal for switching the switchable power supply means to an inactive condition, thereby removing power from the radar transceiver. [A3772]

"Suppressor of second-time-around clutter echoes for MTI pulse radar provided with power oscillator"

A device for suppressing second-time-around echoes from far-out clutter in an MTI pulse radar lies in shunt with a digital signal processor connected to the receiver output of the radar whose transmitter includes a power oscillator maintaining phase coherence only for the duration of an outgoing pulse. In order to minimize the occurrence of blind speeds, the oscillator is triggered for different pulse-repetition frequencies of predetermined values in alternate scanning intervals each lasting for an antenna rotation by half a beamwidth. Echoes from a group of radar pulses emitted in one interval are accumulated and then compared in magnitude with accumulated echoes from another such group emitted in an adjoining interval. If these magnitudes--relatively adjusted to compensate for the different numbers of pulses per group--are substantially equal over a sequence of antenna revolutions, they are classified as due to second-time-around clutter echoes and the output signal of the processor is eliminated for the corresponding scanning intervals. [A3773]

"Ground clutter suppression technique"

A ground clutter suppression technique is disclosed utilizing two parallel return signal processing paths, both utilizing linear-to-logarithmic conversion capability and one having a signal delay capability for one pulse repetition. The outputs are subtracted and are subsequently compared with a factor related to the root-mean-square (rms) of two deviation inputs, one input functionally related to apparatus limitations and one deviation input functionally related to antenna position (step between samples) for each signal received. The Doppler frequency standard deviation inputs are then summed rms and used to select an amplitude standard deviation which is compared with the amplitude difference between successive return signals. Thereafter, the logic decision output is operated on utilizing a digital filter to essentially eliminate ground clutter or small variance (PRF to PRf) return signals from the display. [A3774]

"Inter-vehicle distance control system for vehicles"

An inter-vehicle distance control system for a vehicle wherein the distance between the vehicle and a preceding object and a relative velocity therebetween are detected by a detection system such as a radar system, and when this distance has become shorter than a predetermined value, a reaction force is imparted to a throttling operation member such as a throttling pedal. The vehicle operator is effectively advised of this fact. [A3775]

"Positioning jig for edgewise bracket"

A positioning jig for an edgewise bracket having a lingually disposed vertical slot or opening to position the bracket on a tooth when bonding the bracket to the tooth. The jig is disposable and mounted on the bracket to be handled as a unit during the bonding procedure and thereafter removable from the bracket once the bonding material has cured. Indicia is provided on the jig and the bracket to identify the tooth on which the bracket is to be mounted and the spacing of the archwire slot from the occlusal or incisal edge of the tooth. [A3776]

"Surface acoustic wave passive transponder having acoustic wave reflectors"

A passive transponder for use in an interrogation/transponder system comprises a substrate having a substrate surface defining a path of travel for surface acoustic waves, at least one transducer element arranged on the surface for converting between electrical energy and surface acoustic wave energy which propagates along the path of travel, and a circuit, connected to the transducer element (s) , for supplying interrogating signals to the transducer element (s) and for receiving reply signals therefrom. In order to minimize insertion losses in the substrate, acoustic wave reflectors are provided to reflect the surface acoustic waves back towards the transducer element (s) . [A3777]

"Surface acoustic wave passive transponder having amplitude and phase-modifying surface pads"

A passive transponder for use in an interrogation/transponder system comprises a substrate having a substrate surface defining a path of travel for surface acoustic waves, a launch transducer element arranged on the surface for converting interrogating signals into surface acoustic waves which propagate along the path of travel, a plurality of tap transducer elements arranged on the surface at spaced intervals along the path of travel for converting surface acoustic waves into respective output signals, and a circuit, connected to the tap transducer elements, for combining the output signals of these transducer elements to form reply signals. In order to control the delay time from transducer element to transducer element, one or more "delay pads" are provided on the substrate surface between these transducer elements. [A3778]

"Collision avoidance apparatus"

Apparatus for assessing maneuvers of a first vehicle (6) so fitted relative to other vehicles (58, 68, 71-74) comprises sensing means for providing signals representative of the positions and velocities of the other vehicles relative to the first vehicle (6) , computing means responsive to said signals for computing symbology respectively associated with the other vehicles, and display means coupled to the computing means for displaying the symbology relative to the position of the first vehicle, thereby providing indicia to assess maneuvers of the first vehicle which will avoid collision with the other vehicles, and which will ensure that the first vehicle will not pass closer to the other vehicles than a predetermined distance for all relative positions and velocities thereof, the symbology associated with each of the other vehicles in all encounter circumstances comprises at least a final escape point (FEP) (40) which, if reached by the first vehicle (6) , will allow the first vehicle still to avoid the associated other vehicle by said predetermined distance, and two vectors (49, 50) , originating at the FEP, for the first vehicle, which will take the latter clear ahead or clear astern of said other vehicle by said predetermined distance. [A3779]

"Apparatus for compensating non-linearities in frequency-modulated signal"

A "passive interrogator label system" (PILS) comprises an interrogator for transmitting an interrogation signal, one or more "labels" or passive transponders which produce a reply signal containing coded information in response to the interrogation signal, and a receiver and decoder for receiving the reply signal and decoding the information contained in it. The frequency of the interrogation signal assumes a plurality of frequency values within a prescribed frequency range. The decoder includes a mixer (four quadrant multiplier) for mixing together the interrogation and reply signals (or signals derived therefrom) to produce a mixed signal containing frequencies which are the sum and difference of the frequencies of the interrogation and reply signals. A signal processor, responsive to this mixed signal, detects the amplitude and phase of at least some of the frequencies contained in the mixed signal and thereby determines the informational code associated with the transponder. Non-linearity in the transmitted frequency values is compensated by a circuit which produces a sampling signal when the frequency has changed by a prescribed amount .DELTA.f. This sampling signal triggers an analog-to-digital converter which converts the mixed signal (or a signal derived therefrom) into a digital value upon receipt of each sampling signal. [A3780]

"System and method for automatically controlling vehicle speed"

A system and method for automatically controlling the speed of an automotive vehicle holds the vehicle speed constantly at a set vehicle speed when there are no other vehicles in front of the vehicle and controls the vehicle speed so as to follow another vehicle moving in front of the vehicle according to the distance between the two vehicles. The system disables both of the above-described functions when the vehicle speed is outside of a predetermined speed range around a set vehicle speed after the leading vehicle is no longer in front of the vehicle or a predetermined interval of time after the other vehicle has disappeared from a front detection area. [A3781]

"System for automatically controlling vehicle speed"

In a system and method for automatically controlling a vehicle's speed, the rate of change of the inter-vehicle distance per predetermined unit of time is calculated from the detected inter-vehicle distance between the controlled vehicle and a preceding vehicle, a basic safe inter-vehicle distance is corrected according to the calculated rate of change of the inter-vehicle distance per predetermined time, and the vehicle speed is controlled according to the difference between the corrected safe inter-vehicle distance and the detected inter-vehicle distance. [A3782]

"Method and apparatus for measuring water level in a well"

A method for measuring the water level in a well including the steps of radiating an electromagnetic wave to a gap between a boring drill rod and a casing pipe by using a transmitting antenna, receiving the electromagnetic wave reflected by a surface of the water level in the casing pipe by using a receiving antenna, then measuring a distance between the surface of the water level and the receiving antenna based on the going and returning time of the electromagnetic wave. [A3783]

"Surface acoustic wave passive transponder having parallel acoustic wave paths"

A passive transponder for use in an interrogation/transponder system comprises a substrate having a substrate surface defining a path of travel for surface acoustic waves, a launch transducer element arranged on the surface for converting interrogating signals into surface acoustic waves which propagate along the path of travel, a plurality of tap transducer elements arranged on the surface at spaced intervals along the path of travel for converting surface acoustic waves into respective output signals, and a circuit, connected to the tap transducer elements, for combining the output signals of these transducer elements to form reply signals. In order to reduce the effect of spurious signals, the tap transducers are arranged both in series and in parallel with respect to the path of travel. [A3784]

"Chirp signal gating circuit for expander in a pulse compression radar system"

A gating arrangement for a pulse compression circuit includes a surface acoustic wave delay line SAW responsive to an input pulse to generate a frequency-modulated radio-frequency output signal which is applied to an output gate OG. The output signal is also applied to circuit means DC operable to product a digital pulse corresponding to each cycle of the output signal. The pulses are counted by a counter CT and applied to control means CM. This responds to first and second predetermined counter states to control the operation of the output gate OG. [A3785]

"Radar channel including an orthogonal MTI filter pair"

In a radar operating in a moving target indication (MTI) mode with frequency diversity by transmitting N+1 pulse bursts and receiving echo signalling therefrom, a radar channel is included for doppler processing the received N+1 pulse echo signal bursts. Each pulse of the same burst envelopes a fixed carrier frequency. The radar is operative to change the transmitted carrier frequency from one pulse burst to another. The radar channel comprises an MTI filter operative as two different orthogonal MTI filters, each having a frequency response similar to an N-pulse MTI filter, to process functionally in parallel a received N+1 pulse echo signal burst to generate a filter signal from each functional filter. Also included is apparatus for combining the two filter signals non-coherently to generate a composite signal corresponding to the N+1 pulse echo signal burst for target detection. The radar channel is operative to process N+1 pulse bursts with either fixed or variable interpulse periods. The two functionally operative filters have frequency response characteristics substantially similar to each other for target echo signals, but effect uncorrelated noise output signals corresponding to a common N+1 pulse echo signal burst. [A3786]

"MTI Radar"

An MTI radar provided with a MTI processor which includes a single erasing circuit for erasing a vector signal due to a stationary target from among all the input vector signal of reflected waves both from a moving and a stationary target, and an arithmetic circuit for removing any other variations than ones from the moving target by calculating the inner product of the post-single-erasing vector signal and a pre-erasing vector signal. [A3787]

"Microwave detection system"

A microwave detection system is constructed which is useful for detecting the presence or absence of a target within a microwave transmission line. [A3788]

"Radar device"

The novel radar device (1) radiates triangularly frequency-modulated continuous-wave signals via two radiation patterns (3, 4) . If an object (2) is detected by one radiation pattern at a time, relative velocity (V.sub.1, V.sub.2) and distance (r.sub.1, r.sub.2) are measured. The time between the measurements with signals received via the first and the second radiation pattern, respectively, is t. If the velocity of the object (2) relative to the radar device is V.sub.1 =0 when it is detected by the first radiation pattern, the associated distance is r.sub.10. The velocity of the object is determined either by the equation ##EQU1## or by either of the equations ##EQU2## A combination of V.sub.A and V.sub.B is also possible. If the object is so large in extent as to be detected by both radiation patterns simultaneously, switchover between the two radiation patterns is effected at a given clock rate. If no pairs of values are used at which V.sub.1 =0, the evaluation is performed in accordance with either of the equations ##EQU3## [A3789]

"Navigation warning system and method"

A navigation warning system and method for vessels includes one more earth satellites which electro-optically scan whole bodies of water whose signals are analyzed by a computer either on a satellite or at a ground location. The analyzing computer includes a memory which contains coordinates of hazardous ocean conditions. The computer automatically analyzes images generated by vessels travelling within the scanned area and detects when two vessels are on a collision course. Automatic visual and sound indication including a voice recording reproduction unit alerts vessel operators of impending collision conditions. The system may include automatic control of the vessel in response to signals generated by the computer for either modifying the control signals or supplying the computer with information transmitted thereto from the satellite and generated either by analyzing computer in the satellite or by the ground location which is in communication with the satellite and receives information generated by the electro-optical scanner. [A3790]

"Speed detecting device employing a Doppler radar"

A speed detecting device comprises a comparing circuit for comparing the amplitude of a Doppler signal with a reference amplitude value, and an excluding circuit for excluding a speed signal corresponding to the Doppler signal of the amplitude smaller than the reference amplitude value, whereby the speed signal corresponding to the Doppler signal of the amplitude larger than a predetermined value. One embodiment of the device further comprises a circuit for selecting and outputting a Doppler signal of the largest amplitude, thereby detecting a vehicle speed based on the Doppler signal of the largest amplitude. Another embodiment of the device comprises a modulator for sequentially changing transmitting frequency of the Doppler radar into a plurality of frequencies at a predetermined period, a detector circuit for detecting each Doppler signal from the Doppler radar in synchronism with the change of the transmitting frequency, a signal processing circuit for forming a Doppler signal corresponding to the transmitting frequency, and a selecting circuit for selecting a Doppler signal of the largest amplitude. [A3791]

"Surface acoustic wave passive transponder having optimally-sized transducers"

A passive transponder for use in an interrogation/transponder system comprises a substrate having a substrate surface defining a path of travel for surface acoustic waves, a launch transducer element arranged on the surface for converting interrogating signals into surface acoustic waves which propagate along the path of travel, a plurality of tap transducer elements arranged on the surface at spaced intervals along the path of travel for converting surface acoustic waves into respective output signals, and a circuit, connected to the tap transducer elements, for combining the output signals of these transducer elements to form reply signals. In order to maximize energy conversion from the interrogation signals to the reply signals, the launch transducer is made larger than the tap transducers. [A3792]

"Intrusion detector"

An intrusion detector system with a transmitter having a clock operating at a selected frequency, a pseudorandom code sequence generator for generating one of a selected number of codes, a modulator for spread-spectrum modulating an electromagnetic signal with the generated pseudorandom code sequence signal, and an antenna for transmitting the modulated signal through a zone of protection, and a receiver having an antenna, a demodulator for detecting and demodulating the modulated signal to recover the transmitter pseudorandom code sequence signal, a clock operating at a frequency corresponding to the transmitter clock, a pseudorandom code sequence generator for generating one of a selected number of receiver code signals corresponding to the transmitter code signals, a detector for comparing the received code signal to the receiver code signal and generating a detection signal proportional to the signal amplitude of the received code signal when locked in phase with the receiver code signal, a phase detector for detecting the phase difference between the two code signals, a control for phase synchronizing the two code signals, and a monitor for detecting and signalling changes in the detection signal resulting from entry of movement of an intruder in the zone of protection. [A3793]

"Surface acoustic wave passive transponder having non-reflective transducers and pads"

A passive transponder for use in an interrogation/transponder system comprises a substrate having a substrate surface defining a path of travel for surface acoustic waves, a launch transducer element arranged on the surface for converting interrogating signals into surface acoustic waves which propagate along the path of travel, a plurality of tap transducer elements arranged on the surface at spaced intervals along the path of travel for converting surface acoustic waves into respective output signals, and a circuit, connected to the tap transducer elements, for combining the output signals of these transducer elements to form reply signals. In order to minimize reflections from the edges of the transducer elements, these elements are configured with serrated edges facing the path of travel. [A3794]

"Proximity radar"

A proximity radar is described in which a signal phase modulated in accordance with a pseudorandom sequence is transmitted from an antenna, and a return signal reflected from a target is received by this antenna. The return signal is correlated with a signal identical to the transmitted signal but delayed by a selected time interval. The delay imposed on the transmitted signal as fed to the correlator is alternately given the two values n.t and n'.t where n' is less than n and the time interval n.t corresponds to the time taken by the signal to travel to and return from the target when the radar is at a predetermined distance from the target, which distance is to be detected. The correlator output is fed through an amplifier circuit including an automatic gain control circuit when the delay is n'.t and the automatic gain control circuit is inoperative when the delay is n.t. [A3795]

"Vehicle travel control device"

A vehicle direction control device is provided including three receivers in the vehicle with the center receiver controlling the direction along a primary cable in the roadway with change of direction cable systems taking over control through a side receiver originally parallel with the main line of travel, diverging to a new direction and then picking up a parallel relationship with a new primary line of travel automatically switching back to the center receiver control along the new line of travel. [A3796]

"Motion picture camera automatic focusing system"

A focusing system for a variable focus lens of a motion picture camera includes a pulse modulator and a microwave transmitter mounted on a camera frame for generating a high frequency pulsed signal which is transmitted to a selected target which carries a reactive signal generator that is responsive to the first signal for coding and retransmitting the coded signal back to a receiver mounted on the camera frame, and a signal processor for determining the interval of travel of the signal and translating the interval into a distance-analog signal that is transmitted to a focusing motor for driving the focusing mechanism of the lens for focusing the lens at the distance determined by the signal. One alternate embodiment includes multiple reactive signal generators having distinctive signal responsive controls and portable remote transmitters for selectively switching to the selected ones of said reactive generators. Another embodiment includes a system for synchronizing the controls of multiple cameras for preventing interference between them. [A3797]

"Vector phase angle change distribution processor"

A system and technique is disclosed for estimating the real-time spectral width of radar returns to provide an indication of weather turbulence. The system includes a Doppler radar to provide the in-phase and quadrature phase signals from successive range returns which are digitized and converted to a phase angle prior to processing. Successive angular samples at the pulse repetition frequency are subtracted to provide a phase angle change. The phase angle change is filtered to determine an average angular mean which is then subtracted from new angular samples to determine the angular deviation. The angular deviation for each sample is in turn compared with a threshold to provide an output which is averaged over time to determine when the standard deviation of the samples exceeds a reference value. When the standard deviation of the samples exceeds that reference value, the spectral width is of a magnitude which indicates the presence of turbulence. [A3798]

"Method and apparatus for evaluating the range data accumulated by distance measuring equipment"

This invention discloses a DME which employes an improved technique for validating received replies. The technique employed reduces lock-on time by analyzing all of the range data received within a set time period following the transmission of an interrogation pulse pair rather than just one range figure for each interrogation cycle. The DME also provides improved accuracy and reliability by varying the width of the range gate used in analyzing the received range data in accordance with the time difference between the two interrogation cycles from which range data is being compared with system status, i.e., whether the system is in the locked position or not. [A3799]

"Movement monitor"

A proximity monitoring system for individually identifying an object or person, and having a central information processor, and a signal receiver, several remote detectors in various locations at a distance from the information processor, each having a first transmitter for communicating with such processor and having a second transmitter and a receiver, and several individual personalized portable identifiers, each identifier having a continuously activated receiver, a signal transmitter which is normally de-activated, a battery pack, and a switch operated by the receiver in response to a signal from a detector, to switch the battery on to activate the transmitter, for emitting a personalized coded identification signal. [A3800]

"Methods and apparatus for measuring a length of cable suspending a well logging tool in a borehole"

Methods and apparatus are disclosed for measuring a length of logging cable introduced into a borehole, thereby measuring the depth of a logging tool, or sonde, attached to the lower end of the cable. The methods involve producing an electrical signal, which propagates along the cable, and detecting at the mouth of the borehole the time of passage of the initial electrical signal and the time of passage of a subsequent electrical signal reflected or returned upwardly from the lower end of the cable, or, alternatively, the time of arrival of the reflected or returned electrical signal at the upper end of the cable. These times can be determined by means of clocks which are switched on by the passage of the initial electrical signal and switched off by the subsequent electrical signal. Knowing the time intervals and the velocity of propagation of electrical signals in the cable, the length of cable from the mouth of the borehole to the lower end of the cable, and thus the depth of the sonde, is measured. Various embodiments of apparatus including electrical signal detectors which do not electrically contact the cable are disclosed for sensing the electrical signals necessary for measuring the length of cable introduced into the borehole, and thus the depth of the sonde. [A3801]

"Electronic surveillance system employing the doppler effect"

A coherent frequency, velocity responsive electronic surveillance system detects the motion of a transponder relative to two receiving antennas on opposite ends of a surveillance zone positioned at the exit of a retail store. Motion in opposite directions relative to the two antennas indicates that the transponder is within the surveillance zone. As a means of reducing false alarms, motion of a transponder proximate to, but outside the zone is distinguished from motion inside the zone because motion outside the zone is in the same direction relative to both antennas. False alarms are reduced even further by requiring detection of motion through a selected distance before indicating an alarm. [A3802]

"Out-of-range personnel monitor and alarm"

An out-of-range monitor and alarm system that may be used by a convalescent home or the like to alert an attendant in the home that a supervised person has walked beyond a predetermined prescribed distance. The system includes a base unit that transmits a signal at a frequency F1 to a receiver in a mobile unit carried by the supervised person. The receiver includes a threshold circuit that is adjustable to correspond to the prescribed distance and produces a threshold output signal whenever the F1 signal detected by the receiver drops below the threshold level. In response to the threshold output signal, a transmitter in the mobile unit produces an F2 output signal to a receiver in the base unit, which in turn sounds an alarm indicating that the mobile unit has lost adequate F1 signal strength, as determined by the threshold adjustment, by exceeding the range prescribed for the supervised person. [A3803]

"Navigation system including an integrated electronic chart display"

A navigation system particularly adapted for ships making a passing within a harbor or the like, utilizing signal inputs from on-board vessel position determining equipment such as Loran or Decca apparatus and an on-board object detecting equipment such as a radar or sonar apparatus. The system further includes an on-board vessel position computer which operates in a differential Loran mode in response to observed Loran time differences, stored data from an initial calibration, and Loran grid offset data from an on-shore monitor system to compute a highly accurate current or present position fix in longitude and latitude whereupon the computer causes a predetermined electronic chart to be displayed in color on the screen of a cathode ray tube, being generated from a plurality of electronic charts stored in the form of digital files in memory. The selected chart, together with the present position of the ship, is displayed along with preselected alpha-numeric indicia of data relating to bearings, way points, ranges, "time to go", etc., also generated in accordance with the computed vessel position. Radar target returns of the local land mass and other stationary moving targets are additionally received by the ship's radar. The radar image of the target echoes is next referenced to and superimposed on the electronic chart generated, however, the radar's land mass echoes are suppressed in favor of the electronic chart land mass while displaying all other targets. [A3804]

"Tracking servo compensator with rate aiding"

A tracking servo compensator is disclosed for radar systems which steer their antenna beams using a servomechanism that physically moves the antenna. The disclosed tracking servo compensator permits switching between trackers (e.g. from area to point track) and from one tracked target to another without undesirable transients that could cause loss of track. Rate aiding and target range estimates are provided when tracker base motion is known. The compensator works by providing a servo signal that continually monitors the error in estimated track point line-of-sight angular velocity independent of which tracker is employed or the target being tracked. When base motion is known, this signal is used to update the target range estimate so that an accurate rate aiding signal is available. The servo provides smooth controlled-speed transitions between track points during mode switching, and provides an input for manual slewing of the tracker platform during offset track conditions. It also provides an estimate of platform to track point range. [A3805]

"Microwave electromagnetic borehole dipmeter"

A borehole logging tool includes three microwave antennas positioned from the longitudinal axis of the tool and spaced approximately equally around the axis. Microwave energy from a pulsed source is applied to the antennas during a plurality of microwave transmission periods. During a plurality of microwave reception periods, the amplitudes and the phases of the microwave energies received by the three antennas are measured for use in the determination of the dip of the formations surrounding the borehole. [A3806]

"Range doppler coupling magnifier"

A pulse expander-compressor for magnifying the range-doppler-coupling effs that accompany the use of frequency-modulation derived phase coded pulse compressors in order to accentuate the doppler-coupling velocity effects on target echoes. The foregoing magnification is accomplished by generating a doppler tolerant polyphase coded waveform with equal time spaces inserted between successive code elements in order to make the time difference between the first and last code elements independent of the number of code elements involved. These equal spaces may be variable in order to allow any desired target radial velocity to produce a phase difference between the first and last code elements of 2.pi.. The foregoing may be implemented in a pulse expander-compressor by replacing each delay t.sub.c in the compressor input-signal expansion circuit by a set of N delay elements t.sub.c, and a set of N associated switches, the switches permitting each element in the set to be connected or bypassed, as desired. The time-dispersion circuit for the compressor is likewise modified by replacing each of its Mt.sub.c delays by a set of N delay elements Mt.sub.c, each of which is independently connectable or bypassable. [A3807]

"Multi-product acousto-optic time integrating correlator"

A device for processing signals to obtain a multi-product, time integrated, correlated output signal. A laser light beam is expanded and shaped into a sheet beam which is directed across the surface of an acousto-optic medium. Four acoustic transducers are disposed on the acousto-optic medium, two at each end of the medium. Each acoustic transducer is supplied with a signal to be propagated on the surface of the acousto-optic medium. The first two signals diffract the sheet beam to produce a first, product diffracted beam of light containing the product of the first two signals. The second two signals diffract the sheet beam to produce a second product diffracted beam of light containing the product of the second two signals. The two product diffracted beams are rotated so that they are orthogonal to each other, and then combined. A time integrating photodetecting means is disposed in the path of the combined beam for generating a multi-product, time integrated, correlated output signal. [A3808]

"Radar systems"

A radar system includes signal processing means (SP) operable to determine the velocity relative to a receiving antenna (AR) of each object from which transmitted radiation is reflected. The signal processing means delivers signals representing the relative velocities of objects in each of a number of predetermined ranges of velocity values. Storage means (SM) are provided which comprise, for each increment of antenna bearing, a separate storage location for each of the ranges of velocity values. Circuit means (CM) are operable to read out the contents of the storage means and to modify signals delivered by the signal processing means (SP) in accordance with the contents of the storage means (SM) to provide output signals. In addition the circuit means (CM) is also arranged to further modify the output signals to provide new contents for the storage means. [A3809]

"Range reply search apparatus"

Apparatus for searching for range indicating pulse signals received as part of distance measuring equipment which first form a list of distance indications in a first search time. The distance indications obtained in a second search time are then logically combined with those indications in the first list and any combination that results in a difference value of less than a prescribed amount is retained for list updating purposes until there is only a single distance indication left in the list. The apparatus can then change to a track mode by placing a search window around the single distance indication thereby reducing the amount of extraneous information to be manipulated by the receiving apparatus. [A3810]

"Environmental mapping system"

A circuit which detects environmental sources of echos received by a pulscho system such as a radar and classifies the sources of the echo at each range resolution cell as either short-pulse interference, rain clutter or jamming, distributed land clutter, an isolated target or thermal noise. The circuit implements on the screen of a cathode ray tube a digital map of a selected echo source type by modulating the electron beam intensity with a binary digit (0 or 1) at each increment of the sweep corresponding to a range resolution cell. The circuit utilizes a pulse-to-pulse noncoherent subtraction to remove correlated echos, leaving only uncorrelated type echos. Short-pulse interference is then detected and the uncorrelated echo component is compared to thermal noise to determine if rain clutter or noise jamming is present. The threshold for either target detection or land clutter is determined from the uncorrelated echo component, and all correlated targets and land clutter are next detected. The correlated echos are separated into distributed land clutter and isolated targets by the following procedure: the isolated targets are required to have uncorrelated echos on each side of them in range. Finally, if no detection of any of these types is made, thermal noise is declared. [A3811]

"Receiver for a sounder permitting the detection and measurement of phonomena linked with the earths environment"

Receiver for a sounder for the detection and measurement of phenomena linked with the earth's environment, wherein it comprises a reception channel, whereof one input receives the echo signals of the electromagnetic signals emitted towards the phenomenon, an electromagnetic signal frequency shift and amplitude-calibration test channel, whereby the reception channel comprises a first stage having in series means for filtering, attenuating and amplifying the echo signals received, a second stage comprising in series means for the frequency conversion attenuation, filtering and amplification of the signals received from the first stage, and a third stage comprising in series means for frequency conversion, filtering and amplification of the signals received from the second stage, the attenuation means of the first and second stages being independently controllable for each frequency of the signals which they receive, in such a way that the signals from the corresponding amplification means have an amplitude higher than the amplitude of the distortions produced by the reception channel and the amplitude of the interference signals received by the reception channel. [A3812]

"Ground surveillance Doppler radar"

The invention relates to Doppler radar making it possible to subject the ground to surveillance. It consists of providing a conventional Doppler radar having a transmitter, a receiver, processing means making it possible to supply a binary signal indicating the presence or absence of a moving target in the given distance gate series and a display screen with means making it possible to take account of certain relative danger criteria, as a function of the distance at which the targets are located and as a function of the speed at which they are moving. These means make it possible to control the screen, in order that the relative danger is displayed in the form of an overbrightness for the targets considered dangerous. It makes it possible to improve the display conditions of ground surveillance Doppler radars. [A3813]

"Retrospective data filter"

In a target detection communication system, apparatus and method for determining the presence of probable targets based on contacts (which can indicate the presence of a target, noise, chatter, or objects not of interest) detected within a predefined position sector or sectors over a specified number of scans. The position of each detected contact, as a contact of interest, is compared with the positions of contacts detected at previous times or scans. Velocity profiles indicate which previous contacts support the likelihood that the contact of interest represents a target having a velocity within a defined band. The likelihood, which can be represented by a quality value, may be a function of number of contacts, timing of contacts, or both the number and timing of contacts in a given velocity profile. A preselected threshold value, which is related to false alarm rate, is compared to the most likely, or highest quality, velocity profile associated with a contact of interest. If the highest quality value exceeds the threshold value, an output is provided indicating that the contact of interest represents a probable target having a velocity within the band defined by the highest quality velocity profile. [A3814]

"Moving obstacle detection system for a vehicle"

A moving obstacle detection system using a Doppler radar device for an automotive vehicle which detects and informs a vehicle driver that another vehicle (moving obstacle) approaches or moves away from the detecting vehicle, wherein there is provided a means for determining whether the rate of change of the period of a Doppler signal outputted from the Doppler radar equipment with respect to time exceeds a predetermined value so that an erroneous alarm in response to a pedestrian or another vehicle traversing the front detection area of the vehicle, e.g., when vehicle is at rest at in an intersection is inhibited. Consequently, more reliable detection of approach or departure of another vehicle can be achieved. [A3815]

"Moving obstacle detection system for a vehicle"

A moving obstacle detection system for an automotive vehicle utilizing a doppler effect of the transmitted wave against an obstacle which runs in front of the vehicle such as another vehicle. The system generally comprises: (a) a doppler radar unit which operates so as to produce a doppler signal when the vehicle is halted, (b) a detecting means which detects the changing phase of a doppler signal produced from the doppler signal, (c) a discriminating means which discriminates the departure of another vehicle from the front area of the vehicle and the intersection of another vehicle or pedestrian traverse to the vehicle on a basis of the frequency changing rate or amplitude level changing rate of the detected doppler signal, and (d) an alarm unit which produces an alarm in a predetermined form only when the departure of another vehicle from the front detection area of the doppler radar unit or in the case when another vehicle straightly approaches or departed from the vehicle and in the case when another vehicle or pedestrian goes across the vehicle, separately from each other. [A3816]

"Search radar apparatus"

Search radar apparatus containing an MTI video processing unit provided with: a canceller for generating video signals of moving targets, a zero-velocity filter for generating clutter video signals, a conditional circuit connected to the canceller and the filter for generating per range quant of each radar scan a clutter switching signal if for the rang quant the signal value obtained with filter is greater than the signal value obtained with the canceller, a combination circuit connected to said filter and the conditional circuit for selecting the clutter video signals present with the clutter switching signals and for determining therefrom a temporary clutter level in each clutter cell and each antenna revolution period, and clutter level indication means connected to the combination circuit for determining a standard clutter level per range-azimuth clutter cell of the radar range with the application of clutter video signals. [A3817]

"Pilot assistance device"

A device working in conjunction with commercial-grade radar equipment for accurately pinpointing the location of a target or a topological feature with a precision greatly superior to the specified resolution of the radar equipment. This high precision is obtained through on-line treatment of the radar echo signals as the radar scans the target area. In the preferred embodiment of the invention, the device is used for assisting a pilot in steering a ship navigating through coastal or inland waterways. The device provides statistically weighted data relative to the location of a plurality of landmarks in the vicinity of the ship to a KALMAN filter-type circuit which in turn generates an accurate state vector reflecting the ship's present and near future movement. In the course of an initial surveying pass through the waterway, the device can also generate reference charts of the area to be traveled. The device can also be applied to other types of surveying tasks, to the implementation of anti-collision apparatuses, and to other systems requiring a high degree of precision in the measurement of surrounding objects. [A3818]

"Radar terrain signal suppressor"

An apparatus for the suppression of terrain generated clutter in a pulsed weather radar system. Weather induced returns typically having scintillation frequencies greater than 50 Hz may be isolated from terrain backscattered signals utilizing a digital filter technique having a sampling rate equal to the pulsed radar PRF. [A3819]

"Range-enable information system for plural mobile objects"

An information system for communicating information from each of a plurality of separate locations to each of a plurality of mobile objects includes a beacon at each location and a beacon triggering and detecting apparatus mounted on each object. Each beacon triggering and detecting apparatus is assigned a predetermined and unique time window within a common system cycle. During the initial portion of its window, the beacon triggering and detecting apparatus transmits a trigger signal at a frequency f.sub.1, with the trigger signal as transmitted having a substantially constant amplitude and with frequency f.sub.1 being chosen so that the intensity of the trigger signal decays as the cube of radial distance from the object. If the object is within a predetermined beacon trigger range of a location, the beacon at that location detects the trigger signal and transmits a beacon signal at a frequency f.sub.2 (substantially greater than frequency f.sub.1) during the terminal portion of the window which is detected by the beacon triggering and detecting apparatus. The beacon signal contains any information that is desired to be communicated from the location to the objects, such as the identity or location of the beacon. Provision is made for synchronizing the various beacon triggering and detecting apparatus by signals at a frequency f.sub.3 (that is distinct from frequencies f.sub.1 and f.sub.2) from a base station, for disabling operation of a given beacon triggering and detecting apparatus upon the failure of that apparatus to be synchronized by the base station for a predetermined period of time, and for transferring the information that has been communicated from each location to each object to the base station for further processing and centralized information display. [A3820]

"Chirp transform correlator"

A chirp transform correlator having asynchronous operation is made possible by the use of a pair of paralleled signal processing channels to which the unknown signal to be correlated is applied. The two channels include sweeping local oscillators which are interlaced in timing so that any arbitrarily timed unknown input signal will be fully transformed by one or the other of the channels. [A3821]

"Automatic vehicle identification system and method"

An automatic vehicle identification system for use in identifying and routing vehicles, such as railway cars or other vehicles which routinely travel a given track or path. A passive electronic device or electrical circuit is employed to intersect an energy field and respond thereto by generating a code in accordance with energy received and converted to coded electrical signals. Connected to the passive device is a short wave transmitter for transmitting signals generated by the electrical device when so energized. The electrical device may also comprise a plurality of different induction coils or antenna which serve to modify an energy field in a given manner, which modification may be detected by short wave sensing and converted to a coded electrical signal which is employed to identify the vehicle. In another form, a coded array of antenna or induction coils is provided which modify energy fields generated at check points or scanning locations along a trackway or roadway, wherein such energy field modifications are sensed at each such scanning location, resulting in the generation of an electrical code at each location and identification of the vehicle. [A3822]

"MTI Velocity discriminator"

A digital Moving Target Indicator (MTI) radar system for rejection of low velocity "clutter" by utilizing techniques to identify those radar echo returns from targets having radial velocities lower than fixed predetermined values. for digital MTI radars that have a response which is a periodic function of the radar's Pulse Repetition Frequency (PRF) and doppler frequency shift of the received radar signal relationships exist whereby (a) optimum target velocities which correspond to the maximum canceler gain can be calculated from the radar's PRF, (b) the canceler response can be expressed in terms of a periodic canceler response function which incorporates the ratio of the actual target velocity to the optimum target velocity, and, (c) the output amplitude from the canceler can be determined from the input amplitude to the canceler produced by the MTI receiver's coherent phase detector and the periodic canceler response function. Thus, for a particular target velocity and a number of different input amplitudes the corresponding output amplitudes from the canceler are calculated. These canceler output amplitudes are stored in an electronic memory which is accessed in terms of the input amplitude produced by the coherent phase detector. The canceler output amplitude read from the memory is compared with the actual canceler output to determine whether the output should be treated as clutter or a target having a radial velocity greater than the preselected fixed value. [A3823]

"Apparatus and method for the correction of attenuation-induced errors in a weather radar receiver"

Disclosed is a method and apparatus for adjusting the gain in a weather radar receiver to correct for precipitation induced transmission path attenuation. The receiver gain is controlled in a known manner to accommodate known path transmission effects. The gain controlling apparatus comprises fixed and variable AC resistances, where the variable AC resistance is an attenuator diode driven by a varying current source. The variable current source provides an approximation to a hyperbolically decreasing current when no video returns or echoes are present. However, upon sensing the existence of a video return indicative of rain at a moderate intensity, a portion of the charge on the RC networks in the current generator is shunted to ground, increasing the rate of change of current provided by the current source. This modification of the attenuator substantially reduces attenuation-induced receiver errors present within the sensitivity time control (STC) interval. [A3824]

"Method and apparatus for intrusion detection"

CW intrusion detection method and apparatus are shown comprising first and second CW Doppler radar systems which include first and second antennas, respectively. The first antenna is located adjacent ground level for illumination of a protected area adjacent the ground. The second antenna is located directly above the first antenna a spaced distance therefrom, and illuminates the same protected area adjacent the ground. In response to movement of an intruder along the ground in the protected area, first and second Doppler difference frequency signals are obtained from the first and second radar systems. Using the first and second Doppler difference frequency signals, a signal proportional to distance of the moving intruder from the first antenna is generated. Memory elements for storage of combinations of amplitude, range and/or velocity criteria signals are provided and, when the signal proportional to distance and at least one of the first and second Doppler difference frequency signals match the criteria signals, an alarm signal is produced. [A3825]

"Method and apparatus for enhancing radiometric imaging"

Disclosed is a method and apparatus for enhancing target detection, particularly in the millimeter wave frequency range, through the utilization of an imaging radiometer. The radiometer, which is a passive thermal receiver, detects the reflected and emitted thermal radiation of targets within a predetermined antenna/receiver beamwidth. By scanning the radiometer over a target area, a thermal image is created. At millimeter wave frequencies, the received emissions from the target area are highly dependent on the emissivity of the target of interest. Foliage will appear "hot" due to its high emissivity and metals will appear cold due to their low emissivities. A noise power illuminator is periodically actuated to illuminate the target of interest. When the illuminator is actuated, the role of emissivity is reversed, namely poorly emissive targets will generally be good reflectors which in the presence of an illuminator will appear "hot". The highly emissive targets (such as foliage and dirt) which absorb most of the transmitted energy will appear almost the same as in a non-illuminated, passive image. Using a data processor, the intensity of the passive image is subtracted from the intensity of the illuminated, active image which thereby cancels the background foliage, dirt, etc. and the reflective metallic targets are enhanced. [A3826]

"Method and apparatus for automatic control of driving speed"

A system for automatically controlling driving speed includes a fixed speed driving device for keeping the driving speed at a predetermined speed and a control device for maintaining an optimum interval between the vehicle and the vehicle driving ahead. A hold circuit for holding the optimum driving speed, based on the distance from the vehicle driving ahead, is actuated by a circuit for detecting curves in the road, whereby the hold circuit maintains the driving speed of the vehicle as it rounds a curve at the optimum driving speed determined for the vehicle before it entered the curve. [A3827]

"True ground speed sensor"

A Doppler radar sensor is disclosed for use as a true ground speed sensor for a ground vehicle. The sensor comprises novel features resulting in a more efficient construction and improved performance. The sensor comprises an ellipsoidal reflector and when used as a true ground speed sensor in a ground vehicle the far focus is at the surface of the ground. [A3828]

"Method and apparatus for monitoring vehicle ground movement in the vicinity of an airport"

The invention provides an apparatus for processing radar returned video signals in the vicinity of an airport including at least one runway and at least one vehicle roadway intersecting the runway, in order to assist air traffic controllers in detecting potential hazardous situations. Radar returns from each of plural geographic monitored locations are compared with a simulated return for each corresponding location to detect a moving object at any of said geographic monitored locations. The presence of a moving object at one of such locations may be indicative of a hazardous situation, and in that event, the air traffic control operator may be warned by an alarm or the like. [A3829]

"Microwave frequency synthesizer using plural switchable low noise oscillators"

Disclosed is a low noise microwave frequency synthesizer having a plurality of rapidly switchable output frequencies. Two banks of oscillators are selectively mixed to yield a range of output signals of low phase noise and low spurious noise. The first bank of oscillators comprises low noise, highly stable oscillators of a frequency range below the desired synthesized output signal. The second bank of oscillators comprises low noise, highly stable oscillators of a frequency range lower than the first bank. The signal from the second bank of oscillators is frequency multiplied to a desired frequency range by a low multiplication factor and then mixed with the signal from the first bank of oscillators. Multiplied phase noise is reduced by using a low multiplication factor. The upper sideband of the mixed signals is output as the synthesized output signal. Rapid switching between oscillators in both banks provides a frequency range of synthesized output signals which may be rapidly stepped through as desired. [A3830]

"Quasi coherent two-way ranging apparatus"

An accurate radio frequency ranging system is provided for measuring the time required for a signal to be transmitted from a ground station to a remote station and to be returned to the ground station. The ground station is provided with a master reference clock that is employed to drive a first pseudonoise generator. The ranging system in the ground station is started by a unique and predetermined start epoch signal produced by the first pseudonoise generator. The first pseudonoise generated signals are transmitted to the remote station where they are tracked and sensed. When the original start epoch signal is sensed at the remote station, it is employed as a trigger or read signal to initiate the generation of a stop epoch signal. The stop epoch signal is retransmitted to the ground station and stored in a register where it is compared with pseudonoise generated signals being retransmitted from the remote station to the ground station. When the correlation between the two signals occurs, a new epoch stop signal is produced which stops the timing of the ranging system in the ground station. Since the pseudonoise generated signals transmitted from the remote station to stop the ranging system in the ground station are not locked on to the pseudonoise signals being transmitted from the ground station to the remote station, there is no requirement for turn-around coherency. [A3831]

"Remote passive identification system"

A system for passively identifying remote objects such as livestock is disclosed. A power transmitter transmits a plurality of radio frequency burst signals at a given frequency, and a uniquely coded transponder associated with the object to be identified produces a plurality of coded identification signals in response to the burst signals from the transmitter. The coded identification signals are read by a receiver to identify the object. The transmitter and receiver are time division multiplexed for alternate operation. Accordingly, when an object is to be identified, the transmitter is switched on to transmit the burst signals, thereby activating the transponder to produce the coded identification signals. The transmitter is then switched off and the receiver switched on to receive the identification signals for identifying the object. [A3832]

"Automatic adaptive sensitivity time control for a ground mapping radar"

An automatic adaptive sensitivity time control for a ground mapping radar comprises the dynamic range of radar returns for presentation on a video display. A feedback loop including a differential amplifier senses the magnitude of a signal presented to a limit amplifier and compares the same with a clutter threshold reference potential. A low-pass filter in the feedback loop then smooths or averages the clutter deviation from the reference potential to adjust the clutter level out of a log IF amplifier so that the nominal clutter signal level of close-in returns does not exceed a predetermined magnitude. A second embodiment includes a dual time constant filter in the feedback loop. A comparator circuit senses the leading edge of clutter return signals and switches the feedback loop to its faster time constant mode allowing dynamic compression of smaller time constant pulses. [A3833]

"Automatic braking system for vehicles"

An automatic braking system for a vehicle including an automatic command system giving a command including at least one braking signal of a level in response to the need for braking, a fluid pressure source, a braking device having an input member which is manually actuatable, and a device for actuating the input member by applying thereto a fluid pressure from the pressure source in response to the level of the braking signal. An automatic braking may thus be performed while permitting manual braking to be simultaneously effected. [A3834]

"Synthetic pulse radar system and method"

The invention includes a method and apparatus for detecting geophysical phenomena by the use of a synthetic pulse radar. A radar transmitter generates a plurality of component signals of different frequencies which approximate at least a portion of the Fourier transform of a radar short pulse. These component signals are transmitted simultaneously for modulation by the geophysical phenomena, and the modulated component signals are substantially simultaneously received in a receiver. The receiver divides the component signals, and as to each determines representative parameters. The invention also includes a heterodyne receiver which operates with a fixed IF frequency and incorporates a single frequency quadrature system. [A3835]

"Method of producing velocity-aided range gates"

A method of producing a control signal for a range gate in a pulse Doppler radar, the method encompassing the steps of periodically determining the range slip of a selected target and then changing the position of a range gate during each range sweep in accordance with the determined range slip. [A3836]

"MTI Radar adaptable to different environmental conditions"

A radar of the MTI type has a transmitter connected to a source of outgoing pulses whose carrier frequency is variable under the control of a mode selector for selective operation with fixed frequency, frequency diversity or frequency agility, depending on detected environmental conditions. A multiweight Doppler filter serves for the detection of mobile targets in each of these three modes. With frequency-agility operation, samples of echoes of an outgoing pulse received during a given sweep are stored in a memory in accordance with the carrier frequency used for that pulse, this frequency changing in random fashion from one pulse to the next among a certain number of predetermined values. A timer selecting the outgoing frequency also controls a multiplexer which during each sweep delivers to the Doppler filter up to m correlated samples of the same frequency stored in the memory during the last n sweeps, with n>,m determined by the width of the antenna beam to ensure that the samples concurrently evaluated by the filter come from the same target. [A3837]

"Method and means for providing frequency agile operation of MTI _radar"

The obtaining of simultaneous pulse-to-pulse transmitter carrier frequency agility and compatible moving target indicator (MTI) operation in conventional surveillance radars is achieved by the use of pairs of frequencies with a controlled relationship between the frequencies of each pair. A set of four pulses with different frequencies is sequentially transmitted and form two pairs of pulses. The difference between the frequencies of one pair of pulses is made equal to the difference between the frequencies of the second pair of pulses. MTI operation is obtained by differencing the pairs. Pulses having any three frequencies may be selected in any sequence before a constraint is imposed. The frequency of the fourth pulse is then determined by the frequencies of the first three pulses. [A3838]

"Intervehicle distance control system for vehicles"

An intervehicle distance control system for a vehicle which, when there exists a possibility of collision between the vehicle and an interfering object ahead thereof, generates a control signal and imparts to a vehicle accelerator member an operation reaction force corresponding to the control signal. The driver is thereby alerted as to a possibility of collision, while the selection of acceleration operation is substantially entrusted to the driver. In the absence of such control signal, the reaction force has a strength of substantially zero. Regardless of the vehicle speed, the driver will never suffer from a metal burden due to operation of the control system. [A3839]

"Radar ground speed sensing system"

A Doppler radar speed sensing system includes a microwave transceiver and a circuit for generating an input pulse train having pulsewidths related to the ground speed of a vehicle carrying the system. A signal processor includes a microprocessor which executes a signal processing algorithm which converts the input pulse train to an output pulse train having desired characteristics. for example, the output pulse train has output pulses with pulsewidths and frequency related to the vehicle ground speed. The output signal pulse train responds rapidly to changes in sensed ground speed, but is insensitive to Doppler signal dropout. [A3840]

"Interference suppressor for radar MTI"

An impulse interference suppression circuit for use in combination with an -pulse Moving Target Indicator system comprising a gate connected to block the output signal from the MTI system when energized, and a circuit for taking the magnitudes of successive echo return signals, subtracting the magnitudes of consecutive echo signals to remove clutter, comparing the consecutive difference signals from such subtractions against each other, and generating and applying a blocking signal to the gate if the difference between the subtraction difference signals is above a given threshold level. [A3841]

"Collision avoidance system"

A threat warning collision avoidance system at an Own station that produces pseudo range data, identity and, when available, differential altitude data from standard ATCRBS interrogations and Other station's replies, rejecting the identity and data from Other stations that are outside a proximity space surrounding Own station, and producing a threat alert signal and displaying the identity and associated data of any Other station entering said proximity space. [A3842]

"Method and apparatus for preventing the response of a radar beacon to receive radar pulses originating from the side lobes of a transmitter and an arrangement"

A method for preventing a radar beacon's response to received pulses from a vessel which originate from the side lobes of the vessel antenna. The carrier frequency of the radar signal pulses to and received by the beacon is measured and a value of this frequency is stored when the amplitudes of the signal pulses exceed a certain high threshold level (Th) . If signals after that are received which exceed a low threshold level (Tl) (but not the high) the carrier frequency of such signals is measured and a corresponding value is stored. Measuring two subsequent and equal carrier frequencies is considered as a criterion that a response signal from the beacon responding to the second received signal should not be transmitted. An arrangement to carry out the method is described. [A3843]

"Apparatus for the detection and prevention of collision risks in deep sea and coastal navigation"

Apparatus for the detection and prevention of collision hazards between a ship fitted with a radar on board and moving or fixed obstacles identified on the radar screen on board of the ship, consists in determining with respect to said obstacles, taking into account such parameters as distance, speed and heading thereof, dangerous sectors of the heading and the speed for said ship, plotting said dangerous sectors for the heading and the speed on a support, plotting on the same support the speed vector of the ship, examining whether the end of said vector is within or outside said dangerous heading and speed sectors, a collision risk existing when the end of the speed vector is within at least one of said dangerous heading and speed sectors, and in such case, choosing a new speed vector so as to make the end of such vector be outside the whole of the heading and speed dangerous sectors. [A3844]

"Apparatus for control of clutter breakthrough in MTI radar"

An apparatus for control of ground clutter breakthrough in MTI radar which remove hard limited clutter signals while allowing increased detection sensitivity to moving targets when such strong clutter returns are not present. Logic is provided to prevent the removal of strong moving target return even in the presence of hard limited clutter. [A3845]

"Methods of and circuits for suppressing doppler radar clutter"

Clutter suppressors and methods of clutter suppression for radars which employ the doppler effect for enhancing signals due to moving targets relative to signals due to clutter caused land, sea or rain. Specifically, the disclosure concerns suppressors and methods of clutter suppression for cw doppler, pulse doppler and MTI (moving target indication) radars. The suppressors reduce the occurrence of radar output due to clutter by permitting and prohibiting radar output on the basis of the relative strength of signals that contain doppler frequency components of the radar echo. [A3846]

"Foreground subject-identifying apparatus"

A foreground subject-identifying apparatus includes a signal transmitter for sending forth microwave question signals, a code signal generator for emitting a code signal in response to a question signal delivered from the signal transmitter, and signal-receiving device for interpreting code signal received from the code signal generator. The signal transmitter intermittently generates a microwave check signal in a first operation mode, and sends forth a microwave question signal in a second operation mode. The code signal generator sends forth an output signal in response to a check signal delivered from the signal transmitter, and then the signal receiver causes the signal transmitter to be set at the second operation mode to generate a question signal. [A3847]

"Microwave-type projectile communication apparatus for guns"

Microwave projectile communication apparatus comprises a microwave probe fixed to a gun barrel at its muzzle end. A microwave oscillator, having a reference frequency selected for exciting the single fundamental electromagnetic mode in the barrel, is connected to the probe, for example, through a hybrid mixer configured for extracting, from moving projectile-reflected microwaves, a true Doppler signal for projectile velocity measurements. Connected between the oscillator and the probe is a signal modulator for modulating the reference oscillator signal to the probe. Connected to the signal modulator is a driver signal generator which controls the modulator in a manner enabling information, such as fuse delay time or target range, to be communicated to the projectile fuse. A conventional fire control computer may be used to provide to the modulator the data to be transmitted to the projectile. The barrel muzzle end may be internally shaped to function more effectively as a microwave antenna to enhance communication with projectiles after they have left the barrel. Corresponding methods for microwave communication with fired projectiles are provided. [A3848]

"Millimeter wave monopulse comparator circuit"

An improved monopulse comparator circuit is achieved by a unique circuit layout. Four hybrid junctions are arranged on a low dielectric constant substrate and are interconnected in such way as to form a closed square figure. Distances between adjacent hybrid junctions are thus minimized. Input lines which connect the comparator circuit to a monopulse antenna array are disposed on the substrate external to the closed figure, as are output lines which connect the comparator to a monopulse guidance system. Right angle microstrip to waveguide transitions are used so that the comparator circuit need not be integrated onto the same substrate as the antenna array and the guidance system. The entire comparator layout is channelized to increase isolation between closely spaced lines. [A3849]

"Weather radar with signal compensation for precipitation"

A weather radar incorporating a sensitivity time control modifying circuit for adaptively increasing the gain of the IF amplifier as a function of precipitation rate, thereby increasing the range of the radar through the precipitation and identifying on the display those regions in which the radar might otherwise inaccurately indicate the precipitation rate. Reflections from the precipitation are received by the radar antenna coupled to a mixer wherefrom an IF signal is coupled to the IF amplifier wherein it is amplified in accordance with a gain that is determined by the modified sensitivity time control signal. [A3850]

"Method and apparatus for suppressing clutter"

A method and apparatus for automatic suppression of weather echoes or clutter which can disturbingly appear, apart from the flying target-Doppler signal as further Doppler signals in a pulse Doppler-tracking radar device containing quadrature channels, wherein there is regulated the frequency of the Doppler signals or the phase relationship between the Doppler signals and a reference signal derived from the transmitted signal. [A3851]

"Earth probing radar system"

A ground probing radar method and apparatus which is effective to view the earth in advance of coal mining activity provides visual display of a coal seam and particular discontinuities that may lie therein. The system operates in the frequency range of 10 Megahertz to 5 Gigahertz. The received electromagnetic energy is amplified, sampled and band pass filtered with subsequent time gain amplification. A time analog return signal may be viewed directly and/or the return signal may be digitally processed to enable further signal refinement. A control microprocessor is utilized for both tape record control and digital signal processing, and the processor includes the capability for compositing and/or stacking of common source point data for output record and display. [A3852]

"Three and four product surface-wave acousto-optic time integrating correlators"

A method and device for processing spread-spectrum and other wideband comications and radar signals to obtain three and four product correlated signals. A laser beam is split and shaped into first and second sheet beams. The first beam is directed to a first acousto-optic medium where it is doubly diffracted by first and second signals. The second beam is directed to a second acousto-optic medium which is spatially rotated 90.degree. relative to the first acousto-optic medium where the second sheet beam is either singly diffracted by a third signal or doubly diffracted by a third signal and a fourth signal. The diffracted sheet beams are shaped into square beams, combined and directed to a photodiode area array. [A3853]

"Level gauging systems"

To measure the height of the surface of a fluent material, such as coal, in a bunker or container, pulsed radiation from a microwave source is beamed down on to said surface, and the return radiation reflected from the surface is processed to detect pulses in the waveform with time-varying amplitudes, and therefore denoting returns from the fluent material, and to reject fixed shape pulses denoting returns from the fixed structure of the bunker. To discriminate between returns of time-varying amplitude (i) from the fluent material surface and (ii) from material flowing in from an in-feed, the higher frequency components, denoting the material flowing in, are filtered out. [A3854]

"Radio frequency switch for coupling an RF source to a load"

A radio frequency switch which has input and output diodes and a quarter length impedance inverter interconnecting the diodes. A switch drive signal is clamped to a predetermined voltage between drive signals so that the impedance with respect to the input source remains substantially constant during the entire switch operation. [A3855]

"Doppler speed sensing apparatus"

A vehicle velocity sensing system is disclosed which includes a doppler velocity sensor (10, 12) and means for reducing spurious signal components in the output of the sensor. An accelerometer (30, 32) is mounted so as to sense vehicle accelerations along the boresight of the doppler velocity sensor. A processor (34, 36) processes the output of the accelerometer to provide a signal which corresponds essentially to the spurious components of the output of the doppler radar velocity sensor. A signal combiner (38, 40) combines the output of the processor with the output of the doppler velocity sensor to derive a corrected output signal which is more closely indicative of the velocity of the vehicle. [A3856]

"Device for preventing overwinding of a roller blind"

The invention relates to a slip coupling for preventing the overwinding of the motor spring of a roller blind. In one embodiment the slip coupling is incorporated as part of a bracket for supporting one end of the roller. The bracket has a cylindrical bearing which is rotatable within a circular aperture in the face of the bracket and receives a pin of the spindle of the roller so as to be rotatable therewith. The bearing carries a spring the ends of which engage with stops on the face of the bracket so that the bearing is prevented from rotation when the torque exerted by the motor spring is below a predetermined level. When the motor spring is overwound the ends of the springs are caused to flex to override the stops and so reduce the tension in the motor spring. In a second embodiment the slip coupling is located within the roller. [A3857]

"Secondary radar responders"

The invention relates to secondary radar responders which provide a reply in response to a radar signal received from a primary radar transmitter. The frequency of the received radar signal is monitored by the responder and the frequency of the response is brought into agreement therewith so that the response can be received by the primary radar transmitter at its transmission frequency. The invention is particularly applicable to marine radar systems and the responder may form part of a racon or transponder. [A3858]

"Radar system for collision avoidance"

A radar system is disclosed adapted to detect relative headings between a system-equipped craft such as aircraft and ships at sea and a detected object moving relative to the ground, the system being particularly adapted to collision avoidance application. The system includes forward and rearward radar transmitter antennas, which are carried by each equipped vehicle. Each of the radar antennas is oscillated in synchronism with the other through a 180.degree. sweep, the forward radar set transmitting a scan spectrum of directional pulses of rf radiation at incremental headings through the sweep. A narrow band pass receiver detects return or echo signals in a very narrow frequency band corresponding to doppler shifted transmission frequencies. The rear radar transmits at a constant frequency and the return signal is utilized to generate a differential frequency which is the end result of a given ground speed and antenna heading. The spectrum scan of the forward transmitter is shifted in accordance with the differential frequency in order to avoid transmitting at ground echo frequency, as well as to narrow the scanning spectrum frequency to provide a highly efficient time and energy utilization in the radar scan. [A3859]

"Apparatus for remote temperature reading"

An apparatus for remote temperature reading particularly for the reading of the temperature of an article or animal at a distance by means of an electromagnetically interrogatable label attached to or implanted in the article or animal the label being constructed to be capable of receiving an electromagnetic signal from a transmitter, converting the signal to a surface acoustic wave, passing the wave over a path on the label, reconverting the surface acoustic wave to an electromagnetic signal and retransmitting it to a receiver. The path of the surface acoustic wave is of a material such that the time of travel of the surface acoustic wave over the path is a function of the temperature of the path and thus of the label. The receiver is constructed to measure the time interval between electromagnetic signals produced by the passage of the surface acoustic wave past a transducer or transducers in the path and thereby provide an output indicative of the temperature of the environment of the label. It is preferred that the label includes a plurality of transducers at coded locations along the path arranged for retransmitting to the receiver a coded sequence of electromagnetic signals indicative of an article or animal to which the label is affixed or in which it is implanted in the manner described in U.S. Pat. No. 3,706,094. [A3860]

"Radio communication system and transmitter and receiver equipment therefor"

A system providing radio communication between a first station and at least one additional station wherein the first station is equipped to transmit an interrogation signal and also an information-bearing signal having a key signal component and an information signal component, wherein the additional station is equipped to receive the information-bearing signal and to store the information contained in the information signal component in a read/write memory only when the key signal component corresponds to a pre-selected key code, and wherein the additional station provides for the transmission of the stored information upon the reception of the interrogating signal to facilitate the reception of such information at the first station. [A3861]

"Doppler radar system"

In a Doppler radar system any one received signal contains components having different Doppler frequencies. This is because the received signal is derived from reflections off a range of different positions within the beamwidth of the system. It is often only that frequency component which is derived from a reflection along the boresight of the system which is of interest. Difficulty arises in determining which component this is. Because of variations of the reflective properties of the surface from which the reflections are received, it cannot correctly be assumed to be the strongest component. The invention identifies the components of the received signals derived from reflections along the boresight of the system by analyzing each of two signals received at different times, into components having different Doppler shifts. Values are then calculated of the relative strengths (e.g. ratios or differences) of components of the two signals derived from reflections off the same position. These relative strength values are not greatly affected by variations in the reflection properties of the surface and can be used to determine accurately the frequency components of the signals derived from the boresight. [A3862]

"MTI-Filter in a trackding radar receiver"

An MTI-filter included in the receiver part of a tracking radar for suppressing clutter when receiving echo pulses from a certain target. The transmitting pulses of the tracking radar are transmitted in series where the carrier frequency is varied from pulse to pulse and is repeated from series to series. The MTI-filter (F) contains a number of delay links (DL1-DLN) , for example digital shift registers which are stepped forward timely with the radar PRF. The input of the filter and the output of the shift register M.ltoreq.N are connected to a differentiator (SK) where M=the number of carrier frequencies in a pulse series. [A3863]

"Medium PRF pulse doppler radar having simplified ground moving target rejection capabilities"

In a single channel medium PRF pulse doppler radar receiver, the return signal data is processed to prevent sidelobe return signals from being displayed and rejects ground moving targets up to approximately 80 knots while having no high velocity blind speeds. After the returns are filtered by a doppler filter notch for rejecting returns having a velocity substantially less than the 80 knot example, the return data undergoes three stages of correlations to reject sidelobe returns, and undergoes processing including a fourth correlation which enables the third stage of correlation to output a signal only for unambiguous ranges that contain target data in excess of the 80 knot range. [A3864]

"Doppler radar mounting structure for motor vehicles"

A mounting structure of a Doppler radar vehicle speed sensor for an automobile, especially adapted for damage-free mounting of the radar to a bottom of the automobile which may detrimentally hit on the road surface while the automobile is in motion. In order to protect the radar casing from the attacks by possible flying pebbles and muddy splashes caused by the rotation of the front wheels, the radar casing containing a horn antenna or a slot array antenna is accommodated in a recess or a stepped space formed near the rear wheels in the bottom surface of the floor of the automobile in such a manner that the casing is within the partial space in the recess lying on the side opposite to the road surface with respect to a plane containing the front edge of the recess and the tangent line drawn from the front edge to the outer diameter of the front wheel. The mouth of the antenna is directed toward the rear end of the automobile. [A3865]

"Control systems for radar receivers"

An echo ranging weather radar system in which the bandwidth B of the radar receiver is made roughly equal to the bandwidth of the frequency spectrum of at least some expected weather echoes. In one embodiment, B T.sub.R is made equal to .alpha. during a time interval corresponding to a range increment at maximum range and during an earlier period corresponding to lower ranges, is varied inversely with range, where T.sub.R is the duration of an echo pulse which would be produced by a target of reference size, and .alpha. is a constant such as 1.2. In another embodiment, B is varied according to the duration T of actually received echo signals so as to set BT.congruent..alpha. during each echo reception interval, for different values of T. The gain of the receiver also may be varied with time. [A3866]

"Radar transponders"

An interrogator/transponder for identification of co-operating pulse radar-fitted marine vessels comprises a detector responsive to signals in the radar frequency band and a C-band transmitter/receiver connected such that on receiving a C-band interrogating signal together with a radar signal an identity signal produced by a signal generator is transmitted. When used for interrogation an interrogating signal is produced by a second signal generator for transmission with the radar signal and the received identity signal from the interrogated vessel is presented on a radar display adjacent to the return radar signal. [A3867]

"Signal processing system"

An improved system for processing an electrical velocity information signal in a velocity detecting system in which a detector is utilized for developing an electrical information signal, such as a Doppler signal, having a characteristic (e.g. frequency) that varies systematically with the object's velocity. A converter develops an oscillatory signal having a frequency which varies in accordance with the velocity information signal characteristic. A tracking filter having a center frequency that varies with the oscillatory signal filters all frequencies other than the center frequency. A signal generator is responsive to the frequency of the signal passed by the tracking filter for generating an output signal having a frequency which is a preset ratio relative to the center frequency, whereby the output signal of the system is relatively noise-free and has a frequency which represents the velocity of the object being detected. Another feature of the disclosed embodiment of the invention utilizes a switching network comprising a pair of flip-flops and a pair of shift registers which are responsive to the oscillatory signal passed by the tracking filter and to an oscillatory signal generated by a voltage-controlled oscillator for alternately charging and discharging a storage capacitor which is coupled to the inverting input of an operational amplifier used as a comparator. A variable resistance is placed in either the charging or discharging path and the output of the op amp is used as an error voltage to control the frequency of the VCO to thus provide a frequency locked loop. [A3868]

"Microwave movement detector"

A microwave generating and receiving module generates and transmits a microwave signal which is reflected by a moving target and received back by the module. The module comprises a disc-form Baritt diode BD1 or Gunn diode acting as both oscillator and mixer and forming part of microstrip circuitry and signal processing circuitry which processes the reflected signal to extract relevant target information. The signal processing circuitry can be physically displaced from the module and connected to it by a coaxial line. By operating the diode in the diplex mode the requisite target information can be provided for with a compact construction. [A3869]

"Scanning radar system"

A scanning radar system having the capability of taking a number of succeve looks at the same range and angle resolution cells with several millisecond time intervals between looks. The scanning radar system includes a pulsed transmitter, a receiver, and an array of energy beam radiators having individual beam paths with associated centerlines. A commutator switch and a duplexer sequentially connect a different one of the radiators to the pulsed transmitter at the beginning of each pulse repetition period and to the receiver during the subsequent interval between pulsed transmissions. A motor rotates the array of radiators as a unit to cause the beam path centerlines to rotate and scan the field of view. A plurality of delay units and a commutator switch are connected to the output of the receiver for processing the pulses returned to each of the radiators from resolution cells in the field of view during the intervals of time between pulsed transmissions to cause the pulses returned to different radiators from the same resolution cell to be in time coincidence. [A3870]

"Vehicle speed sensing apparatus with electromagnetic wave interference detector"

A vehicle speed sensing device comprises a Doppler radar unit for producing a Doppler signal related to the vehicle speed and producing a speed signal from the Doppler signal, a first section for extracting noise components in the Doppler signal and producing a noise detection signal, and a second section for producing an output signal of the vehicle sensing device. The device output is the speed signal from the Doppler radar unit when the noise detection signal is absent while the device output is null or a speed signal having an amplitude identical with that of the speed signal just before the appearance of the noise detection signal when the noise detection signal is present. [A3871]

"Sounding apparatus"

The present sounding apparatus is used for the detection and measurement of phenomena relating to the area surrounding the earth's globe. It can in particular be used in the study of the ionosphere and specifically for the study of limited amplitude, short duration modifications in the gradient of the electron density of the ionosphere. It can also be used for studying other phenomena, such as the study or monitoring of the sea swell. [A3872]

"Ground-speed Doppler radar for vehicles"

A Doppler radar wherein, in order to measure the ground speed of an automobile, microwaves are radiated to the ground and the Doppler shift of reflected waves from the ground is detected, characterized in that to the end of avoiding a malfunction ascribable to an external microwave interference, when the differentiated output of the Doppler radar is greater than a threshold value, the frequency of the microwaves of the Doppler radar is controlled so as to prevent the microwave interference from taking place. [A3873]

"Method for calibrating beam emitter type speed sensor for railroad rolling stock"

A beam emitter type speed sensor for railroad rolling stock is calibrated by positioning an endless belt between rails of the track for the railroad rolling stock. The endless belt has a speed which is controllable. The endless belt is so positioned so that the railroad rolling stock can maneuver the speed sensor in proximity thereover having an antenna-to-belt distance comparable to the antenna-to-roadbed distance. A method of calibrating the indicator in the cab includes rotating the belt at a known speed. [A3874]

"Automotive radar monitor system"

An automotive radar monitor system for monitoring an object or objects running in the front and/or in the rear, left and/or right with respect to the vehicle equipped with the system. The radar monitor system is specifically designed to provide a driver with an indication of the state of an approaching object or objects in the traffic at any given moment by way of an integrally simulated pattern which can be recognized at a glance, together with an audible indication. [A3875]

"Television weather radar system"

Information from a weather radar system (10) is gathered by a data transmitter (20) and sent to a data receiver (25) via a telephone or data line (30) . The radar video information for each radial is divided into segments and temporarily stored in a memory (45) . Only the information in those segments which are to be recorded in a random access memory (140) in the data receiver (25) are transmitted. The selection within the data transmitter (20) is made by a programmable read-only memory (95) , and the placement of the data into the receiver random access memory (140) is made by programmable read-only memories (130 and 135) . Synchronizing pulses representing each radial (102) and antenna position (14) are also transmitted. [A3876]

"FM-CW Radar system for use in an automotive vehicle"

An FM-CW type radar system, for use in an automotive vehicle, which is specifically designed with a signal processor of relatively simple construction having an improved capability of identifying an object, particularly a plurality of objects, to be identified in suurrounding traffic or road areas. The system is particularly effective in overcoming possible error in detection of the object (s) due to reflected or scattering waves from the road surface or the like as experienced in the general radar navigation system for detecting the approaching or interfering object (s) by the provision of incessant radar monitoring along with the path of travel of the vehicle equipped with the radar system so as to eventually maintain a safe relative distance and/or velocity of that vehicle with respect to the object (s) in the surrounding traffic or road areas. [A3877]

"Apparatus and method for classifying moving targets"

Method and apparatus for passive classification of moving targets which uses pulse Doppler radar wherein in addition to the primary Doppler echo the radar echo signals of the moving targets also contain periodically repeating Dopplers side line frequencies which can be utilized for classification of the targets. These Doppler side lines occur because of the periodic change of reflectivity of the target as, for example, due to rotating parts on the target and in the invention are investigated by means of spectral analysis for identification of the target. for example, land vehicles, wheeled and track vehicles can be easily distinguished with the invention and a first rough evaluation and in a fine detail evaluation, can be classified for every target type. [A3878]

"Doppler radar mounting structure for motor vehicles"

A Doppler radar speed sensor including an antenna section and a sensor section is mounted on the underside of the automobile undercarriage. A recess for accommodating the Doppler radar speed sensor is formed in part of the underside of the automobile undercarriage within a rectangle surrounded by the wheels, and the Doppler radar speed sensor is mounted fully within the recess. This structure prevents the sensor from being damaged in an unfavorable environment or external vehicle devices from being interfered with by the leakage of the unrequired radar wave. for size reduction, the Doppler radar speed sensor is provided with a metal casing integrated with a slotted waveguide antenna. The slot array of the antenna is formed in one side of the metal casing, so that the metal casing, makes up part of the slot array antenna. [A3879]

"Distance-measuring system with in-range signalling for use with cameras, alarms, and the like"

A distance measuring system generates an in-range signal when an object is located within a range of focus or a zone of protection, as the case may be. The system utilizes a single infrared transmitter and two receivers in order to determine the position of the object by triangulation. [A3880]

"Non-linear dynamic filtering device for the angular measuring of noise in a radar"

To improve the accuracy of angular measurements in a radar or sonar system by suppressing noise due to target glint, an angular-deviation signal .epsilon. derived from the output signals .SIGMA. and .DELTA. of a sum channel and a difference channel is multiplied with a gain-control signal K (t) before being subjected to recursive filtering. Signal K (t) is obtained, also by recursive filtering, from a weighting function P (t) which goes to zero during periods when the measurement of the angular deviation is unreliable as determined from a low value of sum signal .SIGMA. and from a peaking of a quadrature deviation signal .epsilon.q, function P (t) being proportional to the product .SIGMA..sup.n .multidot. (S-.vertline..epsilon.q.vertline.) where the exponent n is at least equal to 1 and S is a predetermined threshold. The recursive filter processing the deviation signal .epsilon. has two cross-connected stages, both controlled by signal K (t) , respectively emitting a corrected deviation measurement .epsilon. and an estimated time differential .tau.d.epsilon./dt, .tau. being a delay introduced in a recursive loop of each stage. Prior to being multiplied with gain-control signal K (t) , the deviation signal .epsilon. may be additively combined with an angular-orientation signal .theta..sub.r of a radar antenna to yield an angular value .theta..sub.c which can then be multiplied by a measured target distance D to provide a transverse-deviation signal d, in that case the two filter stages respectively emit a corrected deviation signal d and a target-velocity estimate v. [A3881]

"Spatially adaptive moving target indicator system for radar equipment"

A radar system is provided with first and second moving target indicator (MTI) systems. The first MTI system generally works better against ground clutter than against sky clutter. The second MTI system works well against sky clutter but generally requires a greater number of radar return echoes to discern targets in the sky clutter. A correlation estimation circuit is employed to calculate the correlation of clutter-like return echoes not suppressed by the first MTI system. If the return echoes are sufficiently correlated, the second MTI system is invoked against the clutter. If the return echoes are less well correlated, on the other hand, then electronic counter-counter measure systems may be invoked. [A3882]

"Vehicle identification system"

A vehicle identification system includes apparatus located on the vehicle for transmitting a continuous wave RF probe signal, a remote interrogator unit responsive to the probe signal for transmitting back thereto an interrogation signal. The apparatus on the vehicle transmits in response to the interrogation signal an identifying code. The probe signal may be further utilized in determining the speed of the vehicle. [A3883]

"Method and apparatus for digitally determining the speed of a target vehicle while the radar platform vehicle is in motion"

A moving doppler radar unit capable of separating the incoming doppler signal into its respective frequency components by means of frequency translation techniques and fixed frequency filters is disclosed. When the radar platform vehicle and target vehicle are both moving, the received doppler signal is a complex wave having frequency components related to the ground speed of the platform vehicle and the relative speed of the platform and target vehicles with respect to each other. Separation of the received doppler signal into its respective frequency components is accomplished by frequency translating the received doppler signal to a preselected reference frequency, discriminating between the frequency translated platform speed and target speed frequency components by means of a narrow band filter and a band pass filter, and frequency translating the separated frequency components downward to provide speed signals representative of the ground speed of the radar platform vehicle and the ground speed of the target vehicle. These speed signals are then converted into digital speed information which can be conventionally displayed. A lock detection circuit is included to inhibit the speed computation if the received doppler signal is not properly frequency translated to the reference frequency. [A3884]

"Traffic radar system"

A traffic radar system is provided in which the speed of a target vehicle is determined by measuring the difference in frequency between a component of a doppler signal which has a frequency proportional to the relative speed of the target vehicle and a moving patrol vehicle and a reference signal having a frequency proportional to the speed of the patrol vehicle. The reference signal is developed from a tachometer device which generates a periodic signal having a frequency proportional to the rotational speed of a vehicle wheel and phase-locked loop arrangements including adjustable dividers are provided for locking an oscillator to the tachometer signal and generating a reference signal at a frequency proportional to the actual speed of the patrol vehicle. for calibration, a component of the doppler signal produced from reflections from stationary objects is used. [A3885]

"Device for distance acquisition in a radar system"

A device for distance acquisition in a radar system, especially a tracking system, comprises a surveillance radar with a mobile directional antenna whose direction is known at each instant, a tracking unit whose line of sight is also known at each instant, and a video extractor. The device further comprises means for detecting the coincidence of the direction of the surveillance antenna with the direction of the line of sight of the tracking unit as well as means for permitting measurement of the distance of a tracked echo-emitting target by the surveillance signals at the time of such coincidence. [A3886]

"Profilometer mounting technique and apparatus"

Apparatus for measuring the contour of a surface without establishing contact therewith includes an energy transmitter movable in at least two directions. When employed in a shaft furnace the transmitter is movable along a longitudinal axis, so as to be either retracted to a protected location where it may be isolated from the furnace environment or extended so as to enable measurements, and is rotatable about the longitudinal axis so that the transmitted energy may be scanned across the surface. [A3887]

"Pulsed microwave motion sensor for intrusion detection applications"

An intrusion detection apparatus including a sensor for sensing an objectionable interference phenomenon within a detection area and developing a pulse train coincident therewith, signal processing circuitry responsive to the pulse train and operation to actuate a Gunn diode microwave generator or the like in a pulsed manner causing it to transmit microwave energy into the detection area in synchronism with the interference phenomenon, a microwave receiver for detecting microwave energy reflected from the detection area and for developing detection signals indicating motion within the monitored area, and further signal processing circuitry responsive to the detection signal and operative to actuate an alarm or the like. [A3888]

"Three dimensional, azimuth-correcting mapping radar"

A terrain mapping radar utilizes two sets of separately processed radar signals, each provided by a coherent pulse doppler synthetic aperture signal processing channel connected to and for processing the signals received from a selected one of a pair of vertically displaced antennas of the type utilized in phase interferometer radars. The invention provides depression angle, and therefore elevation information from the processed signals on a cell by cell basis, uniquely, for each range/doppler cell of each of the processing channels. The invention eliminates azimuthal errors which result from the ambiguity of the range/doppler annulus, and provides a useful map metric: elevation. [A3889]

"Minimizing harmonic distortion apparatus"

An apparatus is provided to minimize harmonic distortion in a microwave circuit which is used with a velocity measuring system. The apparatus is particularly applicable where at least two Doppler signals are generated at substantially the same time from two different targets whose velocity is being measured. The apparatus includes a microwave circuit which transmits a microwave energy signal directed to each of the targets. The microwave circuit also receives the signals reflected by the targets and produces Doppler signals. A control circuit responds to the Doppler signals outputted by the microwave circuit by providing a control signal corresponding to the greatest in amplitude of the Doppler signals. The control signal is fed back to the microwave circuit to control the Doppler signals so that a predetermined amplitude thereof is not exceeded and, as a consequence, harmonics of the Doppler signals are not generated. [A3890]

"Target vehicle tracking apparatus"

Vehicle tracking and position predicting apparatus includes an improved Kalman velocity filter feedback loop having a forward gain matrix for loop coordinate error factors and those of their derivatives, and position predicting computing apparatus in the loop feedback path between the system output and an input error node. Sensor reference target signals (e.g., range, bearing and elevation) are connected as inputs to the filter error node. In accordance with one aspect of the present invention, sensor coordinate reference errors from the input error node are converted to target reference coordinates. Pursuant to a further aspect of the present invention, the gain matrix is varied dependent upon sensor coordinate variables. Gain matrix variations are thus independent of geometry and sensor reference coordinates. [A3891]

"Doppler signal processing apparatus"

A doppler type speed sensor produces a doppler signal having a spectrum of frequencies including a frequency of peak amplitude corresponding to the actual speed of an object. The frequencies are supplied to a narrowband voltage tunable filter, the frequency bandwidth of which is continuously adjusted by a periodically reoccurring sweep signal applied thereto. The output of the filter is coupled to a peak detecting circuit which produces a pulse when the maximum amplitude signal is received thereat. The sweep signal and pulse are applied to the inputs of a sample-and-hold circuit to cause the sample-and-hold circuit to hold and produce a signal corresponding to the value of the peak frequency and therefore the speed of the object. [A3892]

"Short-range doppler radar"

In a Doppler radar system for measuring the velocity of a vehicle, such as an automobile, in order to lessen interference with external electric wave appliances, such as radios and televisions, caused by transmitting microwaves, one of the higher harmonics generated from a mixer diode driven by the fundamental waves of a local oscillator is selected by a filter for transmission and is used as the transmission output wave, whereby the power of the transmission waves is remarkably reduced in comparison with the mixer driving power. [A3893]

"Automatic ground clutter rejection in weather pulse radar system"

In a weather radar system wherein echo signals are linear-detected from the waves received at the radar, each one of echo signals being compared with the later one to derive AC component, and the mean power of the weather echo estimated from the power of the AC component, the linear-detected echo signals are amplitude suppressed before compared. The amplitude suppression effectively removes the errors due to the fluctuation of ground clutter, and the variation of AC power of weather echo due to the existence of ground clutter. An amplitude suppressor is used which has an amplitude suppressing property expressed by Y=X.sup.k, where X is an amplitude of the input signal, Y is an amplitude of the output signal, and k is a constant (0< k< 1) . The value of k is advantageously 0.3-0.9, and, more advantageously 0.6-0.7. If the echo signals are obtained in a form of a logarithmic signal, an amplitude suppressor which has an input-output characteristic expressed by, for example, Y=10.sup.kZ/20 (Z: amplitude of input signal, Y: amplitude of output signal) can be used. [A3894]

"Clutter filter using a minimum number of radar pulses"

A clutter filter which reduces by (N-1) the number of input pulses required or operation of an N-pulse MTI canceler when L>,N consecutive filtered outputs are desired. The clutter filter includes the two channels of an N-pulse MTI canceler which weight and sum the in-phase and quadrature-phase components of N radar returns, and a pair of delay circuits which introduce a delay of N interpulse time periods to the N and subsequent in-phase and quadrature-phase components of the radar returns. The stored outputs of the two channels of the canceler and the consecutive outputs of the delay circuits are combined in a complex multiplier to generate the consecutive in-phase and quadrature-phase outputs of the filter. The clutter filter has utility in a multiple-stage filter system employing a Doppler filter as the last stage. [A3895]

"Cross correlated doppler radar/infra red velocity and presence sensor"

A doppler radar and infra red sensor focused by common means onto a region, will, with appropriate cross correlation, provide improved velocity and presence sensing in a complex uncontrolled environment. The illustrative overhead, roadside traffic sensor employs a common microwave/infra red parabolic reflector and illuminating feed. The sensor can be conveniently mounted onto utility poles without cutting up the road or hanging overhead arbors. The velocity and presence data it provides can be used to determine vehicular headway, density, volume, vehicle size, aggregate momentum, aggregate congestion, platoon arrival, queue length, etc. This novel sensor reduces spurious indications, permits oblique angle viewing of vehicles, reduces doppler transmitter power levels so as to be well below normally accepted environmentally safe levels, and discriminates against vehicles moving in the wrong direction. The improved information will make possible better adaptive traffic signal timing methods to reduce fuel consumption and auto emissions. An additional feature provided by this sensor is that it detects emergency and mass transit vehicles to expedite their safe movement. [A3896]

"Doppler radar vehicle speed sensing system including means for checking system operation based on the detection of low frequency Doppler frequency components"

A vehicle speed sensing apparatus with means for checking its operation comprises a Doppler radar unit for producing a Doppler signal related to a vehicle speed and producing a speed signal from the Doppler signal, a first section for extracting low frequency components in the Doppler signal and a second section connected with the first section for producing an operation check signal. The extracted low frequency components correspond to vertical motion of the vehicle and are considerably lower than a Doppler signal frequency which corresponds to a minimum vehicle speed. If these low frequency components corresponding to vertical motion are not present, it is an indication that the speed sensing system is not operating properly. [A3897]

"Navigational systems using phase encoded angular coordinates"

This invention generally relates to navigation systems which seek to position in real time with appropriate accuracy one or more mobile platforms in reference to a known system of coordinates by the emission of signals into a propagation medium and processing them after detection. Broad-band, broad-beam signals are employed. All received signals convey phase encoded angular coordinate information which characterizes the particular signal path. When the angular coordinate information is used in conjunction with range determinations from detected signals, an especially useful navigation system is provided which can operate using only a single reference station. [A3898]

"Microwave proximity sensor"

An improved microwave proximity sensor including 1/4-wavelength folded dipole antenna performing the functions of a transmitting antenna, a receiving antenna, and a frequency determining element in a microwave oscillator. [A3899]

"Collision avoidance apparatus"

Collision avoidance apparatus for assessing manoeuvres of a first vehicle (6) to avoid collision with other vehicles (22) in which closed regions are computed respectively associated with the other vehicles and which, if avoided by the first vehicle, will assure that the latter will not pass closer to the other vehicles than a predetermined distance (CPA) . The periphery of each of said regions is defined by lines joining the following points: the point (49) at which the first vehicle (6) would be at said predetermined distance (CPA) from the other vehicle (22) in question when on a heading to cause the other vehicle (22) to pass ahead (ahead CPA joint) , the possible point (51) of collision (PPC) of the first vehicle (6) and the other vehicle (22) based on the present speeds of the two vehicles and the present heading of the other vehicle, the point (52) at which the first vehicle (6) would be at said predetermined distance (CPA) from the other vehicle (22) in question when on a heading to cause the other vehicle to pass astern (astern CPA point) , and the points of intersection (56,57) of a line parallel to the heading of the other vehicle (22) , and spaced from it by said predetermined distance (CPA on the side nearest to the first vehicle (6) , with said astern and ahead headings of the first vehicle (6) . [A3900]

"Anti-collision vehicular radar system"

The present invention includes an anti-collision vehicular radar system which incorporates a microprocessor. The system provides a warning of a potential collision of the vehicle with other vehicles or objects in the path of the vehicle and automatic braking. More particularly, the present invention utilizes a pulsed radar system with overlapped antenna beams for off-axis object discrimination which determines the pattern of the change in relative velocity of the vehicle and the object which is detected by its radar to provide signals which are processed by a microprocessor and associated digital circuitry to determine whether the detected object is a potential obstruction which must be avoided by braking or maneuvering of the vehicle. [A3901]

"Method utilizing electromagnetic wave pulses for determining the locations of boundary surfaces of underground mineral deposits"

The locations of compositional discontinuities in salt deposits and the like are determined by measuring the travel time of electromagnetic waves reflected off of boundary surfaces between underground geological regions of differing mineralogical characteristics. A spark transmitter is used to generate pulses each composed of a plurality of cycles of electromagnetic waves. The electromagnetic waves have a frequency between 1 and 500 MHz. The pulses have a pulse duration of 0.1 to 1 microsecond and a pulse repetition frequency of 10 to 1000 Hz. The thusly generated pulses of electromagnetic waves are radiated into the solid body of a mountain or other geological structure from within the interior of an underground excavation, so that the transmitted radiation will be reflected back from one or more boundary surfaces with different respective travel times. The reflected-back radiation is received and recorded. The travel times are measured, in order to determine the locations of the boundary surfaces. [A3902]

"Ranging radar including a modulating reflector"

A ranging radar of the radio frequency (RF) frequency modulated-continuous wave (FM-CW) type transmits an RF FM-CW signal to a reflecting surface at an unknown range R from the radar. The reflecting surface reflects the signal to a modulating device. The modulating device further modulates the signal at a frequency F which is high in comparison to the modulating frequency of the FM-CW signal. The further modulated signal is transmitted by the device to the reflecting surface and back to the ranging radar where it is subtractively mixed with a sample of a transmitted signal. The mixed signal is at frequency F amplitude modulated by a beat frequency, the period of which corresponds to range R. The frequency F is removed from the mixed signal leaving the beat frequency signal from which is determined range R. [A3903]

"Radar system for determining range and speed of an object"

A system for determining the range H to an object and the relative velocity v of the object, including means for generating first and second high-frequency signals, transmitting, receiving and mixing the received high-frequency signal with the high-frequency signal transmitted for generating first and second beat signals, and an arithmetic unit determining in an iterative manner from the point at which one of the two beat frequencies has the lowest value, the value of H and the value of v. [A3904]

"Station watch alarm system"

A system which cooperates with a conventional radar system produces an alarm upon departure of a reference target from a predetermined area relative to a vessel as an indication of vessel drift from anchor or assigned station by the use of a variable range gate and a variable azimuth gate together with discriminating and timing or counting means. [A3905]

"Warning system for traffic routes at an avalanche danger hillside"

A warning system for traffic routes at an avalanche danger hillside is provided wherein the hillside ground is divided in an assumed avalanche falling direction, thus into a series of areas which are e.g. about 30 meters wide. These areas each have at least one associated indication device with an electronic signal output, and the signals of the indication device are fed to a memory which, for a downhill correct sequence of the signals, energizes an avalanche alarm and releases the alarm when, by virtue of the stored experience data, there is no longer a risk below the avalanche area. The indication devices receive an electronic signal output of a receiver for the reflected waves of at least one radar transmitter, and these signals from the indication device are fed to an electronic logic circuit which, for a downhill correct sequence of the signals energizes and releases an avalanche alarm in accordance with the snow movement on the hillside. [A3906]

"Method and apparatus for measuring distances"

Measurement of distance is carried out by transmitting a VHF wave train crising a sinusoidal signal modulated by phase inversion in accordance with a pseudo-random sequence, at a receiver shifting a like second sequence until it coincides with the received sequence, re-transmitting a signal modulated by the second sequence, receiving the second sequence and shifting a like third sequence until it coincides with the received second sequence, and measuring the phase shift between the third sequence and a like reference sequence. [A3907]

"P-I-N type diode high frequency switch for secondary radar interrogation devices and transponders"

A P-I-N type diode high frequency switch in a secondary radar interrogation device working with ISLS and RSLS and consisting of a transmitter, two receivers and two antennas. So as to reduce the high cost for P-I-N type diodes, including driver stages for the transmission and reception separation and to eliminate the necessity of an antenna switching unit, the terminals 19 and 20 of a pair of antennas are directly connected through single lines 23 and 24 to band pass filters 5 and 6 connected to respective receivers 7 and 8 with the band pass filters 5 and 6 blocking the transmission signal and allowing reception of received signals and wherein the electrical lengths of the line and the band pass filter is such that the input impedance corresponding to no-load operation occurs at the corresponding antenna terminal for the transmission frequency. The invention can be used in secondary radar transponders operating with two antenna diversity and the high frequency switch of the invention can be used in both civil secondary radar interrogation devices as well as military IFF interrogation devices as, for example, in ground stations. [A3908]

"Traffic radar unit"

A one-piece traffic radar unit has a housing containing both the transceiver and signal processing circuitry and the directional antenna of the radar system. A bracket plate extends from the top portion of the housing and overlies the dashboard of the patrol vehicle to mount the unit therein with the housing depending from the bracket plate in front of the dashboard, thereby leaving the driver's view through the windshield unobstructed. The antenna is of the conical horn type and is vertically disposed to beam the transmitted signal up through the housing to a rotary reflector mounted on the top of the housing. The reflector is rotatable about a vertical axis and permits the operator to aim the beam in any horizontal direction through the windshield or a window of the vehicle. A special safety mount for the reflector provides for 360.degree. rotation and also permits the reflector to break away from the housing on impact. The housing is specially shaped in that the front panel thereof, containing the controls and readout, is positioned obliquely with respect to the fore-and-aft axis of the vehicle to face the panel generally toward the driver and provide a convenient reading angle. [A3909]

"Digital CFAR signal processor for phase coded radars"

Use of multi-bit digital arctangent function-generator to remove noise-clutter amplitude-modulation from in-phase and quadrature phase multi-bit successive samples of MTI canceller outputs and n-bit running correlation of digitized samples with serial phase code, result in increasing effective CFAR sensitivity of radar receiver. [A3910]

"Surface acoustic wave time chirp devices"

Surface acoustic wave dispersive delay lines provide a chirp signal generator and filter capable of producing signals of which the frequency-time slope can be varied. The chirp signal generator includes two surface acoustic wave delay lines, means for impulsing the delay lines with a variable relative time delay, and a mixer for combining the outputs of the two delay lines. The variable dispersion filter includes two delay lines, means for impulsing the delay lines with a variable relative time delay, a first mixer for combining an input signal with the output of one delay line and a second mixer for combining the output of the first mixer with the output of the other delay line. Variation in the time delay between the impulsing of the two delay lines produces a variation in the chirp rate at the output signal. The amplitude frequency characteristics of the signal generator and filter may be made non-linear by amplitude weighting one delay line. [A3911]

"Automatic vehicle identification system and method"

An automatic vehicle identification system for use in identifying and routing vehicles, such as railway cars or other vehicles which routinely travel a given track or path. A passive electronic device or electrical circuit is employed to intersect an energy field and respond thereto by generating a code in accordance with energy received and converted to coded electrical signals. Connected to the passive device is a short wave transmitter for transmitting signals generated by the electrical device when so energized. The electrical device may also comprise a plurality of different induction coils or antenna which serve to modify an energy field in a given manner, which modification may be detected by short wave sensing and converted to a coded electrical signal which is employed to identify the vehicle. In another form, a coded array of antenna or induction coils, is provided which modify energy fields generated at check points or scanning locations along a trackway or roadway, wherein such energy field modifications are sensed at each such scanning location, resulting in the generation of an electrical code at each location and identification of the vehicle. [A3912]

"Moving object detecting device"

A moving object detecting device employing a pair of Doppler signals as a pair of vector signals of respective received-wave signals representing momentary reflected waves from a moving object. These vector signals are processed to obtain signals denoting in which ones of predetermined zones for the vector rotation depending on the movements of the object the vector is momentarily present, and shifting states of such zone signals through the zones are traced to sequentially determine the direction and period of the vector rotation and to actuate an alarm or the like when the rotation is in a fixed direction. [A3913]

"Method for shaping and aiming narrow beams"

A method and apparatus is disclosed for use of a linear frequency chirp in a transmitter/receiver (14/16) having a correlator to synthesize a narrow beamwidth pattern from otherwise broadbeam transducers when there is relative velocity between the transmitter/receiver (14/16) and the target. The chirp is so produced in a generator (20) in bandwidth, B, and time, T, as to produce a time-bandwidth product, TB, that is increased for a narrower angle. A replica of the chirp produced in a generator (26) is time delayed and Doppler shifted for use as a reference in receiver (16) for correlation of received chirps from targets. This reference is Doppler shifted to select targets preferentially, thereby to not only synthesize a narrow beam but also aim the beam in azimuth and elevation. [A3914]

"Ranging quadrature doppler microwave intrusion alarm system"

Movement of an object (intruder) in a specified area is sensed by transmitting microwave energy from an antenna (10) that also receives energy reflected from the intruder, where the received energy is quadrature processed using Doppler techniques. Connected to the antenna (10) is a transceiver (12) that includes a quadrature mixer (48) coupled to an RF oscillator (50) through an RF switch (52) . The RF switch (52) is controlled by a switch driver (54) to provide pulse energy from the antenna (10) . Doppler outputs E.sub.1 and E.sub.2 from transceiver (12) are processed in the same manner except for a 90-degree phase lead applied to the Doppler output E.sub.2 by a phase lead network (18) . Doppler outputs E.sub.1 and E.sub.2 (E.sub.2 90-degree phase shifted) are applied simultaneously to a sum and signature processor (24) and to a difference and signature processor (22) . The sum and signature processor provides the "approach" receiving signal and processes the signature to further reduce the nuisance alarm rates. The difference and signature processor (22) provides the "recede" receiving signal and similarly processes the signature to reduce nuisance alarms. Outputs of the processors (22) and (24) are respectively applied to rectifiers (32) and (28) and to integrators (34) and (30) which are similar in design and serve to rectify, amplify and filter the inputs applied thereto. A voltage comparator (36) responds to the output of the integrators (34) and (30) to trigger an alarm (38) when the voltage difference between the outputs of the integrators reaches a predetermined magnitude. [A3915]

"Doppler-type projectile velocity measurement and communication apparatus, and method"

Projectile velocity measurement and communication apparatus comprises a microwave probe fixed to a projectile barrel near a muzzle end. An oscillator, having a reference frequency selected for exciting a fundamental electromagnetic mode in the barrel, is connected to the probe through a hybrid mixer configured for extracting, from moving projectile-reflected microwaves, a true Doppler signal having a varying frequency related to projectile barrel velocity. A processor, connected for receiving the Doppler signal, measures, by a clock oscillator, Doppler signal periods (half periods) . A data presorter in the processor selects a last "N" number of period measurements before the projectile reaches an interference position relative to the probe, to be fed to a fire control computer interface for determination therein of projectile barrel and muzzle velocities, calibration means being provided to update barrel diameter values used in such determination. An alternative, dual reference frequency variation is described, in which a dual hybrid mixer provides two independent Doppler signals, to eliminate dependency of projectile velocity determinations on barrel diameter. A reference frequency modulator and control means therefor are provided to enable microwave communication of information to the projectile, for example, of projectile target time of flight for fusing purposes. Corresponding methods for projectile velocity measurement and communication are provided. [A3916]

"Navigation-monitoring apparatus"

A navigation-monitoring apparatus comprises a fixed ground station sending forth an interrogation signal to a ship and a transponder carried on the ship and transmitting a reply signal to the fixed ground station in response to the interrogation signal. A microwave sensor carried on the ship measures the distance between the ship and the nearest bank. Data on the measured distance is added to a reply signal sent forth from the ship to the fixed ground station. The fixed ground station measures an interval between a point of time at which the interrogation signal was issued and a point of time at which a reply signal from the ship was received, thereby defining the position of the ship from said time interval and data on the ship-to-bank distance. [A3917]

"Microwave speed meter"

A meter for measuring the relative velocity of an object, including a diplexer for illuminating the object with a beam of microwave energy and for developing from energy reflected from the object a difference signal having a frequency which is proportional to the relative velocity of the object, a phase-locked loop for synchronizing the frequency of an internal oscillator with that of the difference signal and for developing a lock signal when synchronization is achieved, a lock detector and timer and a timer for developing a reset signal from the lock signal, a predetermined period after synchronization is achieved and for developing a latch signal a predetermined period thereafter, a circuit for counting the cycles of the internal oscillator which are developed after the occurrence of the reset signal until the occurrence of the latch signal to develop a sum signal indicative of the relative velocity of the object, and a circuit for displaying the sum signal. [A3918]

"Detector for doppler device"

A doppler detector for measuring the speed and/or the direction of a moving body utilizing the principle of the doppler effect that the reflected frequency from a moving body is slightly changed has been found. The present doppler detector comprises a rectangular waveguide inserted between a microwave oscillator and an antenna, an elongated ferri-magnetic body inserted between a pair of H planes of said waveguide, and said body being magnetized in the axial direction of the same, and a pair of diodes each inserted between H planes of said waveguide so that the first diode being symmetrical with the second diode concerning the lateral plane including the center axis of said ferri-magnetic body. [A3919]

"Swept frequency radar system employing phaseless averaging"

Described herein is a microwave radar system which employs heterodyned swept frequency at approximately two millisecond sweep intervals. The power source is a reliable solid state, low power device such as a Gunn diode. The heterodyned difference frequency signals are converted to digital form, transformed into the frequency domain by means of a Fourier power transform, and then averaged by computer processing. Performing the Fourier power transform before averaging enables the processing of quasi-incoherent data whereby signal-to-noise ratio improvement is a function of the square root of the average number of samples taken. High-speed processing is used to off-set the loss of statistical averaging of phase-coherent data which cannot be preserved because of target motion. Thus, the sequence of the power transform allows phase-less averaging over the entire collection period. Complementary elements including signal isolation and stability, through interdependent design features of the antenna and circulator, permit the use of low-power CW radar which minimizes danger to ecology and human safety. Thus, the invention has particular applicability to the analysis of clouds, the extraction of range and thickness data of clouds, and the presence and velocity of rainfall. The invention can be used for point targets as well. Algorithms are built into the computer to compensate for various factors such as wind, temperature, and the nature of scattering nuclei. [A3920]

"Washbox with conveyor discharge"

A washbox comprising a vessel divided into a stratification compartment and an adjacent reject compartment, a perforate grid plate extending across upper parts of the compartments. First pulsation means activates the water in the stratification compartment, and second pulsation means activates the water in the reject compartment separately and in isolation from the stratification compartment. A divider is mounted above the part of the grid plate which extends over the reject compartment, an upper surface of the divider defining a first outlet channel by which material of a lower density may pass from the washbox, whilst a lower surface of the divider, together with the said part of the grid plate which extends over the reject compartment, defines a second outlet channel along which material of higher density may pass from the washbox. Adjacent to the reject compartment is a reject extraction chamber, which is not in under water communication with the pulsations applied to the two adjacent compartments and which is open upwardly to atmosphere. A first conveyor means extends through the reject extraction chamber, which is adapted to convey that reject material which passes through the second outlet channel into the reject extraction chamber from the washbox. A separate, second conveyor means is mounted on the washbox for conveying from the washbox that reject material having fallen through the apertures in the grid plate towards the bottom of the washbox. [A3921]

"Apparatus for identifying objects and persons"

A system for identifying persons and objects includes an information carrier adapted to be secured to an object to be identified, and a read unit coupled to the information carrier by means of electromagnetic waves. The information carrier incorporates a plurality of passive elements interconnected with a receive-transmit antenna system so that an interrogation signal is processed and retransmitted as a unique signature of the information carrier. The passive elements of the information carrier include delay elements, attentuation elements, and filters, interconnected in a plurality of parallel paths to generate the identifying signature. [A3922]

"Collision avoidance system using short pulse signal reflectometry"

A collision avoidance system for rapid transit vehicles employing baseband radar principles in which signals with duration in the order of nanoseconds are transmitted down track along a surface wave transmission line. Reflections from a passive target located on the preceding vehicle are processed to establish the distance between the vehicles to within an accuracy previously unachievable. [A3923]

"Apparatus for eliminating blind velocities in MTI radars"

A system and method for reducing the blind velocity problems in MTI coherent pulsed Doppler radar systems comprising an agile local oscillator which is preprogrammed to operate sequentially at more than one frequency unitl a target of interest is acquired. [A3924]

"Following distance measuring communication system"

A following distance measuring communication system comprising a transmitter and a receiver which are mounted on the front part of a following automotive vehicle, a time measuring unit connected to the transmitter and the receiver provided on the following automobile, and an answering transmitter-receiver unit mounted on the rear part of a preceeding vehicle. A pulse modulated signal is transmitted from the transmitter on the following vehicle, and this signal is received by the answering transmitter-receiver unit on the preceeding vehicle. At the instant that the signal is received, the answering transmitter-receiver unit on the preceeding vehicle generates a reply signal which is in turn received by the receiver on the following vehicle. The time required for this process is measured by the time measuring unit connected to the following vehicle receiver to determine the distance between the following vehicle and the preceeding vehicle. [A3925]

"Stratifier discharge control"

A wash box for separating materials produced in, for example a mining operation, into fractions of different densities. The machine is divided vertically into compartments, including at least one stratification compartment and at least one reject compartment, the raw material being delivered onto the grid, the level of water in the compartments being higher than the grid. Vertical pulsations are applied to the water in the compartments, causing the water to travel through the perforations of the grid. The pulsations applied to the stratification compartment are effective to stratify the material on the grid, movement of the water through the wash-box tending to carry the lighter fraction from the wash-box while the pulsations applied to the reject compartment determine the rate at which the heavier fraction reject material falls from the grid plate into a reject extraction chamber adjacent to the reject compartment. The pressure produced in the stratification compartment upon the application thereto of each stratifying pulse, and which is dependant upon the quantity of the heavier fraction on the grid over the stratification compartment, is measured by sensing means, and this measurement is used to control the amplitude of the pulsations applied to the reject compartment. Valves applying the pulsations to the stratification and reject compartments are driven by a common drive means, and the frequency at which the pulsations are applied to the reject compartment is higher than, preferably at integral multiple of, the frequency at which pulsations are applied to the stratification compartment. In this manner, the maximum rate of which reject material may be removed from the grid may be considerably extended and, by a finer control of the amplitude of the pulsations applied to the reject compartment, this may be achieved without any significant reduction in the efficiency of separation. [A3926]

"Method and apparatus for detecting and measuring inclusions in subsoil"

A method and apparatus is described comprising a transmitter for transmitting an unmodulated carrier of selected wave length into the ground and a receiver adapted to receive reflected signals. Circuitry is described for producing narrow pulses from the transmitted and received signals for displaying them on an oscilloscope and on a plotter. The display on the oscilloscope is rotated through 90.degree. from the conventional display so that the pulses corresponding to the transmitted and reflected signals appear as horizontal bars spaced apart vertically by distances which correspond to the depth of the inclusions below the surface. The wave length is selected to be at least four times the anticipated depth of the inclusions. The apparatus is described as being incorporated into a motor vehicle such as a Land Rover with the transmitting antenna mounted at the front and the receiving antenna at the rear of the vehicle. The apparatus is most conveniently situated in place of the co-driver's seat for operation by an operator sitting in the rear of the vehicle. Decoupling between transmitting and receiving antennae is partially achieved due to the rotation through 90.degree. of the polarity of the reflected wave relative to the transmitted wave. [A3927]

"Signal processor"

A signal processor having a plurality of charge transfer devices adapted for coupling to an input signal source. Each one of such devices produces a sample of the input signal in response to a sampling signal. An input shift register having a plurality of serially coupled stages is provided, each one of such stages being coupled to a corresponding one of the charge transfer devices. Circuitry is included for enabling the sampling signal to be sequentially produced at an output of each one of the serially coupled stages, enabling sequential samples of the input signal to be produced in corresponding ones of the charge transfer devices. [A3928]

"Device for registration of objects"

Devices for registration of an object and its movements in relation to another object by means of a high frequency signal transmitted from one of the objects and reflected from the other object, the reflected signal being modulated with an identification code and received back at the first mentioned object where the registration of the code takes place. To separate the reflected signal, from the first transmitted signal the frequency of the reflected signal is changed at the same time as it is reflected, the frequency change of the reflected signal being made in a way which allows the frequency of the reflected signal to be chosen according to wish, and that the frequency of the reflected signal is not equal to any of the stronger harmonic of the fundamental frequency of the first, originally transmitted signal. Thereby the reflected signal can be properly received and detected even though much weaker than the transmitted signal or any of its harmonics. [A3929]

"Delay line digital code detector"

Digital codes, each of which is comprised of a series of equally spaced pulse positions bracketed by framing pulses are passed through a delay line having a plurality of taps. The taps are connected in a gating structure which extracts only valid codes and suppresses garbled and phantom codes. [A3930]

"Target detection device"

A target detection device which functions a warhead at a predetermined het above the surface of the earth. A frequency modulated, pseudo-noise coded signal reflects from the surface of the earth to provide Doppler signals to a dual gate Doppler amplifier system. The voltage outputs of the two gates are compared, and a signal is sent to a threshold circuit to ascertain when a predetermined relationship exists between the two voltage outputs to decide when the target detection device is at a predetermined height, at which time a trigger signal actuates a time delay circuit using the Doppler frequency to generate a time delay that is dependent upon the vertical velocity of the target detection device. After the time delay, a signal is sent to a firing circuit which produces a firing pulse to function the warhead. [A3931]

"Traffic radar device"

A traffic radar device has a microprocessor controlled system for facilitating the Doppler signal processing. Related circuits enable the Doppler signal to be gathered on a digital basis and arrayed in the memory of the microprocessor unit. The array is then examined and by executing a predetermined algorithm, a decision is made as to whether or not a series of samples of Doppler signals, comprises within the array, represents a valid signal suitable for display as a number indicative of speed of a target vehicle. The microprocessor also controls a tracking filter system over the expected Doppler frequency range and has a duty factor modulation and tunable notch to facilitate the filter operation. The radar device includes a range control that limits the range of the detection of the target vehicle without affecting the detection of the platform vehicle speed. A hold mode is provided with respect to the radar device so that radiated RF energy is controlled to decrease the probability of detection by a traffic radar detector. The radar device is also capable of converting from one unit of measure to another without modification of the associated time base. As a further check on accuracy, the device includes the ability to determine the calibration of the time base within the radar system and to control the display based on the time base calibration. High speed lock onto a target vehicle speed is also provided along with the unique "power-on" calibration sequence. x [A3932]

"Speed control apparatus and method for railroad car retarders"

An acceleration servo control system for railroad car retarders in which a computed desired instantaneous deceleration signal and a measured actual deceleration signal are compared and any resulting error signal is fed back through the servo network to adjust retarder braking pressures to achieve and/or hold the desired deceleration rate which will allow the cut of cars to leave the retarder at a selected speed. The desired instantaneous deceleration is computed using an algorithm incorporating actual measured speed, the selected exit speed, the number of axles in the retarder, and the remaining distance-to-go for all axles of the cut over which retarder braking will be effective, and based on the principle of braking each axle-wheel unit throughout the entire retarder length. [A3933]

"Method and apparatus for measurement of the contents of a bunker or silo"

To measure the contents of a bunker or silo a transmitter mounted over the bunker beams down on to the contents surface a very high frequency signal that is caused repeatedly to rise and fall in frequency with either a constant sweep time and a progressively varying amplitude of frequency change or a constant amplitude and a progressively varying sweep time. The reflected target return signals are mixed with the transmitted signal to obtain a beat frequency which is filtered and processed to derive a signal representative of the range of the target, i.e. the contents surface, below the transmitter. To discriminate against target returns from fixed parts of the bunker structure, such as support members, a control unit is provided with a memory store into which are preloaded signals representative of fixed structure returns. The target returns received when the apparatus is in operation are then compared with the stored signals and any that are the same as stored signals are rejected. The control unit may also include a processor capable of distinguishing between returns from fixed targets and returns from a target moving toward or away from the transmitter. [A3934]

"Dynamic digital time interval discriminator and method"

Circuitry for indicating the occurrence of a predetermined separation time between adjacent pairs of pulses in a sequence of pulses including a first counter having a first relatively high frequency clock signal applied thereto and the sequence of pulses applied to reset the counter for each pulse, a second counter having a relatively low frequency clock signal applied thereto with the second counter counting the total number of cycles from an initial or starting time, and comparators for comparing the number of cycles in the first counter to the number of cycles in the second counter and providing output signals when the comparison indicates that the separation time between adjacent pairs of pulses is within a predetermined range. [A3935]

"Range detector"

A doppler range detector with early and late range gates responding to radar returns or either side of maximum velocity range and supplying a peak output amplitude when the early and late gates have the same doppler frequency. A peak detector is used to detect slant range with a dual pulse ranging system. The returns are supplied to two zero beat mixers, the output signals of which are passed through separate bandpass filters to a multiplier. The multiplier output is supplied through a low pass filter to the peak detector. [A3936]

"Radar speedometer"

Method and apparatus for measuring the speed of a land vehicle over a surface. A narrow beam of RF energy is directed toward the surface at a substantial angle. Reflected RF energy is mixed with that transmitted to produce Doppler signals having a spectrum. The spectra of the Doppler signals are normalized by the Doppler signals being applied to an AGC circuit so that the maximum amplitudes of the spectra are substantially constant and being applied to one or more tracking band pass filters which eliminate unwanted frequency components in the spectra. From the normalized spectra, output signals are produced from which can be determined the speed of the vehicle relative to the surface. [A3937]

"Radar clutter suppressor"

This disclosure describes a radar clutter suppressor and target classifier that compares two or more video signals. Various signal conditioning and processing means are used for enhancing echo differences between targets and clutter caused by differences in polarization, carrier frequency, pulse length, antenna beamwidth, and antenna pointing direction. Signals are processed as if due to targets if the ratio of the video amplitudes are within a band of ratios and signals are suppressed as if due to clutter if the ratios are not within the band of ratios designated for targets. The invention includes methods for suppressing clutter caused by rain, land and sea. [A3938]

"Ranging system and method for determining the range of a vehicle from a plurality of reference points"

Systems and methods for determining the range from a vehicle to a plurality of reference points. In one system a mobile transceiver is located on the vehicle for transmitting a ranging interrogation signal pulse modulated on an RF carrier having a given frequency in response to a timing pulse and for receiving ranging response signal pulses modulated on RF carriers having the given frequency. A plurality of reference transponders are individually located at each of the plurality of reference points for receiving the timing pulse and the ranging interrogation signal pulse on a carrier having the given frequency and for responding thereto by transmitting a ranging response signal pulse on a carrier having the given frequency during an interval that is discrete from the intervals during which ranging response signal pulses are transmitted from the other reference transponders. Within a given time slot in relation to the timing pulse, a single ranging interrogation signal pulse is followed by a sequence of discrete ranging response signal pulses. A data processor determines and processes the phase of the received ranging response signal pulses in relation to the transmitted ranging interrogation signal pulse to determine the range from the vehicle to individual reference points, and processes the range determinations to determine the position of the vehicle by multilateration. The mobile transceiver, transponders, and transmitter each include an RF transmitter having a modulator circuit for modulating an RF carrier signal to have a predetermined shape envelope determined by the shape of a modulating signal. [A3939]

"Radar signal processors"

Radar signal processor utilizing a technique for detecting targets moving slowly and clutter. The technique comprises dividing the clutter spectrum into a large number of narrow bands and in each band measuring the power ratio between upper and lower side bands. When this ratio exceeds a fixed threshold, the target is declared and, if necessary, its velocity signature can be detailed. [A3940]

"Turbulence detector for non-coherent pulse radar"

Information about air turbulence and wind shear can be obtained by analyzing the fluctuation of the envelope, at the detector output of a pulse radar, of backscatter from hydrometeors which trace the wind field. Further, under some conditions, radar returns can be identified as being backscatter from weather targets or from the ground or sea. The detector output signal is quantized into one of several class intervals whose boundaries, in mid-range, are in the same ratio. Consecutive radar returns from scatterers at the same nominal range and scan angle are quantized into either the same or different class intervals. The ratio of the number of consecutive quantizations that are different to the number of trials is a measure of the variance of relative velocities at that range and scan angle. This technique permits economical implementation of a plan position display of, for example, the expected severity of turbulence or wind shear at each increment of range and azimuth angle since duplication of circuits is not required. [A3941]

"Charge transfer device input circuitry"

A charge transfer device having a source diffusion region, an isolation gate region, a reference voltage gate region and an input signal gate region disposed contiguously along such device, the isolation gate region being adapted for coupling to a pulse voltage source, the duration of such pulse being related to a predetermined sampling interval (and therefore related to the bandwidth of an input signal being sampled) , the reference voltage gate region being adapted for coupling to a reference voltage source and the input signal gate region being adapted for coupling to the input signal. During each clock interval prior to the sampling interval the source diffusion region is pulsed, thereby enabling charge to pass from such region into the reference voltage gate region and the input gate region. During the sampling interval the potential energy level of the isolation gate region is lowered to enable equilibration of the potential of the charge in the input gate region with the potential in the reference voltage source region, the charge in such input gate region thereby being proportional to the input signal level during the sampling interval. At the end of the sampling interval the potential energy level of the isolation gate region is raised to isolate the source diffusion region from the input gate region and thereby inhibit charge flow from the input gate region to the source diffusion region if the input signal level varies prior to the time at which the charge in the input gate region is transferred to the first storage stage of the device. [A3942]

"Moving target indication radar"

A moving target indication radar (MTI) having a high azimuthal position detection accuracy. The received radar return signal is separated into quadrature components which are each converted to a series of digital samples. A continuous discrete fast Fourier transform is then performed on groups of samples corresponding to a predetermined number of contiguous azimuthal units of identical range producing an equal number of output Doppler frequency components which represent the relative speeds of stationary and moving objects within the contiguous azimuthal units. A new separate transform operation is performed for each new sample received. The transform outputs are processed to separately detect the stationary and moving objects. [A3943]

"Speed measuring device"

A special accessory for traffic radar devices includes two operating routines. These routines are to be used with a programmable microprocessor which comprises a portion of the traffic radar device. The routines are designated as a stopwatch routine and an interrupt routine. The stopwatch routine controls the overall operation of the speed computation within the programmable microprocessor of the traffic radar device while the interrupt request routine causes the microprocessor to perform as a precision clock capable of measuring elapsed time. [A3944]

"Signal processor"

A signal processor having a plurality of charge transfer devices fed by a series of input signals, input addressing circuitry for enabling sequential samples of such each one of input signals to be stored in corresponding ones of the charge transfer devices, such charge transfer devices storing corresponding sets of samples, output addressing circuitry for reading, sequentially, the sets of samples, the charge transfer devices, input addressing circuitry and output addressing circuitry being formed on a single crystal substrate. [A3945]

"Moving target indicator (MTI) radar systems"

Method and apparatus for the detection of a ground moving target using a moving platform MTI radar system are disclosed. Such a moving target is detected by comparing the power level of radar return signals passing in a difference channel of a monopulse receiver with a predetermined power level. In one embodiment, a monopulse antenna of such receiver scans a swath of ground and the power level of radar returns passing in the difference channel having a Doppler frequency equal to the Doppler frequency associated with clutter disposed along the boresight axis of such antenna is compared with a predetermined power level. When the power level of returns in such difference channel at such Doppler frequency is greater than the power level of returns from clutter disposed along the boresight axis (i.e., the predetermined power level) , a moving target is indicated. Such embodiment is particularly adapted to detect "slow" moving targets, that is, targets disposed in the main beam of the monopulse antenna and having a Doppler frequency within the Doppler frequency spectrum of returns from clutter disposed within such main beam. In a second embodiment of the invention the power level of returns passing through the difference channel having a Doppler frequency outside the Doppler frequency spectrum of returns from clutter disposed within the main beam is compared with the power level of returns passing through a sum channel of such monopulse receiver having such Doppler frequency. When the former power level is less than the latter power level, a moving target is indicated. This embodiment is particularly adapted to detect "fast" moving targets (that is, targets disposed in the main beam but having Doppler frequencies outside the Doppler frequency spectrum of returns from clutter disposed in the main beam) from large stationary objects disposed outside the main beam and illuminated by the side lobes of the monopulse antenna. [A3946]

"Radar system for detecting approaching vehicles from behind"

A radar system of the invention transmits a series of microwave burst energy backwardly of stationary vehicle to receive a return signal. When the return signal occurs within a preset time interval, a first and second Doppler signals are derived by mixing the return signal with first and second locally generated oscillations having a phase difference therebetween so that there is a varying phase difference between the first and second Doppler signals depending upon the direction of movement of the detected vehicle. A phase discrimination circuit generates a warning signal when the two Doppler signals have a predetermined phase relation. [A3947]

"Surface wave phase correlator and monopulse radar system employing the same"

A surface wave phase correlator comprises a pair of substantially identical launch and receiving filter electrode patterns disposed on a common piezoelectric substrate. The correlator is employed with receiving and processing circuitry in a monopulse radar system to provide relative phase information for target calculations by a digital processor. Fast rise and fall times for the correlator output signals enable rapid digital processing of incoming target signals. [A3948]

"MIPS Hover attachment"

An attachment is provided for aircraft, and particularly for helicopters, for use in conjunction with a microwave interference pattern sensor (MIPS) system, to sense low velocities, for example, such as are encountered when the helicopter is in a hover mode. The attachment includes an antenna array which is separated from the MIPS antenna array, and which comprises two sets of transmitting and two pairs of receiving antenna horn apertures mounted in orthogonal relationship with one another, the transmitting apertures of each set being scanned in sequence to produce a moving energy pattern which is intercepted by the receiving antenna apertures of the attachment, even though the aircraft is stationary. [A3949]

"Harmonic detector for traffic radar"

A traffic radar unit capable of operation from a moving patrol vehicle has a receiver provided with phase recognition circuitry that prevents the display of "ghost" readings. After initial processing of the incoming composite Doppler signal, the phase recognition circuitry receives logic conditioned, low and high frequency speed signals derived from the Doppler signal and produces an abort command to prevent the determined target speed from being displayed if the phase relationship between the two speed signals remains constant for a predetermined number of cycles of the low frequency speed signal. The latter signal corresponds to a low frequency component of the Doppler signal representing the speed of the patrol car, but the high frequency signal may be a harmonic that would produce an invalid reading. The circuitry employs a serial to parallel type shift register having a data input receiving the high frequency speed signal. The register is clocked by the low frequency speed signal. If all outputs of the shift register assume the same logic level, phase coherence (and hence a harmonic relationship) is recognized and the display is aborted to prevent ghost readings from stationary objects such as road signs, mixed outputs indicate a valid target (moving target vehicle) and the reading is displayed. [A3950]

"Coded pulse radar fuze"

1. A coded pulse radar proximity fuze with improved electronic countermeae protection, comprising: (a) transmitting means for radiating a recurring sequence of three pulses of two alternate frequencies at a target, each of said pulses being separated in time by the desired radar round trip delay time and each of said sequences of pulses being separated in time by a greater time than the desired radar round trip delay time, (b) means for receiving reflections of said recurring sequence of three pulses radiated at a target by said transmitting means, (c) means connected to said receiving means and to said transmitting means for combining the output of said receiving means with a portion of the output of said transmitting means, (d) means connected to said combining means for amplifying that portion of the output of said combining means having a frequency equal to the difference between said two alternate frequencies, and (e) means connected to said means for amplifying for detecting a sequence of two pulses separated in time by the desired radar round trip delay time. [A3951]

"Integral enable-disable means for guided wave radar intrusion detector system portals"

The intrusion detection capability of a guided wave radar intrusion detection system is selectively disabled in certain areas, such as gates or portals to permit ingress and egress of personnel and vehicles without affecting overall system performance and without requiring an independent detection system. This is realized by means of an integral system portal enable-disable device. Guided wave radar intrusion detection systems employ two parallel leaky transmission lines, one transmitting and the other receiving radar signals. Violation of the area between the leaky transmission lines by an intruder results in a signal that indicates the occurrence and its location. Gate areas are remotely enabled or disabled by a switching circuit that switches a segment of non-radiating transmission line into or out of the transmitting leaky transmission line in each selected gate region. [A3952]

"Portable buried object detection system with error reducing signal processing"

A portable apparatus used for geophysical exploration for buried objects h as mines, relics and minerals utilizing a means to represent the endpoints of the apparatus sweep and means responsive thereto to blank data received at these points, thereby eliminating erroneous signals likely to occur when the search head is in a tilted position. The end-point representation may be achieved by either a metronome-type signal generator or by an accelerometer. [A3953]

"Surface acoustic wave code reader"

A system is disclosed for reading a code established by a surface acoustic wave device. The system has a first antenna connected to a supply for transmitting a signal, a second antenna for receiving said signal and supplying it to a first transducer on a surface acoustic wave device, the first transducer converting the signal into surface acoustic waves, a second transducer on the surface acoustic wave device for converting the surface acoustic waves to a coded signal, a third antenna for transmitting the coded signal, and a fourth antenna for receiving the coded signal and connected to a receiver for providing an output dependent upon the coded signal. This system is particularly useful for access control systems. [A3954]

"Radar-operated vehicle safety assurance system"

A radar-operated vehicle safety assurance system includes a radar device which detects the vehicle relative speed or range to an object. A safety limit value of the detected operating parameter is computed by means of a safety range detection or safety speed detection circuit as a function of a detected operating parameter. A visual indicator is provided which visually indicates the difference between the detected value and the computed safety limit value to allow the vehicle driver to become continuously aware of the marginal conditions of the vehicle in relation to the safety limit. [A3955]

"Railroad radio frequency waveguide"

Disclosed is a waveguide for conducting radio frequency signals along a railroad line comprising the ballast, ties and rails of the railroad line. If the waveguide is utilized for intra-train communication, the wheels, axles and under-vehicle parts of the vehicles of the train comprise the side and upper surfaces of the waveguide. The waveguide may be utilized to: (1) transmit data such as train vehicle journal bearing temperatures, from remote locations to either the caboose or engine of the train, (2) guide radar-type radio frequency pulses ahead of the train, or (3) transmit any other data. In the radar embodiment, reflections received by a receiver on the train represent changes in the characteristic impedance of the waveguide. These reflections may be compared to anticipated reflections in order to detect improper conditions such as broken track or the presence of another train. [A3956]

"Radar systems"

The invention principally concerns marine radar systems and seeks to reduce "sea clutter". The radar transmitter is arranged to transmit a set of four pulses forming two pairs of pulses in which the pulses of a pair are time spaced by the radar interpulse period and frequency spaced by the reciprocal radar pulse length. The pairs of pulses are frequency and time spaced by several times the frequency and time spacing of the two pulses in a pair. Transmission takes place from a rotatable antenna which exhibits squint and the antenna is rotated at a rate which having regard to the squint effect and the time separation of the pulses is such that all of the four pulses irradiate the same areas in the plane of rotation of the antenna. This renders possible signal processing in the radar receiver to achieve both frequency and time decorrelation of clutter. [A3957]

"Device for measuring the range of a moving target and the speed at which it approaches or recedes"

A radio range measuring apparatus having a controlled modulation slope in order to keep the beat frequency between the transmitted signal and the received signal constant. The apparatus also measures the speed at which a mobile target approaches or recedes by means of a generator of a fixed frequency which, after frequency division, maintains the duration between the start of two consecutive sawtooth modulation signals fixed. A particular spectral line of the beat signal is demodulated by this fixed frequency via a mixer whose output is filtered by a passband filter. The signal at the output of the filter has a frequency which is equal to the Doppler frequency, proportional to the speed. [A3958]

"Radar device including a circuit arrangement for reducing interference"

A radar device such as the type which uses a non-constantly scanning radar antenna including a circuit arrangement for reducing interference due to ground reflection wherein an interference value is subtracted from the sampled received signal and wherein the interference value is obtained by recursively calculating from the sampled values with the use of a recursion factor which changes during the sampling sequence so as to reduce interference due to ground reflections and allow the detections of objects which are moving slowly in the radial direction. [A3959]

"Acquisition system for continuous-wave frequency modulation object detector"

A continuous-wave frequency-modulation active radiometric target seeking device performs search, acquisition, and tracking functions. A technique is provided for target range discrimination and recognition using a pair of narrow band i.f. filters also improving both signal-to-clutter ratio and signal-to-receiver noise ratio. Target search is accomplished with simultaneous and synchronized range and antenna azimuth scanning with range bins effectively swept across the target by variably modulating the transmitted carrier frequency. Recognition of a substantially point target is achieved by a bipolar pulse discriminator responsive to the i.f. filter pair. Upon target acquisition, tracking is maintained by imposing a high frequency dither upon the modulation frequency in a closed loop control using only a single i.f. filter. [A3960]

"Transponder reply limiting by means of recognition of fixed interrogation periods"

It is shown that the interrogation repetition period (IRP) of an interrogr can be recognized by a transponder and then used by it to both determine when the interrogator has elicited a predetermined number of replies called an adequate response and limit the interrogator to that number during each scan. This form of reply limiting by a transponder requires absolutely no change in the type of signals transmitted. Logic circuits that perform the required functions are provided. [A3961]

"Enhancing radar returns from targets having a small radar cross section"

A method for locatingweak targets such as power lines and tree tops in the presence of terrain clutter by separating the weak target from the clutter in the elevation plane. [A3962]

"Apparatus and methods for position determining and plotting"

Apparatus and methods are disclosed wherein the relative location of a point of position is mathematically determined based solely on knowledge of the included angles defined by an observation point and three non-colinear reference points, and of the distance between the three reference points. Apparatus and methods are also disclosed for position determining and position plotting which are not dependent on the existence of a predetermined or known relationship between the frames of reference defined for a chart, a plotter, and an external frame of reference for the positional data which is utilized to determine position. [A3963]

"System for protecting a vehicle-borne tracking radar against an off-target jammer"

A protective system for a vehicle-borne tracking radar, designed to counter the effect of an off-target jammer whose interfering signals are picked up by a directive antenna together with echoes from an actual target, comprises a receiver with a sum channel and a difference channel. In the absence of a jammer, the sum channel is connected via a signal processor to telemetric circuitry in the radar associated with the vehicular guidance system which keeps the antenna axis trained upon the target as the vehicle homes in on same. When a strong jamming signal is detected, a switching device in the processor cuts off the sum channel from the telemetric circuitry and supplies the latter, instead, with rectified error signals from the difference channel, these error signals being also delivered prior to rectification to a tracking-control circuit which energizes an antenna rotator to hold its axis in line with the jammer. The presence of a jammer may be detected by a signal-level comparator with two circuit branches connected to the sum channel, these branches including respective integrators which are alternately supplied with incoming signals in a target window and in a jammer window occurring at different instants of a recurrence period. Another possible jammer-signal detector, which may be included in the processor, receives the rectified error signal from the difference channel in the target window and produces a "jammer present" signal whenever the accumulated error signals exceed a predetermined threshold. [A3964]

"Motor actuating circuitry"

Motor driver/control apparatus employs a motor speed regulating amplifier configuration, e.g., two push-pull power amplifiers operable responsive to a motor speed-direction command input signal, and having the motor differentially connected between amplifier output ports. The amplifier (s) are supplied with an energizing potential of variable amplitude just sufficient for amplifier operation and to satisfy the then obtaining motor consumption. Accordingly, system power is effectively utilized, needless power drain avoided, and the amplifier cost and complexity is reduced since the amplifier need not dissipate inordinate source-supplied energy not required for motor actuation. In accordance with one further aspect of the present invention, a power supply switching regulator for a motor utilized in a radar application is operated at the radar pulse repetition rate. This produces a non-interferring zero frequency beat between the power supply and radar pulse rate in the radar receiver. [A3965]

"Passive navigation system with frequency coding"

On a vehicle to be navigated, a transmitter for radiating a signal having a plurality of frequencies and a receiver tuned to receive a predetermined harmonic of each of the plurality of frequencies, discriminate between the predetermined harmonics, and determine the range of position markers reradiating each of the predetermined harmonics, with a plurality of passive markers, each having a nonlinear electrical response characteristic and each tuned to reradiate the predetermined harmonic of a different one of the plurality of frequencies when the radiated signal from the transmitter impinges thereon, fixedly mounted at predetermined positions relative to a desired course to be traveled by the vehicle. [A3966]

"Short range precision navigation and tracking system and method therefor"

A short range, precision navigation and tracking system and method therefor are disclosed. The navigation and tracking system utilizes a master-repeater configuration with a phase lock loop controlling the modulation frequency of the master FM transmitter. [A3967]

"Ground station for the DME distance measuring system"

A novel DME transponder having a plurality of directional antennas arranged equidistantly on a circle each having a radial, highly directional pattern and as a group covering 360.degree. in the azimuth plane. The antennas are divided into at least two groups of nonadjacent antennas. Each group is connected to a receiver. The DME reply signal is radiated from the group containing the antenna which has received the DME interrogation signal with the greatest amplitude. The signal radiated in the direction of the interrogator is the DME reply signal, and the signals radiated in the other directions are used as filler pulses. [A3968]

"Radar target for remotely sensing hydrological phenomena"

Apparatus for remotely measuring and accessing water status relative to snow and glacial melt, surface runoff, rainfall, evaporation, flow rate, and soil moisture. A radar target located at a selected location on the surface of the earth is designed to collect water and render its cross-sectional area variable as a function of the height of the water level within the target. The target is remotely monitored by an orbiting or airborne synthetic aperature radar. The target appears as a bright spot embedded within the radar image. The target brightness is indicative of the height of the water level within the ground located target. [A3969]

"Range and angle determining Doppler radar"

A range, angle, and Doppler (velocity) measuring radar in which a CW, PRC radar floodlights a volume of interest. A receiving antenna in the form of a linear array generally broadside with respect to the bisector of the volume of interest is commutated (sampled) element-by-element to provide a phase modulated received signal from which angle information may be derived. Autocorrelation of the PRC signal received against the transmitted code provides for range determination and a Doppler filter bank is provided corresponding to each discrete receiving angle, the outputs indicating range and velocity of a target at each discrete angle of reception. [A3970]

"Multiple beam receiving array signal processor"

An array (aperture) signal processor using surface acoustic wave delay lines for reordering of the received signals according to the prime number transform algorithm. The output of the processor is a radar response equivalent to forming a multiplicity of narrow beams essentially simultaneously. Reordering of the received signals is simply a matter of rearranging the hardwired connections to a first SAW delay line, and convolution of the reordered signals is achieved by phase weighting the taps in a second SAW delay line which forms part of a transversal filter. [A3971]

"Auto theft detection system"

A system is disclosed for locating missing vehicles. Each vehicle broadcasts a locator signal when queried from a central station by an encoded call signal having a code characteristic of the vehicle. Indicators responsive to the locator signal are provided to determine the location of the missing vehicle. [A3972]

"Method and device for measuring the velocity of an object relative to a reference"

A method and apparatus for measuring the velocity of an object relative to a reference wherein the object has receivers thereon which scan a spatial function which originates from the reference. A signal is developed in each receiver, the value of which is dependent upon the position of the scanning range of the receiver relative to the reference. Signal values from a number of scanning ranges at various positions relative to the object are stored either simultaneously or cyclically at a first instant and then are compared with corresponding signal values obtained at a later time. The displacement of the spatial function relative to the object between the two scanning instants is determined and the velocity of the object is calculated from the magnitude of the displacement and the time elapsing between the scanning instants. [A3973]

"Materials separation"

A wash box for separating materials produced in, for example, a mining operation, into fractions of different densities. The machine is divided vertically into compartments, including at least one stratification compartment and at least one reject compartment, the raw material being delivered onto the grid, the level of water in the compartments being higher than the grid. Vertical pulsations are applied to the water in the compartments, causing the water to travel through the perforations of the grid, to stratify the material on the grid, while movement of the water through the wash box tends to carry the lighter fraction from the wash box. The pressure which pertains in the stratification compartment is continually monitored, such as by the use of a beam, emitted into a stand pipe connected to the stratification compartment, and which is reflected by the surface of the water in the stand pipe, the time taken for the beam to travel from the emitter to a receiver being used to produce an output signal, dependent upon the pressure pertaining in the stratification compartment. This continual monitoring is advantageously used to control the pulsations applied to the adjacent reject compartment, controlling the rate at which reject material falls over the edge of the grid, but may be used to advantage in the general control of operation of the wash box. Alternatively or in addition, separate conveyor means are provided, at differing vertical levels, for removing the reject materials of smaller size, which pass through the perforations of the grid, and the reject materials of larger size, which pass over the edge of the grid. Such an arrangement is particularly advantageous where the wash box is a compound wash box. [A3974]

"Apparatus for deriving information concerning the movements of a vehicle"

The invention provides an apparatus for deriving information concerning the movement of a road vehicle. In a preferred example a single microwave source is mounted under the vehicle to illuminate the road surface. Two receiving ports are provided, one to receive energy reflected from the illuminated surface to one side of the center line of the vehicle and the other to receive energy reflected from the illuminated surface to the other side of the center line. The two Doppler shifts are determined and compared to determine if there is a difference which indicates that the vehicle is turning, the sign of any difference indicating the direction of turn. One of the Doppler signals is shaped and counted to provide an indication of the speed of the vehicle and one of the Doppler signals is processed to provide an indication of forward or reverse motion. [A3975]

"Circuit for speed measurement of vehicles according to the Doppler-radar principle"

A circuit for speed measurement of vehicles according to the Doppler-radar principle wherein a Doppler-useful signal is evaluated in a computer to which such signal is infed by means of a threshold value switch. A single sideband modulator is provided, at the input side of which there is supplied the Doppler-useful signal and also a high-frequency signal produced by a high-frequency oscillator. The output side of the single-sideband modulator is connected with the input of a phase-locked loop, the output signal of which is converted into the original frequency band of the Doppler signal by means of a demodulator connected at its output side with the input of the threshold value switch. [A3976]

"HF coastal current mapping radar system"

A system for radar remote sensing of near surface ocean currents in coastal regions. The system employs a pair of low power, transportable high frequency radar units to scatter signals from the shore off to the ocean waves. Underlying surface currents impart a slight change in velocity to the ocean waves which is detected by the radar units. Each radar unit can determine the angular direction of arrival of the radar echo signals by comparing the phase of the signals received at three short antennas on the shore. Signals scattered from the same point on the ocean by each of the two geographically separated radar units are used to construct a complete current vector for that point. The radar pair takes simultaneous measurements over an ocean area with a predetermined grid pattern. Vectors are constructed for each square section of the grid, and a map of the near surface current field is output in real-time by an on-site minicomputer. [A3977]

"Amplitude selected phase interferometer angle measuring radar"

A phase interferometer elevation angle measurement radar has its antennas tilted slightly relative to each other so as to detect differences in amplitude from ground return signals, the phase difference in signals (normally utilized as an indication of depression angle below boresight in an interferometer radar) is checked for a positive rate of change, it is then compared against amplitude differences and is accepted as valid for use in generating an elevation angle only if within prescribed limits thereof. This resolves ambiguity in phase which results from a wide spread of antennas with respect to the wavelength of the radar. [A3978]

"Anti-collision radar system provided with circuitry for monitoring driver's"

A counter is provided for detecting the frequency of generation of collision imminence signals produced in a conventional type of anti-collision radar system for a vehicle. An odometer and/or a clock pulse generator is connected to the counter for applying a reference counting period so that the counter is utilized for generating a signal with which an alerting device which is independent from that of the radar system, is energized when the frequency reaches a predetermined value during the reference counting period. [A3979]

"Method and apparatus for identifying radar targets"

A method for identifying radar targets, especially ships at sea involves transmitting a first interrogation pulse, thereby causing a responder to generate a first identification signal containing a first set of data concerning the identity of the target, transmitting a second interrogation pulse causing the responder to generate a second identification signal containing a second set of data concerning the identity of the target and thereafter combining the two sets of data. The method reduces bandwidth requirements and garbling. An interrogator and responder for use in the method are also provided. [A3980]

"Reduction of echoes of irrelevant targets in a vehicle anti-collision radar system"

A signal proportional to steering angle is produced by a potentiometer controlled by the steering wheel, except for steering angles below about 0.1.degree. that are frequently used for corrections in driving on a straight course. for steering angles above about 0.5.degree., the signal remains constant in magnitude. The signal controls a range gate of the radar system suppressing the effect of echoes beyond a maximum range limit smaller than the intercept of a radar ray at the beam edge on an arc concentric with the curved path of the vehicle having a radius of curvature exceeding that of the vehicle path by a predetermined amount which is chosen so as to preclude reception of echoes from guard rails situated on the outside of highway curves. The steering angle signal can be provided together with other functions contributing to a maximum range limit operation for the radar for a more comprehensive elimination of echoes irrelevant to the anti-collision purpose of the radar, thereby reducing unnecessary warnings. [A3981]

"Synthetic aperture using image scanner"

In a system for generating a synthetic aperture, a lens or antenna for focusing the radiation from an object scene onto an image sensor which is shifted by a clock at the rate of motion of objects in the object scene and thereby to produce the real tire imaging of the object scene with high resolution. A system for reconnaissance, surveillance and ground mapping. A system for high speed data imaging, medical patient scanning, label scanning, and image correlation. [A3982]

"Focused synthetic array"

This invention relates to a focused synthetic array wherein a different signal from a crossed beam antenna is converted to a bipolar video signal and applied as the input to a synthetic array processor. In another embodiment of the invention there is a separate reduction of each beam output from a crossed beam antenna to bipolar video signals with a separate application of asymmetrical amplitude weights to the two bipolar video records and a subsequent subtraction in the course of synthetic array processing. [A3983]

"Means for developing a radar tracking error signal"

A tracking radar error signal that is independent of pulse to pulse variations of amplitude of the received signal is derived by combining separately detected sum signal energy and difference signal energy in a manner that provides composite error signal pulses that are one-half sum signal energy and one-half sum plus difference signal energy. The pulse composition is realized by means of an RF switch that interrupts the difference signal during approximately one-half of each pulse period. The composite error signal is detected by an IF logarithmic detector and subsequently processed by two parallel box car generators. One box car generator is gated to process sum signal energy and the other is gated to process sum plus difference signal energy. The tracking error signal is obtained from a single pulse by feeding the outputs of the two box car generators to a differential amplifier and obtaining the difference voltage at its output. [A3984]

"Radio determination using satellites transmitting timing signals with correction by active range measurement"

The time-of-arrival of timing signals transmitted by two satellites is measured relative to a crystal clock, and an approximate position fix is computed for the ship or other object being located. Because of clock error the position fixes are displaced along a hyperbolic line of position. A two-way active range measurement through a third satellite or one timing signal satellite enables computation of an independently determined line of position, the true position fix being at its intersection with the hyperbolic line of position. The clock error is corrected and the method of position fixing from two timing satellites is repeated until the clock drift exceeds acceptable limits. A continuous navigation service and also position surveillance are realized. [A3985]

"Method and apparatus for measuring the interior dimensions of a hollow body"

An apparatus for measuring the interior dimensions of the walls of a hollow body. The apparatus is insertable into a restricted opening of the hollow body and includes means for transmitting a beam of electromagnetic energy toward an interior wall of the hollow body. When the electromagnetic energy illuminates the interior wall, acoustic waves are radiated back to the apparatus. The apparatus detects the acoustic waves and measures the elapsed time between transmission of the electromagnetic energy and detection of the acoustic waves. From elapsed time measurements the dimensions of the interior walls are obtained. [A3986]

"Hybrid dual mode radiometric system"

An improved high frequency radiometric system features time shared passive and active modes of operation for correlation of active and passive signal returns. The processed, normalized, and stored passive signals are subtracted from similarly treated active signals to suppress the effect of returns from back ground terrain, thus enhancing true target recognition. A second channel provides discrimination against jamming and spurious signals, thus reducing false alarms. [A3987]

"Method and apparatus for the control of the safety distance of a vehicle relative to preceding vehicles"

A method and apparatus for the control of the safety distance of a vehicle with respect to preceding objects wherein various measurements and controls are effected so as to provide control magnitudes for enabling prevention of a collision of the vehicle with an object. The various measurements and controls which may be effected include the determination whether a detected object lies within a maximum inference-free measuring distance from the vehicle, the changing of the pivot angle of an antenna of the vehicle and possibly also the opening angle of the transmitted beam independence on the steering wheel deflection and/or traverse acceleration of the vehicle, suppressing large extended objects by a separate measurement of the distance of the vehicle to the object and relative velocity of the vehicle with respect to the object by comparison of the measure change and distance with a calculated change in distance or the measured relative velocity with a calculated relative velocity, preferring an object recognized as a preceding vehicle among all objects, and combining in accordance with the maximum inference-free measuring distance values of at least one of the measured distance of the vehicle to the object, the measured relative velocity of the vehicle with respect to the object and the measured velocity of the vehicle to provide the control magnitudes. [A3988]

"Hybrid terminal assist landing"

Control of multiple remotely piloted vehicles provided through a system ced the Hybrid Terminal Assist Landing. This system, also referred to as HYTAL, is composed of two principal subsystems, an RF approach control subsystem and a precise optical landing point homing and ranging subsystem. By using a hybrid combination of RF and optical sensors, the remotely piloted vehicle, RPV or other aircraft approach control and recovery guidance system can be optimized with respect to performance complexity, size, weight and cost. [A3989]

"Range gate generator with velocity aiding"

Apparatus and method for controlling the operation of a range gate generator used in a pulse radar is shown. In accordance with the disclosure, the position of the range gate, or gates, out of the range gate generator is controlled from pulse to pulse primarily in accordance with the Doppler velocity of a selected target and the pulse repetition interval of the pulse radar with a periodic correction in accordance with the range of such target. [A3990]

"Anti-collision vehicle radar system"

The anti-collision vehicle radar system overcomes interference problems due to radar beams from similar radar systems on other vehicles by providing a radar transmitter having a transmitting antenna which transmits a radar beam having circular polarization with a particular direction of rotation of the polarization, a radar receiver for receiving the radar beam after reflection thereof and including a receiving antenna having means for discriminating in favor of received signals having circular polarization with said particular direction of rotation while discriminating against received signals having circular polarization with the opposite direction of rotation of the polarization, the receiving antenna thereby being effective to discriminate in favor of a reflected radar beam from the associated transmitting antenna while discriminating against any interfering radar beam from another vehicle radar system, and utilization means connected to the receiver for utilizing received radar signals to control the operation of the vehicle. for example, the brakes of the vehicle may be applied if the received radar signals indicate that the vehicle must be stopped to avoid a collision. The transmitting and receiving antennas may include helical antenna elements which are coiled in opposite directions to achieve such discrimination. [A3991]

"Transponder for a moving vehicle tracking system"

In a Doppler (frequency shift) spacecraft tracking system, a transponder mounted on the spacecraft including, two or more, receivers connected to spaced-apart antennas for receiving an RF tracking signal transmitted from a ground based station regardless of the attitude, or position, of the spacecraft. The intermediate frequency (IF) signals from the receivers are combined to provide a continuous third IF signal at the proper frequency and at a phase dependent upon the signals received, which third signal is utilized to control a transmitter for retransmitting coherent reply carrier frequency signals to the ground based station. [A3992]

"Dual frequency transmission apparatus for frequency-agile radar systems utilizing MTI techniques"

This invention discloses pulse radar apparatus for the transmission of radar pulses having a pair of frequencies in each rf pulse. One of the frequencies transmitted in each pulse is repeated in the succeeding pulse while the other frequency is changed to a new frequency. Moreover, the repeated frequency appears in the same relative position in the pulse pair as in its original occurrence. [A3993]

"Navigational aid"

A navigational aid enables the effect of a course and/or speed alteration of one vessel on the nearest possible approach distance of another vessel to be calculated, using data readily obtainable from a simple relative radar display on said one vessel. The aid comprises a plurality of sealed manually-settable means for individually setting in data inputs respectively representative of the following: (1) the minimum nearest approach distance if no course or speed change is made, (2) the range of said other vessel, (3) the present speed of said one vessel, (4) the proposed course alteration, (5) the proposed speed alteration, and (6) the time for which the proposed course and speed will be held. The aid further comprises means to compute from the foregoing input data the resultant nearest possible approach with the proposed manoeuvre, and indicating means to provide an indication of said resultant nearest possible approach. [A3994]

"MTI radar system and method"

An MTI radar system having a four pulse canceller where the interpulse periods vary preferably according to a double or triple sawtooth pattern is disclosed. The four pulse canceller is comprised of a two pulse canceller cascaded with a three pulse canceller. The three pulse canceller is arranged to accomplish summations of three weighted pulses in two operations, one involving fixed binomial weights (1, -2, 1) and the other variable components (a', b', c') . The interpulse period choices and sequence of use permit the variable weights to be defined by polarity and binary fractions implemented by the use of controllable scalers and polarity reversers. [A3995]

"Process and apparatus for the detection of objects, especially of objects having a very small equivalent surface area"

A process and apparatus for the detection of an object in air, wherein a beam of electromagnetic radiation is emitted, the reflected beam is received, the frequency of the reflected beam being varied discontinuously over a frequency band. The amplitude of the energy of the beam received for the various frequencies of the emitted beam is measured so as to utilize, for the detection of the object, the particular frequency or frequencies of the beam for which the reflected beam possesses a substantially higher energy than the energy of the beam reflected at the other frequencies. [A3996]

"Obstacle detecting radar apparatus for a motor vehicle or the like"

A vehicle mounted obstacle detecting radar is disclosed. An electromagnetic wave radiated from the radar apparatus is received by a first antenna mounted on the ground and passed through a transmission line to a second antenna mounted on the ground and radiated thereby to a monitor area. A response electromagnetic wave from an obstacle within the monitor area is received by the second antenna and passed through the transmission line to the first antenna and received by the radar apparatus. When the transmission channel is arranged along a curved road, an obstacle in the curved road can be detected. [A3997]

"Interferometric protective system for vehicles"

A base band transmitter cooperates with dual base band receiver antennas, a single receiver channel, and a tapped delay correlator device for the prevention of vehicular collisions, the configuration effectively narrowing the normally wide base band antenna pattern to span a single predetermined forward traffic lane. [A3998]

"System for estimating acceleration of maneuvering targets"

A radar system of the type utilizing an optimal estimator to process raw range and angle track data for driving a radar antenna, where the tracking computations, range rate, and angular rate of the range vector are utilized in estimating the target velocity vector and the target acceleration vector. The attenuation inherent in the practical estimation of target acceleration is effectively removed for severely maneuvering targets by a compensating system that provides an attenuation factor, and multiplies the estimated acceleration output signal by the reciprocal of such factor. The implement control system is governed by the estimated target position and estimated target velocity from the estimator, and the modified acceleration signal of the compensating system. [A3999]

"Radar system for an anti-collision system for a vehicle"

A pair of antennas mounted on a vehicle receive an echo wave reflected from an obstacle to produce a pair of Doppler signals, the variation of the phase difference of which is used to indicate the direction of the relative movement of the obstacle. The phase difference also represents the difference in propagation lines and is proportional to the relative angular displacement of the obstacle so the rate of variation of relative angular displacement is detectable because the increase and decrease of phase difference negate each other. [A4000]

"Surface roughness measuring apparatus"

A doppler radar of the type normally used to measure relative speed between a transmitter and a reflector is mounted so that its antenna is directed toward the surface to be measured. The radar is coupled to a means for de-emphasizing the doppler shift frequencies of the return signal associated with the speed of the vehicle and emphasizing the lower frequency components of the back scattered signal. The energy contained in these components provides an indication of the roughness of the surface which is in relative motion to the radar. [A4001]

"Vehicle collision preventing apparatus"

A vehicle collision preventing apparatus determines the danger by an output of a radar for detecting the distance to an obstacle and the relative velocity in a danger determining circuit wherein the distance to the obstacle and the relative velocity at the present are estimated from the data given before disappearing the data of the radar by an estimate arithmetic circuit when a signal reflecting from the obstacle reduces to be incapable of detecting the obstacle by the radar. [A4002]

"Range rate measurement"

A continuous wave frequency modulated signal is radiated from a range rate measuring system and returned by a target, the range rate of which, relative to the measuring system, is to be determined. The radiated signal and return signal are mixed to produce a beat frequency signal which is converted to a square wave signal marking passage of the beat frequency signal above and below its average value. A detector produces signals indicative of the presence and absence of transitions of the square wave signal at the turnaround points of the modulation waveform. The range rate of the target is directly related to the rate of the presence and absence of such signals. [A4003]

"Vehicle guidance system"

Terminal guidance of vehicles is accomplished by accurately determining true position and speed of the vehicle from terrain contour measurements and updating a dead reckoning navigation system with precision to permit navigation by following a programmed flight path. A narrow beam radar altitude sensor measures vehicle clearance altitudes and a reference altitude sensor measures the vehicle clearance above a reference level. These measurements are input to a digital processor for comparison to stored digital terrain contour reference data. Recursive data matching is performed in the digital processor by a nonlinear Kalman filtering technique to provide vehicle position and vehicle velocity correction signals to a navigation controller that generates steering commands to the vehicle control system. Three vehicle position and three vehicle velocity signals are generated and updated in the nonlinear Kalman filtering technique to give near real-time three dimensional position and velocity information. [A4004]

"Vehicle collision anticipating method and device"

An improvement of a vehicle collision anticipating method and device using transmitted and reflected frequency-modulated continuous waves is provided. A low frequency wave is produced by mixing a part of transmitted wave and a reflected wave from the object. The low frequency wave and a Doppler signal obtained from the low frequency wave are signal processed so as to generate signals. A predetermined distance range is obtained by multiplying a time which is determined by the distance between the vehicle and object and the velocity of said object with respect to the vehicle obtained from the Doppler signal, by a relative velocity of the object with respect to the vehicle. A collision of the object against the vehicle is anticipated by detecting the object entering the predetermined distance range in front of the vehicle. [A4005]

"Dual frequency alarm device using Doppler effect for sensing a moving object"

An electrical or supersonic wave having a predetermined frequency is emitted as a monitor wave from an emitting device into a zone to be monitored. When a moving object having an inherent velocity range intrudes into the zone, a reflected wave of the monitor wave from the moving object is received by a receiver and an alarm signal is issued when the frequency deviation of the reflected wave relative to the frequency of the emitted monitor wave is within the frequency range corresponding to the velocity range. The alarm device has a circuit for producing a first alarm responsive to the alarm signal, a circuit for changing the frequency of the monitor wave when the first alarm is issued, and a circuit for producing a second alarm when a further alarm signal is obtained from the monitor wave with changed frequency within a predetermined time after change of the monitor wave frequency. The circuit for changing the frequency of the monitor wave comprises a variable capacitance diode and a voltage regulating circuit which progressively changes the reverse bias voltage for the variable capacitance diode. The circuit for producing the second alarm comprises a signal processing circuit that produces a trigger signal for producing the most important alarm when an alarm signal has been produced for the overall frequency relative to the monitor wave with progressively changing frequency. The alarm is designed for inclusion of different degrees of seriousness of warning by gradual reduction of the monitor zone with changes in the frequency of the monitor wave. [A4006]

"Automatic ground-clutter rejection in weather pulse radar system"

Ground clutter is automatically eliminated from echo signals in a weather pulse radar system to provide signals having an amplitude corresponding to the average intensity of the weather echo over a number of pulses. The reflected waves received in the receiver are linear-detected to provide echo signals. Each one of successive echo signals is compared with another later one which is apart from the each one echo signal by a predetermined time period during which fluctuation of weather target becomes independent, to derive an AC component signal corresponding to the fluctuation. The variance of the amplitude of the derived signal is proportional to the mean power of the weather echo. Thus, the ground clutter and the DC component of the weather echo are eliminated. The AC component signals are unipolarized and, thereafter, averaged. The averaged signals have an amplitude corresponding to the average intensity of the weather echo. These averaged signals may be logarithmic-converted to provide logarithmic signals similar as in weather radar system employing radar receivers having a logarithmic characteristic. [A4007]

"Angle/vector processed, phase-accumulated single vector rotation, variable order adaptive MTI processor"

In-phase (I) and quadrature (Q) radar return signals are converted to phase to provide phase difference between like range bins of successive pulse repetition intervals (PRI's) , the phase differences being reconverted to I and Q format for accumulation across multi-range-bin windows surrounding each range bin to be processed, the normalized range bin accumulations being continuously accumulated in the angle domain, in successive PRI's, to provide clutter phase angle estimates used to rotate incoming target video vectors, a single time, back to the estimated zero-doppler phase of the first PRI of a multi-PRI batch for clutter-elimination filtering. Third-order and fourth-order filtering (utilizing four-PRI and five-PRI batches, respectively) , is achieved on a constant one-out-of-four PRI output basis by utilizing the same weighted data for the highest PRI of one fourth-order batch and the lowest PRI of the next higher fourth-order batch, which is rendered possible by the continuous accumulation of estimated phases, over successive PRI's. [A4008]

"VIP doppler filter bank signal processor for pulse doppler radar"

A low PRF pulse doppler radar system utilizing a VIP digital filter bank signal processor to suppress echoes from terrain, rain, and chaff, and pass echoes from aircraft moving at higher speeds is disclosed. Each of a plurality of VIP filters individually provides high attenuation to undesired signals over designated frequency bands, the width of which are a large fraction of 1/T.sub.av where T.sub.av is the average interpulse period. Little or no attenuation of desired signals having doppler frequencies greater than 1/T.sub.av occurs. The outputs of the plurality of filters are desensitized to prevent false alarm from clutter, and the presence of a desired radar pulse echo is determined by a comparison with a threshold level. [A4009]

"Method and apparatus for orally announcing vehicle speed"

Apparatus for orally announcing the speed of a moving vehicle. A radar speed detector produces a multi-digit binary-coded-decimal representation of vehicle speed. These signals are converted to a modulated audio frequency signal that a demodulator, audio amplifier and speaker convert into oral digits for the driver to hear. [A4010]

"Transponder decoder/encoder circuitry"

A single crystal controlled oscillator provides clock pulses that are used to drive both the decoder shift register and the encoder shift register of an ATC transponder. An input pulse of the interrogation signal from a ground station is shifted down in the decoder shift register and is time correlated with a subsequent pulse of the input signal to verify the validity of the interrogation. A valid interrogation signal triggers gate logic circuitry which loads data into the encoder shift register. The clock pulses from the oscillator are processed to the appropriate frequency for driving the encoder shift register, which outputs serial data for transmission as a coded reply signal responsive to the interrogation signal. The decoder shift register and cooperating edge trigger coincidence gate circuitry suppress side lobe interrogation signal and inhibit operation of the transponder when same are present. [A4011]

"Miniature doppler radar systems and microwave receivers suitable therefor"

A doppler radar system comprises a solid state microwave source which is pulsed on and off with a duty cycle typically around 10.sup.-3. The microwaves are transmitted towards a nearby target with a small amount supplied to a mixer also supplied with signals received from the target. The mixer output is passed through a gate opened in coincidence with the mixer pulsed output, and supplied to an integrator whose output forms a doppler signal representing target velocity. Target directionality is found by providing two channels fed in quadrature phase. [A4012]

"Range mark generation"

In a digital weather radar display, of the type which displays information on a cathode ray tube in the form of parallel intensity modulated sweep lines and which displays range marks in the form of a plurality of arcs of concentric circles, the positions of the range marks along each of the sweep lines are determined by utilizing a read only memory which stores, for each sweep line, an indication of the distance between range marks and the distance from the beginning of scan of the line to the first range mark. [A4013]

"Ground station for a round-trip-path distance-measuring system"

This DME ground station permits the distance from the touchdown point (where no transponder can be installed) to be measured on the aircraft without any change in the airborne equipment. The time difference between the reception of an interrogating signal and the transmission of a reply signal is chosen so that the transmission of reply signals from the DME transponder located on one side of the runway corresponds to a transmission from the touchdown point with respect to the signal transit time. On the ground, a DME transponder is located on one side of the runway on a level with the touchdown point, and a receiver and a direction finder are provided on the other side. [A4014]

"Mobile radar method for sensing inclusions in subsoil"

A method and apparatus is described comprising a transmitter for transmitting an unmodulated carrier of selected wave length into the ground and a receiver adapted to receive reflected signals. Circuitry is described for producing narrow pulses from the transmitted and received signals for displaying them on an oscilloscope and on a plotter. The display on the oscilloscope is rotated through 90.degree. from the conventional display so that the pulses corresponding to the transmitted and reflected signals appear as horizontal bars spaced apart vertically by distances which correspond to the depth of the inclusions below the surface. The wave length is selected to be at least four times the anticipated depth of the inclusions. The apparatus is described as being incorporated into a motor vehicle such as a Land Rover with the transmitting antenna mounted at the front and the receiving antenna at the rear of the vehicle. The apparatus is most conveniently situated in place of the co-driver's seat for operation by an operator sitting in the rear of the vehicle. Decoupling between the transmitting and receiving antennae is partially achieved due to the rotation through 90.degree. of the polarity of the reflected wave relative to the transmitted wave. [A4015]

"Electronic detection and identification system"

An electronic detection and identification system for use in the rapid identification of vehicles at a toll stop, and like uses, is provided which employs an electronic identification card that is carried by the vehicle to be identified and a fixed transmitter-receiver unit that transmits a signal to the card and receives a reflected signal therefrom. The card contains passive resonant circuitry for producing an output signal having a frequency which is a selected harmonic of the signal transmitted thereto. In operation, the card is radiated with a signal which has a freqency in the Gigahertz range and which is produced by frequency sweeping and multiplying a frequency stable RF signal. The signal reflected by the card is narrow band-filtered and RF amplitude (envelope) detected. The detection envelope, which is the "signature" of the received signals, is compared with a reference profile to determine whether a match exists. An appropriate action, such as the generation of a "go" signal, is initiated based on the results of the comparison. [A4016]

"Pulse radar apparatus"

Pulse radar apparatus particularly for marine use has a dispersive antenna so that transmitted pulses sequentially of two or more different frequencies are radiated in different azimuthal directions. The antenna is continuously rotated and the receiver has separate channels for the different frequencies and display means correlating information received on different frequencies from the same azimuth thereby to reduce sea-clutter on the display. [A4017]

"Passive transponder apparatus for use in an interrogator-responder system"

A passive transponder for use in an interrogator-responder communication system is disclosed, including a first signal receiving element having a variable reflection property, a code signal generator for supplying a code signal, a modulating device responsive to the code signal for varying the signal reflection property of the first signal receiving element, and a power supply for supplying direct-current operating power to the code signal generator and to the modulating device, the power supply including a second signal receiving element for receiving a second electromagnetic signal having a second frequency different from the first frequency, and an a-c to d-c converter for converting the second signal to direct-current power. [A4018]

"Detection of angular displacement to an object from the moving vehicle"

A pair of first and second antennas is mounted at the front end of a roadway vehicle. A first sequence of recurring bursts of energy at two different frequencies is transmitted from the first antenna and a second sequence of similar bursts of energy is transmitted from the second antenna at alternate intervals with the bursts of energy transmitted from the first antenna. The signals transmitted from the first and second antennas are reflected from an object and received respectively by the first and second antennas and sampled at appropriate intervals to derive a first set of two Doppler signals from the signal received by the first antenna and a second set of two Doppler signals from the second antenna. The relative phase between the Doppler signals derived from the first antenna and the relative phase between those derived from the second antenna are detected by first and second phase detectors, respectively. The outputs from the phase detectors are subtracted from each other to utilize the difference therebetween as an input data to a microcomputer to determine the angular displacement of the object from the center axis of the vehicle. [A4019]

"Device for controlling the conical scanning frequency for conical scanning radar systems"

A device for controlling the conical scanning frequency of conical scanning radar systems. An antenna illuminator is caused to revolve by means of a three-phase asynchronous rotary field motor. The angular frequency of conical scanning is changed in a random or pseudo-random manner by means of a reference generator associated with the asynchronous motor, a random or pseudo-random signal generator, and a circuit comparing the signal of the reference generator and the signal of the signal generator. The comparison circuit provides "greater," "less" and "equal" outputs. A switching device driven by those outputs couples a braking magnetic-field or the three-phase supply to the motor, depending upon whether a "greater" or "less" output, respectively is the present comparison circuit. The "equal" output also controls the change of state for the random or pseudo-random signal generator. [A4020]

"Digitally processed radar speed sensor"

A Doppler speed sensor for a ground vehicle wherein errors due to vehicle tilt relative to the ground surface and initial mounting angle error are substantially eliminated by using a first antenna with its radiation pattern directed down and forward and a second antenna with its radiation pattern directed down and rearward, so the principal axes of the radiation patterns are 90.degree. apart. A novel digital technique for processing the signals received from such antennas is also disclosed. [A4021]

"Trans-horizon navigation system"

A trans-horizon navigation system wherein a predetermined sequence of control pulses is phase-encoded onto an RF carrier for transmission from a first transceiver to a second transceiver, the second transceiver including a correlator which provides an output pulse in response to detecting the sequence of control pulses in a received transmission. An improved AGC circuit configuration is also disclosed. [A4022]

"Transponder-responder system"

A transponder-responder system is provided which comprises a home station and at least one remote station. A transmitter at the home station periodically generates interrogation pulses by means of a directional sweep antenna across a search area. Each remote station includes a receiver and transmitter. Upon receipt of an interrogation pulse by the remote station receiver and while enabled, the remote station transmitter transmits a digitally encoded response signal which is received by a receiver at the home station. Upon receipt of the response signal by the home station receiver, timing circuitry at the home station determines the distance between the home and remote station by measuring the elapsed time between the transmission of the last interrogation pulse and the receipt of the response signal. Additionally, the home station includes circuitry which determines the rotational position of the sweep antenna and circuitry which decodes the response signal. [A4023]

"Polar to rectangular coordinate converter"

A memory for a coordinate converter stores, for each azimuth at which information from an information source may be received in a polar coordinate system, the incremental X and Y coordinate values, .DELTA.X and .DELTA.Y, for an incremental change in range along the azimuth. for each azimuth these incremental coordinate values .DELTA.X and .DELTA.Y are retrieved from memory and entered into summing devices which are incremented respectively by .DELTA.X and .DELTA.Y for each increment of range. The integers of the values of the summing devices represent X and Y coordinate values in a rectangular coordinate system and may be utilized to address an information reception device such as a random access memory. [A4024]

"Range resolving doppler radar system"

A system for measuring unambiguous target range for targets at high velocities in which target range and doppler frequency data from three sequential transmission dwells of radar returns are stored, each dwell having a different pulse repetition frequency (PRF) . The dwell storage unit which includes three sets of dynamic registers is loaded and unloaded serially with respect to range and supplied to a 17 path doppler frequency correlator. After the three dwell storage registers have been loaded with a basic PRF plus jitter, the range interval unfolding is performed by a recirculation process in each of the registers. During recirculation the data is applied to a correlation unit, the purpose of which is to insure that the velocity of the target satisfies a 17 path algorithm across three adjacent dwells in at least one of five range azimuth profiles or paths. Because the same target velocity may cause outputs in adjacent doppler filters due to PRF jitter, the correlation utilizes a criteria that for all three possible PRF sequences the filter numbers across the three range bins and paths must be within one of each other. As the filter correlation function is capable of multiple path selection the filter path outputs are priority selected to produce a valid target. The final output from the system is a verification that the data in the three range bins of interest satisfies the seventeen path correlation algorithm formed of three dwells and three adjacent range bins with a possible PRF jitter of one filter in each range bin. [A4025]

"Ground plane corner reflectors for navigation and remote indication"

A device to be used as a guidance system for sonar or radar or similar transmissions in which a dihedral reflector is used in association with part of the earth's surface (land or sea) whereby a trihedral reflector results for such transmissions in which spurious signals are avoided because the earth forms one of the reflective surfaces to thereby remove spurious signals which could otherwise occur with a normal trihedral reflector. [A4026]

"System for preventing collision of vehicles"

A system for preventing collision wherein a radar system is mounted on a vehicle for generating a relative speed signal and a relative distance signal. There are provided a brake signal generating logical circuit responsive to the relative speed signal and the relative distance signal for actuating a brake actuator, first and second comparators for comparing the relative speed signal and the relative distance signal respectively with reference signals, and an information processing signal responsive to the outputs from the first and second comparators for actuating the brake actuator. There is also provided a braking signal releasing circuit for disenabling the brake actuator after the vehicle has stopped. [A4027]

"Vehicle identification system, using microwaves"

A vehicle identification system, using microwave, in which every vehicle to be identified has an identification panel attached to its side, containing a very low level power drain tunnel diode transponder and a digital coder plus a small battery and a resonant frequency array. Interrogating transmitter-receivers are placed at designated ground stations. for verification purposes there is a resonant reflective array printed on the identification panel to reflect back a doppler offset signal emitted by the interrogating transmitter, thereby registering that a vehicle with an identification panel has passed, even if the transponder has failed. Unlike optical scanners used for freight car identifications, this system cannot be disrupted by dirt, ice and snow. Vehicles do not have to slow down to be interrogated, and the emitted field strength from this plate is so low that F.C.C. licensing is not required. The code stored in the panel is readily programmable, if desired. [A4028]

"Marine radar interrogator-transponder target detection, identification, and range measurement system"

A marine radar interrogator-transponder navigation and collision avoidance system provides facilities for early detection of, identification of, and communication with cooperating marine vessels. for these purposes, a general coded call may be transmitted by own ship to all other ships in radio range, the reply then being returned from each answering ship with the coded identification of that ship. In this manner, the other ships may be identified. Own ship may call a specific second ship or a shore based transponder, the called transponder returning only the coded message it received. Own ship may call a specific second ship causing an alarm to call the ship's operator to a radio telephone, the identical coded message being reradiated. The invention provides means for application in cooperative systems using a finite number of such discrete interrogator-transponder addresses for receiving proper replies from responding transponders lying on a radial line with respect to own ship so that the replies are not destroyed by overlap. Other problems are solved related to the use of a finite number of addresses which may be less than the expected population of addressed ships, rendering it possible that two or more transponders will reply with the same address codes. [A4029]

"Constant false alarm rate moving target indication radar system (CFAR-MTI)"

A constant false alarm rate (CFAR) moving target indication (MTI) radar system, operable in various electronic countermeasures (ECM) environments is disclosed. A modified Dicke-Fix circuit is used to drive the MTI. Operation of the invention results in automatic restoration of signal level out of a filter. Thus the invention provides a CFAR-MTI that is not degraded significantly by swept jammers and is not captured by off-frequency jammers. [A4030]

"Surface roughness measuring system"

Apparatus for obtaining significant height information of ocean waves, or peaks of rough terrain utilizing means for compressing the radar signal over different widths of the available chirp or Doppler bandwidths, and means for cross-correlating one of these images with each of the others, where the center frequencies of the images have a spacing .DELTA.f.sub.rO. Upon plotting a fixed (e.g., zero) component of the cross-correlation values R.sup.E (.DELTA.f.sub.rO) as the spacing is increased over some empirically determined range, such as 0 to 1 MHz, the system is calibrated. Thereafter to measure height with the system, a spacing value is selected and a cross-correlation value is determined between two intensity images at a selected frequency spacing, such as 0.1 MHz. The measured height is the slope of the cross-correlation value determined to the spacing value used. Both electronic and optical radar signal data compressors and cross-correlations are disclosed for implementation of the system. [A4031]

"Radar reconnaissance system for track vehicle recognition"

A radar reconnaissance system for recognition of echo signals from track type vehicles such as tanks. Circuits are included for identifying a Doppler spectrum shift on either side of the spectral line 2FD (harmonic of the main moving target Doppler frequency) due to echo signals from a track of the vehicle, the tracks inherently having point-by-point velocities up to double the vehicle velocity. [A4032]

"Anticollision car radar"

The radar has two antennas which radiate RF signals of different frequencies and whose radiation patterns overlap. The frequencies of the radiated signals are generated by amplitude-modulating a single RF signal with two low frequency signals. The signals received by one of the two antennas are evaluated by determining, in an evaluating device, the difference between the amplitudes of the RF signals of different frequency which are reflected from an object. A DC voltage signal proportional to the above difference is generated and the DC voltage signal is fed to a threshold circuit whose threshold is determined by a predetermined azimuth range. Therefore, it can be determined if the reflecting object is in the same road lane as a car equipped with the radar. [A4033]

"Microacoustic shear bulk wave device"

A microacoustic signal processing device for propagation of shear bulk waves in a substrate. A preferred embodiment of the device includes a substrate having opposed, polished principal and second surfaces. An input interdigital transducer supported on the principal surface includes a plurality of aluminum electrodes photoetched on the principal surface, a ZnO layer overlying the electrodes, and a conductive aluminum film overlying the ZnO layer. Shear bulk waves propagated by the input transducer are available for processing at various locations on the principal and second surfaces of the substrate. [A4034]

"Beacon system employing ramped gain receiver"

A beacon receiver or IFF system in which the gain of the receiver is time varied to enhance the discrimination between response from transponders located ahead of the interrogator as compared with the responses from transponders in the side or rear lobe regions of the interrogator antenna pattern. The system is employed with a directional antenna and signal processing apparatus giving sum .SIGMA. and difference .DELTA. channels. In accordance with this invention, the gain of the receiver in the sum .SIGMA. channel is increased from the minimum value to a maximum value beginning after the end of interrogation pulse. The difference .DELTA. channel is varied in gain from the time in the beginning after the end of the interrogator pulse but the gain is varied inversely from the maximum level at the beginning of reception to a maximum level at the end of reception. [A4035]

"Radar-operated vehicle safety apparatus"

The apparatus of the invention comprises a radar device for measuring the range of an object and the vehicle speed relative to the object, and a vehicle speed sensor for measuring the vehicle roadway speed. A first computing circuit is provided to set up a first minimum distance allowed for the vehicle when approaching a stationary object and a second computing circuit for setting up a second minimum distance allowed for the vehicle approaching an object moving ahead of the vehicle. An alarm will be given either when the range of the stationary object reaches the first minimum distance or that of the moving object reaches the second minimum distance. [A4036]

"Intra-pulse MTI system with range ambiguity suppression"

A dual-pulse coherent MTI system having a time interval between pulses as short as zero. The pulses are "chirped" in opposite sense, the latter constituting a unique coding for eliminating range ambiguity problems. Video return signals are received and applied to two parallel channels each containing pulse compression and limiting circuits. The pulse compression circuits are matched uniquely to the positive chirp slope pulse in one channel and to the negative chirp slope pulse in the other channel. The channel corresponding to the earlier of the two pulses is subjected to a fixed delay of one pulse width before the outputs of the channels are differenced to produce a net MTI signal. This is a continuation of application Ser. No. 159,751, filed July 6, 1971, now abandoned. [A4037]

"Identification system using coded passive transponders"

An identification system including a transmitter, a receiver, a decoding subsystem, and a passive transponder identifier. One passive transponder identifier of the invention is a surface acoustic wave device provided with pad means for applying and removing pressure on a substrate of the device at preselected locations. A second identifier of the invention is a microacoustic shear bulk wave device. The passive transponder identifiers are programmed to produce a characteristic coded electronic reply in response to an electromagnetic signal interrogation. [A4038]

"Control system for mobile radio communication"

A control system for mobile radio communication, in which the whole service area is composed of a plurality of small radio service zones in each of which communication is sufficiently possible with the transmitting power of any of mobile stations belonging to the service zone, a base station of each of the small radio service zones and a control station for controlling the whole service area are interconnected through a binary code transmission line, and in order to prevent simultaneous transmission of the control signal from a plurality of mobile stations when the mobile stations in the whole service area achieve transmission and reception of the control signal between each of them and the control station over a common control channel, the control station transmits to the mobile stations information representative of the busy or idle status of the common control channel from the mobile stations by the interruption and transmission of an idle line indication signal. By reversing the signal state of the binary code transmission line to its normal state, information of the detection of transmission from the mobile stations by the base stations is transmitted to the control station, and in the control station, the idle channel indication signal is interrupted by the earliest one of the reversed signals arriving from the plurality of base stations. The start of the control signal is indicated by restoring the signal state of the binary code transmission line to its normal state. The control station resumes transmission of the idle channel indication signal upon completion of the reception of the control signal. [A4039]

"Apparatus for preventing collision of vehicles"

An apparatus for preventing collision of a vehicle comprises A device for measuring a distance R from a driving vehicle to an obstacle and a relative velocity V of the driving vehicle to said obstacle, A circuit for generating a damping signal when the relation of the distance R, the relative velocity V and a preset deceleration .alpha. becomes the relation of R < V.sup.2 /2.alpha., a deceleration detector for detecting the actual deceleration .alpha.' of the driving vehicle, A correction circuit which compares the actual deceleration .alpha.' detected by the deceleration detector with the preset deceleration .alpha. and the damping signal is corrected depending upon the comparative data. [A4040]

"Compensation for simultaneous platform motion and antenna scanning in MTI radars"

The effects of simultaneous platform motion and antenna scanning are compated for in radar systems of the moving-target-indicator type. Signals from auxiliary sub-arrays of the antenna compensate signals from main sub-arrays of the antenna for the effects of antenna scanning. Delayed, scanning-compensated signals from the main sub-arrays are then combined with undelayed, uncompensated signals from the main sub-arrays to provide signals that are compensated for the effects of scanning motion and platform motion. A first embodiment provides a clutter canceller having motion compensation at each stage of cancellation. A second embodiment provides a large number (N) of motion-compensated signals which are synchronized in time and phase for further MTI processing. [A4041]

"Motion-compensation arrangements for MTI radars"

The effects of platform motion or antenna scanning in radar systems of the oving-target-indicator type are compensated for by arrangements which use difference-channel signals to correct sum-channel signals for the changes in phase and amplitude of the backscattered sum-channel signals due to the platform motion and antenna scanning, respectively. Clutter-canceller arrangements having motion compensation at each stage of cancellation and an arrangement for providing a large number (N) of motion-compensated signals which are synchronized in time and phase are shown. [A4042]

"Clutter tracker using a smoothed doppler frequency measurement"

A clutter tracker in which received clutter velocity signal is shifted to zero doppler in order that optimum moving target indicator (MTI) cancellaton can be achieved is disclosed. A frequency controllable voltage controlled crystal oscillator (VCXO) is used as the coherent oscillator (COHO) source. The subject digital system changes the VCXO output bus only once per dwell, thus allowing adequate filtering to achieve desired performance without adversely affecting tracking performance. [A4043]

"Digital weather radar including target severity analysis capability"

A digital weather radar system having a mode that clears the display of all clutter and lighter precipitation to reveal or positively present only the contoured areas, i.e., the severe "cores" or "hard spots." Data representative of the searched space is stored at least temporarily in a digital memory. In the preferred embodiment, a controllable decoder operates on this data according to the particular decoder state selected, the decoder output is D/A converted, and the resultant analog signal is used to intensity modulate a cathode ray tube (CRT) . [A4044]

"Monopulse, fan-beam, search-radar system with improved height and azimuth determination"

Multipath signals are eliminated at all but the lowest elevation angles awing monopulse techniques to be used to determine target height and azimuth in a two-dimensional, fan-beam, search-radar system. A narrow-azimuth fan beam is oriented at an angle to the vertical plane and has its boresight centered approximately on the horizon so that a V-beam is formed by the direct beam and the portion of the direct beam reflected from the surface (i.e., the portion that is below the horizon) . The reflected beam does not interfere with the direct beam except in a multipath region near the reflecting surface. Frequency diversity or a receive-only beam in the vertical plane may be used to determine if a target is in the multipath region. [A4045]

"Communication apparatus for communicating between a first and a second object"

An improved communication method and apparatus for communicating between a first object and a second object wherein the first object includes apparatus for generating and transmitting a modulation signal having at least a predetermined number "L" pulses within a predetermined time interval and less than a predetermined number "M" pulses within the same predetermined time interval, and wherein the second object includes apparatus for receiving and detecting the modulation signal and providing an output signal in response to detecting at least the predetermined number "L" a pulses and less than the predetermined number "M" pulses. This CROSS-REFERENCE TO RELATED APPLICATIONS this application is a division of the Applicant's co-pending application entitled "COMMUNICATION APPARATUS for COMMUNICATING BETWEEN A FIRST and A SECOND OBJECT," Ser. No. 462,247, filed Apr. 19, 1974 and now U.S. Pat. No. 3,986,167, which was a continuation-in-part of a then co-pending application entitled "COMMUNICATION APPARATUS for COMMUNICATING BETWEEN A FIRST and A SECOND OBJECT," Ser. No. 221,712, filed Jan. 28, 1972 and now U.S. Pat. No. 3,839,717. [A4046]

"Digital sidelobe canceller"

A digital open-loop canceller is used to decorrelate one signal from anot in such applications as coherent sidelobe cancellers and moving target indicators. The invention measures the correlation between a complex main input signal and a complex auxiliary input signal in digital form. It divides the correlation coefficient by the average value of the auxiliary signal magnitude squared, multiplies the ratio by the auxiliary signal and subtracts the result from the main input signal to cancel correlated components. [A4047]

"Method for measuring physiological parameter"

A method for measuring such physiological parameters as pulse rate and respiration without physically connecting electrodes or other sensors to the body. A beam of phased energy, for example microwaves, is directed toward the body of a person at a region thereon which undergoes physical displacement corresponding to variations in the parameter being measured. The phase relationship of the energy reflected from the body is compared with that of the transmitted energy to determine the extent of physical movement of the body region as affected by the parameter being measured. The present method may be used as an overt or covert lie detection technique. [A4048]

"Vehicle guidance system"

A vehicle guidance system is disclosed that is suitable for guiding a vehicle or person along a straight line navigational aspect with signaling and processing typical of hyperbolic navigational systems, for example, in certain farming operations where the farm vehicle utilized must repeatedly be caused to traverse an unmarked field in substantially straight parallel paths that are evenly spaced with respect to one another, such as in fertilizing the field. An electronic navigation system is utilized which includes a transmitter and a receiver positioned upon the navigating vehicle and a pair of repeating transmitter/receivers spaced with respect to one another a known or measured distance and along a line normal to the intended straight line path to be followed by the vehicle. The transmitter causes each repeater to be alternately energized and the resulting signal is detected at the vehicle mounted receiver and the phase difference between each transmitted and received signal is measured. The measured signals are then used to determine an error signal if the vehicle has departed from a predetermined straight line path. A typical use in a farming operation is to position two repeaters at one edge of a field and then cause the farm vehicle to repeatedly traverse the field in straight lines that are equally spaced with respect to one another a distance so as to give substantially equal coverage, such as, for example, to substantially evenly fertilize a field. [A4049]

"Doppler shift actuator and intrusion systems"

In a first mode, a security system uses the Doppler effect to permit the automatic activation of a bolt by the patterned movement of a reflecting card in the vicinity of a Doppler unit. In a second mode, the system behaves as a conventional intrusion detection system to activate an alarm for an unauthorized intruder present within an area to be monitored. The first mode operates to verify a combination given a user implemented by the movement of a reflecting member towards and away from the Doppler unit based on a predetermined code. If the movement of the reflector is proper and within a predetermined time period, a valid comparison will be had to automatically cause a bolt to unlatch and open the door. The unit is placed in the second mode when all access to the door is prohibited and the system operates as a conventional intrusion detector. [A4050]

"FM-CW radar for range and relative speed determination"

An FM-CW vehicular distance and relative speed measuring device which compares instantaneous reflection signal frequency to the instantaneous FM-CW transmitted frequency to derive distance (range) and speed information. Searching means including a mixer, frequency programmer, and logic circuits evaluates a plurality of fractional range increments for signal presence and Doppler spectrum evaluation to determine relative velocity with sense. The FM-CW waveform is a sawtooth and means are included for blanking the sawtooth flyback. [A4051]

"Target detection system in a medium PRF pulse doppler search/track radar receiver"

In a medium PRF pulse doppler type radar receiver, target detection is achieved in both search and track modes. In the search mode, the video signal from the receiver section is notch filtered to cancel the main beam clutter. The remainder of the signal is threshold detected, followed by ranging each of the thresholded signals to resolve the range ambiguity of the signals. The unambiguous signals are gated through a range sensitive threshold which operates along a power curve of R.sup.4, resulting in true target returns being thresholded by the range sensitive threshold circuit and blocking out discrete sidelobe returns. In the track mode, the video signal from the receiver is clutter cancelled to remove main beam clutter, as in the search mode, and the remaining signals pass through a velocity track filter with a narrow band window. The true target return signal ranged during the search mode, is passed by the velocity track filter which is adjusted to match the true target return doppler shift during the correct range gate. The velocity track filter is controlled to track the true target return signal and is narrow enough to reject discrete sidelobe signals which occur in the same range cell. The signals passed by the velocity track filter are subsequently monitored, and guard gates are established in both adjoining range cells to insure that lock on the tracked target will not be lost due to interfering signals such as returns from moving ground targets. When the interfering signals are detected in the guard gates, the system goes on memory until the interfering signal passes. [A4052]

"Obstacle detecting system"

An obstacle detecting system comprising an oscillating device for generating and directing to an obstacle a first oscillating signal in a first time period and a second oscillating signal having a different frequency than that of the first oscillating signal in a second time period, an antenna for receiving the signals reflected from the obstacle, a detector for mixing the signals received by the antenna and the output of the oscillating device to generate a detected signal which comprises a first signal component derived by mixing the first oscillating signal reflected by the obstacle and received by the antenna with the second oscillating signal generated by the oscillating device and a second signal component derived by mixing the second oscillating signal reflected by the obstacle and received by the antenna with the second oscillating signal generated by the oscillating device, and an information signal circuit for receiving the detected signal and generating information relating to the distance between the antenna and the obstacle and information relating to the relative velocity of the antenna and the obstacle. [A4053]

"Braking system for avoiding a collision of a vehicle with an obstacle thereof"

A radar sensor and a vehicle velocity sensor are mounted on a vehicle, producing three signals representative of, vehicle velocity, a distance and a relative velocity between the vehicle and an obstacle ahead thereof. These three signals are fed to a collision imminence computing circuit which generates two signals representative of collision imminences depending upon whether the obstacle is stationary or moving. [A4054]

"Method and apparatus for measuring the distance between two stations"

A method and system for determining the distance between two stations interconnected through a carrier wave connection for data transmission by frequency modulation (FM) or phase modulation (PM) and, if necessary, transferring the data concerning the distance determined. At least one of the two stations is movable and each station comprises a transmitter, a receiver and a transceiver antenna for said FM or PM data transmission. During operation the antennas are interlocked. The carrier wave transmitted by the first station and being normally FM or PM modulated by data signals is interrupted a number of times in this station. Upon detection of each one of these interruptions, the second station introduces a similar, corresponding interruption into the carrier wave transmitted by this second station. The carrier wave is normally also FM or PM modulated by data signals. The period of time between the transmission and reception of the associated interruptions is measured in the first station as a measure of the distance between the stations. [A4055]

"Radar-operated collision avoidance system for roadway vehicles using stored information for determination of valid objects"

A radar-operated collision avoidance system for a roadway vehicle comprises a radar device for sensing the vehicle speed relative to an object and its distance thereto to decide whether the vehicle is approaching the object at a dangerously high speed. A minimum allowable distance represented by a digital code is stored in a memory location within an array of rows and columns and read out in response to a sensed vehicle speed relative to the roadway and to a sensed magnitude of steering movement. The minimum allowable distance is compared with the distance sensed by the radar to determine that the decision is valid only when the latter is smaller than the former. [A4056]

"Imminent collision detection apparatus"

Apparatus is herein disclosed for imminent collision detection equipment for acknowledging proximity between a first object carrying the equipment and a second object. The imminent collision detection apparatus is a radio distance measuring device and includes a transmitter and a receiver. The transmitter has a pulsed energy output which is reflected back by a target and mixed with a reference source of pulsed energy generated a predetermined time after the transmitted output and coherent thereto. The coherent feature of the equipment lies in the fact that the transmitter pulsed output and the pulsed reference signals are both generated with the same starting phase each generated pulse. Furthermore, the transmitted and reference signals are jittered to provide a resistance to countermeasures capability. [A4057]

"Apparatus for the detection of buried objects"

Apparatus for the detection of buried objects comprising a broadband, high resolution short pulse transmitter and a bistatic or monostatic noncontacting antenna for radiating the transmitted signal through the ground for reflection from a buried object, a sampling type receiver which reduces the bandwidth and center frequency of the received signal, and a locking circuit controlled by the first reflection from the ground or soil surface to thereby lock the range sweep to the soil surface and eliminate the effects of antenna height variations. [A4058]

"Underwater monitoring"

Apparatus for detecting the presence of an underwater object measures variations in the input impedance of a monopole antenna to provide data on the object. A sweep generator supplies a first electrical signal of varying frequency for transmission as an electromagnetic signal propagated through water from the antenna, and means are provided for detecting reflections of the electromagnetic signal to provide a second electrical signal, which is compared with the first electrical signal to provide an output signal. Preferably, the monopole antenna is one of three such antennas, which are provided with means for comparing input impedances of the antennas to provide an output signal representing the bearing of the object. [A4059]

"Target range sensor"

The specification discloses a radar sensor for detecting short-range, slowly moving objects and using the range versus time data to develop a prediction of the time at which the range of the object will be at a minimum to the sensor. The sensor uses a pulse transmission of a radio frequency signal with object reflections being received and detected. Subsequent signal processing eliminates returns from clutter and stationary objects so that signals from low velocity objects can be detected. Computations are performed in a digital processor to compute an estimate of the time and of the range when the object will be closest to the sensor. [A4060]

"Foreground subject-identifying apparatus"

A foreground subject-identifying apparatus comprises a sweep signal generator for issuing a sweep signal having frequencies f.sub.s falling within a prescribed range, a carrier wave generator for producing a carrier wave having a frequency f.sub.0 , a first frequency mixer for mixing output signals from the sweep signal generator and carrier wave generator to generate an output signal having a frequency f.sub.0 .+-.f.sub.s , a first antenna through which to transmit an output signal from the first frequency mixer, a second antenna mounted on the foreground subject to receive an output signal sent forth from the first antenna, a coding circuit carried on the foreground subject which is provided with a plurality of resonance circuits resonating at different frequencies f.sub.T and adapted to form a specified code from a combination of these different resonance frequencies, a signal mixer for detecting an output signal from the second antenna to supply a signal having frequencies f.sub.s to the coding circuit and modulating the signal having a frequency f.sub.0 by resonance signals from the coding circuit to deliver a signal having a frequency f.sub.0 .+-.f.sub.T to the second antenna, a second frequency mixer for mixing an output signal having a frequency f.sub.0 from the carrier wave generator, and a signal having a frequency f.sub.0 .+-. f.sub.T received from the signal mixer through the second and first antennas and thereby issuing a signal having a frequency f.sub.T , and a coded signal interpreting circuit for detecting resonance frequencies out of a signal delivered from the second frequency mixer, thereby interpreting a coded signal supplied from the coding circuit. [A4061]

"Passive encoding microwave transponder"

A passive transponder which provides remote identification of objects including cargo and trailers, vehicles or a variety of objects which move through an interrogator beam. The passive transponder is mounted onto the vehicle or object or at the location to be identified. A transmitted beam from the interrogator is directed to the transponder. Some of the beam's energy is rectified and used to power digital electronic circuitry within the transponder which generates a signal with a serially-coded digital waveform. This signal amplitude modulates a harmonic generator in the transponder which produces and emits harmonic energy derived from the incident beam from the interrogator. This harmonic energy is readily identified by an interrogator receiver which is tuned to that harmonic of the incident signal. The transponder information from the interrogator receiver is decoded in the interrogator data processor to provide the desired identification number. An internal clock frequency is generated within the passive transponder as a result of transmitted energy from the interrogator beam, and this clock determines the read-out rate of the encoded data from a field programmable read-only memory. [A4062]

"CCD focal plane processor for moving target imaging"

A CCD focal plane processor having a plurality of columns of individual sensor elements with plural sensor elements per column. The structure includes plural CCD shift registers corresponding to the number of columns of sensors, each CCD shift register including a pair of stages corresponding to each of the element sensors of the corresponding column of the array. Two "snapshots" of the scene are taken at time-displaced intervals and are compared to detect differences therebetween to eliminate background, or unchanging scene content. The individual sensors provide outputs which are injected into the .alpha. stages of the corresponding paired shift register stages of each CCD shift register in a first time interval corresponding to the first "snapshot". The resulting charge packets in the first (.alpha.) stages then are advanced to the second (.beta.) stages of each shift register pair. The second "snapshot" corresponds to injecting a second signal into the .alpha. stages of the plurality of pairs of .alpha., .beta. stages. The CCD shift registers then are read out simultaneously and in succession as to the plural, related .alpha., .beta. pairs of stages containing the time-displaced elemental signal samples. A further CCD shift register including a number of .alpha., .beta. pairs of stages receives the parallel .alpha., .beta. outputs in corresponding time sequential manner to maintain the .alpha., .beta. related pair arrangement of the time-displaced elemental samples. An output circuit compares the .alpha., .beta. signals for each elemental area and determines the difference therebetween. A CRT display receives the difference signal outputs for displaying moving target information. [A4063]

"Clutter subtraction system"

A radar system having transmitted and received signals, the system including a feedback loop for modulating a sample of the transmitted signal to duplicate the phase and amplitude of the clutter echoes from nearby points of reflection. The modulated transmitted sample is subtracted from the received signal to remove the clutter. The feedback loop detects differences between the clutter-free signal and the transmitted sample to produce an error signal, the error signal being filtered and applied to the modulator for modulating the phase and amplitude of the transmitted sample. BACKGROUND of THE INVENTION This invention relates to echo ranging systems such as radar and sonar systems and, more particularly, to an echo ranging system in which clutter returns from nearby objects are removed from echoes from distant objects. Echo ranging systems frequently utilize transmitted pulses of radiant energy in which the duration of the pulse is equal to a substantial portion of the overall round trip time of propagation of radiant energy signals from the echo ranging system to a distant object and back to the echo ranging system. The use of a long duration pulse of radio frequency energy permits the transmission of a large amount of radiant energy as compared to that which can be transmitted in a relatively short pulse from transmitting equipment which is limited in its maximum peak power capability. To produce enhanced discrimination in range between closely spaced reflecting objects, the spectrum of the transmitted pulse of radiant energy is broadened by a modulation of the carrier, such modulation being typically a phase modulation of the carrier, one such form of phase modulation employing a quadratic phase shift pattern which results in a frequency modulation pattern in the form of a linear sweep. Such a modulation pattern is conveniently employed with pulse compression filters in radar and sonar receiving equipment for the discernment of closely spaced points of reflection. A problem arises in that echo ranging systems are frequently employed in situations wherein nearby objects of reflection and distant objects of reflection, often referred to as targets, are simultaneously present. While the leading edges of echoes from nearby targets arrive at the radar or sonar system prior to the leading edges of echoes from distant targets, the relatively long duration of the transmitted pulses may result in extensive overlap of the major portion of the echoes of nearby targets with the echoes from distant targets. When the aforementioned linear sweep frequency modulation is employed, the instantaneous frequency of a portion of an echo from a nearby target differs from the instantaneous frequency of an overlaping portion of an echo from a distant target. Furthermore, the amplitude of an echo from a nearby target, such as the echo from a wave in a sea clutter situation, is much larger than the amplitude of the echo received from a distant target. In view of these differences in frequency, or phase, and amplitude of the echoes, the clutter of echoes from the nearby targets masks the echoes from the distant targets. Difficulties are encountered in echo receiving equipment in that automatic gain control used therein must have a large dynamic range to accommodate the large and the small amplitude echo signals. Such automatic gain control equipment, when tracking the large amplitudes of the clutter, tends to distort the waveforms of the echoes received from the distant targets with a resulting loss in data obtainable from such distant targets. The foregoing situation relates to both electromagnetic and sonic echo ranging systems and, since the invention to be described hereinafter applies to both electromagnetic and sonic echo ranging systems, the ensuing description will be given in terms of a radar system, it being understood that the description relates equally well to a sonar system. SUMMARY of THE INVENTION The aforementioned problems of the prior art are overcome and other advantages are provided by a radar system having transmitted and received signals, and which, in accordance with the invention, modulates a sample of the transmitted signal to substantially duplicate received clutter signals, the modulated sample being subtracted from the received signal to provide a received signal free of clutter. In a preferred embodiment of the invention, the transmitted signal is phase modulated quadratically with time, this being a linear frequency sweep over the duration of the transmitted signal pulse. Such modulation provides a transmitted signal having an increased bandwidth suitable for the pulse compression of received signal echoes. In accordance with the invention, the aforementioned subtraction of the transmitted signal sample is accomplished by a feedback loop in which the clutter-free signal is compared to the transmitted sample by a detection of inphase and quadrature components of the clutter-free signal to develop an error signal of the feedback loop. The error signal is then filtered and applied to a modulator which modulates the phase and amplitude of the transmitted sample to match the phase and amplitude of the clutter. Thereby, the clutter component of the received signal may be subtracted from the received signal. The bandwidth of the feedback loop provides a sufficient speed of response for tracking clutter of nearby reflecting objects for which the frequency and phase of the echo approximates that of the transmitted signal phase. The loop bandwidth is sufficiently narrow to preclude the tracking of echoes from distant reflecting objects for which the frequency of the echoes differs substantially from that of the transmitted signal pulse. Thereby, distant objects, or targets can be observed since the echoes therefrom are essentially unaffected by the feedback loop. [A4064]

"Electronic docking system"

An electronic docking system utilizing a multiplicity of sensing subsystems to derive and display docking parameters during the docking operation is disclosed. The parameters displayed include bow and stern velocities ship's velocity perpendicular and parallel to the jetty and ship's orientation to the jetty during the docking maneuver. Parameters are derived from data gathered by sensors that include a receive only monopulse and a receive only doppler system which determine the angular position of a selected reference location aboard the ship and a signal with a frequency representative of the ship's velocity from a signal radiated from a beacon antenna aboard the ship. Range measurements are accomplished by utilizing baseband pulse radar systems capable of determining range to accuracies in the order of one foot. A telemetry link between the ship and the shore based system provides a means for simultaneously displaying data on board and on land and for relaying docking commands from the jetty master to the docking pilot. [A4065]

"Range or doppler gate deception rejection system"

A doppler radar wherein the range signal is differentiated to obtain a range rate of change and a velocity signal is obtained from the doppler frequency shift of signals returned from a target, and wherein the range rate and velocity signals are compared and, if the difference exceeds a predetermined amount, the range and doppler or velocity circuits are reset. [A4066]

"MTI System processor and method"

A method and apparatus for removing the effects of radar platform movement and for otherwise processing doppler radar signals in a moving target indicator doppler radar in which targets in the main beam having reflective characteristics sufficient to override side lobe attenuation are tracked relative to the side lobes and the residual doppler frequency for such targets resulting from side lobe detection calculated. Based on this calculation, the appropriate ones of a bank of doppler filters are inhibited at the appropriate range bin to prevent a false target indication without inhibiting the display of moving targets in the main beam at the same range but having different doppler frequencies. A novel automatic gain control circuit which provides dynamic amplitude adjustment of the radar return signal to match the dynamic range of the radar processor on a range bin-by range bin basis is also provided as is a novel signal processing circuit for removing the effects of radar platform movement from the radar return signal. The use of a sensitivity time control is disclosed as is the method of vector rotation and quadrant resolution. [A4067]

"Underground pipe detector"

An apparatus and method wherein an electrical impulse source transmits a radar-type signal through an antenna into the ground and is reflected by a target. The reflected signal or echo is detected by the antenna and an analog-to-digital converter converts it to a digital form which may be readily operated on, stored and recalled. A memory stores the information until recalled for comparison with a subsequent signal to give an indication of the location of metallic and non-metallic buried targets. [A4068]

"Passive transponders using acoustic surface wave devices"

A passive transponder sensitive to electromagnetic pulses received in the form of surface acoustic waves. The device utilizes a plurality of interdigital transponders each consisting of a metallic deposit on a piezoelectric substrate and serving as an electrode. Transponder deactivation and energy interruption means provide programability and coding. [A4069]

"Fuze modulation system"

1. An improved noise-modulated distance-measuring fuze comprising in combtion: an oscillator, a transmitting antenna coupled to said oscillator for radiating a signal towards a target, a modulator coupled to said oscillator to cause frequency modulation thereof, said modulator comprising a random noise generator, a band-pass shaper connected to the output of said noise generator for frequency shaping the random noise output thereof, a limiter coupled to said band-pass shaper for amplitude shaping the frequency-shaped noise output thereof, an integrator coupled to said limiter for integrating the frequency-shaped and amplitude-shaped output thereof, and means connecting the output of said integrator to said oscillator in such a manner as to frequency modulate said oscillator, a receiving antenna adapted to receive a portion of the signal radiated from said transmitting antenna after reflection from a target, mixer means for mixing the received signal from said receiving antenna with a local signal taken from said oscillator to produce a difference-frequency mixer output signal, said mixer output signal having a frequency spectrum peaked at a frequency greater than zero that decreases with decrease of fuze-to-target distance, the frequency at which the mixer output signal is peaked and the broadness of the spectrum in the vicinity thereof for a given fuze-to-target distance being dependent upon the characteristics of said band-pass shaper and said limiter, and means coupled to said mixer and responsive to the frequency at which said mixer output signal is peaked for functioning the fuze at a predetermined fuze-to-target distance. [A4070]

"Electromagnetic intrusion sensor"

An electromagnetic intrusion sensor for detecting the presence of moving ects within a specified detection range by sensing the interaction between the moving objects and an electromagnetic field generated by the sensor. [A4071]

"Non-linear spread spectrum transmitter/receiver for a homing system"

A spread spectrum transmitter/receiver in a pulse ranging system including surface acoustic wave devices with a nonlinear transducer to reduce frequency shift errors due to doppler effects. [A4072]

"Doppler radar system"

A Doppler radar system for controlling portable traffic signals in response to on-coming traffic. Each of two channel amplifiers of the system is fixed at high gain and passes both noise signals and Doppler signals to a phase detector. A threshold element provides a control signal when the average level of the phase detector output between high and low levels changes sufficiently, due to the presence of Doppler signals, from a mean level which is due to noise alone. [A4073]

"Stepped dual-frequency, ocean-wave spectrometer"

A coherent stepped dual-frequency, ocean-wave, spectrometer radar system for measuring the characteristics of ocean-surface gravity waves includes: a transmitter for transmitting in successive steps coherently related pairs of frequencies having different, small, and known frequency separations, a coherent receiver for receiving and separating the radar returns of the stepped pairs of frequencies, a frequency-shifter for offsetting the doppler spectrum of each radar return, a multiplier for multiplying together the two frequencies of each pair for each step to obtain a Bragg resonance condition for each step, and a plurality of stepped detectors each for detecting a different step of said multiplier output. [A4074]

"Moving target indication radar"

A moving target indication radar is disclosed in which the zero-Doppler-speed components of the radar return signal are eliminated by correlation processing in the azimuthal direction. In some cases, a similar correlation processing is concurrently performed in the range direction. The moving target indication radar has both a radar signal analog processing portion and a radar signal digital processing portion. The received pulse returns are processed by quadrature phase detectors to provide outputs which are in phase and quadrature phase analog data signals representing real and imaginary parts of the Doppler frequency data. These signals are converted to corresponding digital words which are then divided into a plurality of digital Doppler frequency components by a discrete Fourier transform circuit. A buffer memory is connected to store the outputs of the discrete Fourier transform circuit. An amplitude calculator selectively receives the outputs of the buffer memory and computes the root-mean-square value for each output of the discrete Fourier transform circuit stored in the buffer memory. A second buffer memory is connected to store the outputs of the amplitude calculator, and a correlation processing circuit averages the outputs of the second buffer memory which represent the data of a plurality of every n-th one of the unit azimuthal regions and subtracts the average output from the data for the center of the plurality of unit regions. [A4075]

"High prf unambiguous range radar"

A pulse-compression MTI doppler radar system includes an antenna, a transter, a coded modulator, a receiver and a display. The coded modulator is connected to the transmitter and has at least two waveform generators for coding pulses having low cross-correlation. A pulse-compression filter having at least two pulse compressors for providing pulse compressed signals is connected to the receiver. Each pulse compressor is matched autocorrelatively to a different one of the waveform generators. An MTI processor has two MTI processing channels which are responsive to the pulse-compressed signals and provide an output to the display. [A4076]

"Fixed dual beam range scanning and tracking radar with digital display"

A light weight, low power radar principally adapted for use on small vehicles such as sailboats, which has a fixed antenna providing a continuous forward looking beam which provides range information and limited azimuth information in manual and automatic range scanning modes of operation, and which is capable of automatically tracking targets in range. In the manual mode of operation, a voltage representing a manually selected range is compared with a sweep voltage synchronized with the radar transmitter pulse to generate a pulse having a time relationship to the transmitter pulse corresponding to the selected range. This pulse is utilized to gate a video echo from the radar receiver to logical control circuit which operates in conjunction with the antenna lobing control to actuate a display indicating whether the target is to port or starboard of the vehicle heading. The range voltage is also converted to digital form for display on a digital display device. In the automatic scanning mode, the range scale of the radar is scanned at a slow speed by a sweep voltage representing this range scale. At any ranges at which targets appear, the scan is interrupted for a short period of time during which time the range voltage for this particular portion of the scan is gated through for conversion to digital form and displayed on the digital range display. In the tracking mode, a target to be range tracked is selected from either the manual or scan mode and automatically locked onto by means of a range tracking circuit. During the tracking mode, the range voltage is continually converted to digital form and displayed on the digital range display. The range rate (speed) of the target and the estimated time of arrival (ETA) to the target are computed. Either one can be selected for display on a second digital display. [A4077]

"Logic circuit for an automatic braking system for a motor vehicle"

Braking of a vehicle is prolonged by an improved logic circuit for a time or a distance to overcome stop starting braking due to momentary "safe" signals caused by multiple reflection of a radar signal. [A4078]

"Traffic radar and apparatus therefor"

Apparatus is provided for determining the frequency of unknown periodic input signals and primarily generally sinusoidal signals which may be accompanied by very substantial noise. More particularly, the system for determining the frequency of unknown periodic input signals accompanied by substantial noise is adapted to a unique traffic radar or doppler radar system. The apparatus includes a phase locked loop in which the incoming signal accompanied by noise is compared with the output from a voltage controlled oscillator to generate a synthetic signal which is substantially free of noise and is well adapted for counting, measuring and display circuitry to give a direct indication of the input signal frequency or a parameter directly related to that input signal frequency. Specifically in doppler radar systems the direct readout is in "miles per hour", a direct function of doppler frequency. The signal which is being subjected to frequency determination is applied directly to the comparator portion of the phase locked loop circuit and it is also applied to the comparator portion of the phase locked loop circuit through a tunable band pass filter whereby speed of response is obtained without loss of noise rejection or frequency or harmonic range. Also an automatic frequency control loop is employed with the comparator to adjust the voltage control oscillator and this AFC loop has adjustable gain which is directly related to the frequency of the incoming signal to enhance the stability over the entire frequency range. The system is also capable of an instantaneous determination of locked operation whereby false readings are avoided. [A4079]

"Bi-static radar speed sensor"

A doppler speed sensor for a ground vehicle wherein errors due to perpendicular velocity and vehicle tilt relative to the ground surface are substantially eliminated by utilization of a first receiving antenna having a radiation pattern disposed facing forwardly and covering a portion of the ground surface, and a second receiving antenna having a radiation pattern disposed facing rearwardly and overlapping the first antenna radiation pattern on the ground surface portion. [A4080]

"Complex pulse repetition frequency generator"

A complex pulse repetition frequency generator for producing a pulse repeion frequency (PRF) signal having programmable stagger intervals. The device consists of a clock for selecting one of a series of standard clock pulses which are used to increment a counter. A comparator compares the accumlated clock pulses with a stagger data output signal produced by a data memory source. When the outputs are equal, the comparator produces a PRF output pulse. Two data memory bands are provided, a random access memory in which stagger data can be programmed by a series of switches, and a preprogrammed read-only memory. Address counters are used with each memory unit and provide capability for addressing selected memory locations from the data memory sources. A pulse width generator allows the operator to vary the pulse width and utilizes an injection lock oscillator to prevent jitter whenever a standard clock pulse is used which is not an even multiple of a hundred nanoseconds. [A4081]

"Alarm system for emergency braking"

In a vehicle an alarm issues a warning signal just before actuation of an automatic emergency brake which operates in response to the relative speed and relative distance beween the vehicle and an obstacle in the vehicle's path. [A4082]

"Measurement of contents of tanks etc. with microwave radiations"

A microwave signal that varies linearly in frequency through a sweep period is radiated to and reflected back from a target body. In one mixer the directly generated signal is mixed with the reflected signal to produce a difference frequency corresponding to distance, another mixer mixes the directly generated signal with the same signal delayed for a constant time, to produce a reference difference frequency. Each difference frequency is digitized as a pulse train. The sweep period is divided into successive short time intervals, each of which can begin with a pulse of the lower frequency train and to each of which is assigned a numerical weighting factor, said factors for successive intervals differing stepwise in value. Pulses of each train occurring during each such interval are multiplied by the factor for the interval. All such multiplied pulses are counted through the sweep period to obtain a pair of pulse totals, and a quotient relationship between those totals gives an accurate measure of distance. [A4083]

"Microwave level gaging system"

A method and apparatus for measuring liquid level. A generated broad-band swept-frequency C.W. microwave signal (2-4 GHz) is upverted to a high frequency band signal (34-36 GHz) , which is transmitted towards, and reflected from, a liquid surface. The reflected signal is downverted to the frequency band of the original generated signal, and then the phase difference between the original and downverted signals is measured by a microwave phase discriminator and a quantizer, which generates video pulses proportional to the total phase shift across the swept C.W. band. During an adjacent sweep in the same direction, the original signal is compared with a signal transmitted through a calibration cable equivalent to a known free-space path length. The unknown signal path to and from the liquid surface, can then be calculated by comparison of the video pulse train outputs during the CALIBRATE and OPERATE modes of operation, either by the ratio of the number of pulses, or the average time between pulses during each sweep. Alternately, the mode of operation can be switched several hundred times during a single sweep across the bandwidth, and the unknown signal path corresponding to a particular liquid level can be calculated by comparison of the spacing during adjacent CALIBRATE and OPERATE modes to give several hundred measurements at different frequencies. Deviate measurements can then be eliminated, and the remaining measurements can be averaged to give a highly accurate true average measurement by known methods. [A4084]

"Automatic transponder"

A method and apparatus for the automatic, remote measurement of the internal delay time of a transponder at the time of operation is provided. A small portion of the transmitted signal of the transponder is converted to the receive signal frequency of the transponder and supplied to the input of the transponder. The elapsed time between the receive signal locally generated and the receive signal causing the transmission of the transmitted signal is measured, said time being representative of or equal to the internal delay time of the transponder at the time of operation. [A4085]

"MTI clutter tracking and cancelling system"

A clutter tracking and cancelling system, for use in a MTI radar system, comprising an auxiliary channel consisting primarily of a phase detector and a canceller. The phase detector provides an output which represents the phase difference between the IF and the coho output, while the output of the canceller, which responds to the phase detector output, represents clutter MTI residue from one transmission to the next. Clutter MTI residue from several successive range bins is smoothed and integrated to provide a control output which is used to shift the phase of the coho frequency, which is supplied to the phase detector in the conventional main MTI channel, to set the mean clutter velocity at zero velocity in order to produce optimum clutter cancellation in the main MTI channel. [A4086]

"Sea clutter reduction technique"

A multi carrier-frequency pulsed radar system in which each carrier-frequy reflected radar signal is separately processed by parallel receiver branches. The output of each receiver branch is multiplied together to form the product of the separate receiver outputs, which product is then displayed on a plan-position-indicator (P.P.I.) display. [A4087]

"Method of measuring the velocity of an object relative to a reference and a device for effecting said method"

Method and apparatus for measuring the velocity of an object relative to a reference by means of signals that are transmitted and received by transmitters and receivers fixed to the object at a certain geometric distance from each other in the direction of measurement, signals being transmitted by the object and being reflected by the reference. The receivers set up signals which correspond to the auto-correlation and cross-correlation of the received signals, the correlation signals being functions of the transmitter-receiver system geometry and being substantially independent of the reflection properties of the reference. The auto-correlation and cross-correlation signals are operated on to determine a time shift therebetween which is a function of the displacement of the object over a given period of time, the velocity of the object relative to the reference location being determined from said time shift. [A4088]

"Installation for controlling a measuring beam and/or a light beam in motor vehicles"

An installation for controlling a measuring beam and/or a light beam in motor vehicles, in which at least one measuring and/or light beam transmitted from the vehicle serves for measuring the distance or illuminating objects which are located ahead of the vehicle in its own lane, measuring devices are thereby arranged in the motor vehicle which determine at least the vehicle velocity and the transverse acceleration as well as possibly the longitudinal acceleration or deceleration for correcting the assumed theoretical braking action and, under certain circumstances, still other relevant vehicle magnitudes, the beam transmitter is then controllable as regards the beam range and/or beam opening angle and/or angle deviation of the beam with respect to the vehicle longitudinal axis by a computer as a function of these measured values. [A4089]

"Radar contour edge restore circuit"

Contour correction circuitry is provided for use in a weather radar which has iso-contour circuitry and which has a digital display having a tendency to undesirably not display the trailing edge boundary, for example, of a storm cloud. The correction circuitry is responsive to even a momentary signal indicating the close of a contour for forcing a contour boundary to appear on the digital display. The correction circuitry also enhances the texture of the radar when displaying snow flurries, ground returns, etc. which exhibit unique pattern characteristics. [A4090]

"Multiple ranging DME"

A method and system for obtaining and displaying distance information to multiple DME ground stations using a single airborne transmitter-receiver and for displaying groundspeed to one of the stations. A DME is time multiplexed between two channels and display-memory means, the distance value being held in the display corresponding to each channel until that channel and the display corresponding thereto is updated or until a predetermined period of time has elapsed. Further, a DME which provides a distance data output in both search and track modes is multiplexed between primary and secondary channels and display-memory means, and is permitted to go into track on the primary channel but only into search on the secondary channel. When the system is on the secondary channel appropriate information is stored and the DME is returned to primary channel operation in the track mode. [A4091]

"Short-pulse non-coherent MTI"

A non-coherent, non-doppler, MTI radar system has its cancellation notch adened to include a selected range of target velocities. The apparatus includes a transmitter/receiver for transmitting and receiving short pulses in the nanosecond range. Also included is apparatus for generating multiple MTI responses having cancellation notches at different target velocities and multiplying the responses together to obtain a broadened cancellation notch. [A4092]

"Digital mean clutter doppler compensation system"

A digital technique is disclosed for filtering clutter in a pulse doppler I radar which allows a filter notch to be set for different doppler frequencies. In particular, the system includes two or more MTI filters cascaded to cancel different kinds of clutter signals that interfere with target signal reception. In each filter a digital detection circuit senses the mean-clutter-doppler frequency for a particular clutter type and automatically places a notch at that frequency. Each notch is fixed by treating the radar samples as complex numbers and replacing the conventional filter coefficients with complex coefficients indicating amplitude and phase as derived from the radar returns. [A4093]

"Temperature compensated acoustic surface wave device"

A temperature compensated acoustic surface wave device, such as a surface wave delay line is provided in which temperature compensation is provided by the deposition of an interdigital electrode structure on a substrate with an overlay film surface of piezoelectric material of a predetermined thickness. A double substrate arrangement is also disclosed in which the interdigital electrode structure is deposited upon the surface of a non-piezoelectric layer which in turn is placed upon the surface of a piezoelectric substrate. [A4094]

"Object detecting system"

1. A system for detecting the movement of a remote object comprising trantting means for illuminating said remote object with a signal of wave energy, receiving means for recovering an echo reflected by said object, signal display means responsive to said echo to provide a separate visual display of each cycle of said reflected echo, and frequency comparing means responsive to a difference in frequency between the wave energy of said received echo and the wave energy of said transmitted signal to vary the orientation of said visual indication from a

reference orientation, whereby a variation in said orientation will provide an instantaneous indication of a doppler effect on said transmitted wave energy. [A4095]

"Airborne moving-target indicating radar system"

Radar detects relatively low velocity moving ground targets having relatively tiny radar cross sections, although the radar itself is moving at relatively high velocity with respect to ground. This is achieved with the use of spectrum tracking means and range-gated filters incorporated in the radar detecting means. [A4096]

"Noise resistant zone penetration detection system"

A system for detecting the existence of a projectile within a penetration ne of a target and providing a score indication for each projectile penetrating that zone. The system utilizes a doppler signal generator, a doppler cycle detector and an intercept detector for indicating penetration. A voltage controlled oscillator in the target area provides signal information for transmission by FM telemetry. The unit for scoring the number of intercepts utilizes an FM telemetry receiver for demodulating the signal information. A hit indicator produces a score indication pulse in a manner which is highly resistant to background noise. A score indication device, controlled by the control pulse, counts the score indications and signifies intercepts by an electromechanical counter, audible signals and/or a light display. [A4097]

"Muzzle velocity chronograph"

A chronograph uses a Doppler radar technique to determine the muzzle velocity of a bullet discharged from small arms such as pistols and rifles. A radar unit is placed in near proximity to the firearm to track the bullet while it is still relatively close to the muzzle. The radar unit is equipped with an antenna which is insulated from the sonic disturbance created by the firearm blast by sonic damping means formed exteriorly on the antenna. Measured spacing and orientation of the antenna with respect to the firearm diminishes the sensitivity of the antenna to the electromagnetic disturbance associated with the firearm blast. Doppler signal processing means are also disclosed. [A4098]

"Antenna for underground pipe detector"

An apparatus and method wherein an electrial impulse source transmits a radar-type signal through an antenna into the ground and is reflected by a target. The reflected signal or echo is detected by the antenna and an analog-to-digital converter converts it to a digital form which may be readily operated on, stored and recalled. A memory stores the information until recalled for comparison with a subsequent signal to give an indication of the location of metallic and non-metallic buried targets. [A4099]

"Passing vehicle signalling apparatus"

This disclosure pertains to a signaling apparatus installed within a movable large vehicle, such as a truck. Two sensing heads are utilized by mounting one of each on the frontmost opposed sides of the vehicle. Each sensor is manually selectively energized so as to detect the distance separating a vehicle being passed from the equipped vehicle on the side of the energized sensor. The sensors may utilize sound, radio or light waves to operate a conventional range detecting apparatus. A comparetor circuit compares the range of the vehicle being scrutinized with the range manually predetermined by setting a minimum range control element. A warning light continues to indicate the proximity of the scrutinized vehicle until such time that the vehicle remains within the pre-set distance manually selected by the operator. A timer may be used to shut off the sensing activity of the sensor in the event of intentional herding of adjacent vehicles oftentimes encountered in heavy traffic. [A4100]

"Vehicle position indicator with radar interrogation each of spaced transponders disposed along a pathway for the vehicle"

This invention applies to an automatic train control system. A low power radar mounted beneath a train interrogates simple passive transponders mounted between the rails. Each transponder includes a reflective delay line. The radar has a number of range gates. The transponder delays are arranged in a simple code which provides information as to the location of the train along the track. The outputs of the range gates can be fed to a simple computer which can also receive wheel revolution pulses from an axle mounted transducer. The computer can then calculate the distance travelled at any given moment to within one meter from the last transponder over which the train has passed. [A4101]

"Collision avoidance/proximity warning system using secondary radar"

Proximity indication and evaluation of mobile vehicles, using the signals emitted by the hundreds of existing secondary radar ground stations and the nearly 100,000 cooperating transponders on the vehicles, to detect intrusion in a monitored proximity volume and to determine slant range and/or relative bearing to the intruder. [A4102]

"Traffic control system"

A traffic control system particularly suitable for aiding the blind includes an interrogating FM radio transmitter-receiving unit, which can be incorporated into a cane or the like, and a responding FM radio receiver-transmitter unit operatively associated with the traffic signal light control circuits at a street intersection. The interrogating unit transmits an FM signal modulated by a coded signal indicative of which direction its blind operator wishes to cross the intersection. The responding unit, in response to the FM signal received from the interrogating unit, transmits an FM signal modulated by a coded signal corresponding to that received from the interrogating unit whenever the traffic signal light conditions are such that a safe crossing in the desired direction is possible. The interrogating unit produces an audio or mechanical output signal when the coded signal received from the responding unit corresponds to the coded signal it transmitted under the control of its blind operator, this output signal indicating that it is safe to cross the intersection in the desired direction. [A4103]

"Imaging systems"

Echo data relating to the distance away of reflective elements of an object surface is received by an array of receivers. A signal processing device receives the data and together with information as to the range of the object surface defines equitime loci of the object surface corresponding to the data. Image elements are displayed at positions in an image plane corresponding to the intersections of the equitime loci. [A4104]

"Signal modification techniques"

Signals producing each spot in a digital two-dimensional spot matrix display, such as in a digital weather radar, are compared on a spot-by-spot basis with signals for immediately proceeding and following spots in each dimension. When the preceding and following spots have the same value, the spot being compared is caused to have that same value when displayed. The comparing circuitry may be provided signals from a radar antenna which receives, serially, signals at succeeding range points at a given azimuth and then at the same range points at succeeding azimuths. Signals at each given range at a plurality of succeeding azimuths may be averaged to produce an improved visual display. The compared signals may be further smoothed by averaging signals for succeeding azimuths and displaying the averaged signals alternating with the unaveraged signals. [A4105]

"Traffic radar and apparatus therefor"

Apparatus is provided for determining the frequency of unknown periodic input signals and primarily generally sinusoidal signals which may be accompanied by substantial noise. More particularly a unique traffic radar or doppler radar is provided employing such frequency measuring apparatus. The apparatus includes a phase locked loop in which a frequency multiplier effect is produced and in which a frequency 12 times the periodic input signal being subjected to measurement is employed for taking two independent samples of the input signal and providing a synthetic representation of that signal. The two samples are centered about quadrature time references and are preferably conterminous. This signal can be measured and utilized for speed measuring purposes and other purposes where the accurate measurement of a periodic signal accompanied by noise is desired. The system includes two sampling gates to control the frequency of a variable controlled oscillator in a manner which accurately matches the oscillator output to a harmonic of the input and selects portions thereof to eliminate harmonic ambiguities. Circuit means is also provided for signal verification and for improved long-term noise rejection by utilizing variable time constants. [A4106]

"Testing of automobile headlights"

A machine which surveys the focussing of motor vehicle headlights, said surveying accomplished by the invented machine using an existing light-sensitive element and in correlation with a radar detecting system. [A4107]

"Method and system for measuring doppler frequency shift of an echo"

A beam of diverging electromagnetic radiation of a predetermined frequency is transmitted to a target and the doppler shift of frequency of an echo due to relative movement of the target and a point of reception is detected conventionally by combining the frequency of the echo and the predetermined frequency. The number of cycles within the detected doppler shift frequency is counted to provide a delay to initiate measurement of doppler shift at a preselected angle of incidence of the echo. The effective area of measurement is thus restricted to a narrow region of the beam with the resultant high degree of precision. [A4108]

"Method for avoiding unwanted echo signals and automotive radar embodying same"

An automotive radar is provided with a device for sensing the location of the entry and exit ways of a zone as the vehicle passes therethrough to reduce the detectable range of the radar upon the vehicle entering the zone so that false targets within the range-controlled zone are discriminated from valid targets. The device restores the range upon the vehicle leaving the zone to normal range. [A4109]

"Multiple target data receiver for a collision avoidance system"

In an interrogation vehicle, a receiver of data from a plurality of remote vehicles such as aircraft or maritime vessels in a cooperative collision avoidance system is arranged to receive such data reply signals in reply to interrogation signals. The reply signals are suitably coded in the remote vehicles to provide information in a predetermined plurality of sequential replies from each replying vehicle. [A4110]

"Method and apparatus for acousto-optic pulse compression"

There is disclosed a pulse processing method and apparatus for compressing or changing the time scale of signal information represented by the modulation of a pulse of carrier energy which method and apparatus utilizes a crystal through which both a pulse of radio frequency acoustic energy and a pulse of polarized optical energy are simultaneously and colinearly transmitted to scatter energy in the optical pulse from one polarization state into the orthogonal polarization state. The crystal output is thus comprised of two optical pulses. One is the pulse having the original state of polarization and the other is the pulse resulting from the energy scattered to the orthogonal polarization state. The optical energy of rotated polarization is modulated in a fashion reproducing the modulation of the ultrasonic wave by which it is scattered. Furthermore, a short optical pulse can pass through the ultrasonic wave in a time short compared to the duration or length of the ultrasonic wave in the crystalline device. In so doing it reads the modulation of the acoustic pulse and transfers it to a time compressed pulse scale on the scattered optical output pulse. It is shown that the compression ratio is equal to the ratio of the velocity of light divided by the product of the velocity of sound in the crystal times the absolute value of birefringence of the crystal. If both the optical and acoustic pulses are passed through the crystal colinearly and in the same direction, the device takes a time function represented by the acoustic pulse, reverses it in time and compresses it by the ratio of light velocity to sound velocity thus producing a compressed inverse function. If the acoustic pulse and the light pulses are transmitted through the crystal colinearly but in opposite directions, the device takes a time function and without reversing it, compresses it in substantially the same ratio. The device may be applied, for example as a means of improving the signal-to-noise ratio, detection ratio and range resolution in radar systems or the like. [A4111]

"Digital MTI radar"

A digital MTI radar wherein, after an initial period, differences between the composite video signal of a present range sweep and a prediction of the composite video signal of such range sweep are digitized by an analog-to-digital converter. [A4112]

"Method and apparatus for interrogating and identifying fixed or moving targets"

Hijacked vehicles, or the like, are identified by illuminating a transpon mounted to the vehicle by a beam of microwave energy, e.g., from a helicopter flying over the traffic. The transponder includes non-linear diodes which reradiate a signal back towards the helicopter. Means are disclosed for modulating the return signal with a 16-bit identification code, each bit of which is transmitted as a 31-bit pseudo-random code. [A4113]

"Radar detection of turbulence in precipitation"

A technique for processing the IF portion of a radar return signal in order o provide the remote detection and measurement of atmospheric turbulence occurring within precipitation. The technique employs an amplitude limiter, a wideband discriminator and a video amplifier to provide real time measurement of the precipitation velocity. A velocity comparison at various radar ranges is made to provide an indication of the turbulence. The analog circuit employed to make this measurement operates with high speed and is capable of being used with any pulsed (coherent or non-coherent) weather radar. [A4114]

"Real time analog doppler processor for weather radar"

A technique for processing the IF portion of a radar return signal in order o produce a continuous voltage output which voltage is proportional to the instantaneous frequency of the received signal. The technique employs an amplitude limiter and a wideband discriminator comprised of a delay line and phase detector followed by a video amplifier for processing the desired output signal. The output signal is indicative of velocity of precipitation in the radar target range. This information may be employed to detect and measure the degree and intensity of precipitation fall velocities, winds within a storm and other velocity dependent characteristics. [A4115]

"Radio-frequency direction-finding arrangement"

A scanning radio-frequency direction finder which includes two synchronously scanned beams (antenna patterns) having their boresite (symmetry) axes angularly offset by a predetermined amount, either physically or by control of time of operation. A first of the beams is double-lobed with a null at its boresite while the second has its maximum at its boresite. The signals received through each pattern are continuously phase measured and the phase of signals through the second beam is stored when the received signal strength therethrough reaches a predetermined value. The continuously measured first beam signal phase is compared with the aforementioned stored second beam signal phase, the instantaneous scan angle of the first beam at the time of phase equality being taken as the correct angle of the target reflector or source of received signals (target) . The result is much improved angle measurements, especially in elevation at low angles. [A4116]

"Radar speedometer"

The speedometer is for use on a vehicle such as an automobile or train for providing a continuously updated digital reading of vehicle speed and a cumulative digital reading of total mileage traveled. By means of a front end transmitter-receiver antenna arrangement, a signal is provided, the frequency of which corresponds to velocity of the vehicle. This signal is coupled to a novel duty cycle detector which essentially rejects spurious noise signals and passes only signals of a predetermined duty cycle. A true signal is passed to a signal stabilization circuit which is responsive to the frequency of the signal for essentially replacing lost signal pulses. The pulse signal which is representative of vehicle speed is then coupled to both the odometer counter for ultimately providing a reading of mileage traveled and to the speedometer counter for ultimately providing a reading of vehicle speed. [A4117]

"Multiple rate digital command detection system with range clean-up capability"

A multi-rate digital command system is disclosed which uses the composite signal of a .mu.-type ranging system as a subcarrier to transmit range codes and data from a station to a receiver where the range codes are sequentially phase modulated on a subcarrier of frequency f.sub.sc by one of its own subharmonics as follows: and data is phase modulated on a selected ranging component, C.sub.i, where i is a number selected from the sequence 1, 2 . . . n in which the ranging components are transmitted. A range cleanup loop in a spacecraft locks the phase of a locally generated reference component C.sub.i to a received ranging component C.sub.i and retransmits the component to a ground station. When the inverse phase, C.sub.i, of a ranging component is received and detected, the cleanup loop is modified to demodulate phase modulated command symbols while continuing tracking the same ranging component C.sub.i. The command symbol rate is coherently related to the ranging signal component bit rate. [A4118]

"Variable range automotive radar system"

An automotive ranging and detecting system wherein clutter returns from out of lane objects at curves in a road are eliminated by adjusting the maximum range of the radar in accordance with the radius of curvature of the path of travel of the vehicle. BACKGROUND of THE INVENTION 1. Field of the Invention The present invention relates to collision avoidance radars, and more particularly to a ranging and detecting system for an automotive radar. 2. Description of the Prior Art Conventional non-cooperative radar detecting and ranging systems, wherein a probe signal is transmitted towards a target and is "skin"-reflected therefrom back to the interrogating unit, have typically been impractical for utilization as automotive collision avoidance systems due to undesired signals known in the art as "clutter." Clutter returns from extraneous targets such as fixed objects along a roadway or moving vehicles in non-critical spatial relationships to the interrogating vehicle, for example, vehicles in another lane, are not distinguishable from reflections from targets in critical relationship to the interrogating vehicle. Clutter returns thus cause a false alarm problem whereby driver alert indicators, automatic braking, or passenger restraints, such as air bags, may be inopportunely employed. The majority of clutter returns occur when a vehicle is traveling along a curving road and receives returns from vehicles in non-critical adjacent lanes and stationary targets along the shoulder of the road. for a more detailed discussion of such clutter problem, reference is made to Department of Transportation Report DOT HS-801 011 "Analysis of Problems on the Application of Radar Sensors to Automotive Collison Prevention", Wood, Chandler, and Warner, Final Report, December 1973-Contract DOT-HS-314-3-601. To reduce road curve clutter, systems have been proposed wherein the radiation pattern of the radar probe signal is changed in direction in accordance with the position of the steering wheel. However, oversteer or understeer in the steering mechanism make such a system impractical. In addition, even if the probe signal were properly directed, the clutter would not be eliminated, but rather only reduced. Such systems are referred to in the above-mentioned DOT report by Wood, Chandler and Warner. Cooperative systems, wherein the radar is responsive only to specifically tagged targets which tagged targets are capable of generating a reply signal that is in some way distinguishable or discriminated from radar probe signals and from skin reflections, are not subject to clutter. Such a cooperative detecting and ranging system is disclosed in U.S. Pat. No. RE.28,302 to Staras et al., issued Jan. 14, 1975. Cooperative systems, however, do not respond to untagged targets or to targets having inoperative tags. Hence, the efficacy of cooperative systems as automotive detecting and ranging systems is dependent upon acceptance and use of the system by the driving public at large and upon proper maintanance of the tag. The above-mentioned copending application "Dual Mode Automobile Collision Avoidance Radar" by Sterzer and Kaplan, Ser. No. 593,016 describes a dual mode system comprising a continuous wave frequency modulated (FM-CW) radar which responds to reply signals from tagged targets and to skin reflections from proximate untagged targets, reducing thereby the radars sensitivity to clutter. Such a dual mode system, however, is at long ranges responsive to only tagged targets. Accordingly, a non-cooperative radar system wherein clutter returns from targets outside of the lane of travel of the interrogating vehicle are ignored is desirable. SUMMARY of THE INVENTION The present invention provides a vehicular ranging and detecting system wherein the maximum range of the system is altered in accordance with the radius of curvature of the travel of the vehicle to eliminate thereby clutter from out of lane targets. [A4119]

"Simplified digital moving target indicator filter"

A digital filter for generating a frequency domain output signal in response to an incoming signal arriving in successive receiving cycles whenever the incoming signal has any frequency component lying within the passband of the filter. A means for generating a timing signal is provided. An analog-to-digital converter responsive to the timing signal converts the incoming analog signal into a series of digital input pulses during each range gate interval. A reference generator responsive to the timing signal provides a train of digital reference pulses for each of the successive receiving cycles. A predetermined number of successive receiving cycles constitutes a single correlation frame. The amplitude of each train of digital reference pulses is determined by a composite correlation function. A multiplier multiplies each digital reference pulse with each digital input pulse to generate a train of discrete digital output pulses for each receiving cycle. An accumulator stores the discrete digital output pulses from the multiplier and generates a frequency domain output signal for each frame of reference pulses. The digital filter can also be constructed with either a two-channel or four-channel processor to provide a more sophisticated filter system. [A4120]

"Systems for the detection of moving objects within a survey area by microwave diffraction"

A microwave transmitter and receiver are placed at a distance from each other to define between them a survey area in which the field of transmission is modified by reflection and/or absorption by objects in the survey area. A modulation generator is used for controlling modulation in the transmitter and for controlling the cycling period of a commutative filter in the receiver in accordance with the modulation period, thereby automatically tuning the receiver to the transmitter. The receiver further comprises an alarm unit which analyses the signal admitted through the commutative filter and strikes an alarm in response to such changes of that signal as are caused by the presence of moving objects in the survey area. [A4121]

"Marine radar transmission and reception system"

A marine radar transmission and reception system in which first and second transmission pulse radar waves are emitted as first and second pulse radar waves from first and second radar antennae or a common radar antenna, reflected waves of the first and second emitted pulse radar waves are received as first and second received pulse radar waves by the first and second radar antennae or the common radar antenna, the modes of the first and second transmission pulse radar waves are selected in cooperation with those of the first and second radar antennae or that of the common radar antenna so that the first and second received pulse radar waves may be received by the first and second radar antennae or the common radar antenna independently of each other, a quotient or difference output corresponding to the quotient or difference of the first and second received pulse radar waves or the first and second received outputs based thereon is obtained, and sea clutter eliminated received pulse radar waves or outputs based thereon that signal components of the period--in which the quotient or difference output exceeds one predetermined threshold value or lies between two threshold values--are eliminated or suppressed, are obtained. [A4122]

"Correlator to reduce bin straddle in a collision avoidance system"

In a cooperative collision avoidance system the detected reply signals to interrogation probe signals are correlated by a digital circuit that processes all the reply signals identifying targets over non-targets ("fruit") . The correlator is capable of detecting all targets in any desired range during a given correlation period and is provided with means to reduce the effect of bridging or straddling adjacent bins in the correlator to minimize thereby the duplication of detected replies which would overload the following processor and cause loss of desired replies. [A4123]

"Signal processing in short-pulse geophysical radar system"

Signal processing techniques and apparatus for use in short-pulse geophysical radar systems to improve signal-to-noise ratio, reduce r.f. interference, improve resolution and reduce ambiguities. [A4124]

"Underground, time domain, electromagnetic reflectometry for digging apparatus"

An apparatus for detecting the presence of a buried, hidden object in the vicinity of a digging tool in order to prevent a human disaster and damage to utility lines or other buried structures. The apparatus includes an impulse generator and data processing means connected to a slot antenna formed in the tool of an earthmoving machine for radiating a burst of broad spectrum electromagnetic energy into the ground and for receiving and data processing reflected electromagnetic echoes. One antenna embodying the invention comprises a slot formed through a wall of a hydraulically driven shovel and filled with a ceramic absorber. The slot has four radially extending, orthogonally arranged loops having unclosed central portions of the loops joined end to end to form four apexes. [A4125]

"Pulse coherent transponder with precision frequency offset"

A radar reply transponder for use with existing radar tracking systems wherein a reply pulse is generated and trasmitted in response to an associated interrogation pulse. The reply pulse is delayed in time and offset in frequency by a precise amount with respect to the interrogation pulse, but it is nevertheless phase coherent therewith so as to preserve the required Doppler frequency information and thereby permit accurate velocity measurements. Phase coherence is effectively maintained by utilizing a single continuously operating local oscillator for down-converting the received interrogation pulse to an intermediate frequency as well as up-converting the signal information to provide the delayed and frequency offset reply pulse. The precision frequency offset is obtained by switching in an additional reactance element in the oscillator-determining circuitry during the time up-converting is being effected. The radar transponder may thus be used in a high-vibration environment with no substantial introduction of error in velocity measurements caused by using two independent oscillators to formulate the frequency offset. [A4126]

"Frequency spectrum analyzer"

A frequency spectrum analyzer adapted for use in a real time signal processing radar system is disclosed. In such system a plurality of sets of radar returns, each one of such sets corresponding to radar returns from objects disposed in each one of a like plurality of range cells, is stored in a time compressor section, the radar returns in each one of the sets thereof being stored at the pulse repetition frequency (PRF) of such radar system. After storage of such radar returns, a like plurality of chirp pulses is produced, each one of such pulses having a dispersive time K.tau.. Synchronously with each one of the chirp pulses, one of the plurality of sets of stored radar returns is retrieved from the time compressor section, in a time duration equal to K.tau.. Each one of the retrieved sets of radar returns is mixed with a corresponding one of the plurality of chirp pulses to produce a series of mixed signals which is coupled to a pulse compressor. Each one of the mixed signals is compressed into a pulse occurring at a time related to the Doppler frequency of any object in the range cell producing such associated radar returns. The time compressor section is used prior to pulse compression to effectively "match" the radar dwell time, generally several milliseconds in duration, to the dispersive time of the chirp pulse, generally several microseconds in duration, thereby enabling the pulse compressor to include a practical surface acoustic wave (SAW) delay line. Further, the "compressive" bandwidth, .beta., of the pulse compressor is equal to, or greater than, the dispersive bandwidth of the chirp pulses, thereby to maximize the power in the compressed pulses. Means are provided to adjust the dispersive time of the chirp pulse, thereby to correspondingly adjust the effective number of frequency resolution cells of the frequency spectrum analyzer. [A4127]

"Mine detector system"

A mine detector system that utilizes an explosive comparator to increase sensitivity and selectivity. The system utilizes a generator to transmit a signal simultaneously toward the area to be scanned for mines and towards a sample of the explosive sought. Detectors are positioned within the device to receive the reflected signals from both the area to be scanned and the sample explosive. The outputs from both detectors are fed to preferably a null type comparator for correlation. When the two signals correlate, mine presence is indicated. [A4128]

"Target adaptive radar system"

A radar system transmitting a signal of given carrier frequency which is quency modulated at a given rate and wherein the nature of the target return is utilized to eliminate sea and ground clutter. The reflected signal from a hard target has a unique modulation imposed on it by the interference of the incident and reflected waves and this unique modulation is converted to the modulated voltage thereby permitting the use of a video amplifier having a narrow bandwidth. [A4129]

"Digital prefilter for clutter attenuation in MTI radars"

In a digital moving target indicator (MTI) employing digital filters for rejecting low frequency clutter signals having magnitudes which are 20 to 60 db greater than the moving target return signal, the dynamic range and resolution accuracy requirement of an analog-to-digital (A/D) converter, used to convert the return radar analog video signal to a plurality of digital signal equivalents for presentation to the digital filters, is reduced from that normally required by prefiltering the return video signal through a prefilter network. The digital prefilter utilizes: a low resolution accuracy (low order bit capacity) analog-to-digital (A/D) converter to convert the return analog video signal (comprising both low frequency clutter and high frequency moving target component signals) to a digital signal, a low-pass digital filter to pass only the low frequency clutter signal, a digital-to-analog converter to reconvert the digital clutter signal to an analog clutter signal which is substantially equivalent to the clutter component signal value of the analog video signal, and a summing circuit which provides an analog sum signal representative of the amplitude difference between the analog clutter signal and the return analog video signal, to provide a video signal with a greatly enhanced moving target to clutter signal ratio. The sum signal is presented to the system A/D converter, permitting the use of a low resolution system A/D converter having a substantially reduced dynamic range and lower cost, the system A/D converter providing the digital equivalent signal of the enhanced return video for further processing in the digital MTI filters. [A4130]

"Full range correlator for use in a collision avoidance system"

In a cooperative collision avoidance system, the reply signals to interrogation probe signals are correlated by a digital circuit that processes all the reply signals identifying targets over non-targets or "fruit." The correlator is capable of detecting all targets in any desired range during a given correlation period. [A4131]

"Pulse radar apparatus"

Pulse radar apparatus provided with a control circuit comprising at least an error voltage generator, a dither-tuned magnetron and a servo unit driving this magnetron, and also with a conditional circuit and an angular position indicator connected to the servo motor shaft for tuning the magnetron frequency f.sub.z to a frequency f.sub.zo, showing a fixed difference f.sub.o with the local frequency f.sub.lo, where f.sub.o = f.sub.zo - f.sub.lo. When, by means of the indicator, the conditional circuit determines that the magnetron is being tuned in a defined frequency range comprising the frequency f.sub.zo, the auxiliary voltage (V.sub.1) , used to coarse tune to frequency f.sub.zo is replaced by a fine tuning error voltage proportional to .vertline.f.sub.z - f.sub.lo .vertline. - .vertline.f.sub.o .vertline.. This error voltage is delivered by the generator supplied with the local oscillator signal and a sample of the magnetron pulse. [A4132]

"Electronic license plate for motor vehicles"

An electronic license tag or plate formed into a unitary structure and including a single antenna system cooperating in a system comprising a harmonic radiator which transmits a pulse coded identification signal in response to an interrogation signal, and in a signal communication path for detecting and decoding code modulations in the interrogation signal and deriving therefrom an information signal which is communicated to the operator of a vehicle to which the tag or plate is affixed. [A4133]

"Four beam printed antenna for Doopler application"

A novel approach for generating four symmetrically located beams from a printed antenna using a corporate feed system is described. One approach used to generate four low side lobe beams utilizes a planar aperture. The second approach generates four low side lobe beams from a cylindrically shaped aperture. The generation is accomplished without the use of active phase shifting devices. The output phase function of the feed can be reversed which causes the beam to be pointed equally in the opposite direction. The radiating elements are designed to be symmetrical about the center of the aperture in a direction orthogonal to the radiating elements. By placing identical feeds at both ends, four beams can be obtained, each pointed in a direction symmetrically located about the normal to the antenna. Such an approach is applicable to both planar arrays and cylindrically shaped arrays. [A4134]

"Semipassive responder utilizing a low voltage, low power drain reflective varactor phase modulator"

A semipassive responder for use in a communication system wherein an interrogating unit transmits an interrogation signal to illuminate the responder. The responder generates, in response to incident interrogation signals, a phase-coded reply signal, utilizing a low voltage, low power-drain reflective varactor phase modulator. [A4135]

"Pulse doppler proximity fuze"

1. An oscillator-detector circuit comprising operating potential energy rces, first self pulsing circuit means intermittently oscillatory for developing high frequency electromagnetic energy pulses of a preselected carrier frequency and repetition rate, electromagnetic energy radiating means electrically coupled to said first circuit for effecting radiation of said developed pulses into space and for receiving any reflected electromagnetic pulses, and a second oscillatory circuit means inductively coupled to said first circuit means and being rendered intermittently oscillatory during the occurrence of said developed pulses for selectively detecting variations in the magnitudes of said developed pulses caused by said reflected pulses and for developing an output signal having a frequency correlative to said variations, said first and second oscillatory circuits being parallel connected across said energy sources. [A4136]

"Doppler radar"

A Doppler radar for use in a vehicle for predicting a collision with another vehicle, capable of detecting noise due to a false wave i.e., the transmitted wave from another vehicle having a frequency in the vicinity of the true transmitted wave frequency and having entered through a receiver antenna into a mixer, and controlling the frequency of the true transmitted wave to depress said noise to zero, thereby avoiding the interference of the false wave with the Doppler signal output. [A4137]

"Optical tracking analog flywheel"

An optical tracking system wherein an analog computer program is operated multaneously with a real projectile firing. The program is forced to match its output of projectile position with real-time data. When no data is available, the analog program acts as a very sophisticated flywheel to keep optical tracking mounts continuously positioned very closely to the actual target position until it can be reacquired. [A4138]

"MTI canceller utilizing fiber optic delay medium and frequency reiteration"

A pulse cancellation system, particularly adapted to moving target indicator (radar) stationary signal cancelling equipment. A cancelling circuit which is basically a signal differencing device compares the signal train within a given scan cycle with that of the previous cycle by delaying the signals of said previous cycle in order to bring them into time coincidence in the canceller circuit. Delay is achieved in a stable electro-optical device by modulating a light source, preferably a laser beam, in accordance with the signal train to be delayed. Signals are passed through a fused silica fiber optic cable, detected at the other end of the cable, remodulated onto a source of a different optical frequency (color) and retransmitted back over the same fiber optic delay means. Several such reiterations can be effected to reduce the amount of delay required in the fiber optic cable. After the last such reiteration the final color transmission is detected and sent to the canceller to be subtracted from signals provided to the canceller directly from the MTI radar receiver output (undelayed) . [A4139]

"Pseudo pulse doppler radar"

An amplitude monopulse radar, in which quadrature sum and difference signals are processed in order to determine the magnitude and direction of antenna tracking angle error, utilizes coherent detection which clutter reference for moving target indication (MTI) operation. In the absence of clutter, point targets (both fixed and moving) are detected on a per-pulse coherent basis (as between the sum and difference, in phase and quadrature signal channels) using as a reference either signal channel noise or an oscillator nominally at the IF frequency. Both modes of operation are accommodated by using bandpass doppler filters which are convertible to low pass filters in order to permit zero-doppler signals relating to point targets to pass in the absence of clutter, the filter mode being selected by a point target discriminator which senses the presence of clutter in range bins straddling the signal range bin. The dual mode filter may consist of a high frequency, low pass filter and a low frequency, low pass filter, the presence of clutter causing the low frequency characteristic to be subtracted from the high frequency characteristic so as to form a bandpass filter. [A4140]

"3-Channel selectable polarization, target discrimination antenna"

A monopulse radar antenna having an improved three-channel feedhorn for piding selectable polarization and greater target discrimination. The antenna feed employs a comparator having a difference port, a first sum port, and a second sum port utilizing a coupling pin or probe therein, between the comparator ports and an adjustable polarization device, for receiving and separating returned energy which has become cross-polarized with respect to the polarization of the transmitting sum arm, by reflection from an asymmetrical target. The three-channel feedhorn makes possible the identification of different types of targets, and the detection of hidden targets in rough terrain, forests, underbrush, and rough seas. [A4141]

"Digital MTI radar system"

A digital MTI radar system is disclosed which is adapted to reject moving clutter returns and to pass, for detection and display, returns from moving targets. The radar system includes means for producing a series of complex digital words representative of the average moving clutter Doppler velocity at each one of a series of range cells. A canceller network is provided to modify the returns from a range sweep with the complex digital words and to combine such modified returns with the returns of a successive range sweep, thereby to effectuate the desired moving clutter rejection. [A4142]

"Communication apparatus for communicating between a first and a second object"

An improved communication apparatus for communicating between a first object and a second object wherein the first object includes apparatus for generating and transmitting a transmit signal and the second object includes apparatus for receiving the transmit signal and providing an emitted signal in response thereto, the emitted signal having a frequency coherently related to the frequency of the received transmit signal. The second object also includes an apparatus for encoding an identifying code having a unique code format wherein the beginning and the end of the code format are identifiable, the first object including apparatus for receiving the encoded emitted signal, identifying the code format encoded therein and determining the received emitted signal represents a valid code format. In one aspect, the first object apparatus receives encoded emitted signals via two receivers, identifies the code format encoded in the first-received and the second-received encoded emitted signals, determines that each received signal has a valid format encoded therein and compares the code formats encoded in the first-received and the second-received emitted signals to determine the signals were emitted via the same second object. In one operational embodiment, the communication apparatus transmits a transmit signal and receives encoded emitted signals from a moving second object in response to the received transmit signal at a first position and a second position of the second object, the first and the second received encoded emitted signals being determined to represent a valid predetermined code format and it being determined that the received code formats are identical, the speed and direction of the moving object being determined in response to such valid determinations, the code format encoded in the received emitted signals being compared with predetermined identification code formats for locating predetermined second objects. The first object apparatus also generates and transmits a modulation signal, the second object apparatus including apparatus for detecting the modulation signal via a pulse width detector and providing an output indication in response thereto. In one particular operational embodiment, the first object apparatus is utilized to detect and monitor vehicle traffic, each vehicle (second object) having apparatus for receiving the transmit signal and providing the encoded emitted signal in response thereto, and for receiving the modulation signal and providing a driver-perceivable output indication in response thereto. [A4143]

"Relative distance indicating speedometer for a vehicle"

There is provided a relative distance indicating speedometer for a vehicle comprising relative distance detecting means for measuring the relative distance of a vehicle carrying the speedometer with respect to an object such as the vehicle in front, and relative distance indicating means for indicating the measured relative distance in accordance with the output signal of the relative distance detecting means. The relative distance indicating means are arranged in the speedometer which indicates the speed of the vehicle, and therefore the apparatus of this invention is inexpensive to manufacture and simple in construction. [A4144]

"Homodyne communication system"

A homodyne communication system comprising an interrogating unit and a plurality of responsive remote units wherein a continuous wave RF signal is transmitted from the interrogating unit to illuminate a remote unit. The remote unit causes a return (reply) signal to be transmitted or reflected back to the interrogating unit. A sample of the transmitted (interrogation) signal is mixed with the return signal. Amplitude nulls in the mixer output signal at given relative phase relationships between interrogation and reply signals, are substantially eliminated by selectively shifting the relative phase of the signals. Also disclosed are a homodyne communication system utilizing phase modulation to impress FSK signaling on the reply signal and an automatic vehicle location system utilizing the present invention. [A4145]

"Moving target indicating (MTI) radar systems employing vehicle discriminator apparatus"

There is disclosed a radar system of the type employing a receiver capable f responding to a signal reflected from a moving target, which signal includes a doppler frequency component indicative of target motion. Included therewith are means for responding to an even harmonic component of said returned signal to provide an indication of the magnitude of the same, the magnitude of said even harmonic component indicative of the nature of said vehicle, as, for example, whether said vehicle is a tracked type (tank) or a wheeled type (automobile) . [A4146]

"Device for transmission of information from an information emitter to an information seeker"

A device for automatic transmission of information includes an information emitter and an information seeker wherein the information is transmitted from the emitter to the seeker in response to an interrogating signal from the information seeker. The emitter relies for transmission on energy which is extracted from the interrogating signal. The emitter is provided with several resonant circuits, each of which generates an information signal component. The information carrying signal comprises a multitude of such signal components. From the information carrying signal the information is captured by detection in the information seeker of the respective information signal components. [A4147]

"Object identification system using an RF roll-call technique"

An object identification system using an RF roll-call technique wherein an interrogator illuminates a multitude of cooperating objects with a sequence of codes and receives from each such cooperating object an acknowledge signal immediately following the transmission of the code associated with that object and which terminates prior to completion of transmission of the next code in the sequence. [A4148]

"Navigational and collision avoidance apparatus"

Marine surface radar processing equipment provides digitized target range pulses at a plurality of ranges, and includes target evaluation apparatus that comprises target leading edge signal means providing a target leading edge signal pulse at successive azimuths, and target trailing edge signal means providing a target trailing edge signal pulse at successive azimuths and initially separated in range from the target leading edge signal. The edge signal pulses describe a target envelope. The coincidence in range of a leading edge signal pulse and a trailing edge signal pulse provides a target envelope end recognition signal. The target evaluation apparatus further comprises discriminating means responsive to a maximum number of target leading edge signal pulses at successive azimuth intervals. The maximum number decreases at successively increasing ranges. The discriminating means discriminates between landmass targets of greater than a predetermined actual length in azimuth representing a maximum ship length, and possible ship targets of less than the predetermined actual length in azimuth. The discriminating means provides a discriminated target output signal responsive to possible ship targets of less than the predetermined length for display of ship targets with their speed and course vectors. [A4149]

"Pulse-type radar with modulated carrier frequency"

A radar system emitting a recurrent sequence of n equispaced bursts of carrier frequency, varying from one burst to the next, has a transmitter including a carrier-frequency generator with a frequency-varying motor driven by a synchronizing circuit to produce a repetitive frequency pattern recurring a whole number of times in a program cycle of n pulse periods. An associated receiver includes a local oscillator whose frequency is incremented, from one pulse period to the next, by a feedback circuit comprising a modulator with inputs connected to the output of this oscillator and to a coupler picking up the instantaneous carrier frequency from the transmitter output, this modulator works into a frequency discriminator, tuned to a predetermined intermediate frequency, returning an error signal to a control input of the oscillator via a multiple integrator concurrently storing all the error signals for the several pulse periods, an adder superposes these error signals upon a monitoring signal extracted at the beginning of each pulse period from the carrier-frequency generator. The multiple integrator includes an operational amplifier with n parallel capacitors in respective feedback paths which are normally open-circuited and are sequentially connected in circuit under the control of a shift register restarted at the beginning of each program cycle. A similar multiple integrator may be inserted in an automatic-gain-control circuit for an intermediate-frequency amplifier in the output of a mixer which heterodynes the received echoes with the local-oscillator output. [A4150]

"Range readout apparatus"

A range measurement system wherein range accuracies of fractions of a meter may be obtained. Nanosecond pulses, one triggered by the transmitter trigger with an appropriate delay and the other triggered by a received echo pulse, are launched from opposite ends of a transmission line. The location on the transmission line at which the two short pulses coalesce and the delay time of the transmitter triggered short pulse establish the range to the echoing object to an accuracy determined by the short pulse, pulse width. [A4151]

"Anti-collision vehicular radar system"

A radar system mounted on a vehicle and having an RF signal transmitted preferably in a confined beam in front of the vehicle and reflected from obstacles in the path of the beam to be reflected back to the vehicle. The system includes an asymmetrical magic tee which receives both the transmitted and received signals and provides a pair of Doppler frequency signals whose relative phase relationship determines whether the signal is an opening or closing Doppler signal. The signal employs a diplex Doppler detection scheme for providing both range and rate data. Under an imminent collision situation the system provides control signals to power means for pulsating the brakes of the vehicle to thereby avoid a collision. To minimize false target detections and to provide target discrimination, there is provided in this system both a range gated circuit for detecting normal closing rates and an amplitude gated circuit that is operable primarily for detecting fast closing rates such as may occur when a vehicle is stopped in the roadway. A ground speed detector is provided and has an output analog voltage which is usable as a gain control voltage for the range and amplitude gated circuits. The system is also provided with means for inhibiting braking action below a predetermined vehicle speed for use in slow traffic, and means for altering the braking action at speeds above a predetermined speed such as on the order of 35 MPH. [A4152]

"Velocity sensing apparatus"

Velocity sensing apparatus which permits measuring the velocity magnitude and sense of direction using the single radiating antenna illuminating a spot on the ground from which power is back-scattered to three receiving antennas. The receiving antenna outputs are grouped into pairs and processing of the signals done to obtain direct sum and quadrature sum waveforms with the point of crossing of the spectrum of the direct sum and quadrature sum waveform indicating the magnitude of velocity and the sign of the slope of the spectrum of the quadrature sum waveform determining the direction of the velocity. [A4153]

"Weather radar transistorized pulse modulator"

A transistorized active switch radar pulse modulator has a unique means for pulse current control which includes a transformer interconnected with a magnetron. Transistor switches and related circuitry pulse a step up transformer with voltage pulses to drive the magnetron with a desired current pulse having the appropriate shape and width. A capacitor in the secondary of the transformer acts as a load to the transformer prior to the conduction level of the magnetron so that no current transients occur after the magnetron fires. Suitable protective features operate to sense an arcing condition and to dissipate the arcing effects. A unique slope control circuit insures that the requisite flat current pulse drives the magnetron. [A4154]

"Hydraulic brake system with automatic brake means for vehicles"

A hydraulic brake system for an automobile comprises an automatic brake valve disposed in a fluid passage between a pump and a reservoir. The automatic brake valve is actuated by an obstacle-sensing computer to increase the fluid pressure in the fluid passage irrespective of foot brake pedal depression. Therefore, the brake may be applied even when the automobile driver should be unaware of an obstacle on the road. [A4155]

"Adaptive clutter velocity cancellation system for pulsed digital MTI system"

A digital MTI radar system for improved handling of "moving clutter" which employs a double phase detector scheme to provide both Doppler sine and Doppler cosine terms which are separately digitally encoded in a series of range increments throughout each pulse repetition interval. The discrete digitally encoded values thus represent instantaneous echo signal phase angle in each corresponding range increment. This angle data is compared by range increments with that of the last previous pulse repetition period, to provide net signal phase angle change in digital form (a velocity related term) by range increments successively. The remaining circuitry comprises a device for sampling this net phase angle change over a predetermined number of range increments to compute average clutter velocity with respect to the radar system location. A bona fide signal in the moving clutter may then be recognized on the basis of its exceeding the average clutter velocity. A quantized output is effected by means of a logic arrangement which detects the condition of signal presence in one or two adjacent ones of the range increments provided these increments are preceded and followed by a predetermined relatively small number of range increments exhibiting no signal above the said average clutter velocity. [A4156]

"High capacity recirculating delay loop integrator"

A system for integrating recurring pulses. A pulse compression system. A delay network for recirculating the input pulses. The system output is a pulse which substantially equals the sum of input pulses. [A4157]

"Marine traffic conflict assessment system"

The invention is a radar harbor surveillance sensor, computer, and display system for providing a graphic display of vessels negotiating confined navigation channels and permitting rapid and accurate assessment of the degree of hazard or safety in the movements of the monitored vessels. [A4158]

"Radar MTI processor with CFAR"

Disclosed is a radar signal processor providing Moving Target Indicator (MTI) operation with Constant False Alarm Ratio (CFAR) capability. The processor affords substantially reduced incidence of false alarms due to large clutter scatterer returns which exceed normal detection thresholds even after suppression by conventional MTI processing, and at the same time it affords largely unimpaired subclutter visibility. These capabilities are achieved by paralleling the MTI channel with a second processor channel which provides CFAR operation by imposing an additional detection threshold effective to blank the response of the MTI channel to very large clutter scatterers. [A4159]

"Large area motion sensor"

An intrusion detector operating with electromagnetic sensors to detect intruder motion within large, defined areas is disclosed. The system provides an acceptably low false alarm rate by means of range discrimination whereby moving objects outside the protected area do not affect the system and by improving sensitivity to slow-moving targets even when located very close to the sensor location. The system incorporates a transmitter which is frequency modulated by a triangular or sawtooth wave and a receiver which produces an output signal that varies in accordance with the instantaneous difference between the transmitted and received frequencies. The frequency of this difference signal is the beat frequency, and is proportional to the range of the target. Storage means are provided to permit comparison of successively received signals over a predetermined period of time, and this comparison serves to reveal slowly varying changes in the return signal pattern. Alarm means are provided which respond to significant variations in successive measurements, and when a threshold level of difference is exceeded for a certain number of consecutive sweeps, an alarm is sounded. [A4160]

"Underground pipe detector"

An apparatus and method wherein an electrical impulse source transmits a radar-type signal through an antenna into the ground and is reflected by a target. The reflected signal or echo is detected by the antenna and an analog-to-digital converter converts it to a digital form which may be readily operated on, stored and recalled. A memory stores the information until recalled for comparison with a subsequent signal. A processing means compares the stored and subsequent signal to give an indication of the location of metallic and non-metallic buried targets. [A4161]

"Switchable beamwidth monopulse method and system"

In a switchable beamwidth monopulse method and system, an antenna comprising a curved reflector and a first set of monopulse feeds positioned in the effective region of the Airy disc of the antenna includes a second set of monopulse feeds. The second set of monopulse feeds is positioned outside the Airy disc in the region of first bright Airy ring. In narrow beamwidth monopulse operation, monopulse sum and difference channel patterns are obtained from the first set of feeds within the Airy disc. In wide beamwidth monopulse operation, the difference channel pattern is obtained from the second set of feeds in the Airy ring, the sum channel pattern is obtained by attenuation and phase shifting the sum channel signal obtained from the first set of feeds, and adding the resultant to the sum channel signal obtained from the second set of feeds. In a simplified form of the invention, the difference channel patterns for both narrow and wide beamwidth mode operation are obtained from the second set of feeds, while the sum channel patterns are obtained as described above. [A4162]

"Moving target indicator clutter tracker"

An improved MTI (Moving Target Indicator) cancelling system that provides cancellation in the first canceller stage of clutter at a first frequency and cancellation in a second or subsequent canceller stage of clutter such as weather or chaff with a substantial doppler frequency offset from that cancelled in the first MTI canceller. The first canceller stage may be a conventional in-phase (I) and in-quadrature (Q) digital MTI unit to develop the I and Q first differences followed by a conversion of these differences into a combined first difference designated as a quantity M and representing an angle times an amplitude multiplier. This M signal is then applied to a second canceller to develop a second difference signal which is then normalized to represent a pure angle term. A computer then determines the average angular error percentage over a selected number of adjacent range bins at each range bin interval and this percent error is then multiplied by the time aligned value of M to provide an actual error and a modified value of M is developed by subtracting the actual error from the value of M. The modified first difference signal is then subtracted from the delayed first difference signal to generate a second difference output signal with the undesired clutter at different doppler frequencies being cancelled. [A4163]

"Proximity indication with means for computing the distance from an own station to an interrogating secondary surveillance radar"

A method and apparatus for determining the distance to a secondary surveillance radar (SSR) station from an own transponder station when another transponder station lies within a monitored region surrounding the own station. The distance information is utilized to modify the operating mode of a proximity indicating system at the own station. [A4164]

"Marine radar transmission and reception system"

A marine radar transmission and reception system in which first and second transmission pulse radar waves are emitted as first and second pulse radar waves from first and second radar antennae or a common radar antenna, reflected waves of the first and second emitted pulse radar waves are received as first and second received pulse radar waves by the first and second radar antennae or the common radar antenna, the modes of the first and second transmission pulse radar waves are selected in cooperation with those of the first and second radar antennae or that of the common radar antenna so that the first and second received pulse radar waves may be received by the first and second radar antennae or the common radar antenna independently of each other, a quotient or difference output corresponding to the quotient or difference of the first and second received pulse radar waves or the first and second received outputs based thereon is obtained, and sea clutter eliminated received pulse radar waves or outputs based thereon that signal components of the period--in which the quotient or difference output exceeds one predetermined threshold value or lies between two threshold values--are eliminated or suppressed, are obtained. [A4165]

"Fixed beam radar with dual range light display providing both range and azimuth information"

A radar principally for use on small vehicles such as sailboats, utilizing a fixed antenna which provides a continuous forward looking beam and has a dual range display providing range and limited azimuth information. Separate antenna elements are utilized to receive echoes in the paths of left and right radar beams respectively, these left and right beams being slightly to the left and right of the boresight of the radar antenna. Utilizing digital techniques, the video representing radar echoes received in the left and right beams is gated in proper time sequence corresponding to target range, to a series of indicator lights for left and right range display respectively. These indicator lights each represent a different target range and are excited in accordance with video signals received in the left and right beams respectively. The indicator lights vary in their intensity so as to indicate whether targets are to the left or right of the antenna boresight and thus to the left or right of the heading of the vehicle. The indicator lights thus indicate both the range and relative azimuth of targets ahead of the boat. [A4166]

"Marine radar transmission and reception system"

A marine radar transmission and reception system in which first and second transmission pulse radar waves are emitted as first and second pulse radar waves from first and second radar antennae or a common radar antenna, reflected waves of the first and second emitted pulse radar waves are received as first and second received pulse radar waves by the first and second radar antennae or the common radar antenna, the modes of the first and second transmission pulse radar waves are selected in cooperation with those of the first and second radar antennae or that of the common radar antenna so that the first and second received pulse radar waves may be received by the first and second radar antennae or the common radar antenna independently of each other, a quotient or difference output corresponding to the quotient or difference of the first and second received pulse radar waves or the first and second received outputs based thereon is obtained, and sea clutter eliminated received pulse radar waves or outputs based thereon that signal components of the period--in which the quotient or difference output exceeds one predetermined threshold value or lies between two threshold values--are eliminated or suppressed, are obtained. [A4167]

"Tracking system utilizing Kalman filter concepts"

A monopulse radar tracking system is disclosed employing four tracking channels, one for each of range, velocity, azimuth and elevation. The two angle channels are referenced directly to antenna coordinates. Each channel is mechanized by a stored program in a digital computer, and the mechanization employs Kalman filtering with gain factors continually optimized for measured signal-to-noise ratios. Angular rate commands for the antennas are obtained by passing pointing error estimates from the angle channels through a compensator for antenna motion and adding line-of-sight rate estimates from the angle filter channels. Cross-coupling between channels is provided, and each channel is aided by outputs from an inertial navigation platform. Preaveraging of discriminants received between computational cycles is provided. [A4168]

"Doppler radar for forecasting collision"

A Doppler radar for forecasting collision, in which three consecutive Doppler signals are obtained by radiating microwave forwardly from the front of a car, the frequency of the microwave being consecutively switched in three steps at a constant interval, and combining the aforesaid microwave and reflected microwave reflected from an object for obtaining intelligence about the distance of the object from the car front, residual time left for the object to reach the car front as well as forecasting collision or non-collision from two of the three Doppler signals and obtaining intelligence about the sense of relative velocity of the object relative to the car front from the remaining Doppler signal and one of the aforesaid two Doppler signals. [A4169]

"Synchronous detector with pulse repetition frequency modulation"

A moving target indicating radar that includes a coherent on receive system and a clutter referenced velocity compensator operating in association with a linear predictor to produce coherent IF (intermediate frequency) receive signals shifted in frequency to compensate for the radar platform's motion. A synchronous detector, with pulse repetition frequency modulation, translates the coherent IF received signals to video signals at a desired frequency offset. A storage processor processes and range gates the video signals prior to doppler filtering and displaying the signals as a representation of moving targets. [A4170]

"Digital adaptive speed control for vehicles"

A sensor, such as a radar, is mounted on a moving vehicle equipped with a speed control system which normally maintains the vehicle speed constant at a pre-set speed in the absence of a preceding vehicle within a safe distance. The sensor detects the presence of a preceding vehicle and measures the distance and closing speed of the controlled vehicle with respect to the preceding vehicle, and generates an adaptive speed signal. The adaptive speed signal modifies the error signal of the speed control system which controls either the throttle or brake to cause the controlled vehicle to match its speed to the speed of the preceding vehicle, and to maintain a safe distance from it, thereby making the adaptive speed signal vanish. The error signal may be modified by the adaptive speed signal either by decreasing the desired speed or by increasing the actual speed. The desired, actual, and adaptive speeds may all be represented by digital numbers. [A4171]

"Temperature compensated acoustic surface wave device"

A temperature compensated acoustic surface wave device, such as a surface wave delay line is provided in which temperature compensation is provided by the deposition of an interdigital electrode structure on a substrate with an overlay film surface of piezoelectric material of a predetermined thickness. A double substrate arrangement is also disclosed in which the interdigital electrode structure is deposited upon the surface of a non-piezo-electric layer which in turn is placed upon the surface of a piezoelectric substrate. [A4172]

"Fixed beam radar with range light display"

A radar principally for use on small vehicles such as sail boats, utilizing a fixed antenna which provides a continuously forward looking beam and which provides a range display only. Utilizing digital techniques, the video representing radar echoes is gated in proper time sequence corresponding to target range to a series of indicator lights. These indicator lights each represent a different target range, and thus provide a display indicating the range at which various targets forward of the vehicle are located. [A4173]

"System for and method of analyzing electromagnetic waves"

A high-frequency wave, e.g. from a target reflecting transmitted radar signals, arrives with different phasing at a plurality of spaced-apart receivers or at a single receiver movable with reference to the signal source. The wave components thus received are fed directly to an array of electromechanical input transducers on the entrance side of a piezoelectric crystal, or are transmitted to respective storage elements which temporarily register information of their phasing to modulate a local oscillation delivered to these input transducers, whereby micro-acoustic vibrations are generated in the crystal with a phase relationship corresponding to that of the original wave components. The acoustic waves in the crystal converge, possibly with the aid of an internal or external focusing surface, on the exit side of the crystal to excite one of a multiplicity of mechanoelectrical output transducers producing a signal indicative of that phase relationship. The system can be used to measure angle of incidence, relative radial velocity, source distance, or the harmonics content of the wave to be analyzed. [A4174]

"Combined contiguous filter and acceleration and velocity analyzer for radar"

A single filter to replace a set of parallel filters in an O-T-H radar coising a prelimiting filter connected to amplifying and limiting means and quenching means for shorting out said prelimiting filter at appropriate times. The prelimiting filter is connected to receive the output of the mixer of one range bin of the velocity-and-acceleration analyzer of the radar and the predetection filter of the analyzer receives the output of the amplifying and limiting means. The quenching means also receives the output of the amplifying and limiting means and provides a quenching signal to the predetection filter. [A4175]

"Method and apparatus for digitally measuring speed"

A digital display doppler radar unit has a moving mode and a stationary mode. The incoming doppler signal, which in the moving mode, represents both speed of the radar platform and speed of an approaching target vehicle, is separated into two signal components by selective filtering. One component represents the sum of the ground speeds for the radar platform and approaching vehicles. A time base is generated by a crystal control means and the time base is utilized for correlating the received doppler signals, indicative of speed, with the time base. Each doppler signal component is converted to binary coded decimal (BCD) information and a digital counter counts the cycles of each reeived doppler signal and compares the count with an amount previously stored. Circuit means are provided to validate the received doppler signal, allowing their continual processing only after a preselected number of valid comparisons are made. The radar signal component representing the ground speed sum for the radar platform and the approaching target vehicle, and the component representing radar platform speed are combined. The radar platform speed is subtracted from the combined component, resulting in a digital count representing approaching target vehicle speed. In the stationary mode, there is no radar platform doppler pulses in the radar return and consequently, the returning pulses may be processed directly and no subtracting function is performed. Speeds corresponding to the valid received doppler signals are suitably displayed to indicate a speeding violation. [A4176]

"Plural channel filter"

A signal processing arrangement which discriminates against large-amplitude nterference signals and in favor of information signals. Incoming signals are separated into a plurality of contiguous frequency channels whose total frequency coverage is the frequency band of interest. The signals in the individual channels are then amplitude limited so that relatively narrow band interference signals are limited while a wide band desired signal is not. The desired signal is then spectrally compressed to obtain a high amplitude signal while the remaining interference signals are spread and rejected. [A4177]

"System for resolving velocity ambiguity in pulse-doppler radar"

A pulse-doppler radar tracking system is disclosed employing four filter channels for tracking range, velocity, azimuth and elevation. Each channel is mechanized in a Kalman filter form by a stored program in a digital computer. The range channel estimates target range, R.sub.TPR, range rate, V.sub.TPV and acceleration a.sub.TPV from one of many received signal frequency spectra at multiples of the pulse repetition frequency (PRF) . Once error in the range rate estimate, V.sub.TPR, is within a velocity corresponding to .lambda. PRF/4, the velocity channel is reinitialized in its estimate of target velocity, V.sub.TPV, with a corrected velocity computed from the less accurate but unambiguous estimate of velocity, V.sub.TPR, and the ambiguous estimate of velocity, V.sub.TPV. [A4178]

"Closed loop tunnel diode receiver for operation with a base band semiconductor transmitter"

A vehicle safety apparatus includes a base band pulse transmitter-receiver system for the detection of an impending collision immediately prior to the contact of the vehicle with another object for the actuation of restraining or other safety devices to protect the occupants of the vehicle when the crash event actually occurs. A semiconductor base band transmitter and receiver system is synchronously operated by a master clock, providing precise operation of the receiver gain control, sensitivity time control, and other receiver functions, in a low-cost, rugged, long-lived object detection system. [A4179]

"Temperature compensated acoustic surface wave device"

A temperature compensated acoustic surface wave device, such as a surface wave delay line is provided in which temperature compensation is provided by the deposition of an interdigital electrode structure on a substrate with an overlay film surface of piezoelectric material of a predetermined thickness. A double substrate arrangement is also disclosed in which the interdigital electrode structure is deposited upon the surface of a non-piezoelectric layer which in turn is placed upon the surface of a piezoelectric substrate. [A4180]

СПИСОК ЛИТЕРАТУРЫ

A1. Пат. 10162366 США, МПК G05D1/02, G01S13/93, G01C22/00, G01C23/00, G08G1/00 и др. Methods and systems for semi-autonomous vehicular convoys / J. P. Switkes, J. C. Gerdes. - № 16/028307; Заявлено 05.07.2018; Опубл. 25.12.2018. - 23 с.↑

A2. Пат. 10162052 США, МПК G01S13/93, G01S7/03, G01S13/42, G01S13/87, G01S13/34. Pre-warning method and vehicle radar system / J.-D. Li, H.-L. Hsiao, C.-C. Kuo. - № 14/700153; Заявлено 30.04.2015; Опубл. 25.12.2018. - 15 с.↑

A3. Пат. 10162051 США, МПК G01S13/91, G01S7/04, G01S13/58. USB/Wireless based traffic radar system / M. E. Shelton, M. J. Bietsch, K. F. Hayes. - № 14/657758; Заявлено 13.03.2015; Опубл. 25.12.2018. - 13 с.↑

A4. Пат. 10162046 США, МПК G01S13/44, G01S13/93, G01S7/40. System and method for detecting blockage in an automotive radar / J. Millar, D. Insana. - № 15/072678; Заявлено 17.03.2016; Опубл. 25.12.2018. - 21 с.↑

A5. Пат. 10161770 США, МПК G01F1/00, G01S13/58, G01C13/00, G01P5/00, G01F1/66 и др. Flow meter with adaptable beam characteristics / D. L. Rick, M. Kennerknecht, S. Siedschlag, F. Kratz, L. Audergon. - № 15/199465; Заявлено 30.06.2016; Опубл. 25.12.2018. - 22 с.↑

A6. Пат. 10159218 США, МПК G01S13/88, B64D47/08, B64C39/02, B25J11/00, A01K15/04 и др. Systems and methods for walking pets / Y. Shen, A. Liu, G. Zhou. - № 15/827787; Заявлено 30.11.2017; Опубл. 25.12.2018. - 36 с.↑

A7. Пат. 10159008 США, МПК H04W64/00, H04W24/10, G01S5/02, G01S13/74, H04W4/02 и др. Terminal positioning / H. Li. - № 15/744419; Заявлено 20.07.2016; Опубл. 18.12.2018. - 12 с.↑

A8. Пат. 10156853 США, МПК G01S13/42, G05D1/00, G05D1/02, G01S5/00, G01S5/10 и др. Group for localizing a moving target in a warehouse with automatic guided vehicles / S. Monica, G. Ferrari, M. Magnani, F. Oleari, F. D. Mola. - № 15/088734; Заявлено 01.04.2016; Опубл. 18.12.2018. - 13 с.↑

A9. Пат. 10156635 США, МПК G01S17/93, G01S17/42, G01B11/06, G08G1/16, G01S17/10 и др. Overhead object detection using optical measurements / R. D. Sorenson. - № 15/147748; Заявлено 05.05.2016; Опубл. 18.12.2018. - 18 с.↑

A10. Пат. 10155551 США, МПК B62D35/02, G05D3/10, B62D35/00, G01S13/93, G01S15/93. Controller to quickly raise and slowly lower an air dam / K. J. Miller, D. M. Schaffer, C. J. Hocking. - № 15/417926; Заявлено 27.01.2017; Опубл. 18.12.2018. - 18 с.↑

A11. Пат. 10155476 США, МПК B60Q1/48, B60R1/00, B60W50/14, B60R1/08, B60K35/00 и др. Camera apparatus of vehicle / J. Kim. - № 14/234913; Заявлено 27.07.2012; Опубл. 18.12.2018. - 11 с.↑

A12. Пат. 10152893 США, МПК G01S13/56, G08G1/16, G01S13/93, G01S13/58. Retrofit wireless blind spot detection system / A. Kazemian, F. M. Amuna, I. Kure, D. Edwards, E. Franklin. - № 15/606412; Заявлено 26.05.2017; Опубл. 11.12.2018. - 17 с.↑

A13. Пат. 10152056 США, МПК B60W40/08, G06K9/00, G08G1/16, B62D15/02, B60W30/00 и др. Method for selecting an optimized trajectory / J. Rohde, H. Mielenz. - № 15/292476; Заявлено 13.10.2016; Опубл. 11.12.2018. - 9 с.↑

A14. Пат. 10151840 США, МПК G01S17/87, G01S17/58, G01S17/89, G01S7/48, G01S17/93 и др. Measuring system, measuring process, and non-transitory recording medium / M. Itoh, H. Sekiguchi. - № 14/960645; Заявлено 07.12.2015; Опубл. 11.12.2018. - 32 с.↑

A15. Пат. 10151833 США, МПК G01S13/93, G01S7/292, G01S13/524, G01S7/28, G01S13/02 и др. Accelerator engine, corresponding apparatus and method, for instance for anti-collision systems for motor vehicles / G.
↑

Borgonovo, M. Montagnana. - № 14/972329; Заявлено 17.12.2015; Опубл. 11.12.2018. - 12 с.

A16. Пат. 10151832 США, МПК G01S7/35, G01S13/34, G01S13/58. Method for determining the distance and relative speed of a remote object / R. Mende, F. Kyrisch. - № 14/892241; Заявлено 14.05.2014; Опубл. 11.12.2018. - 8 с.↑

A17. Пат. 10151300 США, МПК G06F19/00, F03D7/02, F03D7/04, F03D9/00, F03D1/06 и др. System and method for protecting a wind turbine against impending weather events / S. M. Bachman, E. Reitz. - № 15/263348; Заявлено 12.09.2016; Опубл. 11.12.2018. - 16 с.↑

A18. Пат. 10150476 США, МПК B60W30/09, B60W30/18, B60W30/14, B60W30/16, B60W30/095 и др. Methods and systems for controlling a vehicle being overtaken / A. J. Norwood. - № 15/828823; Заявлено 01.12.2017; Опубл. 11.12.2018. - 15 с.↑

A19. Пат. 10150416 США, МПК B60R1/08, B60R1/078, B60Q1/26, B60Q1/00, B60R1/12 и др. Automobile or vehicle proximity sensor and warning display mounted on outside rear view mirror / A. Masckauchan. - № 15/601342; Заявлено 22.05.2017; Опубл. 11.12.2018. - 23 с.↑

A20. Пат. 10148917 США, МПК G01C22/00, B60R1/00, H04N7/18, G01C21/36, G06K9/00 и др. Method and device for recognizing marked hazard areas and/or construction areas in the region of lanes / S. Hegemann, M. Komar, S. Lueke. - № 14/417931; Заявлено 10.07.2013; Опубл. 04.12.2018. - 8 с.↑

A21. Пат. 10147326 США, МПК G08G5/00, G01W1/00, G01C23/00, G01C21/20, G01S13/95 и др. Systems and methods of gathering and distributing critical weather event information / A. C. Koduru, K. R. Jongsma, S. P. Narayanan, S. Datta, S. Gudla. - № 15/443298; Заявлено 27.02.2017; Опубл. 04.12.2018. - 16 с.↑

A22. Пат. 10147320 США, МПК G08G1/123, G08G1/127, G01S13/86, G01S13/93. Self-driving vehicles safety system / C. G. Ellis. - № 16/000296; Заявлено 05.06.2018; Опубл. 04.12.2018. - 26 с.↑

A23. Пат. 10146103 США, МПК G03B13/08, G01S17/58, H04N5/225, G08G1/054, G03B17/48 и др. Camera module and folded optical system for laser-based speed gun / J. G. Dunne. - № 15/473307; Заявлено 29.03.2017; Опубл. 04.12.2018. - 7 с.↑

A24. Пат. 10145956 США, МПК G01S17/89, G06T7/73, H04W4/02, G01S17/08, G01C21/00 и др. Geometric fingerprinting for localization of a device / L. Modica, L. Stenneth, J. Lynch. - № 15/346360; Заявлено 08.11.2016; Опубл. 04.12.2018. - 27 с.↑

A25. Пат. 10145954 США, МПК G01S13/93, G01S7/02, G01S13/87, H04L27/227, H04B17/345 и др. Software defined automotive radar systems / C. Davis, M. Maher, J. P. Bordes, M. Hegde, O. A. Schmid и др. - № 15/844994; Заявлено 18.12.2017; Опубл. 04.12.2018. - 33 с.↑

A26. Пат. 10145952 США, МПК G01S13/42, G01S7/03, G01S13/93, G01S7/02. Vehicle-mounted radar device / J. Hayashihara. - № 15/021510; Заявлено 09.09.2014; Опубл. 04.12.2018. - 13 с.↑

A27. Пат. 10145837 США, МПК G01N33/42, G01S13/02, G01S13/88, E01C19/23, G01S13/32 и др. Systems and methods for asphalt density and soil moisture measurements using ground penetrating radar / R. E. Troxler. - № 14/214629; Заявлено 14.03.2014; Опубл. 04.12.2018. - 26 с.↑

A28. Пат. 10145660 США, МПК G01S13/88, F41H11/136, G01V3/08. Land mine detection system / H. U. Fluhler, M. J. Guthrie. - № 14/945421; Заявлено 18.11.2015; Опубл. 04.12.2018. - 22 с.↑

A29. Пат. 10144418 США, МПК B60W30/09, G01S13/93, B60T7/22. Control apparatus for vehicle / Y. Matsunaga, Y. Hoshikawa. - № 15/133860; Заявлено 20.04.2016; Опубл. 04.12.2018. - 17 с.↑

A30. Пат. 10142133 США, МПК H04L25/03, H04J11/00, H04B7/155, G01S13/00, H04B7/145 и др. Successive signal interference mitigation / J. P. Bordes, A. Eshraghi, D. S. Trager, M. Ali, R. K. Rao. - № 15/791495; Заявлено 24.10.2017; Опубл. 27.11.2018. - 37 с.↑

A31. Пат. 10141636 США, МПК H01Q1/32, G01S7/03, H01Q21/06, G01S13/93, G01S13/00. Volumetric scan automotive radar with end-fire antenna on partially laminated multi-layer PCB / J. S. Lee. - № 15/279291; Заявлено 28.09.2016; Опубл. 27.11.2018. - 17 с.↑

A32. Пат. 10140868 США, МПК G08G1/16, G01S5/00, B60K31/00, G01S13/93. V2V messaging based on road topology / O. Lei, A. R. Murray. - № 15/685581; Заявлено 24.08.2017; Опубл. 27.11.2018. - 10 с.↑

A33. Пат. 10139487 США, МПК G01S13/87, G01S13/58, G01S13/95, G01S7/02, G01W1/02. Meteorological radar system and method and device for processing meteorological information / Y. Takechi, Y. Asada. - № 14/912068; Заявлено 03.06.2014; Опубл. 27.11.2018. - 26 с.↑

A34. Пат. 10139486 США, МПК G01S13/95, G01W1/00, G01W1/10. System for predicting path of convective cell and control method thereof / J. Y. Kim, J. S. Ko, H. J. Yang, T. S. Kwon, S. J. Oh и др. - № 14/848112; Заявлено 08.09.2015; Опубл. 27.11.2018. - 19 с.↑

A35. Пат. 10139485 США, МПК G01S13/93, G01S13/86, G01S15/02, G01S17/02, G01S15/93 и др. Device and method for collision risk management for vehicles / R. Backstrom. - № 14/913268; Заявлено 12.06.2014; Опубл. 27.11.2018. - 16 с.↑

A36. Пат. 10139483 США, МПК G01D13/02, G01S7/282, G01S13/02, G01S7/22, G01S13/89 и др. Hybrid pulse compression waveform for high resolution imaging / P. Sankar. - № 15/662063; Заявлено 27.07.2017; Опубл. 27.11.2018. - 58 с.↑

A37. Пат. 10137833 США, МПК B60Q1/00, B60Q9/00, G08G1/16, G08G1/0967, G01S13/93 и др. Vehicle control apparatus, vehicle driving assistance apparatus, mobile terminal and control method thereof / J. Park, T. Cho, Y. Kwon, K. Lee, J. Seol. - № 15/125310; Заявлено 19.03.2015; Опубл. 27.11.2018. - 56 с.↑

A38. Пат. 10137744 США, МПК B60C23/04, B60C11/24, B60C23/02, B60C23/00, G01M17/02 и др. Measurement and monitoring device for tire-related variables of a vehicle / H. Heuermann, T. Harzheim. - № 15/544954; Заявлено 19.01.2016; Опубл. 27.11.2018. - 13 с.↑

A39. Пат. 10136256 США, МПК H04W24/00, E05B77/48, G01S5/02, H04B17/318, H04W4/02 и др. Method for determining the position of a portable user device around a vehicle and associated location device / S. Godet, F. Merlet. - № 15/459904; Заявлено 15.03.2017; Опубл. 20.11.2018. - 13 с.↑

A40. Пат. 10135131 США, МПК H01Q1/42, G01S13/93, H01Q1/44, G01S7/02. Electromagnetic-wave transmitting cover / K. Takao, D. Kawashima, T. Sekiya, H. Maeda, K. Okumura и др. - № 14/959018; Заявлено 04.12.2015; Опубл. 20.11.2018. - 16 с.↑

A. Пат. 10134304 США, МПК G09B21/00, G01S13/93, G01S13/86, E01H5/06, G08B7/06 и др. Scanning obstacle sensor for the visually impaired / W. M. Beals, J. L. McSchooler. - № 15/645735; Заявлено 10.07.2017; Опубл. 20.11.2018. - 17 с.↑

A42. Пат. 10134294 США, МПК G06F19/00, G01S13/87, G08G5/04, G08G5/00, G01S19/48 и др. System, apparatus, and method using ADS-B and TCAS data for determining navigation solutions for a vehicle / G. Feng, G. I. Kim. - № 15/246307; Заявлено 24.08.2016; Опубл. 20.11.2018. - 26 с.↑

A43. Пат. 10132922 США, МПК G01S13/36, G01S13/32, G01S7/35. Proximity sensor and method for measuring the distance from an object / S. Fericean, M. Eberspaecher. - № 14/895012; Заявлено 01.07.2013; Опубл. 20.11.2018. - 21 с.↑

A44. Пат. 10131355 США, МПК B62D6/00, B62D15/00, G08G1/0962, B62D15/02, G06K9/00 и др. Vehicle traveling control apparatus / Y. Takaso, H. Oyama. - № 15/381225; Заявлено 16.12.2016; Опубл. 20.11.2018. - 24 с.↑

A45. Пат. 10127818 США, МПК G05D1/02, G05D1/00, G01S13/93, G08G1/16, G06G7/78 и др. Systems and methods for detecting and avoiding an emergency vehicle in the proximity of a substantially autonomous vehicle / B. Mandeville-Clarke. - № 15/626077; Заявлено 17.06.2017; Опубл. 13.11.2018. - 27 с.↑

A46. Пат. 10126424 США, МПК G01W1/00, G01S7/02, G01S13/95. Dual-polarization weather radar data system and method / M. Eilts, J. T. Johnson, J.C. Porter, M. Gaffner, J. W. Conway и др. - № 15/341444; Заявлено 02.11.2016; Опубл. 13.11.2018. - 11 с.↑

A47. Пат. 10126422 США, МПК G01S13/93, G01S13/58, B60R16/033, B60Q9/00, G08G1/16 и др. Vehicle blind spot sensor / L. Obodo. - № 15/208195; Заявлено 12.07.2016; Опубл. 13.11.2018. - 10 с.↑

A48. Пат. 10126420 США, МПК G01S13/93, G01S13/48, G01S3/16, G01S7/40. Vehicle type radar device and vehicle type radar control method / J. E. Lee, H. S. Lim, S. H. Jeong. - № 14/661523; Заявлено 18.03.2015; Опубл. 13.11.2018. - 16 с.↑

A49. Пат. 10126418 США, МПК G01S13/93, G01S13/10, G01S13/66. Pulse-doppler rada measurement of crossing target dynamics / T. Campbell. - № 14/847579; Заявлено 08.09.2015; Опубл. 13.11.2018. - 16 с.↑

A50. Пат. 10126411 США, МПК G01S7/48, G01S7/481, G01S17/93, G01S17/89, G01S7/486 и др. Beam steering LADAR sensor / P. Gilliland, R. Stettner. - № 14/656936; Заявлено 13.03.2015; Опубл. 13.11.2018. - 41 с.↑

A51. Пат. 10126410 США, МПК G01S7/40, G01S13/93, G01S13/42, G01S13/34, G01S13/44. Determination of an elevation misalignment angle of a radar sensor of a motor vehicle / A. Treptow, D. Bechler, G. Kuehnle, V. Gross. - № 14/891617; Заявлено 01.04.2014; Опубл. 13.11.2018. - 11 с.↑

A52. Пат. 10126408 США, МПК G01C21/00, G01S7/12, G01S7/22, G01S13/86, G01S13/93. Method and device for displaying ship vicinity information / T. Ise. - № 14/849492; Заявлено 09.09.2015; Опубл. 13.11.2018. - 11 с.↑

A53. Пат. 10124805 США, МПК B60W30/18, B60T8/174, B60T7/18, B60K17/35, G01S13/93 и др. Work vehicle and control method for work vehicle / R. Kou, A. Nishijima, S. Kondou. - № 15/329008; Заявлено 31.07.2014; Опубл. 13.11.2018. - 21 с.↑

A54. Пат. 10124727 США, МПК B60Q9/00, G01S13/93. Method for warning a driver of a vehicle of the presence of an object in the surroundings, driver assistance system and motor vehicle / T. K. Ayyappan, M. Heimberger. - № 15/505358; Заявлено 20.08.2015; Опубл. 13.11.2018. - 13 с.↑

A55. Пат. 10123583 США, МПК A63B24/00, A43B5/00, A63B71/08, A63B71/12, G01S13/82 и др. Athletic performance monitoring systems and methods in a team sports environment / J. Molyneux, A. B. Weast, B. S. Burroughs. - № 14/846001; Заявлено 04.09.2015; Опубл. 13.11.2018. - 98 с.↑

A56. Пат. 10123173 США, МПК H04W4/02, G08G1/123, H04W4/029, G08G1/00, H04W8/24 и др. Requesting transportation services / O. M. Lubeck, J. H. Hall. - № 15/692677; Заявлено 31.08.2017; Опубл. 06.11.2018. - 12 с.↑

A57. Пат. 10122067 США, МПК G01F23/00, H01Q3/24, G01F23/284, H01Q21/06, H01Q21/00 и др. Antenna device and method for operating an antenna device / R. Welle. - № 15/855816; Заявлено 27.12.2017; Опубл. 06.11.2018. - 21 с.↑

A222. Пат. 9958539 США, МПК G01S13/02, G01S13/24, G01S13/42, G01S13/00. Real aperture radar system for use on board a satellite and for maritime surveillance applications / A. Torre. - № 14/208162; Заявлено 13.03.2014; Опубл. 01.05.2018. - 13 с.↑

A223. Пат. 9958309 США, МПК G01F23/284, G01S13/88. Method for measuring level of material level measuring apparatus / L.-C. Chang, C.-H. Huang, I.-C. Lin. - № 14/883615; Заявлено 14.10.2015; Опубл. 01.05.2018. - 7 с.↑

A224. Пат. 9956993 США, МПК G01S13/00, B62D21/15, G01S13/93, B60R19/48, G01S7/02. Vehicle front impact sensor with impact resistant carriage / A. P. Klop, R. Vasbinder. - № 15/411035; Заявлено 20.01.2017; Опубл. 01.05.2018. - 12 с.↑

A225. Пат. 9955362 США, МПК H04B1/38, H04W16/26, H02J7/14, H04B1/3888, H04B1/40 и др. System and method for mobile data expansion and pedestrian obstacle detection / T. Berry. - № 15/620624; Заявлено 12.06.2017; Опубл. 24.04.2018. - 35 с.↑

A226. Пат. 9955301 США, МПК G08B13/14, H04L5/00, H04W4/02, G01S3/74, G01S5/02 и др. Multi-path mitigation in rangefinding and tracking objects using reduced attenuation RF technology / F. Markhovsky, T. Prevatt. - № 15/017327; Заявлено 05.02.2016; Опубл. 24.04.2018. - 57 с.↑

A227. Пат. 9954955 США, МПК G01S13/02, G01S13/93, G01S7/00, H04L29/08, H04J13/12 и др. Vehicle radar system with a shared radar and communication system / C. Davis, M. Hegde, W. E. Stark, A. Eshraghi, M. Goldenberg и др. - № 15/496039; Заявлено 25.04.2017; Опубл. 24.04.2018. - 24 с.↑

A228. Пат. 9952320 США, МПК G01S13/93, G01S13/34, G01S13/87, G01S7/28, G01S7/02. Method for operating a radar sensor of a motor vehicle, driver assistance device and motor vehicle / A. Ossowska, U. Luebbert. - № 14/440936; Заявлено 18.09.2013; Опубл. 24.04.2018. - 9 с.↑

A229. Пат. 9952319 США, МПК G01S13/28, G01S7/292, G01S7/288, H04B7/0413, G01S7/03 и др. Residue cancellation for automated vehicle MIMO radar / J. F. Searcy, A. H. Arage, S. W. Alland, S. Cao. - № 14/962092; Заявлено 08.12.2015; Опубл. 24.04.2018. - 14 с.↑

A230. Пат. 9952314 США, МПК G01S7/41, G01S13/34, G01S13/93. Method and device for sensing road environment based on frequency modulated continuous wave radar / J. E. Lee, H. S. Lim, S. H. Jeong. - № 14/316480; Заявлено 26.06.2014; Опубл. 24.04.2018. - 18 с.↑

A231. Пат. 9950723 США, МПК G01S13/04, B61L29/30, B61L23/04, B61L29/00, G01S7/41 и др. Danger zone monitoring at a grade crossing / B. Lehnertz. - № 14/703361; Заявлено 04.05.2015; Опубл. 24.04.2018. - 12 с.↑

A232. Пат. 9950683 США, МПК B60R21/0134, G01S13/87, B60T7/22, G01S13/93, G08G1/16 и др. Sensor handover / T. Abt, P. Loffler. - № 15/526128; Заявлено 10.11.2015; Опубл. 24.04.2018. - 18 с.↑

A233. Пат. 9949201 США, МПК H04B7/00, H04W48/16, G01W1/00, G01S5/00, G01S7/00 и др. Systems and methods for regulating weather information collection / H. Wang, Y. Zhong, L. Wang. - № 14/865037; Заявлено 25.09.2015; Опубл. 17.04.2018. - 19 с.↑

A234. Пат. 9947225 США, МПК G08G1/16, G01S13/93, G01S7/41, B60W30/09, B60T7/22. Apparatus and method for monitoring a target object / M. Cund, P. Widdowson. - № 13/985107; Заявлено 20.02.2012; Опубл. 17.04.2018. - 10 с.↑

A235. Пат. 9945944 США, МПК G08G1/0965, G01S13/93. Blind area warning for vehicles / H.-P. Mauderer. - № 13/370718; Заявлено 10.02.2012; Опубл. 17.04.2018. - 9 с.↑

A236. Пат. 9945942 США, МПК G01S13/88, G01V3/12, G01S7/41, G01S7/02, G01V9/02 и др. System and method of underground water detection / L. Guy. - № 15/014053; Заявлено 03.02.2016; Опубл. 17.04.2018. - 22 с.↑

A237. Пат. 9945935 США, МПК G01S13/93, G01S7/35. Digital frequency modulated continuous wave radar using handcrafted constant envelope modulation / A. Eshraghi, C. Davis, M. Ali, P. Dent. - № 15/492159; Заявлено 20.04.2017; Опубл. 17.04.2018. - 55 с.↑

A238. Пат. 9945930 США, МПК H04B7/14, G01S5/02, G01S7/35, G01S11/02, G01S11/10 и др. System and method for determining an orientation or position of a receiver relative to an emission device / R. Reimann. - № 14/832336; Заявлено 21.08.2015; Опубл. 17.04.2018. - 36 с.↑

A239. Пат. 9945927 США, МПК G01S3/86, G01S13/93, G08G1/16, G01S7/40, G01S17/02 и др. Object detection apparatus / T. Baba. - № 15/513522; Заявлено 10.09.2015; Опубл. 17.04.2018. - 15 с.↑

A240. Пат. 9944259 США, МПК G06F7/70, B60G17/0195, B60G17/016, B60T8/1755, B60T13/68 и др. Method and system for avoiding a vehicle collision / M. Bunk. - № 14/778374; Заявлено 29.01.2014; Опубл. 17.04.2018. - 13 с.↑

A241. Пат. 9939524 США, МПК G01S13/88, G01S13/18, G01S13/58, G01S7/285, G01S13/60. Systems and methods for measuring velocity with a radar altimeter / B. J. Winstead. - № 14/613879; Заявлено 04.02.2015; Опубл. 10.04.2018. - 20 с.↑

A242. Пат. 9939523 США, МПК G01S13/06, B60Q9/00, G01S13/72, G01S13/93, B60W30/14 и др. Vehicle type radar system, and method for removing an uninterested target / H. Y. Jin, G.-H. Seo. - № 14/814515; Заявлено 31.07.2015; Опубл. 10.04.2018. - 15 с.↑

A243. Пат. 9937905 США, МПК B60T7/22, B60W30/095, B60W50/14, G01S13/93, G01S15/93 и др. Side collision avoidance system and method for vehicle / J. S. Kim, J. J. Yoo, J. H. Park, H. J. Lim. - № 15/182641; Заявлено 15.06.2016; Опубл. 10.04.2018. - 19 с.↑

A244. Пат. 9937888 США, МПК B60R21/01, G01S17/93, G01S13/93, B60R21/0134, B60R21/013 и др. Method and device for controlling triggering of at least one passenger protection device for a motor vehicle and safety system for a vehicle / J. L. Foltin. - № 15/182322; Заявлено 14.06.2016; Опубл. 10.04.2018. - 11 с.↑

A245. Пат. 9937861 США, МПК B60Q9/00, G01S13/88, B60R1/00, G08G1/16, G01S15/88 и др. Vehicle blind spot system operation with trailer tow / M. A. Shehan, K. Snarski, J. Mackey, D. McConnell, S. G. Kanzler. - № 15/348620; Заявлено 10.11.2016; Опубл. 10.04.2018. - 13 с.↑

A246. Пат. 9937765 США, МПК G05D1/06, B64D45/04, G05D1/00, G07C5/08, B60G17/0165 и др. Method of adapting an automobile suspension in real-time / R. Sivaraman. - № 14/697620; Заявлено 28.04.2015; Опубл. 10.04.2018. - 12 с.↑

A247. Пат. 9935756 США, МПК H04L5/00, G01S5/14, H04W64/00, G01S13/76, H04W24/10 и др. Methods and systems for ranging protocol / S. M. Sridhar, C. Aldana. - № 14/845893; Заявлено 04.09.2015; Опубл. 03.04.2018. - 21 с.↑

A248. Пат. 9934690 США, МПК G08G1/16, G06T7/60, G06T7/20, B62D15/02, G01C3/08 и др. Object recognition apparatus and vehicle travel controller using same / H. Kuroda. - № 15/307394; Заявлено 03.06.2015; Опубл. 03.04.2018. - 33 с.↑

A249. Пат. 9933520 США, МПК G01S13/93. Orthogonal linear frequency modulation for MIMO radar / T. Campbell. - № 14/753887; Заявлено 29.06.2015; Опубл. 03.04.2018. - 17 с.↑

A250. Пат. 9933519 США, МПК G01S13/02, G01S13/90, G01S13/89, G01S13/524, G01S7/298 и др. Three dimensional radar system / H. M. Braun, G. Maydan, H. Baessler, C. Jonas, O. Klein. - № 14/658619; Заявлено 16.03.2015; Опубл. 03.04.2018. - 17 с.↑

A251. Пат. 9933518 США, МПК G01S13/34, G01S13/93, G01S13/58. FMCW radar having distance range graduation / M. Schoor. - № 14/762292; Заявлено 03.12.2013; Опубл. 03.04.2018. - 11 с.↑

A252. Пат. 9933515 США, МПК G01S7/497, G01S13/86, G01S17/93, G01S7/40, G01S13/93. Sensor calibration for autonomous vehicles / D. V. Prokhorov. - № 14/565293; Заявлено 09.12.2014; Опубл. 03.04.2018. - 12 с.↑

A253. Пат. 9933247 США, МПК G01B11/00, G01B21/00, G05B19/402, G05B19/19, G01S13/00. Mandrel configuration monitoring system / D. M. Clark, A. M. Cangelosi, L. C. Chang, D. E. Errazo. - № 14/153529; Заявлено 13.01.2014; Опубл. 03.04.2018. - 31 с.↑

A254. Пат. 9929471 США, МПК H01P5/12, H01Q13/02, H01P5/19, G01S7/40, H01P5/08 и др. Very compact TM01 mode extractor / N. Fonseca. - № 15/029838; Заявлено 21.10.2013; Опубл. 27.03.2018. - 22 с.↑

A255. Пат. 9928737 США, МПК G08G1/054, B60Q1/50, G01S13/86, G01S19/13, G08G1/017 и др. Mobile number plate recognition and speed detection system / A. Ekin. - № 14/777522; Заявлено 20.12.2013; Опубл. 27.03.2018. - 7 с.↑

A256. Пат. 9927517 США, МПК G01S13/04, G01S13/88, H04B17/318, H04Q9/02, H04B1/10. Apparatus and methods for sensing rainfall / R. Bennett, P. S. Henry, I. Gerszberg, F. Barzegar, D. J. Barnickel и др. - № 15/369971; Заявлено 06.12.2016; Опубл. 27.03.2018. - 139 с.↑

A257. Пат. 9927354 США, МПК G01N21/35, G01N21/954, G01N21/94, B25J5/00, F16L55/32 и др. Method and apparatus for pipe imaging with chemical analysis / J. Starr, J. Lettman, T. Kueny, F. J. Salotti, G. Konakchiev. - № 15/278879; Заявлено 28.09.2016; Опубл. 27.03.2018. - 10 с.↑

A258. Пат. 9925963 США, МПК B60T8/1755, G01S13/93, B60T7/12, B60T8/171, B60T7/22 и др. Autonomous emergency braking system and method of controlling the same / H. J. Lee. - № 15/238683; Заявлено 16.08.2016; Опубл. 27.03.2018. - 15 с.↑

A259. Пат. 9924387 США, МПК H04W24/06, H04W72/04, G01S13/74, G01S5/12, H04L12/26 и др. FTM protocol with angle of arrival and angle of departure / C. H. Aldana, X. Zhang. - № 15/013304; Заявлено 02.02.2016; Опубл. 20.03.2018. - 26 с.↑

A260. Пат. 9923792 США, МПК H04L12/26, H04B7/216, G01S5/00, H04W24/00, H04W64/00 и др. Methods and systems for enhanced round trip time (RTT) exchange / C. H. Aldana, S. Homchaudhuri, X. He, X. Zhang, A. K. Shukla. - № 15/281412; Заявлено 30.09.2016; Опубл. 20.03.2018. - 60 с.↑

A261. Пат. 9923532 США, МПК H03G3/30, H03F3/19, H03F3/45, H03F3/72, G01S13/02. System and method to directly couple to analog to digital converter having lower voltage reference / C. Pavao-Moreira, R. K. Hales. - № 15/480097; Заявлено 05.04.2017; Опубл. 20.03.2018. - 19 с.↑

A262. Пат. 9921304 США, МПК G01S13/04, G01S13/93, G01S13/86, G01S13/00. Object detection apparatus / K. Mizutani. - № 14/686871; Заявлено 15.04.2015; Опубл. 20.03.2018. - 12 с.↑

A263. Пат. 9921293 США, МПК G01S5/14, G01S5/02, G01S13/82, G01S11/06. System and method for location estimation in environments unsuitable for GPS technology / M. Persson, D. Karlsson. - № 13/389297; Заявлено 16.12.2010; Опубл. 20.03.2018. - 12 с.↑

A264. Пат. 9921083 США, МПК G01B7/14, G01S13/75, G06F3/046, G01B7/00, G01D5/20 и др. Device for locating one or more mobile elements in a predetermined zone, and method implemented in such a device / J.-C. Lourme, G. Tendon, J.-Y. Hogrel. - № 14/910361; Заявлено 06.08.2014; Опубл. 20.03.2018. - 16 с.↑

A265. Пат. 9919681 США, МПК G01S13/74, B60R25/24, B60R25/20, E05B81/56. On-board communication system, and on-board device / A. Watanabe, A. Ogawa. - № 15/311760; Заявлено 27.07.2015; Опубл. 20.03.2018. - 43 с.↑

A266. Пат. 9919582 США, МПК B60H1/00, G01S15/87, G01S15/08, G01S13/93, G01S13/86 и др. Humidity estimation / A. Green, D. K. Bidner. - № 15/006447; Заявлено 26.01.2016; Опубл. 20.03.2018. - 12 с.↑

A267. Пат. 9919493 США, МПК B32B15/00, C23C18/44, G01S7/03, H01Q1/42, C23C18/16 и др. Electromagnetic wave penetrative metal film, manufacturing method of electromagnetic wave penetrative metal film, and radome for vehicle-mounted radar devices / S. Yamamoto. - № 14/355888; Заявлено 02.11.2012; Опубл. 20.03.2018. - 16 с.↑

A268. Пат. 9915951 США, МПК G05D1/00, G05D1/02, G01S17/93, G01S13/93. Detection of overhanging objects / X. Mei, K. Sakai, N. Kamata. - № 14/979462; Заявлено 27.12.2015; Опубл. 13.03.2018. - 18 с.↑

A269. Пат. 9915735 США, МПК G01S19/42, G01S19/48, G01C22/00, G01S5/00, G01S19/51 и др. Method for positioning a vehicle / N. Wagner, M. Moebus, B. Praunsmaendel. - № 15/216260; Заявлено 21.07.2016; Опубл. 13.03.2018. - 7 с.↑

A270. Пат. 9915729 США, МПК G01S13/88, G01S7/02. Apparatus and method for high speed subsurface inspection of built infrastructure / M. L. Scott. - № 14/805543; Заявлено 22.07.2015; Опубл. 13.03.2018. - 9 с.↑

A271. Пат. 9915526 США, МПК G01S13/89, G01B15/04, G01S13/88. Method and a device for surface determination by means of microwaves / S. Ahmed. - № 14/765936; Заявлено 23.01.2014; Опубл. 13.03.2018. - 11 с.↑

A272. Пат. 9914475 США, МПК G05D1/00, B62D6/00, B62D1/04, B60G17/016, G01S13/89. Humanized steering model for automated vehicles / L. Sun, M. H. Laur, J. L. Wieskamp, M. Yan. - № 14/874760; Заявлено 05.10.2015; Опубл. 13.03.2018. - 10 с.↑

A273. Пат. 9914419 США, МПК B60R21/00, H01Q1/32, G01S13/93, B60R9/06, G01S7/02 и др. Radar mounting device / B. Fath, D. J. Lawor, S. H. Gaboury, M. A. Aleem. - № 14/695820; Заявлено 24.04.2015; Опубл. 13.03.2018. - 10 с.↑

A274. Пат. 9913244 США, МПК G08B13/14, G01S13/74, G01S13/87, H04W64/00, G01S5/02 и др. Partially synchronized multilateration or trilateration method and system for positional finding using RF / F. Markhovsky, T. Prevatt, R. Markhovsky. - № 14/923299; Заявлено 26.10.2015; Опубл. 06.03.2018. - 76 с.↑

A275. Пат. 9910442 США, МПК G01C22/00, G05D1/02, G01S17/93, G05D1/00, G01S13/93 и др. Occluded area detection with static obstacle maps / N. Kamata, X. Mei, K. Sakai. - № 15/195770; Заявлено 28.06.2016; Опубл. 06.03.2018. - 28 с.↑

A277. Пат. 9910148 США, МПК G01S13/88, G01S7/28, G01S7/34. Advanced techniques for ground-penetrating radar systems / J. LaBarca, M. Keys. - № 14/635646; Заявлено 02.03.2015; Опубл. 06.03.2018. - 7 с. ↑

A278. Пат. 9910134 США, МПК G01S13/88, G01S7/04, H01Q1/32, H01Q21/06, G01S13/90. Enhanced detection and automatic signature extraction of radar resonance reflections in above and below-ground man-made objects / R. Samaniego, E. A. Santiago, J. L. Tomich. - № 14/608977; Заявлено 29.01.2015; Опубл. 06.03.2018. - 13 с.↑

A279. Пат. 9905013 США, МПК G01S13/86, G06K9/00, G06T7/20, G01S13/04, G08G1/16 и др. Speed calculating device and speed calculating method, and collision determination device / R. Inomata. - № 14/425063; Заявлено 03.09.2012; Опубл. 27.02.2018. - 17 с.↑

A280. Пат. 9903951 США, МПК B60W40/02, G01S17/93, G01S7/295, G01S13/93, G08G1/16. Method for processing environmental data in a vehicle / M. E. Bouzouraa. - № 14/848767; Заявлено 09.09.2015; Опубл. 27.02.2018. - 6 с.↑

A281. Пат. 9903949 США, МПК G01S13/93, G01S7/42, G01S7/03, H01Q23/00, G01S7/00 и др. Radio-frequency system / G.-S. Huang, H.-L. Hsiao. - № 14/691547; Заявлено 20.04.2015; Опубл. 27.02.2018. - 15 с. ↑

A282. Пат. 9903947 США, МПК G01S13/88, A01D34/00, G05D1/00. Boundary signal detection / C. E. Das, B. R. Trenhaile. - № 14/822821; Заявлено 10.08.2015; Опубл. 27.02.2018. - 17 с.↑

A283. Пат. 9903945 США, МПК G01S13/93, B60W40/105, G01S13/86, G01S13/60, G01S13/87. Vehicle motion estimation enhancement with radar data / X. F. Song, H. Tan, S. Zeng. - № 14/614164; Заявлено 04.02.2015; Опубл. 27.02.2018. - 13 с.↑

A284. Пат. 9902201 США, МПК G01M17/04, G01S15/93, G01S17/02, G01S15/87, B60Q1/00 и др. Method and devices for detecting and rectifying problems in connection with a vehicle load / M. Schneider, U. Klee, F. Suessenbach, C. Hoffmann. - № 14/367169; Заявлено 21.11.2012; Опубл. 27.02.2018. - 11 с.↑

A285. Пат. 9900858 США, МПК H04W64/00, G01S3/12, G01S5/12, H04J3/06, G01S13/76. Apparatus, system and method of estimating a location of a mobile device / M. C. Walma, R. D. Roberts, C. Cordeiro. - № 14/129301; Заявлено 30.05.2013; Опубл. 20.02.2018. - 29 с.↑

A286. Пат. 9898929 США, МПК G08G1/16, G01S13/86, B60W30/09, G05D1/02, G06K9/00 и др. Vehicle driving assistance apparatus / T. Harada, Y. Ito. - № 14/780189; Заявлено 10.04.2013; Опубл. 20.02.2018. - 13 с. ↑

A287. Пат. 9897685 США, МПК G01S7/02, G01S13/93, G01S13/34. Method for detecting interference in a received signal of a radar sensor, driver assistance device and motor vehicle / A. Ossowska, U. Haberland. - № 14/435858; Заявлено 18.09.2013; Опубл. 20.02.2018. - 12 с.↑

A288. Пат. 9896129 США, МПК B62D15/02, G01S13/86, G01S13/93, G01S15/04, G01S13/04 и др. Driving assistant system of vehicle and method for controlling the same / H.-W. Baek. - № 15/072524; Заявлено 17.03.2016; Опубл. 20.02.2018. - 17 с.↑

A289. Пат. 9896096 США, МПК G08G1/16, B60W30/09, G01S13/93, B60W10/20, G05D1/02 и др. Systems and methods for hazard mitigation / D. E. Newman, R. K. Massengill. - № 15/347573; Заявлено 09.11.2016; Опубл. 20.02.2018. - 54 с.↑

A290. Пат. 9893423 США, МПК H01Q7/00, G01R27/00, H01Q1/24, H01Q5/40, G01N22/00 и др. Electromagnetic wave sensor and/or emitter / A. Debray. - № 14/534030; Заявлено 05.11.2014; Опубл. 13.02.2018. - 25 с.↑

A291. Пат. 9891316 США, МПК G01S13/93, G01S7/41, G01S13/08, G01S13/04, G01S13/46 и др. Apparatus and method for detecting target in periphery of vehicle / A. Mizutani, Y. Samukawa, R. Uyama. - № 14/765821; Заявлено 04.02.2014; Опубл. 13.02.2018. - 21 с.↑

A292. Пат. 9891027 США, МПК F41H11/00, F41H11/02, F41H5/007, G01S13/66. System and method for neutralizing shaped-charge threats / S. Rahav, E. B. Ezra, N. Magen, G. Hazan, L. Glikin. - № 15/303608; Заявлено 27.04.2015; Опубл. 13.02.2018. - 11 с.↑

A293. Пат. 9889858 США, МПК B60W50/00, G01S13/93, B60W30/09, G01S13/72, G06K9/00 и др. Confidence estimation for predictive driver assistance systems based on plausibility rules / J. Schmudderich. - № 14/520501; Заявлено 22.10.2014; Опубл. 13.02.2018. - 16 с.↑

A294. Пат. 9889798 США, МПК G01S13/66, B60Q9/00, G01S13/88, G01S13/93, G06N7/00. Detection of a target object utilizing automotive radar / S. Cong, B. Yan. - № 15/253343; Заявлено 31.08.2016; Опубл. 13.02.2018. - 16 с.↑

A295. Пат. 9886938 США, МПК G10K11/00, G01S7/54, G01S15/00, G01S15/87, G01S15/88 и др. Transducer array having a transceiver / D. Parks. - № 14/618987; Заявлено 10.02.2015; Опубл. 06.02.2018. - 15 с.↑

A296. Пат. 9886858 США, МПК B60Q1/00, G08G1/01, G08G1/04, G08G1/16, G01S13/93. Lane change detection / S. Murray, U. Nordqvist. - № 15/517181; Заявлено 02.10.2015; Опубл. 06.02.2018. - 12 с.↑

A297. Пат. 9886801 США, МПК G07C5/08, G01S7/40, G01S13/93, G01B21/24, G01S7/497 и др. Vehicle sensor compensation / F. W. Huntzicker, P. R. Williams, X. F. Song. - № 14/614176; Заявлено 04.02.2015; Опубл. 06.02.2018. - 13 с.↑

A298. Пат. 9885783 США, МПК G01S13/00, G01S13/28, G01S13/48. Methods and systems for encoded broadcasting and antenna reception, particularly for radar / C. Goutelard. - № 13/001763; Заявлено 30.06.2009; Опубл. 06.02.2018. - 15 с.↑

A299. Пат. 9884624 США, МПК B60W30/165, B60W30/17, G08G1/0967, G08G1/16, G01S13/93 и др. Travel control device / S. Morita, H. Sugawara. - № 15/023741; Заявлено 10.12.2013; Опубл. 06.02.2018. - 22 с.↑

A300. Пат. 9884588 США, МПК B60Q1/00, G08G1/16, G01S13/93, B60Q5/00. Driver supporting device and warning timing control method / S. Park, S. Murayama. - № 15/519263; Заявлено 17.10.2014; Опубл. 06.02.2018. - 17 с.↑

A301. Пат. 9883354 США, МПК G01S13/06, G01S19/51, G01S5/02, H04W4/02. Method and system for localizing a vehicle and vehicle with a device for carrying out vehicle-to-X communications / M. Moebus, N. Wagner. - № 15/007954; Заявлено 27.01.2016; Опубл. 30.01.2018. - 11 с.↑

A302. Пат. 9882559 США, МПК H03K17/95, G01S13/75, G01S13/76. Wireless proximity sensor with a target device comprising an inverter / K. Amin. - № 14/362463; Заявлено 12.12.2012; Опубл. 30.01.2018. - 12 с.↑

A303. Пат. 9880278 США, МПК G01S13/93, G01S13/04, G01S13/18. Object determination using a radar sensor / R. Uffelen, A. Steinmetz. - № 14/448892; Заявлено 31.07.2014; Опубл. 30.01.2018. - 8 с.↑

A304. Пат. 9880275 США, МПК G01S13/93, B60W30/14, G01S13/34, G01S13/00, B60W30/09 и др. Radar for vehicle and method of operating the same / S. H. Jeong, J. E. Lee. - № 14/455823; Заявлено 08.08.2014; Опубл.

30.01.2018. - 14 с.↑

A305. Пат. 9880270 США, МПК G01S7/52, G01N29/26, G01N29/06, G01S15/89, G10K11/34 и др. Test device and imaging device including the same / J.- Kim, Y. Hayashi, A. Okubo. - № 14/883753; Заявлено 15.10.2015; Опубл. 30.01.2018. - 18 с.↑

A306. Пат. 9880263 США, МПК G01S7/48, G01S7/481, G01S17/87, G01S17/02, G01S17/93 и др. Long range steerable LIDAR system / P.- Droz, G. Pennecot, A. Levandowski, D. E. Ulrich, Z. Morriss и др. - № 14/679683; Заявлено 06.04.2015; Опубл. 30.01.2018. - 31 с.↑

A307. Пат. 9878711 США, МПК B60W30/12, G08G1/16, G01S19/48, G05B19/042, H04L29/08 и др. Method and system for lane detection and validation / J. Ichinokawa. - № 14/967792; Заявлено 14.12.2015; Опубл. 30.01.2018. - 14 с.↑

A308. Пат. 9877300 США, МПК H04W24/00, H04W64/00, G01S5/14, G01S13/76, G01S13/87. Determining a location of a disconnected device / S. Sen, D. Kim. - № 15/500617; Заявлено 24.11.2014; Опубл. 23.01.2018. - 10 с.↑

A309. Пат. 9876267 США, МПК G01F23/00, G01B15/04, H04B17/10, H01Q1/22, G01S13/89 и др. Antenna device and method for operating an antenna device / R. Welle. - № 15/354751; Заявлено 17.11.2016; Опубл. 23.01.2018. - 21 с.↑

A310. Пат. 9875657 США, МПК G06F7/70, G01S13/93, G01S17/93, G01S15/93, G08G5/04 и др. Automated un-manned air traffic control system / T. J. Collins. - № 14/847910; Заявлено 08.09.2015; Опубл. 23.01.2018. - 32 с.↑

A311. Пат. 9874634 США, МПК G01S13/93, G01S13/42, G01S13/72, G01S7/41. Radar apparatus / T. Moriuchi, Y. Nakanishi. - № 14/733526; Заявлено 08.06.2015; Опубл. 23.01.2018. - 26 с.↑

A312. Пат. 9874633 США, МПК G01S13/58, G01S13/34, F42B35/00. Deceleration hysterisis measuring apparatus for soft recovery system / J.-H. Choi, M.-S. Song, J.-E. Roh. - № 15/588867; Заявлено 08.05.2017; Опубл. 23.01.2018. - 8 с.↑

A313. Пат. 9874632 США, МПК G01S13/46, G01S5/02, G01S13/06. Electromagnetic reflection profiles / R. R. Miller, I.I.K. A. Li, T. C. Meuninck, J. H. Pratt, H. J. Schroeter и др. - № 14/886004; Заявлено 17.10.2015; Опубл. 23.01.2018. - 45 с.↑

A314. Пат. 9870641 США, МПК G06T15/00, G01S13/00, G01S13/88, G01S7/04, G01S7/295 и др. Using an MM-principle to achieve fast image data estimation from large image data sets / J. M. M. Anderson, M. Ndoye. - № 14/184446; Заявлено 19.02.2014; Опубл. 16.01.2018. - 38 с.↑

A315. Пат. 9869765 США, МПК G01S13/93, G01S13/50, G01S13/58, B60W30/08, G01S13/34 и др. Alarm system and method for vehicle / C.-C. Kuo, H.-L. Hsiao, T.-W. Chang, M.-J. Wu. - № 14/506688; Заявлено 06.10.2014; Опубл. 16.01.2018. - 16 с.↑

A316. Пат. 9869762 США, МПК G01S7/03, G01S13/42, G01S7/282, G01S13/93. Virtual radar configuration for 2D array / S. W. Alland, J. P. Bordes, C. Davis, M. Ali. - № 15/705627; Заявлено 15.09.2017; Опубл. 16.01.2018. - 38 с.↑

A317. Пат. 9869759 США, МПК G01S13/56, H04W64/00, G01S13/00, G01S13/04, G01S11/02. Motion detector device / J. Furuskog, J. Medbo, M. Ringstrom. - № 14/352967; Заявлено 19.10.2011; Опубл. 16.01.2018. - 14 с. ↑

A318. Пат. 9869555 США, МПК G01C21/00, B60P1/04, G01S13/86, G01S19/46, G01S13/93 и др. Construction machine control system, construction machine, construction machine management system, and construction machine control method and program / A. Sakai, M. Ryuman, M. Tojima, A. Nishijima. - № 15/123039; Заявлено 30.10.2015; Опубл. 16.01.2018. - 30 с.↑

A319. Пат. 9868441 США, МПК B60W30/16, G01S13/93. Vehicle control apparatus / M. Tokimasa, Y. Masui, M. Nakadori. - № 14/796887; Заявлено 10.07.2015; Опубл. 16.01.2018. - 22 с.↑

A320. Пат. 9866993 США, МПК H04M1/00, H04W4/02, H04W64/00, G01S5/02, G01S5/14 и др. Distribution and utilization of antenna information for location determination operations / S. M. Das, S. P. Venkatraman, S. M. Sridhar, C. H. Aldana. - № 14/836308; Заявлено 26.08.2015; Опубл. 09.01.2018. - 57 с.↑

A321. Пат. 9865166 США, МПК B60Q1/48, G01S17/88, G08G1/14, G06K9/00, G08G1/04 и др. System and method for detecting a particular occupancy status of multiple parking positions of a parking facility / S. Nordbruch. - № 15/226102; Заявлено 02.08.2016; Опубл. 09.01.2018. - 8 с.↑

A322. Пат. 9865146 США, МПК G08B21/02, G01S15/93, G01S15/02, H04M1/725, G06K9/62 и др. System and method for accident avoidance during mobile device usage / H.-J. Barth. - № 15/397604; Заявлено 03.01.2017; Опубл. 09.01.2018. - 19 с.↑

A323. Пат. 9864056 США, МПК G01S13/95, G01S7/06. Matching system between convective cell in weather radar image and lightning and control method thereof / J. Y. Kim, J. S. Ko, H. J. Yang, T. S. Kwon, S. J. Oh и др. - № 14/848155; Заявлено 08.09.2015; Опубл. 09.01.2018. - 18 с.↑

A324. Пат. 9860688 США, МПК H04W4/02, H04W84/18, H04W64/00, H04W8/00, G01S13/75 и др. Systems, methods and devices for asset status determination / R. Kulkarni, S. Narahari, R. Roopreddy. - № 14/845071; Заявлено 03.09.2015; Опубл. 02.01.2018. - 60 с.↑

A325. Пат. 9859613 США, МПК H01Q1/42, G01S13/02, H01Q1/40, G01S7/03, G01S13/93 и др. Radar sensor including a radome / J. Pontes. - № 14/508484; Заявлено 07.10.2014; Опубл. 02.01.2018. - 7 с.↑

A326. Пат. 9857797 США, МПК G01C22/00, G05D1/00, G05D1/02, G01S7/481, G01S17/93 и др. Structure disposed with peripheral information detection sensor, and self-driving vehicle / Y. Hara, T. Shimizu, T. Yabe, M. Mizuuchi. - № 14/957092; Заявлено 02.12.2015; Опубл. 02.01.2018. - 24 с.↑

A327. Пат. 9857456 США, МПК G01C22/00, G01S17/93, G01S7/481, G01S13/93, G01S7/02 и др. Arrangement structure for peripheral information detection sensor and self-driving vehicle / Y. Hara, T. Endo, S. Yamamoto. - № 14/992512; Заявлено 11.01.2016; Опубл. 02.01.2018. - 22 с.↑

A328. Пат. 9852560 США, МПК G07C9/00, B60R25/00, G01S13/02. Vehicle remote function system and method for effectuating vehicle operations based on vehicle FOB movement / J. G. Bauman, T. O'Brien, J. Ye. - № 14/178324; Заявлено 12.02.2014; Опубл. 26.12.2017. - 10 с.↑

A329. Пат. 9852333 США, МПК A63F9/24, G06F19/00, G01S13/06, G01S5/00, G01S19/19 и др. System and method for detecting a user-dependent state of a sport object / M. Lochmann. - № 14/345974; Заявлено 20.09.2011; Опубл. 26.12.2017. - 16 с.↑

A330. Пат. 9851441 США, МПК G01S13/95, G01P5/00, G01S13/18, G01S13/58. Method and system for generating a distance velocity azimuth display / W.-C. Lee, J.-D. Jou. - № 14/164744; Заявлено 27.01.2014; Опубл. 26.12.2017. - 27 с.↑

A331. Пат. 9851440 США, МПК G01S13/89, G01S15/89, G01S7/41, G01S7/539. Subsurface imaging system and method for inspecting the condition of a structure / P. H. Boyer, N. L. Tofte, J. O. Jordan, I.I. - № 15/170430; Заявлено 01.06.2016; Опубл. 26.12.2017. - 24 с.↑

A332. Пат. 9851438 США, МПК G01S13/88. Method and system to identify and estimate relaxation frequencies for ground penetrating radars / A. A. Masoud, A. A. Al-Shaikhi. - № 14/522171; Заявлено 23.10.2014; Опубл. 26.12.2017. - 23 с.↑

A333. Пат. 9851436 США, МПК G01S13/93, H01Q21/00, H01Q1/32, G01S7/03, H01Q25/00 и др. Radar antenna assembly with panoramic detection / S. Shi. - № 14/589373; Заявлено 05.01.2015; Опубл. 26.12.2017. - 13 с.↑

A334. Пат. 9851432 США, МПК G01S7/40, B60R11/00, G01S7/02, G01S13/00, F16H57/021 и др. Sensor holder for a sensor for object detection / M. Dihlmann. - № 14/386197; Заявлено 21.01.2013; Опубл. 26.12.2017. - 8 с.↑

A335. Пат. 9849876 США, МПК B60W30/00, B60W10/184, B60R1/00, B60Q5/00, B60Q1/04 и др. Collision avoidance assistance device for a vehicle / E. Y. M. Teraoka, S. Tanaka, Y. Oikawa. - № 15/171005; Заявлено

02.06.2016; Опубл. 26.12.2017. - 26 с.↑

A336. Пат. 9849842 США, МПК B60R11/00, G01S13/93, G01S17/93, B60R11/02, G01S13/02 и др. Resettable tranceiver bracket / D. P. Hamilton. - № 15/234187; Заявлено 11.08.2016; Опубл. 26.12.2017. - 10 с.↑

A337. Пат. 9849798 США, МПК H02J7/00, G01V3/10, G01S13/82, G01S13/78, B60L11/18 и др. Positioning with a radio-based locking system / A. Barbul, J. Krammer, J. Berger, H. Wagatha. - № 14/615656; Заявлено 06.02.2015; Опубл. 26.12.2017. - 11 с.↑

A338. Пат. 9849334 США, МПК H04N7/18, G06K9/00, H04N5/262, A63B24/00, G01S13/87. Systems and methods for analyzing event data / D. J. DeAngelis, K. M. Sigel, E. G. Evansen. - № 14/968064; Заявлено 14.12.2015; Опубл. 26.12.2017. - 28 с.↑

A339. Пат. 9847029 США, МПК G08B1/08, G06Q10/08, G08G1/00, G01S13/84, H04W4/02. Apparatus and method for providing shipment information / R. A. Joao. - № 12/317504; Заявлено 24.12.2008; Опубл. 19.12.2017. - 25 с.↑

A340. Пат. 9846235 США, МПК G01S13/78, H01Q21/29, G10K11/34, G01S7/491, G01S13/04 и др. Friend or foe identification system and method / A. Aharoni, D. L. Alon, A. Yifrach. - № 14/419954; Заявлено 08.08.2013; Опубл. 19.12.2017. - 55 с.↑

A341. Пат. 9846226 США, МПК G01S13/00, G01S13/88, G01S13/52, G01S13/56. Motion detection device / T.-S. Horng, F.-K. Wang, Y.-C. Chiu. - № 14/664906; Заявлено 22.03.2015; Опубл. 19.12.2017. - 14 с.↑

A342. Пат. 9843109 США, МПК H01Q21/24, H01Q3/22, G01S13/93, G01S7/03, G01S7/02 и др. Antenna device and signal processing method / M. Nakamura, H. Satoh, S. Nishioka, H. Nishiuchi. - № 15/025195; Заявлено 14.07.2014; Опубл. 12.12.2017. - 38 с.↑

A343. Пат. 9843103 США, МПК H01Q19/10, H01Q3/24, G01S13/88, H01Q3/00, H01Q19/00. Methods and apparatus for controlling a surface scattering antenna array / J. A. Bowers, D. J. Brady, T. Driscoll, J. D. Hunt, R. A. Hyde и др. - № 14/485316; Заявлено 12.09.2014; Опубл. 12.12.2017. - 21 с.↑

A344. Пат. 9843101 США, МПК H01Q17/00, H01Q1/48, H01Q1/38, G01S13/88, H01Q9/30 и др. Antenna system for ground penetrating radar / E. Eide. - № 15/115499; Заявлено 09.01.2015; Опубл. 12.12.2017. - 9 с.↑

A345. Пат. 9841763 США, МПК G05D1/00, G05D1/02, G01S17/02, G01S7/497, G01S13/93. Predictive sensor array configuration system for an autonomous vehicle / J.-S. Valois. - № 14/971866; Заявлено 16.12.2015; Опубл. 12.12.2017. - 21 с.↑

A346. Пат. 9841501 США, МПК G08B5/22, G01S13/87. Use of blink counts to locate movable tagged assets / A. Salour, M. D. McInnis, D. D. Trimble. - № 13/663458; Заявлено 29.10.2012; Опубл. 12.12.2017. - 15 с.↑

A347. Пат. 9841500 США, МПК G01S13/75, G01S13/36, G01S13/32, G01S13/58, G01S13/84 и др. System and method for estimating range to an RFID tag / M. G. Melville, J. T. Elson. - № 15/062766; Заявлено 07.03.2016; Опубл. 12.12.2017. - 11 с.↑

A348. Пат. 9841490 США, МПК G01S3/02, G01S5/02, G06K7/10, G01S13/82, G01S13/75. System and method for detecting movement of a mobile asset and controlling operations of the asset based on its movement / J. C. Swartz, A. Hefner, C. W. Richards, I.V.G. J. Myers, M. Welsh. - № 15/408055; Заявлено 17.01.2017; Опубл. 12.12.2017. - 31 с.↑

A349. Пат. 9840236 США, МПК B60T7/22, B60K31/00, G08G1/16, G01S13/93. Method of, and apparatus for, operating a vehicle / C. Roblin, G. Dupuis. - № 14/245432; Заявлено 04.04.2014; Опубл. 12.12.2017. - 12 с.↑

A350. Пат. 9840192 США, МПК B60Q1/52, B60Q1/30, B60Q1/50, G08G1/16, G01S13/93. Blind spot warning apparatus, assembly and method / S. G. Downey. - № 14/626197; Заявлено 19.02.2015; Опубл. 12.12.2017. - 9 с.↑

A351. Пат. 9839892 США, МПК G01S13/08, B01J8/20, B01J8/00, G01F23/284, B01J8/22 и др. Method for monitoring the level of an ethylene polymerization catalyst slurry / L. Fouarge, A. Brusselle. - № 14/677348; Заявлено 02.04.2015; Опубл. 12.12.2017. - 17 с.↑

A352. Пат. 9836970 США, МПК G08G1/017, G01S15/06, G01S13/06, B60S3/04, G08G1/095 и др. Vehicle positioning guide lights / C. Reed, I.I.I.R. L. Fye, J. - № 15/160834; Заявлено 20.05.2016; Опубл. 05.12.2017. - 8 с.↑

A353. Пат. 9836964 США, МПК G08G1/123, G08G1/017, G08G1/16, B60W30/16, G08G1/00 и др. Vehicle identification system and vehicle identification device / Y. Nemoto. - № 14/125376; Заявлено 26.07.2011; Опубл. 05.12.2017. - 27 с.↑

A354. Пат. 9836961 США, МПК G08G1/01, G08G1/0967, G06K9/00, G06K9/32, G08G1/04 и др. System and method for correcting position information of surrounding vehicle / B. W. Koo. - № 14/811156; Заявлено 28.07.2015; Опубл. 05.12.2017. - 10 с.↑

A355. Пат. 9835723 США, МПК G01S13/93, G01S13/34, G01S13/42, G01S13/22, G01S13/524 и др. Radar ambiguity resolving detector / F. G. Jansen, Z. Zivkovic. - № 14/527840; Заявлено 30.10.2014; Опубл. 05.12.2017. - 22 с.↑

A356. Пат. 9835721 США, МПК G01S13/52, G01S13/95, G01S13/524, G01S7/41, G01S13/89 и др. Clutter suppressing device and radar apparatus provided with the same / M. Minowa. - № 14/836242; Заявлено 26.08.2015; Опубл. 05.12.2017. - 15 с.↑

A357. Пат. 9835719 США, МПК G01S13/00, G01S15/00, G01S19/00, G01S19/13, G01S17/00 и др. Systems and methods for adaptive sensor angle positioning in vehicles / T. D. Nguyen. - № 15/131540; Заявлено 18.04.2016; Опубл. 05.12.2017. - 18 с.↑

A358. Пат. 9835712 США, МПК G01S7/40, G01S7/02, G01S13/02, G01S13/93, G01S13/34 и др. Vehicle radar diagnostic arrangement / N. Kollmer. - № 14/653349; Заявлено 21.12.2012; Опубл. 05.12.2017. - 12 с.↑

A724. Пат. 9453940 США, МПК G01W1/10, G01S13/95. System and method for tornado prediction and detection / Y. K. Sasaki. - № 14/435937; Заявлено 14.03.2014; Опубл. 27.09.2016. - 31 с.↑

A725. Пат. 9453912 США, МПК G01S13/93, G01S7/12, G01S7/10, G01S7/24, G01S13/42. Device and method for displaying ship perimeter information / H. Kaida, M. Kondo, K. Yanagi, M. Nakahama. - № 13/864083; Заявлено 16.04.2013; Опубл. 27.09.2016. - 14 с.↑

A726. Пат. 9453910 США, МПК G01S13/02, G01S7/40, G01S13/93, G01S13/86. Detecting radar blockage based on drive history / S. Elwart, A. L. Mills, D. J. Spero. - № 14/259422; Заявлено 23.04.2014; Опубл. 27.09.2016. - 12 с.↑

A727. Пат. 9453755 США, МПК G01F23/284, G01S13/18. TDR fluid level sensor / R. Lavon, C. E. Carvalho, T. Miskell, V. Rizzo, K. J. Petriel. - № 12/243511; Заявлено 01.10.2008; Опубл. 27.09.2016. - 18 с.↑

A728. Пат. 9452319 США, МПК A63B24/00, G01S13/75, G01S13/34, A63B71/06, A43B5/02 и др. Athletic performance monitoring systems and methods in a team sports environment / J. Molyneux, A. B. Weast, B. S. Burroughs, S. R. Berggren, C. J. Lindsay и др. - № 14/297268; Заявлено 05.06.2014; Опубл. 27.09.2016. - 114 с. ↑

A729. Пат. 9448305 США, МПК H01Q19/10, G01S13/89, G01S13/88, H01Q3/34, H01Q19/00 и др. Surface scattering antenna array / J. A. Bowers, D. J. Brady, T. Driscoll, J. D. Hunt, R. A. Hyde и др. - № 14/226213; Заявлено 26.03.2014; Опубл. 20.09.2016. - 20 с.↑

A730. Пат. 9448304 США, МПК G06F17/00, G06N5/02, G01S7/00, G01S13/72, G01S13/66 и др. Ground moving target indicator (GMTI) radar that converts radar tracks to directed graphs (DG) , and creates weighted DGs aligned with superimposed with digital maps / D. L. MacPherson. - № 14/204850; Заявлено 11.03.2014; Опубл. 20.09.2016. - 21 с.↑

A731. Пат. 9448300 США, МПК G01S13/02, G01S7/00, G01S7/02, G01S7/295, H03M7/30 и др. Signal-based data compression / F. Jansen, Z. Zivkovic. - № 14/288670; Заявлено 28.05.2014; Опубл. 20.09.2016. - 27 с.↑

A732. Пат. 9447773 США, МПК G01S7/40, F03D7/06, G01B15/06, G01S13/08. Arrangement to measure the deflection of a blade of a wind turbine / P. Egedal, J. W. Staerdahl, A. Ziroff. - № 14/181689; Заявлено 16.02.2014; Опубл. 20.09.2016. - 7 с.↑

A733. Пат. 9444523 США, МПК G01R27/26, H04B5/00, G01S13/04, G01S13/08. Proximity sensing using EHF signals / G. D. McCormack, I. A. Kyles. - № 14/881901; Заявлено 13.10.2015; Опубл. 13.09.2016. - 20 с.↑

A734. Пат. 9442527 США, МПК G06F1/16, G01S13/93, G01S17/93. Docking and undocking mechanism for remote devices / N. Schmidt. - № 14/185666; Заявлено 20.02.2014; Опубл. 13.09.2016. - 11 с.↑

A735. Пат. 9442192 США, МПК G01S13/00, G01S13/84, G01S13/75, G01S13/87. Method and apparatus for location determination using reflected interferometry / G. D. Durgin. - № 12/505916; Заявлено 20.07.2009; Опубл. 13.09.2016. - 17 с.↑

A736. Пат. 9442189 США, МПК G01S13/10, G01S13/88, G01S13/02, G01S13/89, G01S13/18 и др. Multichannel UWB-based radar life detector and positioning method thereof / J. Wang, X. Jing, Y. Zhang, H. Lu, Y. Li и др. - № 14/357773; Заявлено 20.06.2011; Опубл. 13.09.2016. - 25 с.↑

A737. Пат. 9442188 США, МПК G01S7/35, G01S13/00, G01S13/87. Negative pseudo-range processing with multi-static FMCW radars / W. C. Rector, D. E. Barrick, B. J. Lipa, H. Aguilar, J. - № 14/213841; Заявлено 14.03.2014; Опубл. 13.09.2016. - 14 с.↑

A738. Пат. 9441949 США, МПК G01B9/02, G01S17/32, G01S7/491, G01S17/36, G01S13/34. Method for generating M demodulation signals using at least one primary interferometer / P. Feneyrou, G. Pillet, J. Minet. - № 14/698658; Заявлено 28.04.2015; Опубл. 13.09.2016. - 18 с.↑

A739. Пат. 9440648 США, МПК G06F7/70, B60W30/09, B60T7/22, B60Q9/00, G06K9/00 и др. Vehicle safety apparatus / M. Uechi. - № 14/439007; Заявлено 30.10.2012; Опубл. 13.09.2016. - 13 с.↑

A740. Пат. 9437086 США, МПК G08B5/36, H05B37/02, G01S13/74. Systems and apparatus for the light-based communication of service orders and personal objects identification / D. G. Loveland, L. L. D. V. D. Poel, D. Sekulovski, A. J. W. A. Vermeulen. - № 14/307867; Заявлено 18.06.2014; Опубл. 06.09.2016. - 21 с.↑

A741. Пат. 9436858 США, МПК G06K7/10, G01S5/02, G01S13/87. Simple and precise radio frequency locating system and method / J. Y. Liao. - № 14/152466; Заявлено 10.01.2014; Опубл. 06.09.2016. - 15 с.↑

A742. Пат. 9435885 США, МПК G06K9/00, G01S13/89, B62D6/00, G01S17/93, G01S17/89 и др. Road-terrain detection method and system for driver assistance systems / J. Fritsch, T. Kuhnl. - № 13/558407; Заявлено 26.07.2012; Опубл. 06.09.2016. - 20 с.↑

A743. Пат. 9435879 США, МПК G01S7/04, G08G1/16, G01S7/22, G01S13/93. Alert display device and alert display method / S. Hayasaka. - № 14/475030; Заявлено 02.09.2014; Опубл. 06.09.2016. - 14 с.↑

A744. Пат. 9435653 США, МПК G01C21/30, G05D1/02, B60W30/095, G01S13/93, B60W30/12 и др. Sensor-aided vehicle positioning system / S. Zeng, J. A. Salinger, B. B. Litkouhi, J. Pazhayampallil, K. A. O'Dea и др. - № 14/028709; Заявлено 17.09.2013; Опубл. 06.09.2016. - 13 с.↑

A745. Пат. 9429650 США, МПК G01S13/86, G06K9/00, G01S13/93, G06K9/62. Fusion of obstacle detection using radar and camera / S. Zeng, W. Zhang, B. B. Litkouhi. - № 13/563993; Заявлено 01.08.2012; Опубл. 30.08.2016. - 10 с.↑

A746. Пат. 9429648 США, МПК G01S13/72, G01S13/58, G01S13/92, G01S13/02, G01S13/34. Radar apparatus and computer-readable storage medium / Y. Sugiyama. - № 14/180905; Заявлено 14.02.2014; Опубл. 30.08.2016. - 23 с.↑

A747. Пат. 9427624 США, МПК A63B24/00, A43B5/02, A63B71/06, G01S13/34, G01S13/75 и др. Athletic performance monitoring systems and methods in a team sports environment / J. Molyneux, A. B. Weast, B. S. Burroughs, S. R. Berggren, C. J. Lindsay и др. - № 14/936273; Заявлено 09.11.2015; Опубл. 30.08.2016. - 114 с. ↑

A748. Пат. 9424750 США, МПК G06F17/10, G08G1/16, G01S7/02, G01S13/06, G01S13/93. Vehicle control system, specific object determination device, specific object determination method, and non-transitory storage medium storing specific object determination program / H. Hayashi. - № 14/682650; Заявлено 09.04.2015; Опубл. 23.08.2016. - 14 с.↑

A749. Пат. 9423794 США, МПК G05D1/02, G08G1/00, G01S13/93. Control system for travel in a platoon / H. Lind, J. Ekmark. - № 13/700318; Заявлено 30.05.2011; Опубл. 23.08.2016. - 12 с.↑

A750. Пат. 9423498 США, МПК G01S13/93, G08G1/00, G08G1/16, G01S7/40. Use of motion data in the processing of automotive radar image processing / A. Brown. - № 13/626673; Заявлено 25.09.2012; Опубл. 23.08.2016. - 16 с.↑

A778. Пат. 9389312 США, МПК G01S13/02, G01S13/93, G01S7/00, G01S13/42, G01S13/58. Radar sensor for a motor vehicle, motor vehicle and communication method / R. Khlifi. - № 13/955758; Заявлено 31.07.2013; Опубл. 12.07.2016. - 9 с.↑

A779. Пат. 9384669 США, МПК H04N7/18, G01S13/00, G06K9/00, G08G5/00, G08G5/04 и др. Method and arrangement for estimating at least one parameter of an intruder / E. Petrini, B.-G. Sundqvist, A. Persson, J. Pellebergs. - № 12/641353; Заявлено 18.12.2009; Опубл. 05.07.2016. - 16 с.↑

A780. Пат. 9383441 США, МПК G01S13/00, G01S13/42, G01S13/86, H01Q15/14. Indoor position location using delayed scanned directional reflectors / S. G. Younis. - № 14/835554; Заявлено 25.08.2015; Опубл. 05.07.2016. - 30 с.↑

A781. Пат. 9383439 США, МПК G01R27/02, G01S13/04, G01V3/12. Detection of conductive material in a thin film / C. G. Buxton, J. S. Huggins. - № 14/317414; Заявлено 27.06.2014; Опубл. 05.07.2016. - 42 с.↑

A782. Пат. 9383426 США, МПК G01S13/04, G01S13/74, G01S13/56, G01S1/02, G01S5/10 и др. Real-time, two dimensional (2-D) tracking of first responders with identification inside premises / F. Mohamadi. - № 14/069237; Заявлено 31.10.2013; Опубл. 05.07.2016. - 25 с.↑

A783. Пат. 9381917 США, МПК B60W30/14, G05D1/00, G01S13/86. Predictive reasoning for controlling speed of a vehicle / D. Dolgov, D. Ferguson. - № 14/827578; Заявлено 17.08.2015; Опубл. 05.07.2016. - 21 с.↑

A784. Пат. 9381916 США, МПК G08G1/16, B60W30/095, G01S13/93, G05D1/00. System and method for predicting behaviors of detected objects through environment representation / J. Zhu, D. I. Ferguson. - № 13/366828; Заявлено 06.02.2012; Опубл. 05.07.2016. - 22 с.↑

A785. Пат. 9379447 США, МПК H01Q13/22, H01Q21/00, G01S7/03, H01Q13/20, H01Q21/06 и др. Coaxially-fed slot array antenna and vehicle radar apparatus / K. Kodama. - № 11/936404; Заявлено 07.11.2007; Опубл. 28.06.2016. - 14 с.↑

A786. Пат. 9377528 США, МПК G01S13/00, G01B11/25, G01S15/89, G01V3/12, G01S13/88 и др. Roaming mobile sensor platform for collecting geo-referenced data and creating thematic maps / R. Birken, M.-L. Wang, C.

M. Rappaport, S. Wadia-Fascetti, J. G. McDaniel. - № 13/636112; Заявлено 21.03.2011; Опубл. 28.06.2016. - 25 с.↑

A787. Пат. 9377527 США, МПК G01S13/06, G01S13/24, G01S7/02, G01S13/00, H04W16/00. Method and apparatus for enhanced multi-node utilization of an electromagnetic state space / H. Marr, C. T. Hansen, B. Pierce. - № 14/078997; Заявлено 13.11.2013; Опубл. 28.06.2016. - 20 с.↑

A788. Пат. 9375628 США, МПК G08B1/08, G06Q10/08, A63B24/00, A63B71/06, G06Q50/28 и др. Associative object tracking systems and methods / D. J. DeAngelis, E. G. Evansen, G. M. Reilly. - № 13/301614; Заявлено 21.11.2011; Опубл. 28.06.2016. - 25 с.↑

A789. Пат. 9373202 США, МПК G07C5/08, B60R21/0136, B60R21/0134, B60R21/013, B60W30/095 и др. Vehicle information recording apparatus / N. Shimizu, Y. Katoh. - № 14/150132; Заявлено 08.01.2014; Опубл. 21.06.2016. - 13 с.↑

A790. Пат. 9372263 США, МПК G01S13/58, G01S13/87, G01S13/42, G01S13/95, G01S13/02. Radar system and method / G. K. A. Oswald, C. D. Webster, A. G. Smithson. - № 12/995169; Заявлено 03.12.2008; Опубл. 21.06.2016. - 51 с.↑

A791. Пат. 9372262 США, МПК G01S13/93, G01S13/86, B60W30/09, G08G1/16, G01S13/72. Device and method for judging likelihood of collision between vehicle and target, vehicle collision avoidance system, and method for avoiding collision between vehicle and target / R. Takaki. - № 14/080868; Заявлено 15.11.2013; Опубл. 21.06.2016. - 19 с.↑

A792. Пат. 9372261 США, МПК G01S13/93, G01S7/35, G01S13/50, G01S13/34, G01S13/58 и др. Radar device and method of processing signal / M. Aoki, H. Asanuma, Y. Kurono. - № 13/847620; Заявлено 20.03.2013; Опубл. 21.06.2016. - 27 с.↑

A793. Пат. 9372260 США, МПК G01S7/292, G01S7/41, G01S13/34, G01S13/42, G01S13/524 и др. Object detecting device, object detecting method, object detecting program, and motion control system / T. Kambe. - № 14/077984; Заявлено 12.11.2013; Опубл. 21.06.2016. - 25 с.↑

A794. Пат. 9372256 США, МПК G01S7/02, G01S13/89, A61B5/05, H01Q9/40, G01S13/88 и др. Wafer scale sensor ultra-wideband array for tissue diagnosis / F. Mohamadi. - № 14/191118; Заявлено 26.02.2014; Опубл. 21.06.2016. - 23 с.↑

A795. Пат. 9366756 США, МПК G08B13/14, G01S13/44, G01S13/76. RF tag reader for accurate position determination / C. C. Bantin. - № 12/329564; Заявлено 06.12.2008; Опубл. 14.06.2016. - 8 с.↑

A796. Пат. 9366751 США, МПК G01S7/40, G01S13/93, G01S7/00, G01S13/00. Method and device for ascertaining and compensating for a misalignment angle of a radar sensor of a vehicle / D. Steinbuch, R. Schnabel. - № 14/250005; Заявлено 10.04.2014; Опубл. 14.06.2016. - 13 с.↑

A797. Пат. 9366745 США, МПК G01S3/02, G01S5/04, G01S1/02, G01S5/14, G01S13/38 и др. Methods and systems for determining the location of an electronic device using multi-tone frequency signals / M. Moshfeghi. - № 14/302378; Заявлено 11.06.2014; Опубл. 14.06.2016. - 23 с.↑

A798. Пат. 9365215 США, МПК G06F7/70, G01S13/00, B60W30/14, G08G1/16, B60W30/16 и др. Vehicle travel assist apparatus / Y. Ohmori, M. Shiota, M. Takeda, Y. Mori. - № 14/405652; Заявлено 13.06.2013; Опубл. 14.06.2016. - 17 с.↑

A799. Пат. 9365155 США, МПК G01S13/88, B60Q5/00, B60Q1/52, G01S13/93, G01S13/86 и др. Advanced warning and risk evasion system and method / E. Hathaway, M. Green, K. Baumann, C. Green, L. Cole и др. - № 14/500778; Заявлено 29.09.2014; Опубл. 14.06.2016. - 23 с.↑

A800. Пат. 9365126 США, МПК H02J7/00, H01Q21/00, G01S13/56, B60L11/18, H01F27/42 и др. System and method for detecting the presence of a moving object below a vehicle / H. Widmer, L. Sieber, M. Bittner. - № 14/059299; Заявлено 21.10.2013; Опубл. 14.06.2016. - 29 с.↑

A801. Пат. 9361801 США, МПК G08G1/00, G08G1/08, G08G1/01, G01S13/34, G01S13/58 и др. Apparatus for measuring vehicle queue length, method for measuring vehicle queue length, and computer-readable recording medium storing computer program for measuring vehicle queue length / M. Ochi. - № 13/561740; Заявлено 30.07.2012; Опубл. 07.06.2016. - 18 с.↑

A802. Пат. 9361650 США, МПК G08G1/16, G06Q40/08, G06T13/80, G07C5/12, G07C5/00 и др. Synchronization of vehicle sensor information / T. Binion, J. Harr, B. Fields, S. Cielocha, S. J. Balbach. - № 14/057435; Заявлено 18.10.2013; Опубл. 07.06.2016. - 35 с.↑

A803. Пат. 9361352 США, МПК G01S13/89, G06F17/30. Point pattern match-based change detection in a constellation of previously detected objects / D. W. Paglieroni. - № 13/748447; Заявлено 23.01.2013; Опубл. 07.06.2016. - 26 с.↑

A804. Пат. 9360279 США, МПК F41H3/00, H01Q17/00, G01S13/00. Device for signature adaptation and object provided with such a device / P. Sjolund. - № 14/122657; Заявлено 05.06.2012; Опубл. 07.06.2016. - 37 с.↑

A805. Пат. 9358963 США, МПК B60K31/00, B60T7/22, B60T8/17, B60W30/09, G01S17/93 и др. Motor vehicle safety arrangement and method / S. Solyom, J. Ekmark. - № 14/481024; Заявлено 09.09.2014; Опубл. 07.06.2016. - 11 с.↑

A806. Пат. 9358924 США, МПК G01S7/41, G01S13/93, B60Q9/00. System and method for modeling advanced automotive safety systems / D. A. Preston, J. D. Preston, K. Schofield, T. A. Manos. - № 12/776137; Заявлено 07.05.2010; Опубл. 07.06.2016. - 51 с.↑

A807. Пат. 9354809 США, МПК G06F3/0488, G06F3/0484, G01S13/86, G01S7/62, G01S7/22 и др. Display device, display program and display method / T. Asahara, M. Ohhora. - № 14/349302; Заявлено 03.10.2011; Опубл. 31.05.2016. - 17 с.↑

A808. Пат. 9354308 США, МПК G01S13/90. Micro climate corrections for radar interferometry measurements / C. Conquest. - № 14/561804; Заявлено 05.12.2014; Опубл. 31.05.2016. - 9 с.↑

A809. Пат. 9354304 США, МПК G01S13/22, G01S13/42, G01S13/93, G01S13/58, G01S13/34 и др. Method for cyclically measuring distances and velocities of objects using an FMCW radar sensor / A. Kirsch, M. Schoor. - № 14/152264; Заявлено 10.01.2014; Опубл. 31.05.2016. - 12 с.↑

A810. Пат. 9354100 США, МПК G01F23/284, G01F23/296, G01F23/292, G01S7/292, G01S13/10 и др. Device and method for determining media characteristics and container characteristics / K. Griessbaum, R. Welle. - № 13/454715; Заявлено 24.04.2012; Опубл. 31.05.2016. - 23 с.↑

A811. Пат. 9348025 США, МПК G08G1/14, G01S15/87, G01S15/04, G01S15/93, G01S13/93. Device and method for lateral environment detection of a motor vehicle / A. Urban, S. Max, C. Prausse, R. Katzwinkel. - № 14/488641; Заявлено 17.09.2014; Опубл. 24.05.2016. - 16 с.↑

A812. Пат. 9348021 США, МПК G01S13/52, G01S13/524, G01S13/18, G01S7/41. Methods and apparatus for adaptive motion compensation to remove translational movement between a sensor and a target / A. C. Wallace. - № 13/826683; Заявлено 14.03.2013; Опубл. 24.05.2016. - 18 с.↑

A813. Пат. 9348020 США, МПК G01S13/89, G01S13/02, G01S13/88, G01S7/35. Offset frequency homodyne ground penetrating radar / A. Wilson-Langman, K. J. Ryerson, W. Rothe. - № 13/797929; Заявлено 12.03.2013; Опубл. 24.05.2016. - 29 с.↑

A814. Пат. 9348017 США, МПК G01S7/40, G01S13/93. Method and device for ascertaining a misalignment of a radar sensor of a vehicle / S. Steinlechner. - № 14/283416; Заявлено 21.05.2014; Опубл. 24.05.2016. - 13 с.↑

A815. Пат. 9348015 США, МПК G01S13/95, G01S7/02, G01S7/292, G01S13/00. Integrated rainfall estimation method using X-band dual-polarimetric radar measurement data / S. H. Lim. - № 14/307792; Заявлено 18.06.2014; Опубл. 24.05.2016. - 25 с.↑

A816. Пат. 9348014 США, МПК G01S13/93, H01Q1/32, G01S7/481, H01Q1/42, G01S7/02 и др. Radar apparatus for vehicle / S. M. Lee, B. C. Lee, P. J. Jeong, H. G. Kim, Y. S. Oh и др. - № 14/010081; Заявлено 26.08.2013; Опубл. 24.05.2016. - 10 с.↑

A817. Пат. 9348009 США, МПК G01S13/06, G01S3/02, G01S5/02, F41G3/22, G01S1/02 и др. Electromagnetic emitter emitting simultaneously along three orthogonal axes to detect object position and orientation / Y. Sontag. - № 13/408827; Заявлено 29.02.2012; Опубл. 24.05.2016. - 18 с.↑

A818. Пат. 9344197 США, МПК H04B10/00, H04B10/50, G01S7/03, H04B10/516, H01Q9/04 и др. Wave dielectric transmission device, manufacturing method thereof, and in-millimeter wave dielectric transmission method / H. Kawamura, Y. Okada. - № 14/721204; Заявлено 26.05.2015; Опубл. 17.05.2016. - 22 с.↑

A819. Пат. 9342988 США, МПК G05D1/00, G05D1/08, G05D3/00, G01C23/00, G01C5/06 и др. Method and device for determining a linear terrain profile along a lateral approach trajectory of an airport / T. Bourret, K. A. Horimoto. - № 14/586461; Заявлено 30.12.2014; Опубл. 17.05.2016. - 10 с.↑

A820. Пат. 9341717 США, МПК G01S13/08, G01S19/18, B63G8/00, F42B12/36, B63G8/41. Apparatus for position notification of vehicle, method and computer-readable medium / I. Yamaguchi. - № 12/944252; Заявлено 11.11.2010; Опубл. 17.05.2016. - 14 с.↑

A821. Пат. 9341711 США, МПК G01S13/86, G01S13/32, G08G1/054, G08G1/052, G08G1/01 и др. Method for detecting traffic infractions in a traffic light zone through rear end measurement by a radar device / O. Blanke. - № 14/211071; Заявлено 14.03.2014; Опубл. 17.05.2016. - 9 с.↑

A822. Пат. 9341708 США, МПК G01S13/93, G01S13/89, G01S7/02, G01W1/14, G06K9/00 и др. Road surface condition detection device and road surface condition detection method / M. Nakamura, H. Satoh. - № 14/419758; Заявлено 01.08.2013; Опубл. 17.05.2016. - 11 с.↑

A823. Пат. 9341707 США, МПК G01S13/08, G01S13/91, G08G1/015, G01S13/52, G01S7/41. Method for classifying moving vehicles / M. Lehning, D. Proefrock. - № 13/945035; Заявлено 18.07.2013; Опубл. 17.05.2016. - 13 с.↑

A824. Пат. 9341706 США, МПК G01S7/292, G01S7/41, G01S13/52, G01S7/28, G01S13/91 и др. Radar system / K. D. Ward. - № 13/879364; Заявлено 10.10.2011; Опубл. 17.05.2016. - 16 с.↑

A825. Пат. 9341702 США, МПК H04M11/04, H04W24/00, G01S5/10, G01S3/14, G01S3/48 и др. Method of distance measurement / R. Reimann. - № 14/832288; Заявлено 21.08.2015; Опубл. 17.05.2016. - 34 с.↑

A826. Пат. 9341581 США, МПК G01N22/00, G01S13/88, G01S13/02, G01N33/18, G01F1/52 и др. Waste water assessment / M. J. Croft, D. K. Wallace. - № 13/634195; Заявлено 07.03.2011; Опубл. 17.05.2016. - 13 с.↑

A827. Пат. 9341471 США, МПК G01B21/02, G01S7/40, G06F17/00, G01S13/08, G01S7/52 и др. Calibrated hardware sensors for estimating real-world distances / S. Vaddadi, J. H. Hong, C. U. Lee. - № 14/537852; Заявлено 10.11.2014; Опубл. 17.05.2016. - 18 с.↑

A831. Пат. 9336627 США, МПК G06F17/50, G06T17/05, G01S13/89. Creating a model of a scanned surface for comparison to a reference-surface model / P. J. Digiacobbe, C. M. Siebern. - № 13/793700; Заявлено 11.03.2013; Опубл. 10.05.2016. - 11 с.↑

A832. Пат. 9335411 США, МПК G01S13/93, G01S13/86, G01S13/02. Forward facing sensing system for vehicle / N. R. Lynam. - № 15/005092; Заявлено 25.01.2016; Опубл. 10.05.2016. - 17 с.↑

A833. Пат. 9335405 США, МПК G01S13/93, G01S13/02, G01S13/91, G01S13/00. Enhanced RF detection system / W. Durand, J. Pesik. - № 14/296108; Заявлено 04.06.2014; Опубл. 10.05.2016. - 11 с.↑

A834. Пат. 9335401 США, МПК G01S13/34, G01S7/03, G01S7/35, G01S13/56, G01S13/58 и др. Full analog microwave sensor for multiple range selection and ultra-low power consumption / C.-H. Chang, L.-W. Yu, Y.-T. Yang, Y.-C. Sung, M.-T. Hsu и др. - № 14/155885; Заявлено 15.01.2014; Опубл. 10.05.2016. - 20 с. ↑

A835. Пат. 9335147 США, МПК G01B7/00, G01S7/03, G01S7/40, G01S13/88. Manual positioning device / H. Sgarz, T. Zibold. - № 13/699183; Заявлено 01.02.2011; Опубл. 10.05.2016. - 9 с. ↑

A836. Пат. 9333954 США, МПК B60T7/22, G01S17/02, G01S15/04, B62D6/00, G08G1/16 и др. Driver assistance system for a motor vehicle / T. Schneider. - № 14/326245; Заявлено 08.07.2014; Опубл. 10.05.2016. - 10 с. ↑

A837. Пат. 9332383 США, МПК H04W64/00, G01S5/14, G01S5/02, H04W4/02, G01S13/87. Time of arrival based positioning system / X. Zhang, N. Zhang. - № 14/345941; Заявлено 19.09.2012; Опубл. 03.05.2016. - 25 с. ↑

A838. Пат. 9329728 США, МПК G06F3/043, G01S13/46. User interfaces / T. Dahl. - № 13/500898; Заявлено 07.10.2010; Опубл. 03.05.2016. - 33 с. ↑

A839. Пат. 9329266 США, МПК G01S13/95, G01S7/28. Weather radar apparatus, observation sequence generation method, and observation sequence generation program / F. Mizutani, H. Marui. - № 14/169505; Заявлено 31.01.2014; Опубл. 03.05.2016. - 11 с. ↑

A840. Пат. 9329072 США, МПК G01S7/529, G01S7/292, G01S13/02, G01S7/34, G01S13/88 и др. Receiver with programmable gain for UWB radar / B. Sai. - № 14/099071; Заявлено 06.12.2013; Опубл. 03.05.2016. - 8 с. ↑

A841. Пат. 9322913 США, МПК G01S13/95, G01S7/288, G01S7/03, H01Q1/02, H01Q3/08 и др. Transportable radar utilizing a fiber optic rotary joint for communication of radar reflectivity data and harmonic drives for positioning the antenna / M. B. Knight, J. C. Fanning, J. R. Helvin, M. A. Jones, N. E. Lawrence и др. - № 13/655447; Заявлено 19.10.2012; Опубл. 26.04.2016. - 25 с. ↑

A842. Пат. 9322912 США, МПК G01S13/95, H01Q19/13, H01Q3/08, H01Q1/02, G01S7/288 и др. Transportable radar utilizing harmonic drives for anti-backlash antenna movement / M. B. Knight, J. C. Fanning, J. R. Helvin, M. A. Jones, N. E. Lawrence и др. - № 13/655443; Заявлено 18.10.2012; Опубл. 26.04.2016. - 27 с. ↑

A843. Пат. 9322910 США, МПК G01S13/89, G01V3/08, G01V3/15, G01V3/16. Method of real time subsurface imaging using electromagnetic data acquired from moving platforms / M. S. Zhdanov, G. A. Wilson, L. H. Cox. - № 13/488256; Заявлено 04.06.2012; Опубл. 26.04.2016. - 25 с. ↑

A844. Пат. 9322909 США, МПК G01S13/93, G01S13/86, G01S13/00. Negative obstacle detection with stereo camera and long range radar / D. L. Agnew. - № 14/101904; Заявлено 10.12.2013; Опубл. 26.04.2016. - 6 с. ↑

A845. Пат. 9322907 США, МПК G06K19/00, G01S13/78, G01S7/04. Behavior based friend foe neutral determination method / S. L. Kadambe, B. J. Haan, M. M. Carvalho, C. A. P. Monsalve. - № 13/568772; Заявлено 07.08.2012; Опубл. 26.04.2016. - 31 с. ↑

A846. Пат. 9322905 США, МПК G01S13/91, G01S13/58, G08G1/015, G08G1/052, G01S7/41 и др. Radar device / T. Kishigami, T. Tokuhiro, T. Morita. - № 14/118087; Заявлено 12.03.2013; Опубл. 26.04.2016. - 41 с. ↑

A847. Пат. 9322904 США, МПК G01R27/26, G01S13/08, G01S13/04, H04B5/00. Proximity sensing using EHF signals / G. D. McCormack, I. A. Kyles. - № 13/524956; Заявлено 15.06.2012; Опубл. 26.04.2016. - 21 с. ↑

A848. Пат. 9321460 США, МПК G06F17/10, B60W30/09, B61L29/24, B61L29/30, G01S17/93 и др. Railroad crossing barrier estimating apparatus and vehicle / Y. Sasabuchi, H. Koike. - № 13/793286; Заявлено 11.03.2013; Опубл. 26.04.2016. - 26 с. ↑

A849. Пат. 9318023 США, МПК G08G1/16, B62D15/02, B60W30/09, B60W10/18, B60W10/20 и др. System and method for collision avoidance maneuver path determination with jerk limit / N. K. Moshchuk, S.-K. Chen, C. T. Zagorski, A. Chatterjee. - № 13/222499; Заявлено 31.08.2011; Опубл. 19.04.2016. - 19 с. ↑

A850. Пат. 9316733 США, МПК G01S13/89, G01S13/86, H01Q1/28, G01S7/02, G01S13/02 и др. W-band, ultra-wide band (UWB) trajectory detector / F. Mohamadi. - № 13/722899; Заявлено 20.12.2012; Опубл.

19.04.2016. - 18 с.↑

A851. Пат. 9316732 США, МПК G01S13/88, G01S13/89, G01S7/41, G01S13/04, G01S7/02. Standoff screening apparatus for detection of concealed weapons / F. Mohamadi. - № 13/794449; Заявлено 11.03.2013; Опубл. 19.04.2016. - 24 с.↑

A852. Пат. 9316730 США, МПК G01S13/56, G01S13/93, G01S7/40, G01S13/62, G01S13/00. Monitoring device and monitoring method / J. Kajiki, M. Ochi, T. Ikeya, K. Shite. - № 13/905040; Заявлено 29.05.2013; Опубл. 19.04.2016. - 35 с.↑

A853. Пат. 9316728 США, МПК G01S13/08, G06K7/10. System and method for estimating range to an RFID tag / M. G. Melville, J. T. Elson. - № 14/734655; Заявлено 09.06.2015; Опубл. 19.04.2016. - 9 с.↑

A854. Пат. 9315151 США, МПК G01C21/00, B60R11/04, H04N7/18, G01C21/36, B60R1/12 и др. Driver assist system for vehicle / D. W. Taylor, K. C. McCarthy, N. R. Lynam, K. Schofield. - № 14/678145; Заявлено 03.04.2015; Опубл. 19.04.2016. - 40 с.↑

A855. Пат. 9313764 США, МПК H04W24/00, G01S13/87, G01S5/14, H04W64/00, G01S13/76. Wireless localisation system / M. Hedley, Y. J. Guo, X. Huang. - № 14/233997; Заявлено 20.07.2011; Опубл. 12.04.2016. - 18 с.↑

A856. Пат. 9313462 США, МПК H04N7/18, G01S13/93, G01S13/72, G01S13/58, G08G1/16 и др. Vehicle with improved traffic-object position detection using symmetric search / N. Einecke, S. Rebhan, M. Nishigaki. - № 13/799338; Заявлено 13.03.2013; Опубл. 12.04.2016. - 16 с.↑

A857. Пат. 9312400 США, МПК H02J1/00, H02M3/07, H02J3/00, H01L31/02, H02M3/156 и др. Power harvesting device / M. Hassan-Ali, B. Golubovic. - № 13/175756; Заявлено 01.07.2011; Опубл. 12.04.2016. - 16 с.↑

A858. Пат. 9311821 США, МПК H04B7/185, H04W4/02, H04W4/20, H04L29/06, H04W4/00 и др. Techniques for reporting on or tracking ground vehicles / M. S. Melum, R. C. Nelson. - № 14/132714; Заявлено 18.12.2013; Опубл. 12.04.2016. - 13 с.↑

A859. Пат. 9310480 США, МПК G01S13/95, G01S13/524, G01S13/532, G01S13/22. Method and arrangement for removing ground clutter / J. Sierwald. - № 14/271796; Заявлено 07.05.2014; Опубл. 12.04.2016. - 18 с.↑

A860. Пат. 9310479 США, МПК G01S13/95, H01Q1/28, H01Q3/08, G01S7/03, G01S7/00 и др. Transportable X-band radar having antenna mounted electronics / M. B. Knight, J. C. Fanning, J. R. Helvin, M. A. Jones, N. E. Lawrence и др. - № 13/655425; Заявлено 18.10.2012; Опубл. 12.04.2016. - 24 с.↑

A861. Пат. 9310476 США, МПК G01S13/84, F42C13/04, G01S7/35, G01S13/34, G01S13/50 и др. Method for detecting a distance, a radar system and a computer program product / R. Prevo, J. A. A. Janssen, R. M. E. Heijster. - № 13/379098; Заявлено 17.06.2010; Опубл. 12.04.2016. - 21 с.↑

A862. Пат. 9310470 США, МПК G01S13/93, G01S7/41, G01S7/35, G01S13/34, G01S13/42 и др. Radar apparatus and signal processing method / T. Moriuchi, M. Kishida, H. Asanuma. - № 14/064577; Заявлено 28.10.2013; Опубл. 12.04.2016. - 56 с.↑

A863. Пат. 9310467 США, МПК A47G5/00, G01S7/40, G01S13/93, G01S7/02. Sensor mounting for a sensor for object detection / G. Zeller, A. Busch. - № 14/125034; Заявлено 10.04.2012; Опубл. 12.04.2016. - 8 с.↑

A864. Пат. 9306112 США, МПК H01L31/00, H01L33/00, H01L31/16, H01L31/09, H01L27/144 и др. Photoconductive antenna, terahertz wave generating device, camera, imaging device, and measuring device / H. Tomioka. - № 13/717835; Заявлено 18.12.2012; Опубл. 05.04.2016. - 20 с.↑

A865. Пат. 9304203 США, МПК G01S7/48, G01S13/06, G01S7/489, G01S7/486, G01S17/06 и др. Methods, devices, and systems for improving dynamic range of signal receiver / P.-Y. Droz, G. Pennecot, D. Gruver. - № 13/802593; Заявлено 13.03.2013; Опубл. 05.04.2016. - 25 с.↑

A866. Пат. 9304196 США, МПК G01S13/93, G01S13/34. Motor vehicle with a radar mechanism and procedure for the operation of a radar mechanism / U. Haberland. - № 13/053402; Заявлено 22.03.2011; Опубл. 05.04.2016.

- 9 с.↑

A867. Пат. 9301096 США, МПК H04W24/00, H04W4/02, G01S19/24, G01S13/76, G01S5/02 и др. Range rate based stopped detection / S. J. Beauregard. - № 14/273392; Заявлено 08.05.2014; Опубл. 29.03.2016. - 21 с.↑

A868. Пат. 9298333 США, МПК G06F3/041, G01S13/04, G06F3/044, G06F3/046. Gesturing architecture using proximity sensing / K. W. Gay. - № 13/334477; Заявлено 22.12.2011; Опубл. 29.03.2016. - 23 с.↑

A869. Пат. 9297896 США, МПК G01S13/95, H01Q3/34, H01Q3/36, H01Q3/30, H01Q3/26. Electronically steered weather radar / J. M. Andrews. - № 13/478944; Заявлено 23.05.2012; Опубл. 29.03.2016. - 16 с.↑

A870. Пат. 9292813 США, МПК G01S13/88, G06Q10/06, A01B69/04. System and method for collecting and organizing information related to utility assets / P. Tucker, L. A. Whitney, I.I.I. - № 14/307369; Заявлено 17.06.2014; Опубл. 22.03.2016. - 25 с.↑

A871. Пат. 9291710 США, МПК G01S13/88, G01V8/00, G01V3/12. Method and apparatus for detecting subsurface targets using data inversion and a temporal transmission line model / P. S. Debroux, B. C. Flores. - № 14/066301; Заявлено 29.10.2013; Опубл. 22.03.2016. - 24 с.↑

A872. Пат. 9291659 США, МПК G01R29/10, G01S7/40, G01S13/93, G01S13/34, H01Q1/32 и др. Antenna blockage detection / J. P. Ebling. - № 14/134576; Заявлено 19.12.2013; Опубл. 22.03.2016. - 10 с.↑

A873. Пат. 9288623 США, МПК G08B13/14, H04W4/22, G01S3/74, G01S5/02, G01S5/14 и др. Multi-path mitigation in rangefinding and tracking objects using reduced attenuation RF technology / F. Markhovsky, T. Prevatt. - № 14/043785; Заявлено 01.10.2013; Опубл. 15.03.2016. - 57 с.↑

A874. Пат. 9286796 США, МПК G08B21/00, G01S13/58, G01S13/34, G08G1/01, G08G1/015 и др. Traffic flow measuring apparatus and method, and computer-readable storage medium for judging size of vehicle depending on number of times reflected wave from vehicle is detected within detection time / T. Ikeya, K. Shite, J. Kajiki, M. Ochi. - № 14/308796; Заявлено 19.06.2014; Опубл. 15.03.2016. - 43 с.↑

A875. Пат. 9285471 США, МПК G08B5/22, G01S13/76, G06K17/00. Method and apparatus for localization of RFID tags / G. M. Lyon, S. Pradhan. - № 11/285370; Заявлено 21.11.2005; Опубл. 15.03.2016. - 15 с.↑

A876. Пат. 9285469 США, МПК G01S13/44, G01S7/28, G01S7/00, G01S13/87, G01S13/524. Multiplatform GMTI radar with enhanced SNR, monopulse / H. K. Schuman, D. D. Thomas, J. - № 14/526775; Заявлено 29.10.2014; Опубл. 15.03.2016. - 19 с.↑

A877. Пат. 9285467 США, МПК G01S13/06, G01S13/34, G01S13/42, G01S13/58, G01S13/72 и др. Radar apparatus, vehicle control system, and signal processing method / H. Ishimori, M. Kishida, H. Asanuma. - № 13/952107; Заявлено 26.07.2013; Опубл. 15.03.2016. - 28 с.↑

A878. Пат. 9280898 США, МПК B60Q1/00, G01S13/88, B60Q9/00, G08G1/16, G08B13/24. Object detection assembly / T. Richmond, K. Richmond. - № 14/146765; Заявлено 03.01.2014; Опубл. 08.03.2016. - 10 с.↑

A879. Пат. 9279884 США, МПК G01S3/28, G01S3/74, G01S13/44, G01S13/93. Method and device for estimating direction of arrival / S.-J. Chung, J.-H. Cheng. - № 13/917400; Заявлено 13.06.2013; Опубл. 08.03.2016. - 10 с.↑

A880. Пат. 9279881 США, МПК G01S7/40, G01S7/04, G01S7/02, G01S13/00. Radar false alert reduction / S. K. Orr, J. Kuhn, J. Stevens, T. W. Humphrey. - № 13/794867; Заявлено 12.03.2013; Опубл. 08.03.2016. - 11 с.↑

A881. Пат. 9279670 США, МПК G01S7/40, G01B11/27, G01S7/497, G01S7/52, G01S13/93 и др. Method and device for calibrating and adjusting a vehicle surroundings sensor / S. Schommer, C. Wagmann, A. Wendt. - № 13/992979; Заявлено 05.12.2011; Опубл. 08.03.2016. - 10 с.↑

A882. Пат. 9279437 США, МПК F16B5/02, G01S7/40, G01S13/93. Adjustable holding device for sensors / M. Gold, M. Rossi. - № 14/360434; Заявлено 20.11.2012; Опубл. 08.03.2016. - 9 с.↑

A884. Пат. 9277339 США, МПК H04R29/00, G01S13/93, G06F17/11, H04R3/00, G01S3/808. Sound source detection apparatus / H. Fukamachi, T. Kindo. - № 14/360564; Заявлено 24.11.2011; Опубл. 01.03.2016. - 20 с. ↑

A885. Пат. 9275548 США, МПК G08G1/16, G01S13/93, G08G1/01. Method and device for detecting a starting intention of a stopped vehicle / O. Pink. - № 14/271048; Заявлено 06.05.2014; Опубл. 01.03.2016. - 9 с.↑

A886. Пат. 9275417 США, МПК G01M17/00, G01S17/02, G06T13/80, G07C5/00, G01S13/02 и др. Synchronization of vehicle sensor information / T. Binion, J. Harr, B. M. Fields, S. Cielocha, S. J. Balbach. - № 14/718338; Заявлено 21.05.2015; Опубл. 01.03.2016. - 34 с.↑

A887. Пат. 9274223 США, МПК G01S15/93, G01S13/46, G01S15/46. System for determining the distance from and the direction to an object / C. Brown, F. Streichert, C. Zott, A. Gerlach. - № 13/642251; Заявлено 19.04.2011; Опубл. 01.03.2016. - 13 с.↑

A888. Пат. 9274221 США, МПК G01S13/93, G01S7/35, G01S13/34, G01S13/86. Method and apparatus for remote object sensing employing compressive sensing / G. Raz, I. Bilik. - № 13/756606; Заявлено 01.02.2013; Опубл. 01.03.2016. - 10 с.↑

A889. Пат. 9274217 США, МПК G01S13/18, G01S7/35, G01S13/34, G01S7/03, G01S13/58. Microwave sensor having function of range gates / C.-H. Chang, Y.-C. Sung, M.-T. Hsu, J.-C. Huang, G.-Z. Lu и др. - № 14/095660; Заявлено 03.12.2013; Опубл. 01.03.2016. - 19 с.↑

A890. Пат. 9274213 США, МПК G08G1/01, G01S7/497, G01S13/93, G01S7/52, G01S7/40 и др. Method for calibrating a plurality of environment sensors in a vehicle / S. Hegemann, M. Komar, S. Lueke. - № 14/377297; Заявлено 09.09.2013; Опубл. 01.03.2016. - 7 с.↑

A891. Пат. 9274211 США, МПК G01S7/28, G01S7/292, G01S7/41, G01S13/93, G01S13/524 и др. Target object detecting device and echo signal processing method / H. Maeno. - № 13/923295; Заявлено 20.06.2013; Опубл. 01.03.2016. - 29 с.↑

A892. Пат. 9274210 США, МПК H04K1/10, H04L27/26, G01S5/14, G01S13/87, G01S11/08. Indoor radio ranging based on a subset of subcarriers employed by orthogonal frequency division multiplexing (OFDM) / P. Enge, L. J. Garin. - № 13/656398; Заявлено 19.10.2012; Опубл. 01.03.2016. - 29 с.↑

A893. Пат. 9272711 США, МПК B60W30/16, B60W30/14, G01S13/88, B60W50/00, G08G1/16 и др. Congestion-friendly adaptive cruise control / S. Sivaraman. - № 14/587315; Заявлено 31.12.2014; Опубл. 01.03.2016. - 15 с.↑

A894. Пат. 9269255 США, МПК G06F19/00, B66C13/40, B66C15/04, G01S17/06, G01S13/06 и др. Worksite proximity warning / E. Beaulieu, G. C. Best, K. L. Maynard, J. F. Cameron. - № 14/624514; Заявлено 17.02.2015; Опубл. 23.02.2016. - 58 с.↑

A895. Пат. 9268016 США, МПК G01S13/89, H01Q15/02, G01S13/88, H01Q15/00, H01Q3/22 и др. Metamaterial devices and methods of using the same / D. R. Smith, D. Brady, T. Driscoll, J. Hunt, A. Mrozack и др. - № 13/891165; Заявлено 09.05.2013; Опубл. 23.02.2016. - 31 с.↑

A896. Пат. 9266534 США, МПК B60T7/12, B60W30/16, G01S13/93. Vehicle control apparatus / M. Tokimasa, Y. Masui, M. Nakadori. - № 14/796912; Заявлено 10.07.2015; Опубл. 23.02.2016. - 21 с.↑

A897. Пат. 9265192 США, МПК G06F19/00, A01C21/00, A01B79/00, G01S13/88, A01B69/00 и др. Systems and methods for detecting soil characteristics / A. K. Chan, W. D. Duncan, R. A. Hyde, L. L. Wood, J. - № 14/468547; Заявлено 26.08.2014; Опубл. 23.02.2016. - 25 с.↑

A898. Пат. 9263804 США, МПК H01Q21/00, G01S13/88, G01S7/41, F42C13/00, F41H13/00 и др. Composites for antennas and other applications / C. C. Fuller, J. R. Lamberg, M. J. Gawronski. - № 14/228627; Заявлено 28.03.2014; Опубл. 16.02.2016. - 26 с.↑

A899. Пат. 9262923 США, МПК G08G1/09, G08G1/16, G01S13/86, B60Q9/00, G01S13/93. Blind spot detection system / T.-W. Chang, M.-J. Wu, C.-C. Tseng. - № 13/313029; Заявлено 07.12.2011; Опубл. 16.02.2016. - 6 с.↑

A900. Пат. 9261590 США, МПК G01S13/32, G01S13/08, G01S13/06, G01S13/93, G01S13/00. Adaptive algorithms for interrogating the viewable scene of an automotive radar / A. Brown. - № 13/778722; Заявлено 27.02.2013; Опубл. 16.02.2016. - 19 с.↑

A901. Пат. 9261589 США, МПК G01S13/93, G01S13/34, G01S13/58, G01S13/04. Signal processing device, radar device, vehicle control system, and signal processing method / J. Itoh, M. Kishida. - № 13/807092; Заявлено 23.06.2011; Опубл. 16.02.2016. - 26 с.↑

A902. Пат. 9261583 США, МПК G01S7/40, G01S7/41, G01S13/95, G01S7/02. Systems and methods for calibrating dual polarization radar systems / M. S. Balaji, J. R. Eillis, R. D. Cartwright, W. H. Walker. - № 13/755388; Заявлено 31.01.2013; Опубл. 16.02.2016. - 25 с.↑

A903. Пат. 9260115 США, МПК B60T7/12, B60W30/16, G01S13/93. Vehicle control apparatus / M. Tokimasa, Y. Masui, M. Nakadori. - № 14/796919; Заявлено 10.07.2015; Опубл. 16.02.2016. - 22 с.↑

A904. Пат. 9260114 США, МПК B60T7/12, G01S13/93, B60W30/16. Vehicle control apparatus / M. Tokimasa, Y. Masui, M. Nakadori. - № 14/796837; Заявлено 10.07.2015; Опубл. 16.02.2016. - 13 с.↑

A905. Пат. 9260059 США, МПК G06F17/10, G08G1/16, B60Q9/00, G06G7/78, G01S13/93 и др. False warning reduction using location data / F. Rayes, M. E. G. Bordes. - № 14/261580; Заявлено 25.04.2014; Опубл. 16.02.2016. - 10 с.↑

A906. Пат. 9255989 США, МПК G01S13/93, G01S13/86, G05D1/02, G08G1/16. Tracking on-road vehicles with sensors of different modalities / A. S. Joshi, M. R. James, M. E. Samples. - № 13/556802; Заявлено 24.07.2012; Опубл. 09.02.2016. - 20 с.↑

A907. Пат. 9255988 США, МПК G01S13/66, G01S13/90, G01S13/87, G01S13/93, G01S13/72. Object fusion system of multiple radar imaging sensors / S. Zeng, J. A. Salinger, B. B. Litkouhi, K. A. O'Dea, J. Pazhayampallil и др. - № 14/156681; Заявлено 16.01.2014; Опубл. 09.02.2016. - 12 с.↑

A908. Пат. 9254846 США, МПК B60W30/16, G08G1/16, G01S13/93, B60W30/17, G08G1/00. Predictive reasoning for controlling speed of a vehicle / D. Dolgov, D. Ferguson. - № 13/886563; Заявлено 03.05.2013; Опубл. 09.02.2016. - 21 с.↑

A909. Пат. 9251627 США, МПК G01S13/94, G07C5/08, H04W4/04, G07C5/00, G06Q10/04 и др. Removable dashboard instrument system / R. Carl. - № 13/785337; Заявлено 05.03.2013; Опубл. 02.02.2016. - 14 с.↑

A910. Пат. 9250324 США, МПК G01S13/93, G01S13/87, G01S7/41, G01S7/40, G01S13/00. Probabilistic target selection and threat assessment method and application to intersection collision alert system / S. Zeng, W. Zhang, M. E. Shields. - № 13/901123; Заявлено 23.05.2013; Опубл. 02.02.2016. - 13 с.↑

A911. Пат. 9250323 США, МПК G01S13/90, G01S13/88, G01S7/41. Target detection utilizing image array comparison / K. I. Ranney, A. F. Martone, R. Innocenti, L. H. Nguyen. - № 13/480420; Заявлено 24.05.2012; Опубл. 02.02.2016. - 30 с.↑

A912. Пат. 9250317 США, МПК G01S13/00, G01S13/89. Methods and apparatus for 3D radar data from 2D primary surveillance radar and passive adjunct radar / J. Wang, E. Brookner, P. R. Drake, B. Fournier, A. M. Ponsford и др. - № 13/721233; Заявлено 20.12.2012; Опубл. 02.02.2016. - 22 с.↑

A913. Пат. 9245448 США, МПК G08G1/16, B60Q1/34, G01S13/93, B62D15/02, B60Q9/00. Driver assistance system for a vehicle / K. Schofield. - № 13/919483; Заявлено 17.06.2013; Опубл. 26.01.2016. - 17 с.↑

A914. Пат. 9245447 США, МПК G08G1/00, G08G1/16, G01S13/93, B62D6/00, G01S13/00 и др. Method and device for the position determination of objects in road traffic, based on communication signals, and use of the device / S. Schrabler, U. Stahlin, M. Menzel. - № 14/359796; Заявлено 21.11.2012; Опубл. 26.01.2016. - 14 с.↑

A915. Пат. 9244164 США, МПК G01S13/00, G01S13/28, G01S13/34, G01S13/22, G01S13/93 и др. Method for unambiguously determining a range and/or a relative speed of an object, driver assistance device and motor vehicle / U. Luebbert, U. Haberland. - № 13/510014; Заявлено 06.12.2010; Опубл. 26.01.2016. - 11 с.↑

A916. Пат. 9244157 США, МПК G01S13/95, G01S7/06. Weather radar threat depiction system and method / V.

A. Sishtla, R. E. Robertson, E. A. S. John, M. C. Fersdahl, L. P. Nicoli. - № 13/919406; Заявлено 17.06.2013; Опубл. 26.01.2016. - 16 с.↑

A917. Пат. 9244153 США, МПК G01S1/68, G01S5/14, G01S13/87, G06K17/00, G05D1/02 и др. Radio frequency identification in safety applications / K. M. Zomchek, D. W. Jones, W. E. Waltz, R. W. Boyd, W. Foster. - № 13/664631; Заявлено 31.10.2012; Опубл. 26.01.2016. - 16 с.↑

A918. Пат. 9240125 США, МПК G08B21/00, G08G1/04, G01S13/48, G01S13/72, G01S13/91 и др. Detecting roadway targets across beams / D. V. Arnold, B. R. Jarrett, T. W. Karlinsey, J. L. Waite, B. Giles и др. - № 14/164102; Заявлено 24.01.2014; Опубл. 19.01.2016. - 27 с.↑

A919. Пат. 9240053 США, МПК G06T7/20, G01S13/72. Target tracking / G. M. Mathews, D. Nicholson. - № 13/635193; Заявлено 08.03.2011; Опубл. 19.01.2016. - 12 с.↑

A920. Пат. 9239382 США, МПК G06N99/00, G01S13/89, G01V3/12, G01S13/88, G01S13/00 и др. Attribute and topology based change detection in a constellation of previously detected objects / D. W. Paglieroni, N. R. Beer. - № 13/219425; Заявлено 26.08.2011; Опубл. 19.01.2016. - 25 с.↑

A921. Пат. 9239380 США, МПК B60T7/22, G01S13/86, B60W30/08, G01S7/41, G08G1/16 и др. Driver assistance system for avoiding collisions of a vehicle with pedestrians / S. Hegemann, A. Yoda, R. Adomat, M. Darms, R. Pongsathorn и др. - № 12/992174; Заявлено 14.05.2009; Опубл. 19.01.2016. - 7 с.↑

A922. Пат. 9239379 США, МПК G01S13/72, G01S13/93, G01S13/536, G01S13/42, G01S13/34 и др. Method and devices for processing radar signals / C. Burgio, D. Catalano, G. Borgonovo. - № 13/888025; Заявлено 06.05.2013; Опубл. 19.01.2016. - 18 с.↑

A923. Пат. 9235821 США, МПК G01S13/00. Methods, apparatus, and systems for providing an enhanced positive response for underground facility locate and marking operations based on an electronic manifest documenting physical locate marks on ground, pavement or other surface / S. E. Nielsen, C. Chambers, J. Farr. - № 14/063417; Заявлено 25.10.2013; Опубл. 12.01.2016. - 73 с.↑

A924. Пат. 9230443 США, МПК G08G1/16, G01S13/93. Method and system for predictive vehicle systems performance selection for enhanced maneuverability / K. O. Prakah-Asante, J. Lu, F. Tseng, D. P. Filev, S. J. Szwabowski. - № 13/847070; Заявлено 19.03.2013; Опубл. 05.01.2016. - 10 с.↑

A925. Пат. 9230442 США, МПК B60Q1/00, G08G1/16, B60Q9/00, G01S13/00, G05D1/02. Systems and methods for adaptive vehicle sensing systems / J. A. Bowers, G. F. Deane, R. J. Hannigan, R. A. Hyde, M. Y. Ishikawa и др. - № 13/956200; Заявлено 31.07.2013; Опубл. 05.01.2016. - 29 с.↑

A926. Пат. 9229906 США, МПК G05D1/00, F02D41/26, G06F17/00, G01S13/00, F02D41/24 и др. Method and apparatus for matching vehicle ECU programming to current vehicle operating conditions / C. M. McQuade, B. Hunt, D. Mayer. - № 13/857985; Заявлено 05.04.2013; Опубл. 05.01.2016. - 40 с.↑

A927. Пат. 9229104 США, МПК G06F17/10, G06G7/78, G08G1/16, H04N7/18, G01S13/93 и др. Sensor assembly for driver assistance systems in motor vehicles / M. Klar, G. Zeller, B. Lucas. - № 13/265798; Заявлено 25.02.2010; Опубл. 05.01.2016. - 5 с.↑

A928. Пат. 9229101 США, МПК G01S13/93, G01S13/76, G08G5/06, B64C25/42, B64D43/00 и др. Systems and methods for performing wingtip protection / J. C. Kirk, L. Bui, D. C. Vacanti, C. L. Freeman. - № 13/899298; Заявлено 21.05.2013; Опубл. 05.01.2016. - 14 с.↑

A929. Пат. 9229099 США, МПК G01S13/74, H01Q3/46, G01S7/03, H01Q21/20, G01S13/42 и др. Omnidirectional retrodirective antennas / E. R. Brown, A. Hartenstein. - № 13/730558; Заявлено 28.12.2012; Опубл. 05.01.2016. - 21 с.↑

A930. Пат. 9229098 США, МПК G01S13/06, G01S13/93. Detection of radar objects with the aid of a radar sensor of a motor vehicle / V. Gross, M. Schoor. - № 13/898168; Заявлено 20.05.2013; Опубл. 05.01.2016. - 12 с.↑

A931. Пат. 9229092 США, МПК G01S5/02, H04W64/00, G01S5/14, G01S13/87. Adaptive passive scanning and/or active probing techniques for mobile device positioning / V. Sridhara, S. M. Das, A. F. Naguib, R. Palanki. -

№ 14/327430; Заявлено 09.07.2014; Опубл. 05.01.2016. - 19 с.↑

A932. Пат. 9229024 США, МПК G01P3/36, G01S13/60, G01S7/491, G01S1/00, G01P21/02 и др. Method for adjusting a self mixing laser sensor system for measuring the velocity of a vehicle / M. Carpaij, A. M. V. D. Lee, B. Engelbrecht, M. Schemmann, C. Heinks и др. - № 13/145261; Заявлено 18.01.2010; Опубл. 05.01.2016. - 24 с. ↑

A933. Пат. 9227604 США, МПК G06F17/10, B60W50/14, B60W30/18, B62D15/02, G01S13/86 и др. Travel control device and travel control method / T. Sugano, T. Gokan, M. Kobayashi. - № 14/378436; Заявлено 07.02.2013; Опубл. 05.01.2016. - 18 с.↑

A934. Пат. 9223311 США, МПК G05D1/02, G08G1/16, G01S13/86, G01S13/93. Vehicle driving support control apparatus / K. Matsuno. - № 14/091197; Заявлено 26.11.2013; Опубл. 29.12.2015. - 11 с.↑

A943. Пат. 9208913 США, МПК H01Q17/00, G21F1/08, H05K9/00, G01S13/00. Wave-absorbing metamaterial / R. Liu, L. Luan, Z. Zhao, W. Wang. - № 14/009023; Заявлено 30.11.2011; Опубл. 08.12.2015. - 15 с.↑

A944. Пат. 9207323 США, МПК G01C3/08, G01S13/86, G01S17/02, G01S17/66, G01S17/93 и др. Methods and systems for detecting weather conditions including wet surfaces using vehicle onboard sensors / J. Zhu, D. Dolgov, D. Ferguson. - № 13/860664; Заявлено 11.04.2013; Опубл. 08.12.2015. - 21 с.↑

A945. Пат. 9207320 США, МПК G08G1/16, G01S13/93, G01S13/91, G01S7/292, G01S7/41 и др. Method and system for producing classifier for recognizing obstacle / J. H. Kim, K. H. Yoo, Y. H. Jang, S. S. Im, H. S. Lee и др. - № 13/713820; Заявлено 13.12.2012; Опубл. 08.12.2015. - 13 с.↑

A946. Пат. 9207316 США, МПК G01V3/17, G01S13/32, G01S7/35, G01S13/88, G01V3/12 и др. Radar for rejecting and looking past surface reflections / L. G. Stolarczyk, R. B. Main. - № 14/152823; Заявлено 10.01.2014; Опубл. 08.12.2015. - 26 с.↑

A947. Пат. 9207307 США, МПК G01V3/12, H01Q21/06, H01Q1/52, H01Q1/32, G01S13/88 и др. Large area ground monitoring / G. L. Stolarczyk, C. D. Valentine, J. D. Hutchins, M. L. Briggs, R. B. Main и др. - № 14/150736; Заявлено 08.01.2014; Опубл. 08.12.2015. - 21 с.↑

A948. Пат. 9207306 США, МПК G01S13/10, G01S7/292, G01F23/284. Level measurement instrument fiducial detection method / C. P. Turcotte, M. J. Linden. - № 13/669676; Заявлено 06.11.2012; Опубл. 08.12.2015. - 11 с. ↑

A949. Пат. 9206588 США, МПК E02F9/20, E02F9/12, E02F9/26, G01S13/04. Shovel provided with electric swiveling apparatus and method of controlling the same / C. Wu, S. Li. - № 14/117101; Заявлено 17.05.2012; Опубл. 08.12.2015. - 34 с.↑

A950. Пат. 9202377 США, МПК G08G1/16, G01S7/41, G01S13/93, B60W30/09. Object determination apparatus and collision avoidance assistance apparatus / H. Ichida. - № 13/896554; Заявлено 17.05.2013; Опубл. 01.12.2015. - 14 с.↑

A951. Пат. 9202323 США, МПК B61L25/04, G01S13/78, G07C9/00, G08B5/40. Secure electronic compartment identifier system / J. A. Queenan. - № 10/771480; Заявлено 03.02.2004; Опубл. 01.12.2015. - 13 с.↑

A952. Пат. 9199668 США, МПК A01B69/00, G01S17/93, B62D15/02, G01S15/93, G01S13/93 и др. Path planning for evasive steering maneuver employing a virtual potential field technique / S. Zeng, N. K. Moshchuk, R. Jafari. - № 14/065279; Заявлено 28.10.2013; Опубл. 01.12.2015. - 23 с.↑

A953. Пат. 9197866 США, МПК H04N7/18, G08G1/04, G01S13/92, G01S13/86, G01S7/295 и др. Method for monitoring a traffic stream and a traffic monitoring device / P. Messely, W. Favoreel. - № 13/874393; Заявлено 30.04.2013; Опубл. 24.11.2015. - 13 с.↑

A954. Пат. 9196150 США, МПК H04N9/47, H04N7/18, B60Q1/26, G01S13/00, G08B21/22. System and method for video monitoring of restricted areas below bucket trucks, lineworkers on power distribution poles or other elevated loads / A. Cs, L. R. Boregowda. - № 13/844765; Заявлено 15.03.2013; Опубл. 24.11.2015. - 8 с.↑

A955. Пат. 9194950 США, МПК G01S13/04, G01V3/08, G01S13/88, G01V3/12, G01V3/10 и др. Handheld locating device / F. S. Watts, C. H. Potter, M. Anjanappa, X. Chen, S. Li. - № 13/742614; Заявлено 16.01.2013; Опубл. 24.11.2015. - 9 с.↑

A956. Пат. 9194949 США, МПК G01C21/00, G01S13/86, G01S13/89. Methods and systems for precise vehicle localization using radar maps / J. Becker, O. Schwindt, S. Kammel. - № 13/277879; Заявлено 20.10.2011; Опубл. 24.11.2015. - 9 с.↑

A957. Пат. 9194944 США, МПК G01S13/04, G01S13/08, G01F23/284, G01S13/75, G01S13/00 и др. Measurement device / T. Nakagawa, A. Hyodo, H. Kurata, S. Oho. - № 13/809746; Заявлено 14.07.2010; Опубл. 24.11.2015. - 26 с.↑

A958. Пат. 9194725 США, МПК G01D11/24, G01S15/93, G01D11/30, G01S13/93, G01P1/02 и др. Mounting for a distance sensor / M. Kaufmann, R. Risse, U. Ronnenberg, A. Stender, A. Stephan. - № 13/825849; Заявлено 21.07.2011; Опубл. 24.11.2015. - 7 с.↑

A959. Пат. 9188669 США, МПК G01S13/04, G01S13/42, G01S13/06, G01S7/292, G01S7/32 и др. Target finder, high resolution processing device, and high resolution processing method / A. Hino. - № 13/891540; Заявлено 10.05.2013; Опубл. 17.11.2015. - 27 с.↑

A960. Пат. 9188668 США, МПК G01S13/06, G01S13/46, G01S5/02. Electromagnetic reflection profiles / R. R. Miller, K. A. Li, T. C. Meuninck, J. H. Pratt, H. J. Schroeter и др. - № 13/685741; Заявлено 27.11.2012; Опубл. 17.11.2015. - 45 с.↑

A961. Пат. 9188666 США, МПК G01S13/00, G01S7/292, G01S7/285. System and method for distribution free target detection in a dependent non-Gaussian background / A. J. Pomerance, R. H. Anderson, K. J. Lightner, K. S. H. Johnson. - № 13/912596; Заявлено 07.06.2013; Опубл. 17.11.2015. - 8 с.↑

A962. Пат. 9188477 США, МПК G01S13/56, G01H1/00, G01S13/88, G01S13/50, G01S13/536 и др. Radar system and method for providing information on movements of object's surface / V. Dvorkin. - № 13/315654; Заявлено 09.12.2011; Опубл. 17.11.2015. - 8 с.↑

A963. Пат. 9183751 США, МПК G08G9/02, G01S13/93, G08G1/16, G01S15/93, G01S13/86 и др. Travel control device and travel control method / T. Sugano, T. Gokan, M. Kobayashi. - № 14/378042; Заявлено

12.02.2013; Опубл. 10.11.2015. - 16 с.↑

A964. Пат. 9182485 США, МПК G01S13/95, H01Q3/26, H01Q3/30, H01Q3/34, H01Q3/36 и др. Transmit/receive module for electronically steered weather radar / J. M. Andrews, T. D. Robinson. - № 13/478988; Заявлено 23.05.2012; Опубл. 10.11.2015. - 15 с.↑

A965. Пат. 9182480 США, МПК H04K1/00, G01S13/82, G01S13/75. Information technology (IT) equipment positioning system / T. M. Larson, C. G. Malone. - № 11/046633; Заявлено 28.01.2005; Опубл. 10.11.2015. - 15 с.↑

A966. Пат. 9182477 США, МПК G01B11/27, G01S13/93, G01S7/40. Vehicle radar alignment method and system / T. R. Jones, T. L. Gasparovic. - № 13/842822; Заявлено 15.03.2013; Опубл. 10.11.2015. - 12 с.↑

A967. Пат. 9182476 США, МПК G01S7/292, G01S13/93, G01S7/03, G01S7/02, G01S7/35 и др. Radar system having arrangements and methods for the decoupling of transmitting and receiving signals and for the suppression of interference radiation / M. Wintermantel. - № 13/256488; Заявлено 01.04.2010; Опубл. 10.11.2015. - 19 с.↑

A968. Пат. 9182238 США, МПК G01S13/88, H04W64/00, G01C21/20, G06F1/32, G01S19/34 и др. Method and apparatus for intelligent acquisition of position information / C. Lau, C. D. Thomas. - № 13/802574; Заявлено 13.03.2013; Опубл. 10.11.2015. - 24 с.↑

A969. Пат. 9178279 США, МПК G06K7/01, G06K19/077, H01Q7/00, H04B5/00, H01Q1/22 и др. Wireless IC tag, reader-writer, and information processing system / N. Ikemoto. - № 13/329354; Заявлено 19.12.2011; Опубл. 03.11.2015. - 23 с.↑

A970. Пат. 9176228 США, МПК G01S7/40, G01S7/285, G01S13/93, G01S7/35, G01S13/26 и др. Driver assistance device for a vehicle and method for operating a radar device / U. Haberland, U. Luebbert, U. Papziner, F. Sickinger. - № 13/636220; Заявлено 21.03.2011; Опубл. 03.11.2015. - 14 с.↑

A971. Пат. 9176223 США, МПК G01S13/04, G01S7/36, G01S7/41. Object detection method, device and system / T. Derham, P. Coupe. - № 13/822912; Заявлено 12.09.2011; Опубл. 03.11.2015. - 28 с.↑

A972. Пат. 9174672 США, МПК B62D15/02, G01S13/93, G05D1/02, B60W10/20, B60W30/09 и др. Path planning for evasive steering maneuver in presence of target vehicle and surrounding objects / S. Zeng, N. K. Moshchuk, R. Jafari. - № 14/065235; Заявлено 28.10.2013; Опубл. 03.11.2015. - 23 с.↑

A973. Пат. 9174650 США, МПК G01S13/91, G08G1/0962, G01C21/36, G08G1/09, G08G1/01 и др. Driver assistance system for a vehicle, vehicle having a driver assistance system, and method for assisting a driver in driving a vehicle / P. Reilhac. - № 13/395961; Заявлено 21.09.2010; Опубл. 03.11.2015. - 16 с.↑

A974. Пат. 9174598 США, МПК G05D1/02, B60R21/0134, B60W30/08, B60R21/0132, B60R21/00 и др. Collision prediction device / T. Harada, H. Satonaka. - № 12/440754; Заявлено 26.02.2008; Опубл. 03.11.2015. - 25 с.↑

A975. Пат. 9172476 США, МПК H04B1/10, G01S13/02, H04B15/00, G01S13/90, H04L27/00 и др. Method and system for removal of noise in signal / L. H. Nguyen, T. D. Tran. - № 13/891050; Заявлено 09.05.2013; Опубл. 27.10.2015. - 23 с.↑

A976. Пат. 9170332 США, МПК B60Q9/00, G01S17/02, G01S17/93, G08G1/16, G01S13/86 и др. Risk calculation apparatus / M. Shimizu. - № 13/697201; Заявлено 10.05.2010; Опубл. 27.10.2015. - 15 с.↑

A977. Пат. 9170329 США, МПК G01S13/93, G08G1/16, G01S17/93. Object detection apparatus for vehicle / A. Kimata, H. Tani, Y. Sasabuchi, H. Koike. - № 14/004206; Заявлено 16.04.2012; Опубл. 27.10.2015. - 10 с.↑

A978. Пат. 9170327 США, МПК G01S13/86, G05D1/02, G05D11/00, G01S13/93, B60W30/16. Apparatus and method for providing obstacle information in autonomous mobile vehicle / T. S. Choe, Y. W. Park, Y. I. Lee. - № 13/878681; Заявлено 14.09.2011; Опубл. 27.10.2015. - 12 с.↑

A979. Пат. 9170316 США, МПК G01S1/00, G01S3/02, G01S1/04, G01S3/46, G01S3/10 и др. Systems and methods for improving bearing availability and accuracy for a tracking filter / R. C. Brandao, E. Shestak, I. Dougherty. - № 13/661064; Заявлено 26.10.2012; Опубл. 27.10.2015. - 7 с.↑

A980. Пат. 9170146 США, МПК G01F23/284, G01S13/08, G01S13/88, G01F23/00, G01S13/00. Method for fill level measurement according to the travel time principle / S. Gorenflo, A. Malinovskiy, K. Pankratz. - № 13/604084; Заявлено 05.09.2012; Опубл. 27.10.2015. - 15 с.↑

A981. Пат. 9167553 США, МПК H04W4/00, G01S5/00, H04W4/02, H04W64/00, G01S13/74. GeoNexus proximity detector network / L. D. Pitt. - № 14/085346; Заявлено 20.11.2013; Опубл. 20.10.2015. - 17 с.↑

A982. Пат. 9167214 США, МПК H04N7/18, G01S13/86, G01S13/93. Image processing system using unified images / B. S. Kriel, D. Morris, H. Chang. - № 13/745641; Заявлено 18.01.2013; Опубл. 20.10.2015. - 16 с.↑

A983. Пат. 9164514 США, МПК G01S13/88, G05D1/02, G08B1/08, G08B13/00. Cooperative perimeter patrol system and method / P. A. Avery, S. E. Slocum, J. A. Towler. - № 14/252581; Заявлено 14.04.2014; Опубл. 20.10.2015. - 12 с.↑

A984. Пат. 9163973 США, МПК G01F23/284, G01S13/08, B65D88/34, G01S13/88, B65D90/48 и др. Identifying undesired conditions in the function of a floating roof of a tank / L. Hagg. - № 13/724697; Заявлено 21.12.2012; Опубл. 20.10.2015. - 8 с.↑

A985. Пат. 9162686 США, МПК B60W50/14, G01S13/72, B60W50/00, B60W30/18, G08G1/0967 и др. Drive support device and drive support method / Y. Ogawa. - № 14/240594; Заявлено 22.08.2012; Опубл. 20.10.2015. - 17 с.↑

A986. Пат. 9162643 США, МПК B60Q1/00, B60R21/0134, G01S13/93. Device and method for the detection of persons / A. Pech, P. Nauth. - № 13/817886; Заявлено 24.08.2011; Опубл. 20.10.2015. - 5 с.↑

A987. Пат. 9162622 США, МПК G08B21/00, B60J1/00, G08G1/16, G02B27/01, G01S13/93 и др. Peripheral salient feature enhancement on full-windshield head-up display / J. F. Szczerba, L. S. Angell, T. A. Seder, D. Cui. - № 14/100284; Заявлено 09.12.2013; Опубл. 20.10.2015. - 51 с.↑

A988. Пат. 9158026 США, МПК G01V3/30, G01S13/88, G01S13/04. Underground cavity detection by electromagnetic shock waves / A. Kesar, B. Ginzburg. - № 13/520370; Заявлено 04.01.2011; Опубл. 13.10.2015. - 6 с.↑

A989. Пат. 9157993 США, МПК G01S13/04, G01S13/06, G01S13/88, G01V3/12. Detecting an underground object / B. Peetz. - № 13/483390; Заявлено 30.05.2012; Опубл. 13.10.2015. - 20 с.↑

A990. Пат. 9157986 США, МПК H01Q1/32, H01Q1/52, H01Q9/04, H01Q21/06, G01S7/03 и др. Radome for a radar sensor in a motor vehicle, and corresponding radar sensor / C. Waldschmidt, R. Hellinger, T. Hansen, T. Binzer. - № 13/812276; Заявлено 01.06.2011; Опубл. 13.10.2015. - 7 с.↑

A991. Пат. 9157750 США, МПК G01C21/32, G01S7/12, G06F3/0485, G01S19/35, B63B49/00 и др. Device having touch panel, radar apparatus, plotter apparatus, ship network system, information display method and information display program / T. Miichi, S. Sato. - № 14/349295; Заявлено 03.10.2011; Опубл. 13.10.2015. - 16 с. ↑

A992. Пат. 9151837 США, МПК G01S13/86, G01S13/88, F16L55/26, G01S13/02, G01S13/10. Sensor fusion framework using multiple sensors to assess buried structures / A. P. Jaganathan, E. N. Allouche. - № 13/629164; Заявлено 27.09.2012; Опубл. 06.10.2015. - 11 с.↑

A993. Пат. 9151836 США, МПК G01S13/87, G01S13/72, G01S7/295, G01S7/292. Detection and tracking radar, anti high speed mobile defense system having the same and high speed mobile tracking method of detection and tracking radar / J.-M. Lee, S.- Sun, B. Cho, J. Lee, S. Park и др. - № 13/579149; Заявлено 29.07.2011; Опубл. 06.10.2015. - 12 с.↑

A994. Пат. 9151692 США, МПК H04N7/18, B60N2/00, B60N2/015, B60N2/02, B60N2/06 и др. Asset monitoring system using multiple imagers / D. S. Breed. - № 11/968844; Заявлено 03.01.2008; Опубл. 06.10.2015. - 55 с.↑

A995. Пат. 9146315 США, МПК G01S17/08, G01S15/08, G01S7/481, G01S17/89, G01S17/42 и др. Three dimensional scanning beam system and method / M. Bosse, R. Zlot. - № 13/811982; Заявлено 26.07.2010; Опубл. 29.09.2015. - 16 с.↑

A996. Пат. 9146309 США, МПК G01S13/44, H01Q3/26, G06G7/12, G06G7/14, H01Q3/40 и др. Super delta monopulse beamformer / T. J. Shaw. - № 13/779471; Заявлено 27.02.2013; Опубл. 29.09.2015. - 17 с.🡑

A998. Пат. 9145286 США, МПК G05D1/00, B66F9/06, B66F17/00, G01S17/93, G01S13/93. Method for operating an autonomous industrial truck / P. Pfaff, C. Sprunk. - № 13/636210; Заявлено 14.03.2011; Опубл. 29.09.2015. - 11 с.🡑

A999. Пат. 9142132 США, МПК G06F17/10, G01S13/00, B60T7/22, G08G1/16. Collision avoidance system and method for vehicles / C.-C. Yao, J.-J. Chen, S.-C. Huang, M.-H. Li. - № 14/141098; Заявлено 26.12.2013; Опубл. 22.09.2015. - 12 с.🡑

A1000. Пат. 9141107 США, МПК G05D1/00, G01S13/93. Mapping active and inactive construction zones for autonomous driving / D. I. Ferguson, D. J. Burnette. - № 13/859990; Заявлено 10.04.2013; Опубл. 22.09.2015. - 20 с.🡑

A1001. Пат. 9140789 США, МПК G01S13/86, G01S13/93, B60T7/22, G01S17/02. Forward facing sensing system for vehicle / N. R. Lynam. - № 14/107624; Заявлено 16.12.2013; Опубл. 22.09.2015. - 17 с.🡑

A1002. Пат. 9140788 США, МПК G01S13/34, G01S13/93, G01S7/41, G01S13/46. Ascertaining an indicator for the drive-over capability of an object / G. Kuehnle, M. Schoor. - № 13/915957; Заявлено 12.06.2013; Опубл. 22.09.2015. - 10 с.🡑

A1003. Пат. 9140787 США, МПК G01S13/93, H01Q3/28, H01Q3/30, H01Q3/34, H01Q3/36 и др. Radar sensor for motor vehicles, especially LCA sensor / T. Binzer. - № 13/821061; Заявлено 18.07.2011; Опубл. 22.09.2015. - 7 с.🡑

A1004. Пат. 9140782 США, МПК G01S13/86, G01S13/93, G01S13/04, G01S13/08, G01S13/00. Inter-vehicle alert system with nagable video look ahead / W. P. Alberth, J.D. E. Thorson. - № 13/556081; Заявлено 23.07.2012; Опубл. 22.09.2015. - 17 с.🡑

A1005. Пат. 9137681 США, МПК H04W24/00, G01S13/46, G01S13/82, G01S5/14, H04W84/10 и др. Device for round trip time measurements / S. M. Das, A. Aggarwal, A. F. Naguib, E. T. L. Hardie. - № 13/752270; Заявлено 28.01.2013; Опубл. 15.09.2015. - 23 с.🡑

A1006. Пат. 9136598 США, МПК H01Q3/00, G01S13/00, H01Q3/44, H01Q1/24. Directional adjustment of voltage-controlled phased array structures / X. Yin. - № 13/129879; Заявлено 18.06.2010; Опубл. 15.09.2015. - 18 с.🡑

A1007. Пат. 9136571 США, МПК G01S13/93, H01Q25/00, H01P1/22, G01S7/03, G01S13/87 и др. Driver assistance device for a vehicle, vehicle and method for operating a radar apparatus / U. Papziner, F. Kuenzler. - № 13/696904; Заявлено 22.03.2011; Опубл. 15.09.2015. - 11 с.🡑

A1008. Пат. 9135825 США, МПК G08G1/16, B60Q9/00, G01S17/02, B60W50/00, G01S13/93 и др. Risk degree calculation device / S. Nagata. - № 13/580304; Заявлено 22.02.2010; Опубл. 15.09.2015. - 19 с.🡑

A1009. Пат. 9134417 США, МПК G01S13/93, B60T7/22, G08G1/16, G01S13/46. Obstacle determination device / J. Itoh. - № 14/378567; Заявлено 14.11.2012; Опубл. 15.09.2015. - 21 с.🡑

A1010. Пат. 9134411 США, МПК G05D1/02, B61L3/00, B61L25/02, G01S13/74, G01B21/16 и др. Distance estimation system and method for a railway vehicle / S. Soderi, H. Viittala, J. Saloranta. - № 13/307746; Заявлено 30.11.2011; Опубл. 15.09.2015. - 11 с.🡑

A1011. Пат. 9134410 США, МПК G01S13/58, G01S13/50, G01S13/536, G01S13/93, G01S7/41 и др. Method and device for detecting a target by masked high energy reflectors / F. Vincent, P. Goy. - № 13/542614; Заявлено 05.07.2012; Опубл. 15.09.2015. - 21 с.🡑

A1012. Пат. 9134409 США, МПК G01S13/58, G01S13/06, G01S7/40, G01S7/41, G01S13/93. Vehicle-mounted radar apparatus / A. Mizutani, K. Matsuoka, K. Shimizu, H. Okazaki. - № 13/763933; Заявлено 11.02.2013;

Опубл. 15.09.2015. - 26 с.↑

A1013. Пат. 9134408 США, МПК G01S13/66, G01S13/58, G01S13/87. Apparatus and method for traffic lane detection / M. Ochi, J. Kajiki, T. Ikeya, K. Shite. - № 13/742132; Заявлено 15.01.2013; Опубл. 15.09.2015. - 34 с. ↑

A1014. Пат. 9134120 США, МПК G01D18/00, G01S7/40, G01B11/27, G01S15/93, G01S17/93 и др. Method for adjusting or calibrating a vehicle surrounding sensor, and a vehicle surrounding sensor adjustment or calibration system / S. Schommer, A. Macchia, C. Wagmann, J. Backes, S. M. Kaefer. - № 12/812842; Заявлено 26.08.2009; Опубл. 15.09.2015. - 9 с.↑

A1015. Пат. 9131119 США, МПК G01S13/88, H04N7/18, G01S17/02, G01S17/06, G01S17/74 и др. Perception based loading / P. R. Friend, Q. Chen, E. A. Reiners. - № 13/686779; Заявлено 27.11.2012; Опубл. 08.09.2015. - 21 с.↑

A1016. Пат. 9129531 США, МПК G01S13/93, G08G1/16. Vehicle control system, specific object determination device, specific object determination method, and non-transitory storage medium storing specific object determination program / H. Hayashi. - № 14/361042; Заявлено 26.11.2012; Опубл. 08.09.2015. - 15 с.↑

A1017. Пат. 9129523 США, МПК G08G9/02, G01S13/93, G01S7/41, G01S7/48, G01S13/86 и др. Method and system for obstacle detection for vehicles using planar sensor data / B. A. Martin. - № 13/900125; Заявлено 22.05.2013; Опубл. 08.09.2015. - 11 с.↑

A1018. Пат. 9128714 США, МПК H04B7/00, G01S13/00, G06F1/32. Method and system for detecting an object or body based on changes in signal phases / F. Fortin, L. Cariou, P. Chazot. - № 13/772122; Заявлено 20.02.2013; Опубл. 08.09.2015. - 10 с.↑

A1019. Пат. 9127956 США, МПК G01C21/30, G01S13/72, B60W40/04, G01S13/93, G01C21/32 и др. Technique for lane assignment in a vehicle / N. Einecke, S. Rebhan. - № 14/325476; Заявлено 08.07.2014; Опубл. 08.09.2015. - 23 с.↑

A1020. Пат. 9125294 США, МПК G01S13/00, H05K7/20, H05K9/00. Shield / A. T. Rowe. - № 13/139414; Заявлено 08.12.2009; Опубл. 01.09.2015. - 9 с.↑

A1021. Пат. 9123134 США, МПК G06K9/00, G06T7/00, G01S13/90, B63B35/08, G06T7/20 и др. Method for tracking and forecasting marine ice bodies / P. D. Anno, K. A. Soofi. - № 14/196607; Заявлено 04.03.2014; Опубл. 01.09.2015. - 12 с.↑

A1022. Пат. 9121920 США, МПК G06F7/00, G01D3/08, B60T8/172, G01S7/40, G01S7/497 и др. Method for operating at least one sensor of a vehicle and vehicle having at least one sensor / N. Wagner. - № 13/277329; Заявлено 20.10.2011; Опубл. 01.09.2015. - 9 с.↑

A1023. Пат. 9117369 США, МПК G08G1/01, G01S13/87, G01S7/41, G08G1/056, G01S13/86 и др. Method for detecting a wheel of a vehicle / O. Nagy. - № 13/929446; Заявлено 27.06.2013; Опубл. 25.08.2015. - 13 с.↑

A1024. Пат. 9116543 США, МПК G01S13/56, G01S15/02, G01S13/86, G01S15/88, G01S17/89 и др. Virtual input system / W. R. Wells. - № 14/158013; Заявлено 17.01.2014; Опубл. 25.08.2015. - 18 с.↑

A1025. Пат. 9116244 США, МПК G01S13/95, G01S7/292, G01S7/41, G01S13/524, G01S13/00 и др. System for and method of weather phenomenon detection using multiple beams / J. B. West, D. L. Woodell. - № 13/781449; Заявлено 28.02.2013; Опубл. 25.08.2015. - 15 с.↑

A1026. Пат. 9116235 США, МПК G01S5/02, G01S7/41, G01S13/52, G01S7/292, G01S13/78 и др. Mode S anti-reflection algorithm for eliminating false tracks due to reflected replies in ground radar systems / S. Gelli, S. Rosati. - № 13/689967; Заявлено 30.11.2012; Опубл. 25.08.2015. - 20 с.↑

A1027. Пат. 9112278 США, МПК G01S7/02, H01Q25/00, H01Q21/06, H01Q13/20, H01Q1/32 и др. Radar device for behind windshield installations / S. Shi. - № 13/904300; Заявлено 29.05.2013; Опубл. 18.08.2015. - 7 с.↑

A1028. Пат. 9111451 США, МПК G01S13/04, G08G1/16, B60Q9/00, G01C21/36, G01C21/00. Apparatus and method for driving guide of vehicle / K. C. Shin. - № 14/064475; Заявлено 28.10.2013; Опубл. 18.08.2015. - 16 с. ↑

A1029. Пат. 9110170 США, МПК G01C23/00, G01S13/94, G01S13/89. Terrain aided navigation using multi-channel monopulse radar imaging / B. R. Woollard, M. A. Owens. - № 14/473483; Заявлено 29.08.2014; Опубл. 18.08.2015. - 21 с.↑

A1030. Пат. 9110162 США, МПК G01S7/03, G01S13/42, H01Q1/42, H01Q1/32, H01Q15/02 и др. Antenna cover / S.- Matsuzawa, M. Ogawa, K. Takeuchi. - № 13/812046; Заявлено 19.07.2011; Опубл. 18.08.2015. - 17 с. ↑

A1031. Пат. 9109919 США, МПК G01S13/88, G01C21/36, G01C21/32, G01C21/30, G09B29/10 и др. Curved-section-information supplying apparatus and curved-section-information supplying method / T. Yabe. - № 14/314504; Заявлено 25.06.2014; Опубл. 18.08.2015. - 25 с.↑

A1032. Пат. 9108388 США, МПК H01Q17/00, B32B27/36, B32B5/26, B32B5/08, H05K9/00 и др. Broadband electromagnetic wave-absorber and process for producing same / Y. Egami, K. Suzuki, T. Tsuduki. - № 13/063788; Заявлено 28.12.2009; Опубл. 18.08.2015. - 35 с.↑

A1033. Пат. 9105192 США, МПК G01S13/93, G01S13/58, G08G1/16, G01S15/58, B60T7/22 и др. Monitoring apparatus and method / M. Cund, S. P. Gilling, P. Widdowson. - № 14/116179; Заявлено 10.05.2012; Опубл. 11.08.2015. - 10 с.↑

A1034. Пат. 9097805 США, МПК G01S7/40, G01S7/02, G01S13/95. Systems and methods for calibrating dual polarization radar systems / M. S. Balaji, J. R. Ellis, R. D. Cartwright, W. H. Walker. - № 13/441419; Заявлено 06.04.2012; Опубл. 04.08.2015. - 15 с.↑

A1035. Пат. 9097801 США, МПК G01S13/93, G01S7/40, G01S13/86, G01S13/34, G01S13/46 и др. Obstacle detection apparatus and obstacle detection program / T. Kambe, K. Sekine. - № 13/523704; Заявлено 14.06.2012; Опубл. 04.08.2015. - 96 с.↑

A1036. Пат. 9097800 США, МПК G01S13/86, G01S13/93, G01S13/42. Solid object detection system using laser and radar sensor fusion / J. Zhu. - № 13/649384; Заявлено 11.10.2012; Опубл. 04.08.2015. - 28 с.↑

A1037. Пат. 9091776 США, МПК G01S13/89, G01V3/12, G01V3/10. Subterranean mapping system including electrically conductive element and related methods / F. E. Parsche. - № 13/711185; Заявлено 11.12.2012; Опубл. 28.07.2015. - 15 с.↑

A1038. Пат. 9091763 США, МПК G01S13/95, G01W1/10, H04B7/185, H04W52/24, G01W1/04. Weather detection using satellite communication signals / R. L. Mills. - № 14/247766; Заявлено 08.04.2014; Опубл. 28.07.2015. - 12 с.↑

A1039. Пат. 9091759 США, МПК G01S13/60, G01S13/95, G01S13/00. Smart beam selection for radar aided navigation / V. A. Sishtla, M. B. Godfrey, J. H. Doty, K. L. Kerley. - № 13/767390; Заявлено 14.02.2013; Опубл. 28.07.2015. - 8 с.↑

A1040. Пат. 9091753 США, МПК G01S13/88, G01F23/284, G01S13/08. Level measuring system operating according to the radar principle / M. Deilmann, M. Gerding, U. Wegemann, N. Pohl. - № 13/755480; Заявлено 31.01.2013; Опубл. 28.07.2015. - 8 с.↑

A1041. Пат. 9088352 США, МПК H04B5/00, H04B10/00, H01Q9/04, G01S7/03, G01S13/93. Wave dielectric transmission device, manufacturing method thereof, and in-millimeter wave dielectric transmission / H. Kawamura, Y. Okada. - № 14/045062; Заявлено 03.10.2013; Опубл. 21.07.2015. - 23 с.↑

A1042. Пат. 9086501 США, МПК G06K9/00, G06T11/00, G01S13/00, G01S7/02, G01S7/295 и др. Imaging, object detection, and change detection with a polarized multistatic GPR array / N. R. Beer, D. W. Paglieroni. - № 13/748417; Заявлено 23.01.2013; Опубл. 21.07.2015. - 16 с.↑

A1043. Пат. 9086485 США, МПК G01S7/02, G01S7/40, G01S13/93, G01S7/03, G01S7/35 и др. Radar sensor for motor vehicles / A. Himmelstoss, D. Steinbuch. - № 13/807212; Заявлено 02.05.2011; Опубл. 21.07.2015. - 5 с.↑

A1044. Пат. 9086472 США, МПК G01S13/78, G01S3/30, G01S13/76, G01S13/87, G01S13/88. Multi-transceiver RF alert system for preventing hunting accidents / G. Ivtsenkov, E. Berik. - № 13/626995; Заявлено 26.09.2012; Опубл. 21.07.2015. - 13 с.↑

A1045. Пат. 9086311 США, МПК G01S13/08, G01F23/284, H01Q13/02, H01Q19/08, H01P3/16 и др. Microwave-sending device / U. Wegemann. - № 13/532012; Заявлено 25.06.2012; Опубл. 21.07.2015. - 9 с.↑

A1046. Пат. 9085310 США, МПК B61L25/02, G01S5/08, G01S5/14, G01S13/87, G01S5/02 и др. Method of determining the position of a vehicle moving along a guideway / B. McKillican, A. Kanner. - № 13/115425; Заявлено 25.05.2011; Опубл. 21.07.2015. - 10 с.↑

A1047. Пат. 9084103 США, МПК H04M11/04, H04W4/22, G01S13/87, G08B21/02, H04W4/00 и др. Analytic and tracking systems and methods using over-the-air identifiers of mobile devices / D. J. Monks, T. D. Bekiares, T. J. Collins, T. J. Miller. - № 14/158045; Заявлено 17.01.2014; Опубл. 14.07.2015. - 21 с.↑

A1048. Пат. 9084076 США, МПК H04W4/00, G06K9/00, H01Q1/32, H01Q1/22, G01S13/87. Techniques for obtaining information about objects / D. S. Breed, W. C. Johnson, W. E. DuVall. - № 13/664567; Заявлено 31.10.2012; Опубл. 14.07.2015. - 33 с.↑

A1049. Пат. 9081116 США, МПК G01S13/89, G01V3/12, G01V3/30, E21B47/022. Subterranean mapping system including spaced apart electrically conductive well pipes and related methods / F. E. Parsche. - № 13/711147; Заявлено 11.12.2012; Опубл. 14.07.2015. - 16 с.↑

A1050. Пат. 9081088 США, МПК G01S13/08. System and method for estimating range to an RFID tag / M. G. Melville, J. T. Elson. - № 13/753338; Заявлено 29.01.2013; Опубл. 14.07.2015. - 9 с.↑

A1051. Пат. 9081087 США, МПК G01F23/00, G01S13/08, G01F23/284, G01S13/88. Method for ascertaining and/or evaluating fill-state of a container containing at least one medium / D. Spanke, C. Reinau, M. Boldt, A. Malinovskiy, S. Greth. - № 12/314655; Заявлено 15.12.2008; Опубл. 14.07.2015. - 11 с.↑

A1052. Пат. 9081086 США, МПК G01S13/04, G01S13/93, G01S7/41, G08G1/16, G01S13/88 и др. Vehicle detection device and vehicle detection method / M. Nakamura, H. Satoh. - № 14/380011; Заявлено 26.02.2013; Опубл. 14.07.2015. - 11 с.↑

A1053. Пат. 9081077 США, МПК G05G3/00, G01S13/00, H04B7/185, G08B23/00, G05D1/02 и др. System for tracking ships at sea / R. Laine. - № 13/517463; Заявлено 13.12.2010; Опубл. 14.07.2015. - 6 с.↑

A1054. Пат. 9079560 США, МПК H01Q1/32, H04W4/02, G01S13/87, H04W4/04, B60R25/24 и др. Device location determination by a vehicle / N. R. Gautama, A. J. Kalhous, C. U. Saraydar. - № 13/667387; Заявлено 02.11.2012; Опубл. 14.07.2015. - 7 с.↑

A1055. Пат. 9078582 США, МПК A61B5/05, A61B5/0444, A61B5/00, G01S13/02, G01S13/56 и др. Fetal monitoring device and methods / J. P. Tupin, J.J. P. Tupin, S. Stephansen, I.V. - № 13/246784; Заявлено 27.09.2011; Опубл. 14.07.2015. - 25 с.↑

A1056. Пат. 9075143 США, МПК G01S13/66, G01S13/89, G01S13/87, G01S7/20, G01S13/72. Sparse array RF imaging for surveillance applications / C. S. Brundick, D. E. Davis, D. E. Norris, E. S. Stickels. - № 13/097812; Заявлено 29.04.2011; Опубл. 07.07.2015. - 13 с.↑

A1057. Пат. 9073548 США, МПК G01S13/93, B60W30/165, G01S7/41, G01S13/00, B60W30/16 и др. Vehicle-mounted radar apparatus / A. Mizutani, K. Matsuoka, K. Shimizu, H. Okazaki. - № 13/764903; Заявлено 12.02.2013; Опубл. 07.07.2015. - 17 с.↑

A1058. Пат. 9073347 США, МПК G01S13/88, B41J3/36, B41J3/407. Hand-held radar device with direct printing based on radar input / J. R. Feigin. - № 13/649157; Заявлено 11.10.2012; Опубл. 07.07.2015. - 14 с.↑

A1059. Пат. 9069078 США, МПК G01S13/93. Radar device / H. Ishimori, H. Kajioka, S. Shibata. - № 13/365542; Заявлено 03.02.2012; Опубл. 30.06.2015. - 28 с.↑

A1060. Пат. 9069076 США, МПК G01S13/78, G01S17/74. Polaritonic meta-material combat identification / I. I. Smolyaninov, I. Mandelbaum, L. C. Sengupta. - № 13/596494; Заявлено 28.08.2012; Опубл. 30.06.2015. - 7 с.↑

A1061. Пат. 9069068 США, МПК G01S19/20, G01S19/14, G01S5/00, G01S13/78. Systems and methods for updating HIL and HFOM integrity components when not extrapolating position data / B. D. Webb, J. Savoy. - № 13/240862; Заявлено 22.09.2011; Опубл. 30.06.2015. - 8 с.↑

A1062. Пат. 9068876 США, МПК G06F17/00, G01F23/00, G01F23/28, G01S13/08, G01S15/08 и др. Device and method for determining media and container properties / K. Griessbaum, R. Welle. - № 13/456861; Заявлено 26.04.2012; Опубл. 30.06.2015. - 23 с.↑

A1063. Пат. 9067603 США, МПК B60T7/12, G01S13/72, B60W10/184, B60W10/06, B60W30/16 и др. Adaptative cruise control / P. Kollberg, F. Sandblom. - № 13/977363; Заявлено 29.12.2010; Опубл. 30.06.2015. - 7 с.↑

A1064. Пат. 9067583 США, МПК G01S13/88, B60W10/08, G08G1/0968, B60W20/00, B60W10/06. Vehicle travel control system / K. Taguchi. - № 12/937929; Заявлено 14.04.2009; Опубл. 30.06.2015. - 25 с.↑

A1065. Пат. 9066463 США, МПК G05D1/02, A01B69/04, A01D41/127, B62D6/00, G01S13/91 и др. Crop feeler system and method / A. F. Lange. - № 13/633757; Заявлено 02.10.2012; Опубл. 30.06.2015. - 13 с.↑

A1066. Пат. 9066202 США, МПК H04W24/00, H04W4/02, G01S13/87. Positioning using observer-based time-of-arrival measurements / P. Dua, L. J. Garin. - № 13/797621; Заявлено 12.03.2013; Опубл. 23.06.2015. - 26 с. ↑

A1067. Пат. 9064408 США, МПК G08G1/01, G08G1/056, G01S13/93, G08G1/16, B60Q9/00. Rear cross traffic alert device / T. Komoguchi, T. Kawasaki, Y. Takahashi. - № 14/008191; Заявлено 26.09.2011; Опубл. 23.06.2015. - 18 с.↑

A1068. Пат. 9063834 США, МПК G06F17/00, G01S13/58, G01S13/93, G01S7/40, B60W50/00 и др. Filtering method and filter device for sensor data / D. Withopf, S. Stierlin. - № 13/800923; Заявлено 13.03.2013; Опубл. 23.06.2015. - 10 с.↑

A1069. Пат. 9063231 США, МПК G01S13/88, G01S13/42, G01S13/89. Method and device for imaging an object using electromagnetic high frequency radiation / T. Loffler. - № 13/132229; Заявлено 27.11.2009; Опубл. 23.06.2015. - 10 с.↑

A1070. Пат. 9063225 США, МПК G01S13/58, G01S13/34, G01S13/93, G01S13/536. High resolution Doppler collision avoidance radar / J. S. Lee, P. D. Schmalenberg, J. P. Ebling, N. S. Subotic. - № 13/414299; Заявлено 07.03.2012; Опубл. 23.06.2015. - 10 с.↑

A1071. Пат. 9063214 США, МПК G01S7/03, G01S13/93, G01S13/00. Monostatic multi-beam radar sensor for motor vehicles / M. Klar, T. Binzer, D. Steinbuch, D. Freundt, B. Lucas. - № 12/673708; Заявлено 25.06.2008; Опубл. 23.06.2015. - 9 с.↑

A1072. Пат. 9063211 США, МПК B60T7/16, G05D1/02, G01S13/87, G01S5/02, G01S5/14 и др. Navigation system and method / T. Anderson, R. S. Cornelius, F. Artner. - № 14/014543; Заявлено 30.08.2013; Опубл. 23.06.2015. - 16 с.↑

A1073. Пат. 9062658 США, МПК F03D1/06, F03D11/00, H01Q15/16, G01S13/52. Rotor blade for a wind turbine, and a combination of a radar station and a wind turbine / J. Bettermann. - № 13/310086; Заявлено 02.12.2011; Опубл. 23.06.2015. - 10 с.↑

A1074. Пат. 9057792 США, МПК G01S13/00, G01V9/02, G01S13/56, G01S13/536, G01M3/18 и др. Device and method for detection of water flow in ground / S. Abrahamson. - № 13/501550; Заявлено 12.10.2010; Опубл. 16.06.2015. - 8 с.↑

A1075. Пат. 9057783 США, МПК G01S13/00, G01S13/88, G01S13/56. Change detection method and system for use in detecting moving targets behind walls, barriers or otherwise visually obscured / A. F. Martone, K. I. Ranney, C. D. Le. - № 13/233434; Заявлено 15.09.2011; Опубл. 16.06.2015. - 35 с.↑

A1076. Пат. 9057782 США, МПК G01S13/88, G01S7/292, G01S13/00. Realization of time-domain ultra wideband ground-penetrating radar using high speed accumulation and interpolated sampling / J. R. Feigin. - № 13/588213; Заявлено 17.08.2012; Опубл. 16.06.2015. - 23 с.↑

A1077. Пат. 9055523 США, МПК H04B17/00, H04W56/00, G01S5/02, G01S5/14, G01S13/76. Apparatus, system and method of calibrating a radio delay of a wireless device / L. Banin, Y. Amizur, U. Schatzberg. - № 13/691801; Заявлено 02.12.2012; Опубл. 09.06.2015. - 18 с.↑

A1078. Пат. 9052392 США, МПК G01P3/50, G06F17/40, G06F19/00, G01S13/60, B61L25/02 и др. Velocity measurement apparatus capable of accurately measuring velocity of moving object relative to ground surface / K. Inomata, M. Watanabe, H. Araki, T. Murakami. - № 13/296837; Заявлено 15.11.2011; Опубл. 09.06.2015. - 43 с. ↑

A1079. Пат. 9052380 США, МПК G01S5/18, G01S13/50, G01S11/14, G01S3/802, G01V1/38. System for doppler positioning of seismic sensors and method / O. Winter, T. Bianchi. - № 13/475169; Заявлено 18.05.2012; Опубл. 09.06.2015. - 18 с.↑

A1080. Пат. 9052207 США, МПК G01C21/30, G01S13/86, G01S13/93, G01C21/00, G01S19/48. System and method for vehicle navigation using lateral offsets / K. Miksa, K. Smiechowicz. - № 13/503399; Заявлено 22.10.2009; Опубл. 09.06.2015. - 27 с.↑

A1081. Пат. 9051008 США, МПК B62D6/00, G01S13/00, B60Q1/00, B62D15/02, B60W40/02 и др. Driver assistance system / J. Schiehlen, J. Felten, S. Hohmann, M. Ayoubi. - № 11/875456; Заявлено 19.10.2007; Опубл. 09.06.2015. - 5 с.↑

A1082. Пат. 9050573 США, МПК G01S13/08, B01J8/22, B01J8/00, C08F110/02. Method for monitoring the level of an ethylene polymerization catalyst slurry / L. Fouarge, A. Brusselle. - № 13/514096; Заявлено 17.12.2010; Опубл. 09.06.2015. - 16 с.↑

A1083. Пат. 9046608 США, МПК G01S13/95, G01S13/00. System for detecting sea-surface wind, using satellite observation, and a method for detecting sea-surface wind / S. W. Hong. - № 13/659706; Заявлено 24.10.2012; Опубл. 02.06.2015. - 15 с.↑

A1084. Пат. 9046603 США, МПК G01S13/88. Radar sensor for motor vehicles, in particular RCA sensor / T. Binzer. - № 13/822676; Заявлено 18.07.2011; Опубл. 02.06.2015. - 7 с.↑

A1085. Пат. 9043108 США, МПК G06F7/70, B60Q1/00, G01S13/00. Driving support apparatus for vehicle / H. Sekiguchi. - № 13/833782; Заявлено 15.03.2013; Опубл. 26.05.2015. - 13 с.↑

A1086. Пат. 9041596 США, МПК G01S3/74, G01S13/42, G01S13/48, G01S13/93. Multibeam radar apparatus for vehicle, multibeam radar method and multibeam radar program / Y. Kuwahara, J. Kanamoto, H. Kamo. - № 13/371047; Заявлено 10.02.2012; Опубл. 26.05.2015. - 37 с.↑

A1087. Пат. 9037413 США, МПК G01S17/89, G01S13/95, G01S17/95. System and method of visualization of species characterization, dynamics and stratification of the magnetosphere / C. T. Rodgers, O. E. Kia. - № 12/902481; Заявлено 12.10.2010; Опубл. 19.05.2015. - 18 с.↑

A1088. Пат. 9035820 США, МПК G01S13/58. Measurement device, measurement system, measurement method, and program / H. Shiba. - № 13/256708; Заявлено 30.03.2010; Опубл. 19.05.2015. - 17 с.↑

A1089. Пат. 9035762 США, МПК G08B1/08, G01C17/00, G01C9/00, G01S13/08, G01C19/00 и др. Method and system for locating signal emitters using cross-correlation of received signal strengths / R. T. Cutler, D. W. Vook, A. D. Fernandez. - № 12/325708; Заявлено 01.12.2008; Опубл. 19.05.2015. - 18 с.↑

A1090. Пат. 9030351 США, МПК G01S7/292, G01S13/86, G01S13/66, G01S13/00. Sensor suite and signal processing for border surveillance / P. A. Fox, J. W. Maresca, J. - № 13/710131; Заявлено 10.12.2012; Опубл. 12.05.2015. - 72 с.↑

A1091. Пат. 9024809 США, МПК G01S13/58, G01S13/34. Object detection system and method / M. Testar. - № 13/407289; Заявлено 28.02.2012; Опубл. 05.05.2015. - 19 с.↑

A1092. Пат. 9024808 США, МПК G01F23/284, G01S13/08, G01S13/00, G01F23/00. Filling level determination using transmit signals with different frequency steps / M. Kleman. - № 13/788738; Заявлено 07.03.2013; Опубл. 05.05.2015. - 14 с.↑

A1093. Пат. 9024802 США, МПК G01S13/56, G01V3/12. Electromagnetic detection and imaging transceiver (EDIT) and roadway traffic detection system / L. G. Stolarczyk. - № 13/862379; Заявлено 13.04.2013; Опубл. 05.05.2015. - 15 с.↑

A1094. Пат. 9020750 США, МПК G01S13/08, G08G1/16. Drive assist device, and vehicle using drive assist device / M. Nakajima, S. Suzuki, M. Murai. - № 14/288537; Заявлено 28.05.2014; Опубл. 28.04.2015. - 15 с.↑

A1095. Пат. 9020696 США, МПК G08G1/16, G01S13/00. Event data recorder having traffic monitoring and warning function within safe range / C.-W. Lo. - № 13/926159; Заявлено 25.06.2013; Опубл. 28.04.2015. - 9 с.↑

A1096. Пат. 9019153 США, МПК G01S13/00. Calibration of large phased arrays using fourier gauge / J. J. Schuss, T. V. Sikina, J. C. Upton. - № 13/331334; Заявлено 20.12.2011; Опубл. 28.04.2015. - 22 с.↑

A1097. Пат. 9019147 США, МПК G01S13/08. System and method for displaying weather information / A. M. Oranskiy, M. B. Godfrey, P. R. Barbosa, J. D. Cahoon. - № 13/361804; Заявлено 30.01.2012; Опубл. 28.04.2015. - 18 с.↑

A1098. Пат. 9019145 США, МПК G01S13/95. Ground clutter rejection for weather radar / V. A. Sishtla, D. L. Woodell, M. C. Fersdahl. - № 13/183314; Заявлено 14.07.2011; Опубл. 28.04.2015. - 19 с.↑

A1099. Пат. 9014903 США, МПК G05D1/00, G01C22/00, G05D3/00, G06K9/00, G01S13/88 и др. Determination of object heading based on point cloud / J. Zhu, D. A. Dolgov, N. Fairfield. - № 13/477871; Заявлено 22.05.2012; Опубл. 21.04.2015. - 22 с.↑

A1100. Пат. 9007258 США, МПК G01S13/00. Radar device and method of calculation of receive power in radar device / Y. Kurono. - № 13/323290; Заявлено 12.12.2011; Опубл. 14.04.2015. - 21 с.↑

A1101. Пат. 9007256 США, МПК G01S13/88. TREES-tree root examination, evaluation and standardization / M. V. Ambusk. - № 13/317425; Заявлено 18.10.2011; Опубл. 14.04.2015. - 7 с.↑

A1102. Пат. 9007215 США, МПК G08B13/14, G08G1/123, G01S13/74, H01Q19/06. Systems and methods for a RFID enabled metal license plate / J. Zhu, C.- Yen, J. Liu, J. Mullis. - № 13/708353; Заявлено 07.12.2012; Опубл. 14.04.2015. - 11 с.↑

A1103. Пат. 9002641 США, МПК G01S13/00, G01S7/00, G01S5/02. Navigation system configured to integrate motion sensing device inputs / P. E. Showering. - № 13/749827; Заявлено 25.01.2013; Опубл. 07.04.2015. - 11 с. ↑

A1104. Пат. 8994586 США, МПК G01S7/35, G01S13/34, G01S13/58. Apparatus and method for detecting target in near field / J.-H. Choi, M.-S. Jung, W.-Y. Uhm, W.-J. Kim. - № 14/092610; Заявлено 27.11.2013; Опубл. 31.03.2015. - 15 с.↑

A1173. Пат. 8823583 США, МПК G01S13/04, G01S7/02, G01S7/35, G01S13/00, G01S7/00. Radar sensor having two oscillators, two I/Q transmit mixers, and two I/Q receive mixers / J. Hasch, A. Manicke. - № 13/499000; Заявлено 02.08.2010; Опубл. 02.09.2014. - 11 с.↑

A1174. Пат. 8823578 США, МПК G01S13/93, G01S13/522, G01S15/93, G01S15/52, G01S13/00 и др. Driving assist apparatus / T. Hattori, M. Matsuura. - № 13/418436; Заявлено 13.03.2012; Опубл. 02.09.2014. - 22 с.↑

A1175. Пат. 8818703 США, МПК G06F17/10, B60R22/00, G06F19/00, G05D1/00, G01S13/00 и др. Object recognition device and object recognition method / T. Harada. - № 13/143615; Заявлено 29.01.2009; Опубл. 26.08.2014. - 23 с.↑

A1176. Пат. 8816901 США, МПК G01S13/00, G01S7/40. Calibration to improve weather radar positioning determination / E. C. Klinger, K. Isaacson. - № 13/486727; Заявлено 01.06.2012; Опубл. 26.08.2014. - 12 с.↑

A1177. Пат. 8816897 США, МПК G01S13/53, G01S13/64. Method for estimating the angular position of a target by radar detection and radar implementing said method / N. Bon, J.-M. Quellec. - № 13/297146; Заявлено 15.11.2011; Опубл. 26.08.2014. - 10 с.↑

A1178. Пат. 8810445 США, МПК G01S13/00. Method and apparatus for recognizing presence of objects / T. Ogawa, H. Sakai. - № 13/093904; Заявлено 26.04.2011; Опубл. 19.08.2014. - 16 с.↑

A1179. Пат. 8803728 США, МПК G01S13/00, B60Q1/00, F21V7/00. Millimeter wave radar-equipped headlamp / N. Yonemoto, A. Kohmura, Y. Kurosawa, T. Watanabe, S. Yamamura. - № 13/105350; Заявлено 11.05.2011; Опубл. 12.08.2014. - 17 с.↑

A1180. Пат. 8803726 США, МПК G01S13/95. Method for detecting icing at an angle-resolving radar sensor in a driver assistance system for motor vehicles / S. Heilmann, V. Gross, G. Kuehnle, D. Bechler. - № 13/202947;

Заявлено 28.12.2009; Опубл. 12.08.2014. - 9 с.↑

A1181. Пат. 8791855 США, МПК G01S13/00. Method for detecting wind power plants using a radar system / A. Weiss. - № 13/254526; Заявлено 09.02.2010; Опубл. 29.07.2014. - 8 с.↑

A1182. Пат. 8791853 США, МПК G01S13/95. Air-to-ground antenna / J. P. Mitchell. - № 13/090792; Заявлено 20.04.2011; Опубл. 29.07.2014. - 23 с.↑

A1183. Пат. 8786485 США, МПК G01S13/00. Mobile coherent change detection ground penetrating radar / R. G. Atkins, J. J. Brooke, M. T. Cornick, B. Zhang. - № 13/221233; Заявлено 30.08.2011; Опубл. 22.07.2014. - 12 с.↑

A1184. Пат. 8786467 США, МПК G08G5/00, G01S13/00, G06G7/76, G01C21/00. Methods and systems for filtering traffic information for display / S. T. Clark, R. R. Bowe, S. B. Ortman, J. M. Crane. - № 13/051146; Заявлено 18.03.2011; Опубл. 22.07.2014. - 24 с.↑

A1185. Пат. 8781790 США, МПК G01B5/02, G01C3/08, G01S13/00. Return pulse shape analysis for falling edge object discrimination of aerosol LIDAR / X. Zhu, S. L. Gagnon. - № 13/127945; Заявлено 05.11.2008; Опубл. 15.07.2014. - 23 с.↑

A1186. Пат. 8779967 США, МПК G01S13/00. Sensor cart positioning system and method / R. P. Jones, P. J. Kelly. - № 13/342330; Заявлено 03.01.2012; Опубл. 15.07.2014. - 34 с.↑

A1187. Пат. 8773299 США, МПК G01S13/93, G08G5/04, G01S13/00, G01S13/95, G08G5/00. System and method for actively determining obstacles / D. L. Woodell, R. D. Jinkins, R. M. Rademaker. - № 12/569805; Заявлено 29.09.2009; Опубл. 08.07.2014. - 15 с.↑

A1188. Пат. 8766846 США, МПК G01S13/00, B60Q1/50, G08G1/123, G01S15/00, G06G7/00 и др. Accident prevention system and a vehicle including the accident prevention system / B. L. Kiehne. - № 13/447159; Заявлено 13.04.2012; Опубл. 01.07.2014. - 31 с.↑

A1189. Пат. 8766845 США, МПК G01S13/88, G01V3/12, G01S15/89. Object detection with a multistatic array using singular value decomposition / A. T. Hallquist, D. H. Chambers. - № 13/313939; Заявлено 07.12.2011; Опубл. 01.07.2014. - 16 с.↑

A1190. Пат. 8762061 США, МПК G01W1/00, G01S13/95. Process for generating spatially continuous wind profiles from wind profiler measurements / Y. P. Yee. - № 12/837909; Заявлено 16.07.2010; Опубл. 24.06.2014. - 11 с.↑

A1191. Пат. 8760342 США, МПК G01S13/00. Circuit board, high frequency module, and radar apparatus / K. Hayata. - № 13/259126; Заявлено 31.03.2010; Опубл. 24.06.2014. - 20 с.↑

A1192. Пат. 8760341 США, МПК G01S13/42, G01S13/58. Radar device / K. Nakagawa. - № 13/077384; Заявлено 31.03.2011; Опубл. 24.06.2014. - 23 с.↑

A1193. Пат. 8754802 США, МПК G01S13/00. Determining root correspondence between previously and newly detected objects / D. W. Paglieroni, N. R. Beer. - № 13/219512; Заявлено 26.08.2011; Опубл. 17.06.2014. - 25 с. ↑

A1194. Пат. 8743654 США, МПК G01S13/90. Reflectivity maps / G. S. Sammelmann. - № 12/931636; Заявлено 24.01.2011; Опубл. 03.06.2014. - 10 с.↑

A1195. Пат. 8738263 США, МПК G06F7/70, G01S13/58, G01S13/08. Method of detecting a vehicle speed and related electronic device / T.-M. Wu, M.-K. Lin. - № 13/609227; Заявлено 10.09.2012; Опубл. 27.05.2014. - 10 с. ↑

A1196. Пат. 8736483 США, МПК G08G1/16, G01S13/93. Collision avoidance apparatus / K. Takeuchi. - № 13/508452; Заявлено 27.11.2009; Опубл. 27.05.2014. - 17 с.↑

A1197. Пат. 8730095 США, МПК G01S13/00. Super-angular and range-resolution with phased array antenna and multifrequency dither / V. Volman, J. B. Stetson. - № 13/919634; Заявлено 17.06.2013; Опубл. 20.05.2014. - 34 с.↑

A1198. Пат. 8730089 США, МПК G01S13/00. Vehicle radar system / Y. Shimizu. - № 13/183095; Заявлено 14.07.2011; Опубл. 20.05.2014. - 18 с.↑

A1199. Пат. 8730086 США, МПК G01W1/10, G01S13/95, G08B21/00. Weather detection using satellite communication signals / R. L. Mills. - № 12/544121; Заявлено 19.08.2009; Опубл. 20.05.2014. - 13 с.↑

A1200. Пат. 8730084 США, МПК G01S13/00, H01Q9/04, H01Q7/08, H01Q1/00, H01Q9/00 и др. Dual mode ground penetrating radar (GPR) / T. A. Al-Khalefah, K. F. R. Almutairi, A. V. Utsi. - № 12/955231; Заявлено 29.11.2010; Опубл. 20.05.2014. - 18 с.↑

A1201. Пат. 8729903 США, МПК G01V3/00, G01V3/02, G01S13/00, G01V1/00. Method for remote identification and characterization of hydrocarbon source rocks using seismic and electromagnetic geophysical data / L. J. Srnka, Q. R. Passey, K. M. Bohacs, D. R. Converse, Y. Zhu. - № 12/872783; Заявлено 31.08.2010; Опубл. 20.05.2014. - 22 с.↑

A1202. Пат. 8725403 США, МПК B60W40/08, B60T8/1755, G08G1/16, G01S13/93. Vehicle control apparatus, vehicle, and vehicle control method / H. Aoki, H. Yasuda. - № 13/375023; Заявлено 26.05.2010; Опубл. 13.05.2014. - 18 с.↑

A1203. Пат. 8723723 США, МПК G01S13/00, G01S13/08. Dual mode ground penetrating radar (GPR) / T. A. Al-Khalefah, K. F. R. Almutairi, P. A. V. Utsi. - № 13/762473; Заявлено 08.02.2013; Опубл. 13.05.2014. - 17 с.↑

A1204. Пат. 8721554 США, МПК G01S13/56, A61B5/055, G01S13/62, G01S13/60. Random body movement cancellation for non-contact vital sign detection / J. Lin, C. Li, Y.-C. Liu. - № 12/668700; Заявлено 11.07.2008; Опубл. 13.05.2014. - 32 с.↑

A1205. Пат. 8717225 США, МПК G01S13/93. Object detection device for vehicle and object detection method for vehicle / Y. Sasabuchi. - № 13/387961; Заявлено 26.05.2010; Опубл. 06.05.2014. - 14 с.↑

A1206. Пат. 8717223 США, МПК G01S13/00. Classification of subsurface objects using singular values derived from signal frames / D. H. Chambers, D. W. Paglieroni. - № 13/219435; Заявлено 26.08.2011; Опубл. 06.05.2014. - 20 с.↑

A1207. Пат. 8713324 США, МПК G06F21/00, G01S13/00, H04B7/185, H04B7/19, H04W4/00 и др. Systems and methods for tracking mobile terrestrial terminals for satellite communications / P. Wahlberg, K. Lejnell. - № 11/623902; Заявлено 17.01.2007; Опубл. 29.04.2014. - 46 с.↑

A1208. Пат. 8711031 США, МПК G01S13/00. Apparatus and sensor for adjusting vertical sensor-alignment / S. H. Jeong. - № 12/949393; Заявлено 18.11.2010; Опубл. 29.04.2014. - 20 с.↑

A1209. Пат. 8704704 США, МПК G01S13/93, G01S13/28, G01S13/00. Motor vehicle radar system, and method for determining speeds and distances of objects / U. Luebbert, U. Haberland. - № 12/303913; Заявлено 16.06.2007; Опубл. 22.04.2014. - 13 с.↑

A1210. Пат. 8692708 США, МПК G01S13/00, G02B26/10. Radiometric imaging device and corresponding method / J. Nogueira-Nine. - № 13/053808; Заявлено 22.03.2011; Опубл. 08.04.2014. - 30 с.↑

A1211. Пат. 8692706 США, МПК G01S13/88, B60G17/019, G01S7/40, G01S7/00, G01S13/00 и др. Sensor device for measuring the compression travel and/or the compression rate of wheels and/or axles of vehicles / F. Hecker. - № 11/885103; Заявлено 24.02.2006; Опубл. 08.04.2014. - 8 с.↑

A1212. Пат. 8686891 США, МПК G01S13/00. Locating device / R. Krapf, H. Braun, M. Mahler, C. Wieland, U. Hoffmann. - № 12/809923; Заявлено 31.10.2008; Опубл. 01.04.2014. - 14 с.↑

A1213. Пат. 8686326 США, МПК F42B15/01, G01S17/93, G01S15/93, G01S13/93, F41G7/22 и др. Optical-flow techniques for improved terminal homing and control / J. C. Dennison, D. C. Campion. - № 12/383638; Заявлено 25.03.2009; Опубл. 01.04.2014. - 15 с.↑

A1214. Пат. 8681036 США, МПК G01S13/88, G01V3/12. Distributed road assessment system / N. R. Beer, D. W. Paglieroni. - № 13/219430; Заявлено 26.08.2011; Опубл. 25.03.2014. - 34 с.↑

A1215. Пат. 8676508 США, МПК G01S13/88. Method for determining a road profile of a lane located in front of a vehicle / T. Schwarz. - № 13/133682; Заявлено 18.01.2010; Опубл. 18.03.2014. - 6 с.↑

A1216. Пат. 8676488 США, МПК G08G1/16, B60R21/00, G01S13/93. Vehicle surrounding monitor device and method for monitoring surroundings used for vehicle / S. Nagata, J. Sakugawa, M. Iwasaki. - № 13/321326; Заявлено 04.06.2009; Опубл. 18.03.2014. - 14 с.↑

A1217. Пат. 8674871 США, МПК G01S13/00. Method and system for aiding environmental characterization by ultra-wideband radiofrequency signals / B. Denis, V. L. Tosa, B. Uguen, F. Tchoffo-Talom. - № 12/809226; Заявлено 15.12.2008; Опубл. 18.03.2014. - 29 с.↑

A1218. Пат. 8665144 США, МПК G01S13/95. Dual-polarization radar processing system using time domain method / C. Venkatachalam, C. M. Nguyen, D. N. Moisseev. - № 12/387839; Заявлено 07.05.2009; Опубл. 04.03.2014. - 20 с.↑

A1219. Пат. 8665138 США, МПК G01S13/00, B64D47/06, G08G5/04, G08G5/00, G01S13/74 и др. Method and system for reducing light pollution / E. D. Laufer. - № 13/159101; Заявлено 13.06.2011; Опубл. 04.03.2014. - 25 с.↑

A1220. Пат. 8665137 США, МПК G01S13/00. Radar system with improved angle formation / M. Wintermantel. - № 12/994752; Заявлено 02.07.2009; Опубл. 04.03.2014. - 42 с.↑

A1221. Пат. 8665134 США, МПК G01S13/00, H01Q19/10, H01Q1/00, H01Q3/00, H01Q19/12. Rotational parabolic antenna with various feed configurations / S. A. McLaughlin, M. M. Sloan, E. M. Lau. - № 13/755484; Заявлено 31.01.2013; Опубл. 04.03.2014. - 23 с.↑

A1222. Пат. 8660531 США, МПК H04M1/66, G05B23/00, G05B19/00, H04M1/00, H04M3/00 и др. Access to locked functions / J. A. Hymel. - № 12/938990; Заявлено 03.11.2010; Опубл. 25.02.2014. - 20 с.↑

A1223. Пат. 8659477 США, МПК G01S5/14, G01S5/02, G01S13/78, G01S13/76. Base station device and distance measuring method / T. Fukagawa, Y. Kimura, Y. Nakagawa, H. Mukai. - № 13/059363; Заявлено 09.10.2009; Опубл. 25.02.2014. - 23 с.↑

A1224. Пат. 8659470 США, МПК G01S13/46. Apparatus for estimating the height at which a target flies over a reflective surface / H. Driessen, M. Podt. - № 12/638755; Заявлено 15.12.2009; Опубл. 25.02.2014. - 6 с.↑

A1225. Пат. 8655079 США, МПК G06K9/46, G01S13/00, H04N5/225, G06K9/00, G06K9/62. Reducing false alarms in identifying whether a candidate image is from an object class / P. Saisan. - № 12/049791; Заявлено 17.03.2008; Опубл. 18.02.2014. - 18 с.↑

A1226. Пат. 8653935 США, МПК G01S13/88. Low-power wireless network beacon for turning off and on fluorescent lamps / M. C. Baker. - № 12/587062; Заявлено 30.09.2009; Опубл. 18.02.2014. - 23 с.↑

A1227. Пат. 8648744 США, МПК G01S13/93, G01S17/93. Object detection apparatus / S. Koike. - № 12/593314; Заявлено 29.05.2008; Опубл. 11.02.2014. - 16 с.↑

A1302. Пат. 8436763 США, МПК G01S13/00. Radar system comprising overlapping transmitter and receiver antennas / M. Wintermantel. - № 12/994755; Заявлено 02.07.2009; Опубл. 07.05.2013. - 41 с.↑

A1303. Пат. 8436762 США, МПК G01S13/42. Determining at least one coordinate of an object using intersecting surfaces / R. M. Yannone. - № 12/751875; Заявлено 31.03.2010; Опубл. 07.05.2013. - 21 с.↑

A1304. Пат. 8432309 США, МПК G01S13/08. Automotive radar system and method for using same / J. D. MacDonald, L. A. Rubin. - № 12/955625; Заявлено 29.11.2010; Опубл. 30.04.2013. - 12 с.↑

A1305. Пат. 8432306 США, МПК G01S13/00. Method and apparatus for the nowcast of lightning threat using polarimetric radar / J. J. Stagliano, J. - № 12/905762; Заявлено 15.10.2010; Опубл. 30.04.2013. - 17 с.↑

A1306. Пат. 8427361 США, МПК G01S13/93. Radar apparatus for use in vehicle / K. Sato. - № 13/199628; Заявлено 06.09.2011; Опубл. 23.04.2013. - 19 с.↑

A1307. Пат. 8427359 США, МПК G01S13/90, G01S13/58. Tracking moving radar targets with parallel, velocity-tuned filters / D. L. Bickel, D. W. Harmony, T. P. Bielek, J. A. Hollowell, M. S. Murray и др. - № 12/985383; Заявлено 06.01.2011; Опубл. 23.04.2013. - 7 с.↑

A1308. Пат. 8423280 США, МПК G06F17/10, B60Q1/00, G01S13/00. Vehicle collision avoidance system / D. Edwards, D. R. Pavlik, R. Subramanian, R. M. Coats. - № 13/572279; Заявлено 10.08.2012; Опубл. 16.04.2013. - 19 с.↑

A1309. Пат. 8421668 США, МПК G01S13/00. Sub-millimeter wave RF and ultrasonic concealed object detection and identification / D. F. Ammar. - № 12/233446; Заявлено 18.09.2008; Опубл. 16.04.2013. - 10 с.↑

A1310. Пат. 8416119 США, МПК G01S13/95. Weather radar apparatus and signal processing method thereof / F. Mizutani, M. Wada, H. Ishizawa. - № 12/825740; Заявлено 29.06.2010; Опубл. 09.04.2013. - 10 с.↑

A1311. Пат. 8416118 США, МПК H04K3/00, G01S7/40, G01S13/04, G01S13/00. Chaff cloud detection and centroid estimation / R. M. Nuthalapati. - № 12/718562; Заявлено 05.03.2010; Опубл. 09.04.2013. - 17 с.↑

A1312. Пат. 8401793 США, МПК G01W1/00, G06F7/60, G01C5/00, G01S13/00. High resolution wind measurements for offshore wind energy development / S. V. Nghiem, G. Neumann. - № 12/770443; Заявлено 29.04.2010; Опубл. 19.03.2013. - 17 с.↑

A1313. Пат. 8392062 США, МПК B62D6/00, G01S13/93, G06F17/00, B62D6/04, B62D1/00. Method and device for avoiding and/or reducing the consequences of collisions upon evasion with respect to obstacles / F. Oechsle, W. Branz, C. Schmidt. - № 11/795108; Заявлено 12.01.2006; Опубл. 05.03.2013. - 12 с.↑

A1314. Пат. 8390521 США, МПК H01Q1/38, G01S13/00, H01Q19/10. Antenna array for a radar transceiver and circuit configuration for supplying an antenna array of such a radar transceiver / J. Hasch, E. Schmidt. - № 12/808079; Заявлено 21.10.2008; Опубл. 05.03.2013. - 10 с.↑

A1315. Пат. 8390507 США, МПК G01S13/00. Radar system with elevation measuring capability / M. Wintermantel. - № 12/994748; Заявлено 02.07.2009; Опубл. 05.03.2013. - 41 с.↑

A1316. Пат. 8390506 США, МПК G01S13/00, G01S13/08. Motor vehicle FMCW radar having linear frequency ramps of different slopes that are set apart, which are associated with different angular ranges / T. Focke, J. Hilsebecher, A. Zender, T. Schoeberl, T. Hansen. - № 12/733605; Заявлено 21.07.2008; Опубл. 05.03.2013. - 9 с.↑

A1317. Пат. 8386163 США, МПК G01C21/00, G01C21/30, G08G1/123, G01S13/78, G01S19/00. GPS navigation code system / G. Severson. - № 13/134214; Заявлено 01.06.2011; Опубл. 26.02.2013. - 13 с.↑

A1318. Пат. 8384585 США, МПК G01S13/88. Low cost, high performance radar networks / T. J. Nohara, A.-N. Premji, A. M. Ukrainec, P. T. Weber, G. S. Jones и др. - № 12/932593; Заявлено 01.03.2011; Опубл. 26.02.2013. - 18 с.↑

A1319. Пат. 8378884 США, МПК G01S13/42, G01S13/91, G01S13/58. Vehicular traffic surveillance doppler radar system / J. L. Aker. - № 13/422796; Заявлено 16.03.2012; Опубл. 19.02.2013. - 18 с.↑

A1320. Пат. 8378883 США, МПК G01S13/93. Device and method of detecting a target object for motor vehicle / S. K. Kuoch. - № 12/640239; Заявлено 17.12.2009; Опубл. 19.02.2013. - 21 с. ↑

A1321. Пат. 8373589 США, МПК G01S13/00, H01Q19/06, H01Q19/10, H01Q3/00, H01Q1/00 и др. Rotational parabolic antenna with various feed configurations / S. A. McLaughlin, M. M. Sloan, E. M. Lau. - № 12/787643; Заявлено 26.05.2010; Опубл. 12.02.2013. - 23 с. ↑

A1322. Пат. 8368587 США, МПК G01S13/00, H01Q1/42. In-vehicle radar device and cover for in-vehicle radar device / K. Takeuchi. - № 13/402515; Заявлено 22.02.2012; Опубл. 05.02.2013. - 15 с. ↑

A1323. Пат. 8368581 США, МПК G01S13/00. Method for determining compound data of weather radars in an overlapping region of the monitoring regions of at least two weather radars / R. Hannesen, A. Weipert. - № 12/745665; Заявлено 27.11.2008; Опубл. 05.02.2013. - 7 с. ↑

A1324. Пат. 8362948 США, МПК G01S13/89. Long range millimeter wave surface imaging radar system / V. Kolinko, C. Sexton, G. Bishop, J. Lovberg. - № 13/374362; Заявлено 22.12.2011; Опубл. 29.01.2013. - 26 с. ↑

A1325. Пат. 8354955 США, МПК G01S13/00. Observation signal processing apparatus / Y. Miyake, A. Kondou, G. Takano. - № 12/928913; Заявлено 22.12.2010; Опубл. 15.01.2013. - 11 с. ↑

A1326. Пат. 8350767 США, МПК H01Q1/28, H01Q1/00, H01Q21/00, G01S13/74, G01S13/08 и др. Notch antenna having a low profile stripline feed / G. A. Brigham, M. Davidovitz, Z. Davidovitz, representative, S. M. Duffy и др. - № 12/126418; Заявлено 23.05.2008; Опубл. 08.01.2013. - 10 с. ↑

A1327. Пат. 8350752 США, МПК G01S13/08. Radar level gauge system with bottom reflector and bottom reflector / E. Hemmendorff. - № 12/833174; Заявлено 09.07.2010; Опубл. 08.01.2013. - 10 с. ↑

A1328. Пат. 8350747 США, МПК G01S13/89. Surveillance with subject screening / P. DeLia, S. T. Trosper, T. E. Breen, J. J. Reilly, P. J. Hurd и др. - № 11/740193; Заявлено 25.04.2007; Опубл. 08.01.2013. - 35 с. ↑

A1329. Пат. 8344943 США, МПК G01S13/00. Low-profile omnidirectional retrodirective antennas / E. R. Brown, A. Hartenstein. - № 12/511065; Заявлено 28.07.2009; Опубл. 01.01.2013. - 20 с. ↑

A1330. Пат. 8344940 США, МПК G01S13/00, G01S7/40. Apparatus and sensor for adjusting sensor vertical alignment / S.- Jeong. - № 12/692049; Заявлено 22.01.2010; Опубл. 01.01.2013. - 22 с. ↑

A1331. Пат. 8344939 США, МПК G01S13/00, H01Q19/06, H01Q15/02. Radar sensor for motor vehicles / T. Focke, J. Hilsebecher, T. Binzer, T. Schoeberl, T. Hansen. - № 12/733008; Заявлено 23.06.2008; Опубл. 01.01.2013. - 9 с. ↑

A1332. Пат. 8334800 США, МПК G01S13/42. On-vehicle radar device / K. Hayase. - № 12/900184; Заявлено 07.10.2010; Опубл. 18.12.2012. - 45 с. ↑

A1333. Пат. 8330649 США, МПК G01S13/00. Method and apparatus for determining whether a moving entity is moving in a predetermined direction / H. Menouar, M. Lenardi. - № 12/292172; Заявлено 13.11.2008; Опубл. 11.12.2012. - 17 с. ↑

A1334. Пат. 8330648 США, МПК G01S13/58. Method and apparatus for measuring distance in a wireless environment / J.-R. Park, J.-S. Baik, S.-K. Park, D.-Y. Ha, B.-J. Kim и др. - № 12/389848; Заявлено 20.02.2009; Опубл. 11.12.2012. - 9 с. ↑

A1335. Пат. 8330647 США, МПК G01S7/292, G01S13/66, G01S13/86, G01S13/00. Sensor suite and signal processing for border surveillance / P. A. Fox, J. W. Maresca, J. - № 11/811353; Заявлено 08.06.2007; Опубл. 11.12.2012. - 72 с. ↑

A1336. Пат. 8326320 США, МПК H04W24/00, G01S13/08. Method and locating device for locating at least one mobile radio subscriber / K. Gaenger, J. Plogsties, R. Kreher, A. Klopfer. - № 12/548369; Заявлено 26.08.2009; Опубл. 04.12.2012. - 9 с. ↑

A1337. Пат. 8325085 США, МПК G01S13/95, G01S13/00. Weather radar signal processing / T. Darlington. - № 12/515803; Заявлено 30.11.2007; Опубл. 04.12.2012. - 5 с. ↑

A1338. Пат. 8321070 США, МПК G06F17/00, G06F19/00, G01S13/00, G01S13/66, G01S13/89 и др. Threat object map creation using a three-dimensional sphericity metric / S. J. Manson. - № 12/467750; Заявлено 18.05.2009; Опубл. 27.11.2012. - 10 с.↑

A1339. Пат. 8314730 США, МПК G01S13/00. Collection of meteorological data by vehicles / J. D. Musiak, B. J. Tillotson, C. B. Spinelli. - № 12/967966; Заявлено 14.12.2010; Опубл. 20.11.2012. - 17 с.↑

A1340. Пат. 8310585 США, МПК H04N5/232, G01S13/08. Range finder and method for finding range / K. M. Lee, J. K. Lee. - № 12/600402; Заявлено 14.05.2008; Опубл. 13.11.2012. - 21 с.↑

A1341. Пат. 8305257 США, МПК G01S13/95, G01S13/08, G01S13/00. Method and apparatus for coherent marine radar measurements of properties of ocean waves and currents / D. B. Trizna. - № 12/868912; Заявлено 26.08.2010; Опубл. 06.11.2012. - 19 с.↑

A1342. Пат. 8299959 США, МПК G01S13/00. Apparatus and imaging method with synthetic aperture for determining an incident angle and/or a distance / M. Vossiek, S. Max. - № 12/821763; Заявлено 23.06.2010; Опубл. 30.10.2012. - 15 с.↑

A1343. Пат. 8299957 США, МПК G01S13/00, G01S13/08, G01S13/58. Method for detecting a vehicle type, a vehicle speed and width of a detecting area by a vehicle radar sensor / M.-T. Tseng. - № 12/837073; Заявлено 15.07.2010; Опубл. 30.10.2012. - 18 с.↑

A1344. Пат. 8299956 США, МПК G01S13/00. Method of maneuvering a moving platform with on-board obstruction / M. A. Friesel. - № 12/764545; Заявлено 21.04.2010; Опубл. 30.10.2012. - 9 с.↑

A1345. Пат. 8294608 США, МПК G01S13/00. Forward facing sensing system for vehicle / N. R. Lynam. - № 13/540856; Заявлено 03.07.2012; Опубл. 23.10.2012. - 21 с.↑

A1346. Пат. 8290424 США, МПК H01Q3/00, G01S13/06. Antenna system for satellite lock-on and method for operating the same / W.-C. Shen, W.-Y. Shen, S.-C. Chen. - № 12/401884; Заявлено 11.03.2009; Опубл. 16.10.2012. - 18 с.↑

A1347. Пат. 8289202 США, МПК G01S13/95. Method and system for generating weather and ground reflectivity information / P. Christianson. - № 13/079105; Заявлено 04.04.2011; Опубл. 16.10.2012. - 8 с.↑

A1348. Пат. 8289201 США, МПК G01S13/04, G01V3/12, G01V3/00, G01S13/00. Method and apparatus for using non-linear ground penetrating radar to detect objects located in the ground / S. Holly, N. Koumvakalis, R. A. Smith. - № 11/758785; Заявлено 06.06.2007; Опубл. 16.10.2012. - 14 с.↑

A1349. Пат. 8284383 США, МПК G01C3/08, G06K9/46, G01S13/93. Object recognition apparatus utilizing beam scanning for detecting widths of objects of various sizes and located at various ranges / T. Beppu, K. Takagi, T. Ogawa, H. Hazumi. - № 12/927923; Заявлено 30.11.2010; Опубл. 09.10.2012. - 24 с.↑

A1350. Пат. 8280634 США, МПК G01V3/38, G01V1/00, G01S13/00. Utility mapping and data distribution system and method / G. N. Young, K. L. Alft. - № 13/089857; Заявлено 19.04.2011; Опубл. 02.10.2012. - 37 с.↑

A1351. Пат. 8280621 США, МПК G06F17/10, B60Q1/00, G01S13/00. Vehicle collision avoidance system / D. Edwards, D. R. Pavlik, R. Subramanian, R. M. Coats. - № 12/081350; Заявлено 15.04.2008; Опубл. 02.10.2012. - 19 с.↑

A1352. Пат. 8279107 США, МПК G01S13/00. Radar vehicle detection system / C. Krstanovic, S. Keller, E. Groft. - № 12/805467; Заявлено 02.08.2010; Опубл. 02.10.2012. - 4 с.↑

A1353. Пат. 8279106 США, МПК G01S13/00. Ground surveillance segment detection radar performance analysis / P. S. Wittenberg, V. Huo. - № 12/955897; Заявлено 29.11.2010; Опубл. 02.10.2012. - 20 с.↑

A1375. Пат. 8207834 США, МПК B60Q1/00, G08G1/00, G01S13/88, G06K9/00. Image processing device and vehicle detection device provided with the same / M. Takemura, S. Muramatsu, T. Monji, Y. Otsuka. - № 12/363129; Заявлено 30.01.2009; Опубл. 26.06.2012. - 17 с.↑

A1376. Пат. 8203480 США, МПК G01S13/95, G01S7/292, G01S7/00, G01S13/00. Predictive and adaptive weather radar detection system and method / D. L. Woodell, R. E. Robertson, P. A. Olander, J. A. Finley. - № 12/405091; Заявлено 16.03.2009; Опубл. 19.06.2012. - 13 с.↑

A1377. Пат. 8195422 США, МПК G01P11/00, G01R23/00, G01R35/00, G01S13/08, H04B7/00. Measuring the distance between devices / M. S. Wilcox, A. S. Leitch. - № 11/720620; Заявлено 30.11.2005; Опубл. 05.06.2012. - 16 с.↑

A1378. Пат. 8193968 США, МПК G01S13/00, G01S13/08, H04B7/185. Systems and methods for space situational awareness and space weather / O. E. Kia, C. Rodgers, B. Bradford. - № 12/688299; Заявлено 15.01.2010; Опубл. 05.06.2012. - 20 с.↑

A1379. Пат. 8193965 США, МПК G01S13/00. Forward-looking detection radar / D. J. O'Donnell, D. Wright, D. D. Weber. - № 12/272927; Заявлено 18.11.2008; Опубл. 05.06.2012. - 4 с.↑

A1380. Пат. 8190278 США, МПК G05B15/00, G09G5/08, G06K9/00, G01S13/78, H01Q15/00 и др. Method for control of a device / J. Kneissler. - № 11/916029; Заявлено 24.05.2006; Опубл. 29.05.2012. - 13 с.↑

A1381. Пат. 8188909 США, МПК G01S13/42. Observation signal processing apparatus / Y. Miyake, A. Kondou, G. Takano. - № 12/928911; Заявлено 22.12.2010; Опубл. 29.05.2012. - 9 с.↑

A1382. Пат. 8188908 США, МПК G01S13/08. System and method for measurement of distance to a tag by a modulated backscatter RFID reader / J. A. Landt. - № 12/840587; Заявлено 21.07.2010; Опубл. 29.05.2012. - 37 с.↑

A1383. Пат. 8188906 США, МПК G01S13/00. Weather radar apparatus and rainfall rate calculation method / F. Mizutani, M. Wada. - № 12/825819; Заявлено 29.06.2010; Опубл. 29.05.2012. - 23 с.↑

A1384. Пат. 8184981 США, МПК G01S13/78, H04B10/00, H04Q5/22. Simplifying and cost-effective IR-RF combat identification friend-or-foe (IFF) system for ground targets / G. Ivtsenkov, A. Mantsvetov, E. Berik. - № 12/465715; Заявлено 14.05.2009; Опубл. 22.05.2012. - 11 с.↑

A1385. Пат. 8184039 США, МПК G01S13/08. Level sensing device / A. G. Garrod, K. Moore, D. Sherry. - № 12/531091; Заявлено 07.03.2008; Опубл. 22.05.2012. - 8 с.↑

A1386. Пат. 8179304 США, МПК G01S13/00, H01P1/20, G01S13/08, H01Q1/38, H01Q13/00 и др. Direct-current blocking circuit, hybrid circuit device, transmitter, receiver, transmitter-receiver, and radar device / K. Hayata, K. Nakazuru. - № 12/664638; Заявлено 02.04.2008; Опубл. 15.05.2012. - 39 с.↑

A1387. Пат. 8179299 США, МПК H04K3/00, G01S13/88, G01S13/00. Method and apparatus for the detection of objects using electromagnetic wave attenuation patterns / J. L. Geer. - № 13/093447; Заявлено 25.04.2011; Опубл. 15.05.2012. - 21 с.↑

A1388. Пат. 8174435 США, МПК G01S13/00. Methods and apparatus for non-isotropic sea clutter modeling / A. W. Habboosh, N. F. Willis, T. E. Wood. - № 12/791038; Заявлено 01.06.2010; Опубл. 08.05.2012. - 15 с.↑

A1389. Пат. 8174434 США, МПК G01S13/36, G01S13/00. Method and device for determining a distance to a target object / F. Kunzler, U. Haberland, R. Rehner, J. Weinzierl, L.-P. Schmidt. - № 11/919555; Заявлено 27.04.2006; Опубл. 08.05.2012. - 8 с.↑

A1390. Пат. 8174433 США, МПК G01S13/06, G01S13/42, G01S13/66, G01S13/00. Bias estimation and orbit determination / M. E. Hough. - № 12/393133; Заявлено 26.02.2009; Опубл. 08.05.2012. - 12 с.↑

A1391. Пат. 8174432 США, МПК G01S7/28, G01S13/00, G01S13/93. Radar apparatus / T. Kawasaki, H. Mitsumata. - № 12/580450; Заявлено 16.10.2009; Опубл. 08.05.2012. - 9 с.↑

A1392. Пат. 8174431 США, МПК G01S13/89. System for measuring turbulence remotely / B. J. Tillotson, C. B. Spinelli. - № 13/014260; Заявлено 26.01.2011; Опубл. 08.05.2012. - 15 с.↑

A1393. Пат. 8174429 США, МПК G01V3/12, G01S13/04, G01V3/11. Mine detection / W. Steinway, G. Stilwell, D. H. Fine, P. Crabb, K. Johnson и др. - № 12/495699; Заявлено 30.06.2009; Опубл. 08.05.2012. - 35 с.↑

A1394. Пат. 8174369 США, МПК G08B13/14, G06K7/10, H04B5/00, G01S13/08. Systems and methods for secure supply chain management and inventory control / C. R. Jones, R. Sadr. - № 11/947474; Заявлено 29.11.2007; Опубл. 08.05.2012. - 39 с.↑

A1395. Пат. 8169362 США, МПК G01S13/538, G01S13/52. Mobile sense through the wall radar system / C. D. Cook, S. E. Adcook, M. D. Lee, M. J. Ghebranious. - № 12/462378; Заявлено 03.08.2009; Опубл. 01.05.2012. - 22 с.↑

A1396. Пат. 8169357 США, МПК G01S13/91. Transmission scheduling for ADS-B ground systems / R. Bruno, B. Veytsman. - № 13/110453; Заявлено 18.05.2011; Опубл. 01.05.2012. - 16 с.↑

A1397. Пат. 8169356 США, МПК G01S13/04, G08B13/181, H01Q19/10, G08B13/00, G01S13/00. Anti-mask motion sensor / X. Wu, J. N. Helland, L. K. Green. - № 11/968094; Заявлено 31.12.2007; Опубл. 01.05.2012. - 11 с.↑

A1398. Пат. 8164745 США, МПК G01B11/26, G01C1/00, G01S13/00. System and method for providing scanning polarized reference sources / J. S. Rastegar, T. Spinelli. - № 11/888797; Заявлено 02.08.2007; Опубл. 24.04.2012. - 14 с.↑

A1399. Пат. 8164512 США, МПК G01S13/00. Gaussian model adaptive processing in the time domain / C. Venkatachalam, C. M. Nguyen. - № 12/575698; Заявлено 08.10.2009; Опубл. 24.04.2012. - 24 с.↑

A1400. Пат. 8164511 США, МПК G01S13/58, G01S13/93. Signal processing device, radar device, vehicle control device, and signal processing method / M. Kishida, H. Asanuma, K. Noda, T. Kawasaki. - № 12/461198; Заявлено 04.08.2009; Опубл. 24.04.2012. - 24 с.↑

A1401. Пат. 8164509 США, МПК G01S13/00, G08B13/00, G08B13/18. System and method for radiating RF waveforms using discontinues associated with a utility transmission line / L. W. Fullerton, M. D. Roberts. - № 11/889519; Заявлено 14.08.2007; Опубл. 24.04.2012. - 35 с.↑

A1402. Пат. 8164508 США, МПК G01S13/93. Proximity sensor for a parking area / S. Merli, A. Desiderio. - № 12/752191; Заявлено 01.04.2010; Опубл. 24.04.2012. - 8 с.↑

A1403. Пат. 8160809 США, МПК G01C21/00, G05D1/08, G01S13/00, G08B23/00. Close-spaced leader-follower navigation using control mimic / M. L. Farwell, C. M. Seldomridge, R. E. Larson. - № 13/116095; Заявлено 26.05.2011; Опубл. 17.04.2012. - 12 с.↑

A1404. Пат. 8159388 США, МПК G01S13/00. Method for filtering sea clutter in a radar echo using a hydrographic model / R. Erkocevic-Pribic, J. Karelse, H. Langeraar. - № 12/299497; Заявлено 26.04.2007; Опубл. 17.04.2012. - 7 с.↑

A1405. Пат. 8159385 США, МПК G01S13/00. Conductive line communication apparatus and conductive line radar system and method / M. Farneth, S. E. McMahon, J. A. Rougas, E. M. Valovage, B. Edward. - № 12/658217; Заявлено 04.02.2010; Опубл. 17.04.2012. - 48 с.↑

A1406. Пат. 8155879 США, МПК G08G1/16, G01S13/00, B60D1/28. Apparatus and process for vehicle driving assistance / Y. Takagi, H. Nishira, Y. Deguchi, T. Negome. - № 12/362583; Заявлено 30.01.2009; Опубл. 10.04.2012. - 32 с.↑

A1407. Пат. 8154436 США, МПК G01S13/00, G01S13/08. Object detection / W. J. Szajnowski. - № 12/083936; Заявлено 23.10.2006; Опубл. 10.04.2012. - 23 с.↑

A1408. Пат. 8149160 США, МПК G01S13/08. Method and apparatus using non-contact measuring device to determine rail distance traveled / A. V. Bray, S. McNeal, J. McDaniel. - № 12/913666; Заявлено 27.10.2010; Опубл. 03.04.2012. - 20 с.↑

A1409. Пат. 8149157 США, МПК G01S13/00, H01Q1/42. In-vehicle radar device and cover for in-vehicle radar device / K. Takeuchi. - № 12/670558; Заявлено 27.02.2009; Опубл. 03.04.2012. - 16 с.↑

A1410. Пат. 8144051 США, МПК G01S13/52, G01S3/16, G01S13/00. Adaptive sidelobe blanking for motion compensation / Y. F. Lok, K. Chang, J. H. Pozgay. - № 12/231802; Заявлено 05.09.2008; Опубл. 27.03.2012. - 21 с.↑

A1411. Пат. 8144048 США, МПК G01S13/00. Systems and methods for gaussian decomposition of weather radar data for communication / B. P. Bunch, J. C. Kirk, D. Zeng. - № 12/731998; Заявлено 25.03.2010; Опубл. 27.03.2012. - 12 с.↑

A1412. Пат. 8138968 США, МПК G01S13/08. Unattended ground sensor system and methods / G. D. Butler. - № 12/694137; Заявлено 26.01.2010; Опубл. 20.03.2012. - 9 с.↑

A1413. Пат. 8138966 США, МПК G01S13/42, G01S13/58, G01S13/91. Vehicular traffic surveillance doppler radar system / J. L. Aker. - № 12/984577; Заявлено 04.01.2011; Опубл. 20.03.2012. - 17 с.↑

A1414. Пат. 8138964 США, МПК G01S13/93. Tracking air and ground vehicles / T. P. Donovan. - № 12/575591; Заявлено 08.10.2009; Опубл. 20.03.2012. - 11 с.↑

A1415. Пат. 8138962 США, МПК G01S13/00. Method for processing measured vertical profiles of the power of the echoes returned following a transmission of radar signals / N. Bon, J.-P. Artis, A. Becker, M. Marcant. - № 12/611566; Заявлено 03.11.2009; Опубл. 20.03.2012. - 14 с.↑

A1416. Пат. 8138960 США, МПК G01S13/90. Map information update support device, map information update support method and computer readable recording medium / T. Nonaka, T. Shibayama, S. Takagishi, T. Sasakawa. - № 12/309595; Заявлено 31.07.2007; Опубл. 20.03.2012. - 8 с.↑

A1417. Пат. 8131460 США, МПК G01C21/30, G08G1/123, G01S13/78. GPS navigation code system / G. Severson. - № 13/066407; Заявлено 14.04.2011; Опубл. 06.03.2012. - 9 с.↑

A1418. Пат. 8125374 США, МПК G01S13/52. Method of preventing false detections in sensors / P. T. Edwards. - № 12/295961; Заявлено 05.08.2008; Опубл. 28.02.2012. - 7 с.↑

A1419. Пат. 8125373 США, МПК G01S13/00, G01S13/08. Microwave system utilizing elevational scanning by frequency hopping / J. S. Lee, P. D. Schmalenberg. - № 12/842078; Заявлено 23.07.2010; Опубл. 28.02.2012. - 6 с.↑

A1420. Пат. 8125372 США, МПК G01S13/93. Driver assistance system and method for checking the plausibility of objects / T. Focke, J.-C. Becker, J. Hilsebecher, A. Zender, M. Mueller-Frahm и др. - № 12/305432; Заявлено 03.03.2008; Опубл. 28.02.2012. - 13 с.↑

A1421. Пат. 8120523 США, МПК G01S13/95, G01S7/292. Method of eliminating ground echoes for a meteorological radar / S. Kemkemian, S. Guguen, C. Chaure. - № 12/473880; Заявлено 28.05.2009; Опубл. 21.02.2012. - 9 с.↑

A1422. Пат. 8120522 США, МПК G01S13/89, G01S13/32, G01S13/90, G01S13/00. System and method for inspecting a wind turbine blade / N. Tralshawala, W. I. Faidi. - № 12/956212; Заявлено 30.11.2010; Опубл. 21.02.2012. - 15 с.↑

A1423. Пат. 8116755 США, МПК H04W4/00, H04W36/00, H04B1/034, H04B1/06, G01S3/02 и др. Mobile communication terminal and moving speed detection method for the same / O. Ootsuka. - № 12/442224; Заявлено 12.09.2007; Опубл. 14.02.2012. - 10 с.↑

A1424. Пат. 8115673 США, МПК G01S13/00. Self-oscillating UWB emitter-detector / T. E. McEwan. - № 11/891364; Заявлено 11.08.2007; Опубл. 14.02.2012. - 12 с.↑

A1425. Пат. 8115670 США, МПК G01S13/91, G01S13/58. Method of verifiably detecting the speed of a vehicle / C. Klein, A. Behrens, B. Dohmann, N. Terlau. - № 12/118275; Заявлено 09.05.2008; Опубл. 14.02.2012. - 9 с.↑

A1426. Пат. 8115669 США, МПК G01S13/42, G01S13/93. Vehicular radar device / M. Mitsumoto. - № 12/715902; Заявлено 02.03.2010; Опубл. 14.02.2012. - 7 с.↑

A1427. Пат. 8115668 США, МПК G01S13/93. Object detecting apparatus for vehicle / K. Mochizuki. - № 12/711721; Заявлено 24.02.2010; Опубл. 14.02.2012. - 17 с.↑

A1428. Пат. 8115667 США, МПК G01S13/88, G01S7/40. Highway speed ground penetrating radar system utilizing air-launched antenna and method of use / J. R. Feigin, A. E. Schutz. - № 12/620012; Заявлено 17.11.2009; Опубл. 14.02.2012. - 14 с.↑

A1429. Пат. 8115600 США, МПК G08B13/14, H04Q5/22, G06K7/10, G01S13/08, H04B5/00. RFID detection and identification system including an RFID reader having a limited transmit time and a time-out period to protect a medical device against RFID-associated electromagnetic interference / R. A. Stevenson, G. F. O. Tyers, C. A. Frysz. - № 12/566490; Заявлено 24.09.2009; Опубл. 14.02.2012. - 51 с.↑

A1430. Пат. 8115148 США, МПК F41G7/30, F41G7/00, G01S13/00, F42B15/00. Method for targeting a preferred object within a group of decoys / J. A. Boardman, N. R. Patel, J. B. Boka. - № 12/473032; Заявлено 27.05.2009; Опубл. 14.02.2012. - 19 с.↑

A1431. Пат. 8112225 США, МПК G08G1/16, G01S3/02, B60Q1/00, G01S13/00. Method and system for collision avoidance / A. Eidehall, J. Pohl. - № 12/955041; Заявлено 29.11.2010; Опубл. 07.02.2012. - 10 с.↑

A1432. Пат. 8111187 США, МПК G01S13/00. Surveillance system and method / P. Newham, M. Michael, M. Roos. - № 12/530346; Заявлено 05.03.2008; Опубл. 07.02.2012. - 13 с.↑

A1433. Пат. 8106814 США, МПК G01S13/68. Method of estimating the elevation of a ballistic projectile / B. Durand, C. Cavallari, O. Adrian. - № 12/517171; Заявлено 30.11.2007; Опубл. 31.01.2012. - 9 с.↑

A1434. Пат. 8102308 США, МПК G01S13/58. Radar apparatus, and measurement method used in the radar apparatus / J. Tsunekawa. - № 13/077126; Заявлено 31.03.2011; Опубл. 24.01.2012. - 28 с.↑

A1435. Пат. 8102303 США, МПК G01S13/74. Method for distance measurement and data transmission in a continuous wave radar system / O. Albert, J. Gila, R. Hladik, M. Schiefer, M. Spandl. - № 12/482667; Заявлено 11.06.2009; Опубл. 24.01.2012. - 10 с.↑

A1436. Пат. 8102298 США, МПК G01S13/00. Ultra-wideband radar waveform calibration for measurements of a heterogeneous material / J. R. Feigin, A. E. Schutz. - № 13/157795; Заявлено 10.06.2011; Опубл. 24.01.2012. - 13 с.↑

A1437. Пат. 8098193 США, МПК G01S13/00, G01S13/08. Digitally controlled UWB millimeter wave radar / B. Sai, L. Mauduit. - № 12/613346; Заявлено 05.11.2009; Опубл. 17.01.2012. - 11 с.↑

A1438. Пат. 8098192 США, МПК G01S13/94. System for distinguishing among radar returns using information from a database / J. M. Wichgers, R. D. Jinkins, R. M. Rademaker, D. L. Woodell. - № 11/901058; Заявлено 14.09.2007; Опубл. 17.01.2012. - 13 с.↑

A1439. Пат. 8098191 США, МПК G01S13/87, G01S13/88, G01S13/00. Electronic curtain for vehicle protection / A. N. Pergande, L. D. Griffin, J.S. G. Gray, H. Q. Le, S. T. Nicholas. - № 12/265063; Заявлено 05.11.2008; Опубл. 17.01.2012. - 6 с.↑

A1440. Пат. 8098189 США, МПК G01S13/00. Weather radar system and method using dual polarization antenna / D. L. Woodell, J. B. West, W. A. ElSallal, J. C. Mather, B. J. Herting. - № 12/236471; Заявлено 23.09.2008; Опубл. 17.01.2012. - 12 с.↑

A1441. Пат. 8098188 США, МПК G01S13/00. Method of characterizing the convection intensity of a cloud, by a meteorological radar / C. Costes, N. Bon, J.-P. Artis, F. Mesnard, O. Pujol и др. - № 12/492426; Заявлено 26.06.2009; Опубл. 17.01.2012. - 8 с.↑

A1442. Пат. 8098185 США, МПК G01S13/00. Millimeter and sub-millimeter wave portal / R. Ridgway, P. Schofield, S. Risser. - № 11/673842; Заявлено 12.02.2007; Опубл. 17.01.2012. - 37 с.↑

A1443. Пат. 8094059 США, МПК G01S13/00. Method for determining the angular aperture corresponding to the extent in a plane of an object seen by a radar antenna / C. Costes, J.-P. Artis, M. Marcant. - № 12/117846; Заявлено 09.05.2008; Опубл. 10.01.2012. - 8 с.↑

A1444. Пат. 8089390 США, МПК G01S13/00. Sensor cart positioning system and method / R. P. Jones, P. J. Kelly. - № 11/804217; Заявлено 16.05.2007; Опубл. 03.01.2012. - 34 с.↑

A1445. Пат. 8086396 США, МПК G01C21/00, G05D1/08, G08B23/00, G01S13/00. Close-spaced leader-follower navigation using control mimic / M. L. Farwell, C. M. Seldomridge, R. E. Larson. - № 11/634986; Заявлено 07.12.2006; Опубл. 27.12.2011. - 12 с.↑

A1446. Пат. 8085181 США, МПК G01S13/95. Polarization-modulated transmitter for a weather radar / F. Gekat. - № 12/305330; Заявлено 22.06.2007; Опубл. 27.12.2011. - 14 с.↑

A1447. Пат. 8077081 США, МПК G01S13/04, G01S13/95, G01S13/00, G01S13/93. Ground collision instrument for aircraft and marine vehicles / C. D. Bateman, J. J. Poe, J. H. Glover. - № 12/351353; Заявлено 09.01.2009; Опубл. 13.12.2011. - 14 с.↑

A1448. Пат. 8077075 США, МПК G01S13/93, G01S13/00. Object verification method for use in radar systems for motor vehicles / M. Randler, R. Jordan. - № 11/662613; Заявлено 20.07.2005; Опубл. 13.12.2011. - 9 с.↑

A1449. Пат. 8072367 США, МПК G01S13/56, G01S13/04, G01S13/00. Organically reactive cell for underground sensing (ORCUS) and system / I. Bausov, G. Stolarczyk, L. G. Stolarczyk. - № 12/815423; Заявлено 15.06.2010; Опубл. 06.12.2011. - 15 с.↑

A1505. Пат. 7953552 США, МПК G01C21/30, G08G1/123, G01S13/78. GPS navigation code system / G. Severson. - № 12/313585; Заявлено 21.11.2008; Опубл. 31.05.2011. - 6 с.↑

A1506. Пат. 7952515 США, МПК G01S13/22, G01S7/483, G01S13/18, G01S13/00. Range gated holographic radar / T. E. McEwan. - № 12/380324; Заявлено 26.02.2009; Опубл. 31.05.2011. - 19 с.↑

A1507. Пат. 7952512 США, МПК G01S13/42. Mobile device enabled radar tags / J. R. Delker, J. M. Everson, J. K. Whitney. - № 12/251201; Заявлено 14.10.2008; Опубл. 31.05.2011. - 12 с.↑

A1508. Пат. 7948431 США, МПК G01S13/74. Radiobased locating system provided with a synthetic aperture / P. Gulden, S. Max, M. Vossiek. - № 11/813369; Заявлено 07.09.2005; Опубл. 24.05.2011. - 12 с.↑

A1509. Пат. 7948428 США, МПК G01S13/04. Millimeter wave imaging system with frequency scanning antenna / J. Lovberg, C. Martin. - № 11/370680; Заявлено 08.03.2006; Опубл. 24.05.2011. - 35 с.↑

A1510. Пат. 7945071 США, МПК G06K9/00, G01S13/00. Automatically generating precipitation proximity notifications / N. J. Harrington. - № 11/971485; Заявлено 09.01.2008; Опубл. 17.05.2011. - 24 с.↑

A1511. Пат. 7940206 США, МПК G01S13/93. Low-cost, high-performance radar networks / T. J. Nohara, A.-N. Premji, A. M. Ukrainec, P. T. Weber, G. S. Jones и др. - № 11/110436; Заявлено 20.04.2005; Опубл. 10.05.2011. - 18 с.↑

A1512. Пат. 7940203 США, МПК H01Q17/00, H05K9/00, G01S13/00. Electromagnetic wave absorption board to be used in wireless LAN / M. Katano, T. Onishi, Y. Shirai, T. Hattori. - № 12/298129; Заявлено 27.04.2007; Опубл. 10.05.2011. - 25 с.↑

A1513. Пат. 7932855 США, МПК G01S13/00, G01S13/08. Distance measuring device and distance measuring method / T. Uebo. - № 11/991384; Заявлено 25.08.2006; Опубл. 26.04.2011. - 41 с.↑

A1514. Пат. 7930103 США, МПК G01V3/38, G01V1/00, G01S13/00. Utility mapping and data distribution system and method / G. N. Young, K. L. Alft. - № 12/218501; Заявлено 15.07.2008; Опубл. 19.04.2011. - 36 с.↑

A1515. Пат. 7928900 США, МПК H01Q19/02, H01Q19/06, G01S7/02, G01S13/00, G01S7/00. Resolution antenna array using metamaterials / C. Fuller, J. R. Lamberg, J. J. Geddes, M. J. Gawronski. - № 11/955795; Заявлено 13.12.2007; Опубл. 19.04.2011. - 16 с.↑

A1516. Пат. 7928899 США, МПК G01S13/08. Detection and compensation of target losses when there is a channel change / T. Ottenhues. - № 12/374299; Заявлено 16.07.2007; Опубл. 19.04.2011. - 7 с.↑

A1517. Пат. 7928897 США, МПК G01S13/58, G01S13/93, G01S13/00, G01S13/32. Target detection method for use in radar and radar device using the target detection method / T. Ishii, T. Nishimura. - № 12/428774; Заявлено 23.04.2009; Опубл. 19.04.2011. - 25 с.↑

A1518. Пат. 7928892 США, МПК G01S13/00. Identification and mapping of underground facilities / R. B. Greegor, C. G. Parazzoli, M. H. Tanielian. - № 12/116540; Заявлено 07.05.2008; Опубл. 19.04.2011. - 11 с.↑

A1519. Пат. 7928891 США, МПК G01S7/40, G01S13/86, G01S13/00. GPS with radar detector / E. Zheng. - № 12/284223; Заявлено 18.09.2008; Опубл. 19.04.2011. - 11 с.↑

A1520. Пат. 7924218 США, МПК G01S13/534. System for enhanced detection of a target / A. Siegel. - № 11/747959; Заявлено 14.05.2007; Опубл. 12.04.2011. - 24 с.↑

A1521. Пат. 7924217 США, МПК G01S13/08, G01S13/32, G01F23/00, G01S13/00. High sensitivity frequency modulated radar level gauge system / A. Jirskog. - № 12/132114; Заявлено 03.06.2008; Опубл. 12.04.2011. - 8 с. ↑

A1522. Пат. 7924216 США, МПК G01F23/284, G01S13/08. Method of determining a disturbance echo profile for a radar level gauge system / H. Delin. - № 12/112148; Заявлено 30.04.2008; Опубл. 12.04.2011. - 18 с.↑

A1523. Пат. 7924215 США, МПК G01S13/93, G01S13/58. Radar apparatus and mobile object / M. Nakanishi. - № 12/212119; Заявлено 17.09.2008; Опубл. 12.04.2011. - 16 с.↑

A1524. Пат. 7924213 США, МПК G01S13/66. Method of and device for tracking an object / H. D. Waard, P. Griffioen, H. Regtop, G. V. D. Brug. - № 12/441431; Заявлено 14.09.2007; Опубл. 12.04.2011. - 13 с.↑

A1525. Пат. 7924211 США, МПК G01S13/00. Electromagnetic pulse reflector detection method / L. Bosser, S. Kemkemian, M. Nouvel. - № 12/301086; Заявлено 14.05.2007; Опубл. 12.04.2011. - 12 с.↑

A1526. Пат. 7920088 США, МПК G01S13/04, G01S7/483, G01S7/00, G01S13/10. Apparatus and method to identify targets through opaque barriers / S. R. Thompson, B. A. Askildsen, A. Gervasi. - № 11/308029; Заявлено 03.03.2006; Опубл. 05.04.2011. - 21 с.↑

A1527. Пат. 7920087 США, МПК G01S13/00, G01S13/08. Apparatus for estimating state of vehicle located in frontward field / T. Ogawa. - № 12/228135; Заявлено 08.08.2008; Опубл. 05.04.2011. - 34 с.↑

A1528. Пат. 7916068 США, МПК G01S13/62. Generalized inner product method and apparatus for improved detection and discrimination / M. C. Wicks, Y. Zhang. - № 12/584590; Заявлено 25.08.2009; Опубл. 29.03.2011. - 24 с.↑

A1529. Пат. 7911372 США, МПК G01S13/00. Active imaging using satellite communication system / M. D. Nelson. - № 12/612492; Заявлено 04.11.2009; Опубл. 22.03.2011. - 10 с.↑

A1530. Пат. 7907082 США, МПК G01S13/00. Method and system for presence detection / A. Antonsson, G. Svedoff. - № 12/253494; Заявлено 17.10.2008; Опубл. 15.03.2011. - 8 с.↑

A1531. Пат. 7907081 США, МПК G01S13/89. Millimeter wave imaging system / Y. Noyman. - № 12/159101; Заявлено 25.12.2006; Опубл. 15.03.2011. - 7 с.↑

A1532. Пат. 7903024 США, МПК G01S13/52. Adaptive moving target indicator (MTI) clutter rejection filter for radar systems / B. W. Tietjen, M. M. Au, K. P. Freeman. - № 11/977639; Заявлено 25.10.2007; Опубл. 08.03.2011. - 13 с.↑

A1533. Пат. 7903023 США, МПК G01S13/08. Obstacle detection system notably for an anticollision system / P. Cornic, P. L. Bihan, Y. Audic, P. Lacomme. - № 12/048910; Заявлено 14.03.2008; Опубл. 08.03.2011. - 11 с.↑

A1534. Пат. 7903021 США, МПК G01S13/00. Obstacle detecting method, obstacle detecting apparatus, and standard moving-body model / K. Aso, T. Kindo. - № 12/083219; Заявлено 28.02.2007; Опубл. 08.03.2011. - 24 с.↑

A1535. Пат. 7898463 США, МПК G01S13/04, G01S13/93, G01S13/00, G01S13/95. Runway identification system via radar receiver / C. A. Mueller, G. M. Bokhtier. - № 11/838135; Заявлено 13.08.2007; Опубл. 01.03.2011. - 18 с.↑

A1536. Пат. 7898458 США, МПК G01S13/00. Disaster countermeasure support method / T. Shibayama, T. Nonaka, Y. Sugimoto. - № 12/375856; Заявлено 03.08.2007; Опубл. 01.03.2011. - 15 с.↑

A1537. Пат. 7898456 США, МПК G01S13/04. Apparatus and method for detecting and locating hidden objects / P. A. Cloutier, D. R. Oehme. - № 12/388672; Заявлено 19.02.2009; Опубл. 01.03.2011. - 11 с.↑

A1538. Пат. 7893868 США, МПК G01S7/40, G01S13/93. Radar device / K. Akita, K. Nakagawa. - № 12/512126; Заявлено 30.07.2009; Опубл. 22.02.2011. - 11 с.↑

A1539. Пат. 7893867 США, МПК G01S13/00. Communications radar system / J. Navarro. - № 12/363347; Заявлено 30.01.2009; Опубл. 22.02.2011. - 12 с.↑

A1540. Пат. 7893865 США, МПК G01S13/58. Vehicular lamp / K. Natsume, H. Tsukamoto, Y. Aiso. - № 12/391869; Заявлено 24.02.2009; Опубл. 22.02.2011. - 9 с.↑

A1541. Пат. 7893862 США, МПК G01S13/04, G01S13/88, G01V3/12, G01S13/00, G01V3/00. Method and apparatus for using collimated and linearly polarized millimeter wave beams at Brewster's angle of incidence in ground penetrating radar to detect objects located in the ground / S. Holly, N. Koumvakalis, R. A. Smith. - № 12/167753; Заявлено 03.07.2008; Опубл. 22.02.2011. - 19 с.↑

A1542. Пат. 7889117 США, МПК G01S13/42. Less than full aperture high resolution phase process for terrain elevation estimation / D. L. Woodell, R. D. Jinkins, R. M. Rademaker. - № 12/167200; Заявлено 02.07.2008; Опубл. 15.02.2011. - 19 с.↑

A1543. Пат. 7889100 США, МПК G08B23/00, G08G3/00, G01S13/78. Water friend or foe system for global vessel identification and tracking / L. C. G. Miller. - № 11/838637; Заявлено 14.08.2007; Опубл. 15.02.2011. - 18 с.↑

A1544. Пат. 7884757 США, МПК G01S7/28, G01S13/00. Scanning ultra wideband impulse radar / F. Mohamadi, A. Niktash. - № 11/874414; Заявлено 18.10.2007; Опубл. 08.02.2011. - 17 с.↑

A1545. Пат. 7884753 США, МПК G01S13/75. Apparatus and method for ranging of a wireless transceiver with a switching antenna / A. Peczalski, F. Nusseibeh. - № 12/025158; Заявлено 04.02.2008; Опубл. 08.02.2011. - 12 с. ↑

A1546. Пат. 7881836 США, МПК G01M17/02, G01S13/74, B60C23/00. Tire state monitoring apparatus / S. Hayasaka, K. Tamagawa. - № 11/925131; Заявлено 26.10.2007; Опубл. 01.02.2011. - 20 с.↑

A1547. Пат. 7881689 США, МПК H04B1/00, G01S13/00, H05K9/00. Vehicle radar sensor assembly / S. P. Leblanc, R. P. Donovan, J. S. Pleva. - № 12/363949; Заявлено 02.02.2009; Опубл. 01.02.2011. - 26 с.↑

A1548. Пат. 7880668 США, МПК G01S13/00. Automated radar elevation angle configuration / S. M. Krause, E. D. Toal, L. Lagonik. - № 12/330238; Заявлено 08.12.2008; Опубл. 01.02.2011. - 12 с.↑

A1549. Пат. 7880667 США, МПК G01S13/74, G01S13/93, G01S13/91, G01S7/40, G01S13/00. Methods and apparatus for using interferometry to prevent spoofing of ADS-B targets / P. J. Lanzkron. - № 12/129835; Заявлено 30.05.2008; Опубл. 01.02.2011. - 15 с.↑

A1550. Пат. 7880666 США, МПК G01S13/95. System for measuring turbulence remotely / B. J. Tillotson, C. B. Spinelli. - № 12/499869; Заявлено 09.07.2009; Опубл. 01.02.2011. - 16 с.↑

A1551. Пат. 7880664 США, МПК G01S13/95, G01S7/292, G01W1/00, G01S13/00, G01S7/28. Method for correcting weather data / R. Hannesen, A. Kammer, A. Weipert. - № 11/920493; Заявлено 12.05.2006; Опубл. 01.02.2011. - 8 с.↑

A1552. Пат. 7876262 США, МПК G01S13/536, G01S13/538. Radar system / S. Greendale, M. Radford, D. Spreadbury. - № 12/487889; Заявлено 19.06.2009; Опубл. 25.01.2011. - 13 с.↑

A1553. Пат. 7876260 США, МПК G01S13/00, G08B21/00, B64D47/02. Method and system for reducing light pollution / E. D. Laufer. - № 12/172604; Заявлено 14.07.2008; Опубл. 25.01.2011. - 24 с.↑

A1554. Пат. 7868813 США, МПК G01S13/93, G01S7/22. Multi-use bearing and range line / M. J. O'Flynn, L. Chang, V. B. Blond. - № 12/381011; Заявлено 05.03.2009; Опубл. 11.01.2011. - 11 с.↑

A1555. Пат. 7868811 США, МПК G01S13/95, G01W1/02, G01W1/00, G01S13/00. Weather radar system and method using data from a lightning sensor / D. L. Woodell, K. M. Kronfield, K. L. Walling. - № 12/177767; Заявлено 22.07.2008; Опубл. 11.01.2011. - 30 с.↑

A1556. Пат. 7866083 США, МПК F41G1/00, G01S13/78. Modular flashlight apparatus for firearm / J. W. Teetzel. - № 11/591886; Заявлено 01.11.2006; Опубл. 11.01.2011. - 12 с.↑

A1557. Пат. 7864104 США, МПК G01S13/08. Device for determining and monitoring the level of a medium in a container / Q. Chen, K. Feisst, E. Bergmann. - № 11/919972; Заявлено 27.04.2006; Опубл. 04.01.2011. - 11 с.↑

A1558. Пат. 7864102 США, МПК G01S13/42, G01S13/91, G01S13/58. Vehicular traffic surveillance doppler radar system / J. L. Aker. - № 11/757872; Заявлено 04.06.2007; Опубл. 04.01.2011. - 18 с.↑

A1559. Пат. 7864099 США, МПК G01S13/00. Low cost short range radar / J. S. Colburn, H.-P. Hsu, O. D. Altan. - № 12/176787; Заявлено 21.07.2008; Опубл. 04.01.2011. - 9 с.↑

A1560. Пат. 7859450 США, МПК G01S13/00, H04B1/00. Detection and ranging appartus and detection and ranging method / K. Shirakawa, K. Ohguchi, Y. Kondo. - № 12/200024; Заявлено 28.08.2008; Опубл. 28.12.2010. - 15 с.↑

A1561. Пат. 7859448 США, МПК G01S13/95. Terrain avoidance system and method using weather radar for terrain database generation / D. L. Woodell, R. D. Jinkins, N. A. Meyer, R. M. Rademaker, C. J. Dickerson. - № 11/899801; Заявлено 06.09.2007; Опубл. 28.12.2010. - 9 с.↑

A1562. Пат. 7855674 США, МПК G01S13/04, G01S15/04, G01S7/523, G01S15/50, G01S7/28 и др. Method and radar system for coherent detection of moving objects / P. A. Valand. - № 12/373644; Заявлено 13.07.2006; Опубл. 21.12.2010. - 6 с.↑

A1563. Пат. 7852261 США, МПК G01S13/66. Tracking waveform selection for multi-function radar / W. K. Stafford. - № 12/159432; Заявлено 29.05.2008; Опубл. 14.12.2010. - 7 с.↑

A1564. Пат. 7852257 США, МПК G01S13/00. Anti-interference microwave motion sensor / X. Wu, L. K. Green, J. N. Helland. - № 11/961480; Заявлено 20.12.2007; Опубл. 14.12.2010. - 7 с.↑

A1565. Пат. 7843383 США, МПК G01S13/89, G01S13/00. Imaging through silhouetting / W. Weems, R. C. Taber. - № 11/552749; Заявлено 25.10.2006; Опубл. 30.11.2010. - 6 с.↑

A1566. Пат. 7843382 США, МПК G01S13/00. Mismatched filter / A. T. Fam, I. Sarkar. - № 12/335214; Заявлено 15.12.2008; Опубл. 30.11.2010. - 26 с.↑

A1567. Пат. 7843381 США, МПК G01S13/08. Radar device / K. Matsuoka. - № 12/117477; Заявлено

08.05.2008; Опубл. 30.11.2010. - 34 с.↑

A1568. Пат. 7843379 США, МПК G01S13/08. Symmetrical multi-path method for determining the distance between two transmitter-receivers / L. Menzer, Z. Ianelli, R. Hach. - № 11/667806; Заявлено 15.11.2005; Опубл. 30.11.2010. - 47 с.↑

A1569. Пат. 7834802 США, МПК G01S13/00. Detection of a concealed object / P. E. Keller, T. E. Hall, D. L. McMakin. - № 12/111023; Заявлено 28.04.2008; Опубл. 16.11.2010. - 36 с.↑

A1570. Пат. 7834801 США, МПК G01S13/89, G01V11/00. Sensor fusion for model-based detection in pipe and cable locator systems / J. W. Waite, R. Welaratna. - № 11/193100; Заявлено 29.07.2005; Опубл. 16.11.2010. - 33 с.↑

A1571. Пат. 7830302 США, МПК G01S13/00, G01S13/08. Remote sensing of wave heights using a narrowband radar arrangement / J. R. Smith, J. - № 12/152127; Заявлено 05.05.2008; Опубл. 09.11.2010. - 8 с.↑

A1572. Пат. 7825850 США, МПК G01S13/58, G01P3/66, G01S13/00, G01P3/00. Method for measuring the muzzle velocity of a projectile or the like / H. Frick. - № 11/953785; Заявлено 10.12.2007; Опубл. 02.11.2010. - 8 с.↑

A1573. Пат. 7817080 США, МПК G01S13/86, G01S13/88, G01S13/10, G01S13/00. Ranging and communication multifunction system / Y. Aoyagi, K. Kamimura. - № 11/874415; Заявлено 18.10.2007; Опубл. 19.10.2010. - 30 с.↑

A1574. Пат. 7817079 США, МПК G01S13/86, G01S13/93. System and method for collection of global AIS and radar track information / C. J. Funk. - № 12/105129; Заявлено 17.04.2008; Опубл. 19.10.2010. - 16 с.↑

A1575. Пат. 7817078 США, МПК G01S13/00. Systems and methods for supplemental weather information presentation on a display / B. Bunch. - № 12/040784; Заявлено 29.02.2008; Опубл. 19.10.2010. - 13 с.↑

A1576. Пат. 7812760 США, МПК G01S13/10, G01S7/28, G01S13/00. Short-range radar and control method thereof / T. Teshirogi, M. Ejima. - № 11/989274; Заявлено 02.03.2007; Опубл. 12.10.2010. - 38 с.↑

A1577. Пат. 7808426 США, МПК G01S13/00, G01S13/08. Remote sensing of wave heights using a broadband radar arrangement / J. R. Smith, J. - № 12/152124; Заявлено 05.05.2008; Опубл. 05.10.2010. - 8 с.↑

A1772. Пат. 7450057 США, МПК G01S13/52, G01S13/00. Signal processing for accelerating moving targets / D. C. Clark. - № 11/584212; Заявлено 20.10.2006; Опубл. 11.11.2008. - 19 с.↑

A1773. Пат. 7450053 США, МПК G01V3/30, G01V3/18, G01S13/00, G01V3/00. Logging device with down-hole transceiver for operation in extreme temperatures / E. E. Funk, E. A. Funk, M. L. Sheriff, S. M. McCarthy, R. R. McDaniel. - № 11/520234; Заявлено 13.09.2006; Опубл. 11.11.2008. - 43 с.↑

A1774. Пат. 7447583 США, МПК G06F17/00, G01S13/00, G05D1/00, G08G1/00. Vehicle control apparatus / H. Ogawa. - № 11/313797; Заявлено 22.12.2005; Опубл. 04.11.2008. - 10 с.↑

A1775. Пат. 7443336 США, МПК G01S13/10, G01S7/28, G01S7/285, G01S13/00, G01S13/93. In-vehicle pulse radar device / S. Noda. - № 11/400524; Заявлено 10.04.2006; Опубл. 28.10.2008. - 11 с.↑

A1776. Пат. 7439903 США, МПК G01S13/00. Method of preventing interference between radars and radar system having interference preventing function / Y. Watanabe, K. Natsume. - № 11/417336; Заявлено 03.05.2006; Опубл. 21.10.2008. - 10 с.↑

A1777. Пат. 7439902 США, МПК G01S13/04. Radar controlled automatic target illumination system / G. E. Robertson, J. L. Webster. - № 11/642166; Заявлено 20.12.2006; Опубл. 21.10.2008. - 11 с.↑

A1778. Пат. 7439899 США, МПК G01S13/95. Encoded transmitted signals in a simultaneous dual polarization weather system / J. J. Stagliano, J.J. L. Alford, J. R. Helvin, D. A. Nelson. - № 11/386312; Заявлено 22.03.2006; Опубл. 21.10.2008. - 11 с.↑

A1779. Пат. 7432850 США, МПК G01S13/58, G01S13/532. Wideband radar / K. Falk. - № 11/577219;

Заявлено 13.10.2004; Опубл. 07.10.2008. - 9 с.↑

A1780. Пат. 7432849 США, МПК G01S13/00. Frequency modulation radar apparatus for vehicle use background of the invention / S. Noda. - № 11/655935; Заявлено 22.01.2007; Опубл. 07.10.2008. - 18 с.↑

A1781. Пат. 7432848 США, МПК G01S13/86, G01S13/91, G01S13/93, G01S13/08. Inter-vehicle distance detecting device and inter-vehicle distance detecting method / K. Munakata. - № 11/562873; Заявлено 22.11.2006; Опубл. 07.10.2008. - 10 с.↑

A1782. Пат. 7432847 США, МПК G01S13/00, H03D1/00. Ultra-wideband transceiver / D. Fedotov, A. Sudakov. - № 11/143315; Заявлено 02.06.2005; Опубл. 07.10.2008. - 10 с.↑

A1783. Пат. 7432718 США, МПК G01R29/12, G01S13/08, G06F19/00. Electronic device and method of controlling same / A. Ishihara, T. Yamada, Y. Chosokabe. - № 11/595799; Заявлено 09.11.2006; Опубл. 07.10.2008. - 27 с.↑

A1784. Пат. 7427943 США, МПК G01S13/95, G01S7/20, G01S13/00, G01S7/04. Method of generating three-dimensional weather information from airborne weather radar imagery / K. M. Kronfeld, M. S. Chackalackal. - № 10/624244; Заявлено 22.07.2003; Опубл. 23.09.2008. - 14 с.↑

A1785. Пат. 7425917 США, МПК G01S13/60, G01S13/34, G01S13/50, G01S13/93. Radar for detecting the velocity of a target / M. Nakanishi, T. Ishii. - № 11/649785; Заявлено 05.01.2007; Опубл. 16.09.2008. - 20 с.↑

A1786. Пат. 7423577 США, МПК G01S13/00, H04B1/00, H04L27/00. System and method for transmitting high data rate information from a radar system / W. K. McIntire, L. S. Thomson, D. H. Robbins, J. J. Boesch. - № 11/592536; Заявлено 03.11.2006; Опубл. 09.09.2008. - 10 с.↑

A1787. Пат. 7420500 США, МПК H01Q17/00, G01S13/00, H05K9/00. Electromagnetic radiation absorber / A. S. Treen, C. R. Lawrence, J. R. Sambles, A. P. Hibbins. - № 10/565047; Заявлено 19.07.2004; Опубл. 02.09.2008. - 9 с.↑

A1788. Пат. 7418345 США, МПК G08G1/16, B62D6/00, G01S13/93. Method and device for reducing damage caused by an accident / J. Diebold, M. Klug. - № 10/579103; Заявлено 12.11.2004; Опубл. 26.08.2008. - 8 с.↑

A1789. Пат. 7417585 США, МПК G01S13/04, G01S7/00. Radar scanning method / T. Yamagami, M. Hitotsuya. - № 10/971165; Заявлено 25.10.2004; Опубл. 26.08.2008. - 26 с.↑

A1790. Пат. 7417582 США, МПК F42C13/00, G01S13/00. System and method for triggering an explosive device / D. L. Troutman, H. U. Fluhler, L. W. Fullerton, D. D. Fitzpatrick, J. Richards. - № 10/971427; Заявлено 22.10.2004; Опубл. 26.08.2008. - 38 с.↑

A1791. Пат. 7417581 США, МПК G01S13/42. System and method for intrusion detection using a time domain radar array / L. W. Fullerton, J. L. Richards. - № 11/980408; Заявлено 31.10.2007; Опубл. 26.08.2008. - 23 с.↑

A1792. Пат. 7417577 США, МПК G01S13/95, G01S13/00, G01S17/95. Methods of estimating precipitation characteristics / J. Testud, R. Ney, E. LeBouar. - № 10/576374; Заявлено 21.10.2004; Опубл. 26.08.2008. - 10 с. ↑

A1793. Пат. 7414569 США, МПК G01S13/00. Vehicular radar sensor with distributed antenna / B. G. D. Mersseman. - № 11/431240; Заявлено 10.05.2006; Опубл. 19.08.2008. - 5 с.↑

A1794. Пат. 7411544 США, МПК G01S13/58, G01S13/00, G01S13/08. System and method for determining patrol speed / J. L. Aker, A. B. Mead, R. S. Gammenthaler, R. Vanman. - № 10/863683; Заявлено 08.06.2004; Опубл. 12.08.2008. - 21 с.↑

A1795. Пат. 7411542 США, МПК G01S13/93. Automotive radar system with guard beam / M. E. O'Boyle. - № 11/307531; Заявлено 10.02.2006; Опубл. 12.08.2008. - 15 с.↑

A1796. Пат. 7409295 США, МПК G01S13/93, B60T7/22, B60W30/08. Imminent-collision detection system and process / M. J. Paradie. - № 10/914360; Заявлено 09.08.2004; Опубл. 05.08.2008. - 21 с.↑

A1797. Пат. 7408501 США, МПК G01S13/08, G01F23/28. Method employing the radar principle for measuring the fill level of a medium in a container / I. Rolfes, T. Musch. - № 11/194947; Заявлено 02.08.2005; Опубл. 05.08.2008. - 7 с.↑

A1798. Пат. 7405693 США, МПК G01S13/95. System and method for synthesizing data in a radar system / J. L. Alford, M. B. Knight. - № 11/612730; Заявлено 19.12.2006; Опубл. 29.07.2008. - 13 с.↑

A1799. Пат. 7400976 США, МПК G01V3/36, G01S13/00, G01V1/00. Utility mapping and data distribution system and method / G. N. Young, K. L. Alft. - № 11/296844; Заявлено 07.12.2005; Опубл. 15.07.2008. - 34 с.↑

A1800. Пат. 7400290 США, МПК G01S13/92, G01S13/58. Vehicle radar system having multiple operating modes / W. G. Woodington, D. Hunt. - № 11/324035; Заявлено 30.12.2005; Опубл. 15.07.2008. - 24 с.↑

A1801. Пат. 7400287 США, МПК H04K3/00, G01S7/495, G01S13/00, G01S17/00. Smart chaff / R. J. Saccomanno. - № 11/356153; Заявлено 17.02.2006; Опубл. 15.07.2008. - 13 с.↑

A1802. Пат. 7397549 США, МПК G01C1/00, G01S13/00. Doppler tracking optical monopulse / B. A. Williams, M. A. Turner, B. C. Baker. - № 11/609085; Заявлено 11.12.2006; Опубл. 08.07.2008. - 30 с.↑

A1803. Пат. 7397417 США, МПК G01V3/08, G01S13/88, G01V3/16. Electromagnetic impulse survey apparatus and method utilizing a magnetic component electromagnetic antenna / J. R. Jackson. - № 11/468628; Заявлено 30.08.2006; Опубл. 08.07.2008. - 14 с.↑

A1804. Пат. 7394422 США, МПК G01S13/42. Interferometer-type radar / H. Nohmi. - № 11/303942; Заявлено 19.12.2005; Опубл. 01.07.2008. - 18 с.↑

A1805. Пат. 7391361 США, МПК G01S13/34, G01S13/58. Signal processing method for FM-CW radar / M. Kishida. - № 10/584178; Заявлено 22.12.2004; Опубл. 24.06.2008. - 20 с.↑

A1806. Пат. 7391358 США, МПК G01W1/10, G01S13/95, G01W1/00, G01S13/00. Weather radar echo tops forecast generation / W. Dupree, M. M. Wolfson, R. J. Johnson, R. Boldi, P. E. Bieringer и др. - № 11/472674; Заявлено 22.06.2006; Опубл. 24.06.2008. - 16 с.↑

A1807. Пат. 7382312 США, МПК G01S13/04, G01S13/89, G01V3/12. Syntactic target classifier / K. J. Hintz. - № 11/247329; Заявлено 12.10.2005; Опубл. 03.06.2008. - 20 с.↑

A1808. Пат. 7379014 США, МПК G01S13/00, G08G1/16. Taxi obstacle detecting radar / D. L. Woodell, R. E. Robertson. - № 10/941616; Заявлено 15.09.2004; Опубл. 27.05.2008. - 14 с.↑

A1809. Пат. 7378948 США, МПК B60Q1/00, G08G1/16, G01S13/08. Digital message display for vehicles / E. Somuah. - № 11/038036; Заявлено 21.01.2005; Опубл. 27.05.2008. - 14 с.↑

A1810. Пат. 7376493 США, МПК G01S15/00, G01S13/08, G08G1/16. Vehicle-surroundings monitor apparatus / M. Takeichi, Y. Sato. - № 11/153369; Заявлено 16.06.2005; Опубл. 20.05.2008. - 15 с.↑

A1811. Пат. 7372395 США, МПК G01S13/60. Ground-speed measuring apparatus / T. Kojima, S. Kuragaki, S. Izumi. - № 10/872457; Заявлено 22.06.2004; Опубл. 13.05.2008. - 21 с.↑

A1812. Пат. 7372394 США, МПК G01S13/95. Variable loop gain and resolution pulse system and method with point target editing capability / D. L. Woodell, R. E. Robertson, C. J. Dickerson. - № 11/235449; Заявлено 26.09.2005; Опубл. 13.05.2008. - 20 с.↑

A1813. Пат. 7365676 США, МПК G01S13/93, G08G1/16, G01S13/00. Sensor for transmitting and receiving electromagnetic signals / R. Mende. - № 10/519563; Заявлено 18.07.2003; Опубл. 29.04.2008. - 8 с.↑

A1814. Пат. 7365675 США, МПК G01S13/95. Measuring wind vectors remotely using airborne radar / J. S. Pearlman, B. J. Tillotson. - № 11/235487; Заявлено 26.09.2005; Опубл. 29.04.2008. - 11 с.↑

A1815. Пат. 7365674 США, МПК G01S13/95. Airborne weather profiler network / B. J. Tillotson, J. S. Pearlman, D. A. Whelan. - № 11/235371; Заявлено 26.09.2005; Опубл. 29.04.2008. - 20 с.↑

A1816. Пат. 7365673 США, МПК G01S13/95. Compression and transmission of weather data / V. V. Makkapati,

P. R. Mahapatra. - № 11/027557; Заявлено 30.12.2004; Опубл. 29.04.2008. - 11 с.↑

A1817. Пат. 7365672 США, МПК G01S13/04. Detection of a concealed object / P. E. Keller, T. E. Hall, D. L. McMakin. - № 10/697965; Заявлено 30.10.2003; Опубл. 29.04.2008. - 34 с.↑

A1818. Пат. 7358890 США, МПК G01S13/88, G01S13/89, G01S7/35, H01Q21/00, G01S13/00 и др. Millimetre-wave illumination source / S. Price, P. R. Coward, N. A. Salmon. - № 10/513545; Заявлено 01.05.2003; Опубл. 15.04.2008. - 12 с.↑

A1819. Пат. 7358888 США, МПК G01S13/42. System and method for intrusion detection using a time domain radar array / L. W. Fullerton, J. L. Richards. - № 10/806131; Заявлено 23.03.2004; Опубл. 15.04.2008. - 24 с.↑

A1820. Пат. 7355547 США, МПК G01S13/00, H01L23/28. Vehicle-mounted millimeter wave radar device, millimeter wave radar module, and manufacturing method thereof / T. Nakazawa, Y. Sasada, S. Ouchi. - № 11/482056; Заявлено 07.07.2006; Опубл. 08.04.2008. - 7 с.↑

A1821. Пат. 7355546 США, МПК G01S13/95. Polarization and frequency diverse radar system for complete polarimetric characterization of scatterers with increased scanning speed / M. Randall. - № 11/325262; Заявлено 03.01.2006; Опубл. 08.04.2008. - 10 с.↑

A1822. Пат. 7353690 США, МПК G01W1/00, G01S13/95. Atmospheric refractivity profiling apparatus and methods / F. S. Solheim, R. H. Ware, M. L. Exner. - № 11/041160; Заявлено 24.01.2005; Опубл. 08.04.2008. - 14 с.↑

A1823. Пат. 7352321 США, МПК G01S13/00. Determining statistical descriptors of a signal from a set of its samples / W. J. Szajnowski, M. Bober. - № 11/232032; Заявлено 22.09.2005; Опубл. 01.04.2008. - 11 с.↑

A1824. Пат. 7345621 США, МПК G01S13/08. Real-time multistatic radar signal processing system and method / J. M. Bourdelais, E. S. Stickles, W. R. Wright, D. E. Norris, M. A. Tiberio и др. - № 11/710868; Заявлено 26.02.2007; Опубл. 18.03.2008. - 13 с.↑

A1825. Пат. 7345617 США, МПК G01S13/88, G01V3/12, G01S13/00. Apparatus for collecting ground radar data with polarization information / J. Friborg, B. Johansson, T. Leijon. - № 10/538843; Заявлено 09.12.2003; Опубл. 18.03.2008. - 5 с.↑

A1826. Пат. 7340277 США, МПК H04M1/00, G01S13/78. Adaptive antenna for controlling the weighting on a plurality of antenna elements / H. Nakamura. - № 10/432865; Заявлено 22.11.2001; Опубл. 04.03.2008. - 12 с.↑

A1827. Пат. 7336222 США, МПК G01S13/95, G01S7/292. System and method for measuring characteristics of a continuous medium and/or localized targets using multiple sensors / A. Praskovsky, E. Praskovskaya. - № 11/159581; Заявлено 23.06.2005; Опубл. 26.02.2008. - 24 с.↑

A1828. Пат. 7336217 США, МПК G01S13/90, G01S7/40. Method and apparatus for interferometric radar measurement / M. Voelker. - № 11/229639; Заявлено 20.09.2005; Опубл. 26.02.2008. - 8 с.↑

A1829. Пат. 7336216 США, МПК H01Q15/00, H04K3/00, G01S13/00. Parachuted radar decoy / G. Weisbrod. - № 11/406446; Заявлено 18.04.2006; Опубл. 26.02.2008. - 12 с.↑

A1830. Пат. 7333048 США, МПК G01S13/62. Periphery monitoring system / M. Nakagawa, H. Okada, M. Fujiwara, N. Mizutani. - № 11/338630; Заявлено 25.01.2006; Опубл. 19.02.2008. - 21 с.↑

A1831. Пат. 7333045 США, МПК G01V3/12, G01S13/88, G01S13/00. Buried object detection sensor / N. Aomori, Y. Sakamoto, C. Joumuta, F. Oka. - № 11/363053; Заявлено 28.02.2006; Опубл. 19.02.2008. - 8 с.↑

A1832. Пат. 7333044 США, МПК G01S7/40, H01Q15/00, G01S13/00. Rocket-powered sensor target assembly / D. W. Sandlin. - № 11/534834; Заявлено 25.09.2006; Опубл. 19.02.2008. - 7 с.↑

A1833. Пат. 7330792 США, МПК G01V1/28, G01S13/00. Method for reconstructing complex wave attributes from limited view measurements / A. Witten. - № 11/518821; Заявлено 11.09.2006; Опубл. 12.02.2008. - 45 с.↑

A1834. Пат. 7330147 США, МПК G01S13/93, G01S13/08, G08G5/04. System and method for ground proximity warning with enhanced obstacle depiction / R. Khatwa. - № 10/907934; Заявлено 21.04.2005; Опубл. 12.02.2008. - 11 с.↑

A1835. Пат. 7327306 США, МПК G01S13/74, G01S7/40, G01S13/00. RF system for tracking objects / J.-L. Laroche. - № 11/418114; Заявлено 05.05.2006; Опубл. 05.02.2008. - 7 с.↑

A1836. Пат. 7324039 США, МПК G01S13/93, G01S7/28. Short-range automotive radar transceiver / N. S. Boltovets, V. V. Basanets, A. V. Zorenko, S. B. Maltsev, A. F. Odnolko и др. - № 11/304502; Заявлено 15.12.2005; Опубл. 29.01.2008. - 20 с.↑

A1837. Пат. 7317417 США, МПК G01S13/66. Methods for detection and tracking of targets / O. Arikan, A. K. Ozdemir, D. S. Gumas. - № 11/180811; Заявлено 12.07.2005; Опубл. 08.01.2008. - 21 с.↑

A1838. Пат. 7315274 США, МПК G01S7/40, G01S13/82, G01S13/93. Method and system for determining the position of marine vessels and similar objects / B. Fossum. - № 10/533656; Заявлено 15.03.2005; Опубл. 01.01.2008. - 10 с.↑

A1839. Пат. 7312743 США, МПК G01S13/95. Systems and methods for displaying hazards / R. Ridenour, S. G. Scott. - № 11/430545; Заявлено 08.05.2006; Опубл. 25.12.2007. - 13 с.↑

A1840. Пат. 7310061 США, МПК G01P3/42, G01P3/00, G01S13/58, G01S13/00. Velocity sensor and ground vehicle velocity sensor using the same / T. Nagasaku, H. Kondoh, H. Shinoda. - № 11/207004; Заявлено 19.08.2005; Опубл. 18.12.2007. - 25 с.↑

A1841. Пат. 7310060 США, МПК G01V3/12, G01S13/88. Multi-mode landmine detector / G. Stilwell, G. Solomon, R. McCoy, S. McCarthy. - № 11/191149; Заявлено 28.07.2005; Опубл. 18.12.2007. - 40 с.↑

A1842. Пат. 7304603 США, МПК G01S13/02, G01S13/56. Radar apparatus and processing method for detecting human carried explosive devices / J. C. Reed, J. D. Gorman. - № 11/356997; Заявлено 17.02.2006; Опубл. 04.12.2007. - 9 с.↑

A1843. Пат. 7304602 США, МПК G01S7/40, G01S13/42, G01S13/93. Axial deviation determining method for on-vehicle radar / T. Shinagawa, S. Ueda. - № 11/145902; Заявлено 06.06.2005; Опубл. 04.12.2007. - 18 с.↑

A1844. Пат. 7304601 США, МПК G01F23/284, G01F23/00, G01S13/08, G01S13/00. Device and a method for accurate radar level gauging / O. Edvardsson. - № 11/516815; Заявлено 07.09.2006; Опубл. 04.12.2007. - 10 с. ↑

A1845. Пат. 7301493 США, МПК G01S13/00. Meta-materials based upon surface coupling phenomena to achieve one-way mirror for various electro-magnetic signals / P. R. Canales, H.-L. Cui, A. Raspopin. - № 11/288061; Заявлено 21.11.2005; Опубл. 27.11.2007. - 8 с.↑

A1846. Пат. 7298314 США, МПК G01S13/08. Near field electromagnetic positioning system and method / H. G. Schantz, D. W. Langford. - № 10/958165; Заявлено 04.10.2004; Опубл. 20.11.2007. - 45 с.↑

A1847. Пат. 7298312 США, МПК G01S13/78, H04B1/00. Detecting small, time domain impulsive communications signals / D. P. McLemore. - № 11/166207; Заявлено 27.06.2005; Опубл. 20.11.2007. - 13 с.↑

A1848. Пат. 7295154 США, МПК G01S13/93. Vehicle obstacle warning radar / E. K. Walton, C.-C. Chen. - № 10/968472; Заявлено 19.10.2004; Опубл. 13.11.2007. - 58 с.↑

A1849. Пат. 7295147 США, МПК G01S13/93. Sensor arrangement and method for regulating the distance of motor vehicles / J. Boecker, G. Braeuchle. - № 10/527180; Заявлено 12.03.2003; Опубл. 13.11.2007. - 8 с.↑

A1850. Пат. 7295146 США, МПК G01S13/89. Holographic arrays for multi-path imaging artifact reduction / D. L. McMakin, D. M. Sheen, T. E. Hall. - № 11/088470; Заявлено 24.03.2005; Опубл. 13.11.2007. - 14 с.↑

A1851. Пат. 7292180 США, МПК G01S13/42. System and method for passively estimating angle and range of a source using signal samples collected simultaneously from a multi-aperture antenna / M. B. Schober. - № 11/152291; Заявлено 13.06.2005; Опубл. 06.11.2007. - 17 с.↑

A1852. Пат. 7292179 США, МПК G01S13/08, G01S13/86. Instantaneous passive range finding / W. K.

Schroeder, B. A. Williams. - № 11/103380; Заявлено 11.04.2005; Опубл. 06.11.2007. - 18 с.↑

A1853. Пат. 7289059 США, МПК G01S13/93. Method and device for course prediction in motor vehicles / A. Maass. - № 11/166520; Заявлено 23.06.2005; Опубл. 30.10.2007. - 7 с.↑

A1854. Пат. 7289057 США, МПК G01S13/00, H03K9/00. Method and apparatus for detection of signal having random characteristics / C. G. Meil. - № 11/187297; Заявлено 22.07.2005; Опубл. 30.10.2007. - 10 с.↑

A1856. Пат. 7283212 США, МПК G01C3/08, G01S13/00. Vehicular radar device / S. Arita, Y. Asada. - № 11/528949; Заявлено 28.09.2006; Опубл. 16.10.2007. - 19 с.↑

A1857. Пат. 7283089 США, МПК G01S13/00, G01S7/40. Radar system and car radar system / K. Nakamura, R. Fukute, A. Okonogi, K. Takano. - № 11/613702; Заявлено 20.12.2006; Опубл. 16.10.2007. - 17 с.↑

A1858. Пат. 7275431 США, МПК G01S13/08, G01S13/93, G01S13/94. Vehicle mounted system for detecting objects / U. Zimmermann, A. Pruksch. - № 10/538259; Заявлено 25.09.2003; Опубл. 02.10.2007. - 6 с.↑

A1859. Пат. 7274436 США, МПК G01C3/08, G01S13/00. Distance measuring device for a vehicle / Y. Matsuura, M. Komaya. - № 11/361300; Заявлено 23.02.2006; Опубл. 25.09.2007. - 16 с.↑

A1860. Пат. 7271762 США, МПК G01S7/40, G01S13/93, G01S13/00. Method for detecting an obstacle around a vehicle / Y. Samukawa, K. Matsuoka, H. Ookata, T. Nozawa. - № 11/043187; Заявлено 27.01.2005; Опубл. 18.09.2007. - 21 с.↑

A1861. Пат. 7269427 США, МПК H04Q7/20, G01S13/08, H04B17/00, H04B7/00, H04B7/08 и др. Transmitter location for ultra-wideband, transmitted-reference CDMA communication system / R. T. Hoctor, J. E. Hershey, N. A. V. Stralen, H. W. Tomlinson, J. - № 09/973140; Заявлено 09.10.2001; Опубл. 11.09.2007. - 15 с.↑

A1862. Пат. 7268721 США, МПК G01S13/00, H01Q3/02. Car reversing radar sensor having fine-tuning feature / S.-H. Li. - № 11/189639; Заявлено 26.07.2005; Опубл. 11.09.2007. - 6 с.↑

A1863. Пат. 7265710 США, МПК G01S13/08. Multipath height finding method / W. C. DeAgro. - № 10/988009; Заявлено 12.11.2004; Опубл. 04.09.2007. - 9 с.↑

A1864. Пат. 7265709 США, МПК G01S13/89. Surveilled subject imaging with object identification / M. Fleisher, S. L. Nikulin, R. L. Rowe, T. W. Grudkowski. - № 10/824893; Заявлено 14.04.2004; Опубл. 04.09.2007. - 20 с.↑

A1865. Пат. 7265551 США, МПК G01V3/11, G01S13/06. Metal detector, in particular mine detector / G. Kellermann. - № 11/203871; Заявлено 15.08.2005; Опубл. 04.09.2007. - 9 с.↑

A1866. Пат. 7259714 США, МПК G01S7/487, G01S7/483, G01S13/00, G01S13/52. Unique space time adaptive system (USS) / T. J. Cataldo. - № 11/415735; Заявлено 01.05.2006; Опубл. 21.08.2007. - 56 с.↑

A1867. Пат. 7259712 США, МПК G01S13/08, G01F23/284. Antenna with integral sealing member for a radar-based level measurement system / J. McKeen, G. M. Serban. - № 10/956959; Заявлено 30.09.2004; Опубл. 21.08.2007. - 8 с.↑

A1868. Пат. 7259711 США, МПК G01S13/93, G01S7/40, G01S13/00. Vehicle control apparatus / F. Okai, H. Kuroda. - № 10/739223; Заявлено 19.12.2003; Опубл. 21.08.2007. - 17 с.↑

A1869. Пат. 7257478 США, МПК G06F7/00, G01S13/04. Vehicle driving control device / T. Sugano. - № 11/010448; Заявлено 14.12.2004; Опубл. 14.08.2007. - 18 с.↑

A1870. Пат. 7256727 США, МПК G01S13/62. System and method for radiating RF waveforms using discontinues associated with a utility transmission line / L. W. Fullerton, M. D. Roberts. - № 11/030310; Заявлено 07.01.2005; Опубл. 14.08.2007. - 35 с.↑

A1871. Пат. 7254401 США, МПК H04Q7/20, G01S13/00. Network-based method and system for determining a location of user equipment in CDMA networks / Y. Keranen, T. Viero. - № 09/740299; Заявлено 19.12.2000; Опубл. 07.08.2007. - 13 с.↑

A1872. Пат. 7254369 США, МПК H04B17/00, G01P21/00, G01S13/78. Process and device for estimating the speed of movement of a mobile terminal of a wireless communication system / D. Chappaz. - № 10/233055; Заявлено 30.08.2002; Опубл. 07.08.2007. - 11 с.↑

A1873. Пат. 7253766 США, МПК G01S13/89. Three-dimensional surface/contour processing based on electromagnetic radiation interrogation / H. P. Foote, T. E. Hall, D. L. McMakin. - № 10/950244; Заявлено 24.09.2004; Опубл. 07.08.2007. - 43 с.↑

A1874. Пат. 7248153 США, МПК B60Q1/00, G01S13/00, G06F17/10, G08G1/14, G06G7/78. Method for parking a vehicle / C. Danz, W. Uhler. - № 10/504216; Заявлено 16.12.2002; Опубл. 24.07.2007. - 5 с.↑

A1875. Пат. 7245252 США, МПК G01S13/08, G01S11/02, G01S13/76, G01S13/00. Method for determining the distance between two transmitting and receiving stations / U. Knepper, S. Rau, T. Oexle, R. Schuler, W. Schulter. - № 10/530912; Заявлено 08.09.2003; Опубл. 17.07.2007. - 11 с.↑

A1876. Пат. 7245251 США, МПК G01S13/00. Apparatus for automatically pointing a device at a target / D. A. Vogel, E. W. Johnson, R. L. McCulley. - № 10/971320; Заявлено 22.10.2004; Опубл. 17.07.2007. - 9 с.↑

A1877. Пат. 7242343 США, МПК G01S13/95. Directed sequential hazard assessment weather radar / D. L. Woodell. - № 10/941598; Заявлено 15.09.2004; Опубл. 10.07.2007. - 16 с.↑

A1878. Пат. 7239268 США, МПК G01S7/28, G01S13/00. Method and apparatus for minimizing the number of power amplifiers required under multiple transmission conditions / S. D. Albert, J. F. Prorok, J. Skudera, representative, W. J. Skudera и др. - № 10/235215; Заявлено 05.09.2002; Опубл. 03.07.2007. - 6 с.↑

A1879. Пат. 7239265 США, МПК G01S13/08. Method for evaluating and controlling a radar installation / F. Tennebo, T.-B. Stenbock. - № 10/543851; Заявлено 03.02.2003; Опубл. 03.07.2007. - 10 с.↑

A1880. Пат. 7236123 США, МПК G01S13/534. System for enhanced detection of a target / A. Siegel. - № 10/977708; Заявлено 29.10.2004; Опубл. 26.06.2007. - 24 с.↑

A1881. Пат. 7236121 США, МПК G01S13/00, F41G7/00, F41G9/00. Pattern classifier and method for associating tracks from different sensors / T. E. Caber. - № 11/151825; Заявлено 13.06.2005; Опубл. 26.06.2007. - 28 с.↑

A1882. Пат. 7236120 США, МПК G01S13/89, G01V3/12. Ultra-wideband detector systems for detecting moisture in building walls / W. Healy, E. V. Doorn. - № 11/094312; Заявлено 31.03.2005; Опубл. 26.06.2007. - 9 с.↑

A1883. Пат. 7227495 США, МПК G01S13/08. Radar fill-level sensing device / A. Bletz, T. Musch. - № 11/109532; Заявлено 19.04.2005; Опубл. 05.06.2007. - 6 с.↑

A1884. Пат. 7227494 США, МПК G01S13/93, G01S13/58. Vehicular traffic surveillance doppler radar system / J. L. Aker. - № 11/279383; Заявлено 11.04.2006; Опубл. 05.06.2007. - 18 с.↑

A1885. Пат. 7224309 США, МПК G01S13/93. Preceding-vehicle detecting apparatus, own-vehicle controlling apparatus, and preceding-vehicle detecting method / N. Shimomura. - № 11/004902; Заявлено 07.12.2004; Опубл. 29.05.2007. - 35 с.↑

A1886. Пат. 7224308 США, МПК G01S13/78. Identification and location system for personnel and vehicles / W. Butler, C. Chase. - № 10/668700; Заявлено 23.09.2003; Опубл. 29.05.2007. - 13 с.↑

A1887. Пат. 7221310 США, МПК G01S7/40, B60R21/00, G01S13/93, B60R21/0134, G01S13/00. Electric wave axis adjusting apparatus for radar mounted on vehicle / K. Nakagawa. - № 11/131351; Заявлено 18.05.2005; Опубл. 22.05.2007. - 10 с.↑

A1888. Пат. 7218274 США, МПК G01S7/00, G01S13/00. System and method for detection and tracking of targets / O. Arikan, A. K. Ozdemir. - № 10/691245; Заявлено 21.10.2003; Опубл. 15.05.2007. - 45 с.↑

A1889. Пат. 7218273 США, МПК G01S7/40, G01S13/00. Method and device for boresighting an antenna on a moving platform using a moving target / J. B. Webster, J.L.M. K. Timothy, F. M. Strohacker. - № 11/441514; Заявлено 24.05.2006; Опубл. 15.05.2007. - 13 с.↑

A1890. Пат. 7218272 США, МПК G01S13/44. Reducing antenna boresight error / D. L. Steinbauer. - № 11/426721; Заявлено 27.06.2006; Опубл. 15.05.2007. - 10 с.↑

A1891. Пат. 7218271 США, МПК G01S13/58. System and method for determining patrol speed / J. L. Aker, A. B. Mead, R. S. Gammenthaler, R. V. Vanman. - № 10/863708; Заявлено 08.06.2004; Опубл. 15.05.2007. - 21 с. ↑

A1892. Пат. 7218267 США, МПК G01S13/86, G01S13/89. System of subterranean anomaly detection and repair using infrared thermography and ground penetrating radar / G. J. Weil. - № 11/442508; Заявлено 26.05.2006; Опубл. 15.05.2007. - 20 с.↑

A1893. Пат. 7218266 США, МПК H01Q17/00, G01S13/00. Electromagnetic wave absorber, method of manufacturing the same and appliance using the same / T. Fujieda, S. Ikeda, S. Ogawa, T. Abe, Y. Aono. - № 11/066305; Заявлено 28.02.2005; Опубл. 15.05.2007. - 26 с.↑

A1894. Пат. 7212153 США, МПК G01S13/89. Millimeter-wave active imaging system with fixed array / R. L. Rowe, T. W. Grudkowski, R. R. Blasing. - № 10/728434; Заявлено 05.12.2003; Опубл. 01.05.2007. - 17 с.↑

A1895. Пат. 7209822 США, МПК B60K31/00, G01S13/72. Method for selecting a target vehicle / T. Linden. - № 10/943231; Заявлено 17.09.2004; Опубл. 24.04.2007. - 7 с.↑

A1896. Пат. 7209073 США, МПК G01S13/08, G01F23/00, G01S15/08, G01F23/284, G01F23/296. Method and device for determining the filling level of a medium in a container / D. Spanke, R. Lalla. - № 11/049884; Заявлено 04.02.2005; Опубл. 24.04.2007. - 9 с.↑

A1897. Пат. 7205933 США, МПК G01S13/06. Hostile platform position location utilizing networked communications / T. E. Snodgrass. - № 10/938679; Заявлено 10.09.2004; Опубл. 17.04.2007. - 8 с.↑

A1898. Пат. 7205931 США, МПК G01S13/38. Method for determining the distance between a base station and a mobile object, in addition to a base station and identification system for a method of this type / J. Gila, W. Konrad, A. Renner. - № 10/940657; Заявлено 15.09.2004; Опубл. 17.04.2007. - 7 с.↑

A1899. Пат. 7205929 США, МПК G01S13/93. Radar system and vehicle controller incorporating radar system / M. Shingyoji, H. Ando. - № 11/166590; Заявлено 25.06.2005; Опубл. 17.04.2007. - 21 с.↑

A1900. Пат. 7205927 США, МПК G01S13/90. Technique for low grazing angle 3D SAR target recognition / K. V. Krikorian, D. J. Mellema, M. Y. Pines. - № 11/144130; Заявлено 03.06.2005; Опубл. 17.04.2007. - 7 с.↑

A1901. Пат. 7205926 США, МПК G01S13/89. Multi-source surveillance system / R. L. Rowe, R. R. Blasing, M. Fleisher, S. L. Nikulin, T. W. Grudkowski и др. - № 10/825530; Заявлено 14.04.2004; Опубл. 17.04.2007. - 21 с. ↑

A1902. Пат. 7205769 США, МПК G01V3/08, G01S13/02, G01V3/10, G01V3/12. Method and apparatus for processing a signal received by an electromagnetic prober / M. Fujiwara. - № 11/273535; Заявлено 14.11.2005; Опубл. 17.04.2007. - 55 с.↑

A1903. Пат. 7202809 США, МПК G01S13/86, G01S17/88, G01S13/00, G01S17/66. Fast acting active protection system / D. A. Schade, T. C. Winant, J. Alforque, J. Faul, K. B. Groves и др. - № 10/842791; Заявлено 10.05.2004; Опубл. 10.04.2007. - 7 с.↑

A1904. Пат. 7202808 США, МПК G01S13/89. Surveilled subject privacy imaging / M. Fleisher, M. M. Radzinski, R. L. Rowe, T. W. Grudkowski. - № 10/825558; Заявлено 14.04.2004; Опубл. 10.04.2007. - 21 с.↑

A1905. Пат. 7199750 США, МПК G01S13/08. Real-time multistatic radar signal processing system and method / J. M. Bourdelais, E. S. Stickels, W. R. Wright, D. E. Norris, M. A. Tiberio и др. - № 11/112390; Заявлено 22.04.2005; Опубл. 03.04.2007. - 14 с.↑

A1906. Пат. 7196656 США, МПК G01S13/00, G01S15/00, G01S17/00, G01S7/40, G01S7/00. Apparatus for estimating direction of arrival of signal / K. Shirakawa. - № 11/018985; Заявлено 21.12.2004; Опубл. 27.03.2007. - 15 с. ↑

A1907. Пат. 7196655 США, МПК G01S13/78. System and method for highly directional electronic identification and communication and combat identification system employing the same / R. E. Hayles, J.T. H. O'Mara. - № 10/972958; Заявлено 25.10.2004; Опубл. 27.03.2007. - 12 с. ↑

A1908. Пат. 7196654 США, МПК G01S13/74, G01S13/75, G01S13/00. Vehicle positioning and tracking radar system / D. J. Edwards, D. R. Pearce, J. Grothusen. - № 10/898705; Заявлено 23.07.2004; Опубл. 27.03.2007. - 4 с. ↑

A1909. Пат. 7196629 США, МПК B60Q1/00, B60R21/16, G01S13/00, G01S13/08, G08B13/00 и др. Radar-assisted sensing of the position and/or movement of the body or inside the body of living beings / H.-O. Ruoss, M. Mahler, J. Seidel. - № 10/497870; Заявлено 23.10.2003; Опубл. 27.03.2007. - 11 с. ↑

A1910. Пат. 7190306 США, МПК G01S13/91, G01S13/58, G01S13/62, G01S13/92, G01S13/00 и др. Method and system for detecting with radar the passage by a vehicle of a point for monitoring on a road / T. M. Janssen. - № 11/061304; Заявлено 18.02.2005; Опубл. 13.03.2007. - 10 с. ↑

A1911. Пат. 7190302 США, МПК G01S13/88, G01S13/90, G01V3/12. Sub-surface radar imaging / R. T. Biggs. - № 10/491237; Заявлено 13.09.2002; Опубл. 13.03.2007. - 10 с. ↑

A1912. Пат. 7184889 США, МПК G01S13/93, G08G1/16. Collision-prediction unit for a vehicle / K. Isaji, N. Tsuru. - № 10/952777; Заявлено 30.09.2004; Опубл. 27.02.2007. - 11 с. ↑

A1913. Пат. 7180441 США, МПК G01S13/89. Multi-sensor surveillance portal / R. L. Rowe, R. R. Blasing, M. Fleisher, S. L. Nikulin, T. W. Grudkowski и др. - № 10/825442; Заявлено 14.04.2004; Опубл. 20.02.2007. - 20 с. ↑

A1914. Пат. 7176830 США, МПК G01S13/08, G01S13/93, G01S17/08, G01S17/93, G01S13/00 и др. Image processing system for mounting to a vehicle / K. Horibe. - № 11/280745; Заявлено 15.11.2005; Опубл. 13.02.2007. - 23 с. ↑

A1915. Пат. 7176829 США, МПК G01S13/56, G01S7/35. Microwave sensor / M. Tsuji. - № 11/045316; Заявлено 31.01.2005; Опубл. 13.02.2007. - 9 с. ↑

A1916. Пат. 7167127 США, МПК G01S13/52. Process for tracking vehicles / N. Collins, R. Bottone, D. R. McMillan. - № 10/983557; Заявлено 08.11.2004; Опубл. 23.01.2007. - 48 с. ↑

A1917. Пат. 7167124 США, МПК G01V3/12, G01S7/02, G01V3/17, G01S13/00, G01S13/08 и др. Data acquisition for a ground penetrating radar system / A. P. Annan, S. Cosway. - № 11/314013; Заявлено 22.12.2005; Опубл. 23.01.2007. - 16 с. ↑

A1918. Пат. 7164382 США, МПК G01S13/93. On-vehicle radar system / K. Kai. - № 11/392582; Заявлено 30.03.2006; Опубл. 16.01.2007. - 14 с. ↑

A1919. Пат. 7161526 США, МПК G01S7/282, G01S13/02, G01S13/04, G01S13/93. Broadband radar and modulator, in particular for microwave switching over a very short period / P. Cornic, P. Laviec, B. Liabeuf, F. Melero. - № 10/450045; Заявлено 11.12.2001; Опубл. 09.01.2007. - 9 с. ↑

A1920. Пат. 7158218 США, МПК G01C3/08, G01S13/00. Vehicular radar device / S. Arita, Y. Asada. - № 10/894654; Заявлено 20.07.2004; Опубл. 02.01.2007. - 18 с. ↑

A1921. Пат. 7158076 США, МПК G01S13/42, G01S7/40. Method and apparatus for correcting velocity-induced range estimate phase errors in a two-tone monopulse CW radar / P. D. Fiore, E. A. Rundquist. - № 10/956837; Заявлено 01.10.2004; Опубл. 02.01.2007. - 12 с. ↑

A1922. Пат. 7158075 США, МПК G01S13/93. Vehicle radar apparatus / M. Nakamura. - № 11/100130; Заявлено 06.04.2005; Опубл. 02.01.2007. - 14 с. ↑

A1923. Пат. 7158071 США, МПК G01S13/95. Radar rainfall estimation technique when attenuation is negligible / J. Testud, E. L. Bouar. - № 10/483188; Заявлено 11.07.2002; Опубл. 02.01.2007. - 7 с.↑

A1924. Пат. 7154590 США, МПК G01C3/08, G01P3/36, G01S13/72. Doppler tracking optical monopulse / B. A. Williams, M. A. Turner, B. C. Baker. - № 10/923241; Заявлено 20.08.2004; Опубл. 26.12.2006. - 32 с.↑

A1925. Пат. 7154433 США, МПК G01S13/52. Method and device for the detection and track of targets in high clutter / J. M. Madewell. - № 10/830805; Заявлено 21.04.2004; Опубл. 26.12.2006. - 14 с.↑

A1926. Пат. 7151479 США, МПК G01S13/93. Radar sensor for motor vehicles / T. Beez, K. Lehre. - № 10/505402; Заявлено 27.09.2002; Опубл. 19.12.2006. - 10 с.↑

A1927. Пат. 7148838 США, МПК G01S13/93. Method for attaching radar for vehicle, radar for vehicle, and monitoring method / E. Kakishita, Y. Yamada, Y. Tanaka, H. Mizuno. - № 10/896980; Заявлено 23.07.2004; Опубл. 12.12.2006. - 18 с.↑

A1928. Пат. 7145506 США, МПК G01S13/89. Depth-based surveillance image reconstruction / G. R. Holt, M. Fleisher. - № 11/041098; Заявлено 21.01.2005; Опубл. 05.12.2006. - 24 с.↑

A1929. Пат. 7145503 США, МПК G01S7/292, G01S13/02, G01S13/04, G01S13/18. Surface wave radar / Y. Abramovich, P. Turcaj, N. K. Spencer, R. M. Ellard, Y. Lyudviga. - № 10/291697; Заявлено 12.11.2002; Опубл. 05.12.2006. - 23 с.↑

A1930. Пат. 7142979 США, МПК G01S13/66, G08G1/01. Method of triggering the transmission of data from a mobile asset / C. W. Shonk. - № 09/598538; Заявлено 21.06.2000; Опубл. 28.11.2006. - 8 с.↑

A1931. Пат. 7140803 США, МПК E01F9/04, G01S13/00. Passive traffic lane marking for on-board detection of lane boundary / R. Cummings, A. Cummings. - № 11/055502; Заявлено 10.02.2005; Опубл. 28.11.2006. - 4 с.↑

A1932. Пат. 7136736 США, МПК G01S3/00, G01S13/36. Vehicular travel control device / S. Kuragaki, T. Yoshikawa, S. Izumi, H. Kuroda, T. Kojima и др. - № 10/419878; Заявлено 22.04.2003; Опубл. 14.11.2006. - 18 с.↑

A1933. Пат. 7136014 США, МПК G01S13/00. System and method for estimating the azimuth pointing angle of a moving monopulse antenna / H. McCord, B. Schweitzer, E. B. Jensen, S. A. Hallman. - № 10/996630; Заявлено 23.11.2004; Опубл. 14.11.2006. - 14 с.↑

A1934. Пат. 7136013 США, МПК G01S13/42, G01S13/93. Radio-wave radar system and adaptive cruise control system / K. Hanawa, H. Kuroda, K. Takano. - № 10/625642; Заявлено 24.07.2003; Опубл. 14.11.2006. - 32 с.↑

A1935. Пат. 7130449 США, МПК G06K9/00, G01S13/00, G01S13/08. Method and system for ground imaging / R. W. Turner. - № 10/329114; Заявлено 23.12.2002; Опубл. 31.10.2006. - 9 с.↑

A1936. Пат. 7129886 США, МПК G01S13/56, G01S13/00. System and method for detecting an intruder using impulse radio technology / D. J. Hall, S. M. Yano, H. G. Schantz. - № 10/971878; Заявлено 22.10.2004; Опубл. 31.10.2006. - 47 с.↑

A1937. Пат. 7129885 США, МПК G01S13/95, G01S7/04. Adaptive weather radar detection system and method used in continental and maritime environments / D. L. Woodell, R. E. Robertson. - № 10/631253; Заявлено 31.07.2003; Опубл. 31.10.2006. - 6 с.↑

A1938. Пат. 7123201 США, МПК H01Q1/34, G01S13/00. Radar antenna leveling system / P. Caudle. - № 10/906193; Заявлено 08.02.2005; Опубл. 17.10.2006. - 9 с.↑

A1939. Пат. 7123185 США, МПК G01S13/88, G01S13/89. Enhanced surveilled subject imaging / M. Fleisher, R. R. Blasing, M. M. Radzinski, T. W. Grudkowski. - № 10/824875; Заявлено 14.04.2004; Опубл. 17.10.2006. - 21 с.
↑

A1940. Пат. 7123183 США, МПК G01S13/93. FM-CW radar apparatus / M. Shouno, M. Hitotsuya. - № 10/762088; Заявлено 20.01.2004; Опубл. 17.10.2006. - 17 с.↑

A1941. Пат. 7123017 США, МПК G01V3/08, G01S13/02, G01V3/12, G01V3/10, G01V3/15. Specific dielectric constant calibration method for an electromagnetic prober / M. Fujiwara. - № 11/273532; Заявлено 14.11.2005; Опубл. 17.10.2006. - 53 с.↑

A1942. Пат. 7119740 США, МПК G01S13/89. Millimeter-wave active imaging system with modular array / R. R. Blasing, T. W. Grudkowski, S. T. Trosper. - № 10/728637; Заявлено 05.12.2003; Опубл. 10.10.2006. - 17 с.↑

A1943. Пат. 7119735 США, МПК G01S7/35, G01S13/93. Vehicle-installed radar sensor system and vehicle-installed radar sensor / M. Hirose, J. Fujihara. - № 10/857024; Заявлено 01.06.2004; Опубл. 10.10.2006. - 16 с. ↑

A1944. Пат. 7119731 США, МПК G01S13/89. Depth-based surveillance imaging / M. Fleisher. - № 11/040597; Заявлено 21.01.2005; Опубл. 10.10.2006. - 24 с.↑

A1945. Пат. 7113130 США, МПК G01S13/06, G01S13/74, G01S3/04. Method and system for determining location by implication / D. J. Zukowski, J. R. Norris, J.J. W. Rojas. - № 10/710294; Заявлено 30.06.2004; Опубл. 26.09.2006. - 11 с.↑

A1946. Пат. 7113125 США, МПК G01S13/08. Method for measuring material level in a container using RFID tags / R. H. L. Sesne. - № 11/014512; Заявлено 16.12.2004; Опубл. 26.09.2006. - 14 с.↑

A1947. Пат. 7113124 США, МПК G01S13/66, G01V3/12. Centerline and depth locating method for non-metallic buried utility lines / J. W. Waite. - № 10/997729; Заявлено 23.11.2004; Опубл. 26.09.2006. - 15 с.↑

A1948. Пат. 7113123 США, МПК H01Q17/00, G01S13/00. Electromagnetic wave absorber and a process of producing same / A. Saito, N. Tanaka. - № 10/878283; Заявлено 29.06.2004; Опубл. 26.09.2006. - 8 с.↑

A1949. Пат. 7106244 США, МПК G01S13/04, G01S13/88. Freight container monitoring system / H. Hsu. - № 10/790563; Заявлено 01.03.2004; Опубл. 12.09.2006. - 18 с.↑

A1950. Пат. 7102532 США, МПК G01V3/00, G01S13/00, G05D1/00, H04B11/00, H04B13/02. Subsea communication / S. M. Hudson. - № 10/250588; Заявлено 20.12.2001; Опубл. 05.09.2006. - 5 с.↑

A1951. Пат. 7102487 США, МПК H04Q9/00, B60R25/10, E05B65/12, G01S13/58, G08B13/18. Detector and lock controller using same / S. Mafune, K. Negoro, Y. Satoh, T. Nishiguchi. - № 10/759760; Заявлено 16.01.2004; Опубл. 05.09.2006. - 13 с.↑

A1952. Пат. 7098842 США, МПК G01S13/00, G01S13/88. Vehicle-mounted millimeter wave radar device, millimeter wave radar module, and manufacturing method thereof / T. Nakazawa, Y. Sasada, S. Oouchi. - № 10/681246; Заявлено 09.10.2003; Опубл. 29.08.2006. - 7 с.↑

A1953. Пат. 7095362 США, МПК G01S13/42. Radar measurement device, especially for a motor vehicle, and method for operating a radar measurement device / J. Hoetzel, D. Schmid. - № 10/517790; Заявлено 17.06.2003; Опубл. 22.08.2006. - 6 с.↑

A1954. Пат. 7095361 США, МПК G01S13/93, G01S13/00. Radar sensor platform / B. Mattes, R. Moritz. - № 10/296074; Заявлено 16.03.2002; Опубл. 22.08.2006. - 9 с.↑

A1955. Пат. 7095358 США, МПК G01S13/90, G01S7/292. Technique for cancellation of elevated clutter for the detection of fixed and ground moving targets under trees / K. V. Krikorian, R. A. Rosen. - № 10/996024; Заявлено 23.11.2004; Опубл. 22.08.2006. - 10 с.↑

A1956. Пат. 7095357 США, МПК G01V3/12, G01S13/88, G01S13/08, G01S13/10. Method and apparatus for transmitting electromagnetic signals into the earth at frequencies below 500 KHz from a capacitor emplaced on the surface of the earth or raised aloft in an aircraft / J. R. Johler. - № 10/437024; Заявлено 14.05.2003; Опубл. 22.08.2006. - 10 с.↑

A1957. Пат. 7091902 США, МПК G01S7/40, G01S13/04, G01S15/04, G01S13/00, G01S15/00. Systems and methods for characterizing the coverage of ad hoc sensor networks / J. Liu, X. Koutsoukos. - № 10/736601; Заявлено 17.12.2003; Опубл. 15.08.2006. - 15 с.↑

A1958. Пат. 7091901 США, МПК G01S13/58, G01S13/00. Traffic radar system with improved patrol speed ↑

capture / M. E. Shelton, S. F. Hocker. - № 11/076003; Заявлено 09.03.2005; Опубл. 15.08.2006. - 6 с.

A1959. Пат. 7084806 США, МПК G01S13/62, G01S7/40. Intruding object detecting apparatus, and setting apparatus, setting process and setting confirmation process therefor / Y. Toguchi, Y. Tada, S. Okamura. - № 10/648035; Заявлено 26.08.2003; Опубл. 01.08.2006. - 24 с.↑

A1960. Пат. 7081849 США, МПК G01S13/52. Process for sensor resources management / N. Collins, K. D. Moore, D. R. McMillan. - № 10/976150; Заявлено 28.10.2004; Опубл. 25.07.2006. - 51 с.↑

A1961. Пат. 7076366 США, МПК G01S13/93, G08B21/00. Object collision avoidance system for a vehicle / S. Simon, E. A. Simon. - № 10/656675; Заявлено 05.09.2003; Опубл. 11.07.2006. - 11 с.↑

A1962. Пат. 7076365 США, МПК G01C21/28, G01S13/08. Enhanced dead reckoning method / A. Tzamaloukas. - № 10/436691; Заявлено 12.05.2003; Опубл. 11.07.2006. - 39 с.↑

A1963. Пат. 7075479 США, МПК G01F23/284, G01S13/08. Radar level-measuring device / A. Andersson. - № 10/488204; Заявлено 27.08.2002; Опубл. 11.07.2006. - 7 с.↑

A1964. Пат. 7071866 США, МПК G01S13/74. 2-d range hopping spread spectrum encoder/decoder system for RF tags / D. R. Iny, M. D. Stenoien, H. E. Lee. - № 10/809369; Заявлено 26.03.2004; Опубл. 04.07.2006. - 15 с. ↑

A1965. Пат. 7068215 США, МПК G01S13/44. Reducing antenna boresight error / D. L. Steinbauer. - № 10/961900; Заявлено 08.10.2004; Опубл. 27.06.2006. - 10 с.↑

A1966. Пат. 7068213 США, МПК G01S13/08, G01F23/00. Level meter / R. Muller, W. Maier, I. Getman, W. Lutke. - № 10/275280; Заявлено 08.05.2001; Опубл. 27.06.2006. - 15 с.↑

A1967. Пат. 7057550 США, МПК G01S7/40, G01S13/58. System and method for calibrating a vehicular traffic surveillance Doppler radar / J. L. Aker. - № 11/059474; Заявлено 16.02.2005; Опубл. 06.06.2006. - 15 с.↑

A1968. Пат. 7057548 США, МПК G01S13/88. Automatic data capture technology to enhance data collection / R. L. Roberts. - № 10/678702; Заявлено 03.10.2003; Опубл. 06.06.2006. - 10 с.↑

A1969. Пат. 7054729 США, МПК G01S13/00. Method for determining geometric data for vehicle parking processes / D. Maier, F. Gensler, H. Spannheimer, H. Graef, A. Pruckner и др. - № 11/120962; Заявлено 04.05.2005; Опубл. 30.05.2006. - 8 с.↑

A1970. Пат. 7053818 США, МПК G01S13/42, G01S13/30. Method for simple and multipurpose tracking / W. B. E. D. A. R. Ahmed. - № 10/248162; Заявлено 22.12.2002; Опубл. 30.05.2006. - 8 с.↑

A1971. Пат. 7053817 США, МПК G01S13/88, G01S13/00, G01S13/93. Target determination apparatus / M. Nakano, E. Kakishita. - № 10/854714; Заявлено 27.05.2004; Опубл. 30.05.2006. - 16 с.↑

A1972. Пат. 7053816 США, МПК G01S13/00. On-vehicle radar system / K. Kai. - № 10/837589; Заявлено 04.05.2004; Опубл. 30.05.2006. - 14 с.↑

A1973. Пат. 7053524 США, МПК G01S13/08, H04Q5/22. Surface acoustic wave sensor or identification device with biosensing capability / P. J. Edmonson, C. K. Campbell, W. D. Hunt. - № 11/139477; Заявлено 31.05.2005; Опубл. 30.05.2006. - 9 с.↑

A1974. Пат. 7049999 США, МПК G01S13/58. Modulation circuit for a vehicular traffic surveillance Doppler radar system / J. L. Aker. - № 11/059199; Заявлено 16.02.2005; Опубл. 23.05.2006. - 12 с.↑

A1975. Пат. 7049997 США, МПК G01S13/95. Simultaneous dual polarization radar system / J. L. Alford, J. R. Helvin. - № 10/984259; Заявлено 09.11.2004; Опубл. 23.05.2006. - 14 с.↑

A1976. Пат. 7046187 США, МПК G01S13/88, G01S13/00. System and method for active protection of a resource / L. W. Fullerton, M. D. Roberts, J. L. Richards. - № 10/991305; Заявлено 17.11.2004; Опубл. 16.05.2006. - 27 с.↑

A1977. Пат. 7046186 США, МПК G01S13/79, G01S13/75, G01S13/78. Friend/foe identification system for a battlefield / A. Rosenberg, A. Deutsch. - № 10/796855; Заявлено 09.03.2004; Опубл. 16.05.2006. - 19 с.↑

A1978. Пат. 7042389 США, МПК G01S13/93, G01S13/86. Device for detecting object in front of vehicle / N. Shirai. - № 11/100154; Заявлено 06.04.2005; Опубл. 09.05.2006. - 8 с.↑

A1979. Пат. 7042387 США, МПК G01S13/95. Systems and methods for displaying hazards / R. Ridenour, S. G. Scott. - № 10/774060; Заявлено 06.02.2004; Опубл. 09.05.2006. - 13 с.↑

A1980. Пат. 7042385 США, МПК G01S13/88. Non-intrusive inspection impulse radar antenna / G. Wichmann. - № 10/664047; Заявлено 16.09.2003; Опубл. 09.05.2006. - 12 с.↑

A1981. Пат. 7038614 США, МПК G01S13/93. Vehicular traffic surveillance Doppler radar system / J. L. Aker. - № 11/059476; Заявлено 16.02.2005; Опубл. 02.05.2006. - 19 с.↑

A1982. Пат. 7035651 США, МПК H04Q7/20, G01S13/00. Process and devices for determining the radio reception direction in a mobile communications network / M. Schreiner, M. Tangemann. - № 10/365409; Заявлено 13.02.2003; Опубл. 25.04.2006. - 11 с.↑

A1983. Пат. 7034746 США, МПК G01S13/89, G01S13/88. Holographic arrays for threat detection and human feature removal / D. L. McMakin, D. M. Sheen, T. E. Hall, W. M. Lechelt, R. H. Severtsen. - № 11/088555; Заявлено 24.03.2005; Опубл. 25.04.2006. - 13 с.↑

A1984. Пат. 7034742 США, МПК G01S13/93. Road curvature estimation and automotive target state estimation system / S. Cong, S. Shen, L. Hong. - № 10/620749; Заявлено 15.07.2003; Опубл. 25.04.2006. - 27 с.↑

A1985. Пат. 7034741 США, МПК G01S13/74, G01S13/06. Apparatus for detecting position information of a moving object / H.-D. Chon, J.-C. Seol. - № 10/656081; Заявлено 04.09.2003; Опубл. 25.04.2006. - 11 с.↑

A1986. Пат. 7034740 США, МПК G01S13/88, G01S13/00, G01S13/89. Method and apparatus for identifying buried objects using ground penetrating radar / A. Witten. - № 10/769965; Заявлено 02.02.2004; Опубл. 25.04.2006. - 26 с.↑

A1987. Пат. 7032858 США, МПК F41G7/00, G01S13/88, G06K9/00. Systems and methods for identifying targets among non-targets with a plurality of sensor vehicles / D. S. Williams. - № 10/919714; Заявлено 17.08.2004; Опубл. 25.04.2006. - 11 с.↑

A1988. Пат. 7026979 США, МПК G01S13/72. Method and apparatus for joint kinematic and feature tracking using probabilistic argumentation / D. Khosla. - № 10/742738; Заявлено 19.12.2003; Опубл. 11.04.2006. - 17 с. ↑

A1989. Пат. 7026978 США, МПК G01S13/00. Object detector and object detecting method / S. Okamura, T. Nishiguchi, H. Furukawa. - № 10/690499; Заявлено 23.10.2003; Опубл. 11.04.2006. - 19 с.↑

A1990. Пат. 7026977 США, МПК B60C23/00, B60T8/00, G01S13/00. Method of and apparatus for acquiring data of dynamic physical processes via a radio link / L. Reindl. - № 10/440402; Заявлено 19.05.2003; Опубл. 11.04.2006. - 9 с.↑

A1991. Пат. 7024308 США, МПК G01S13/78, G08B25/00. Telematic method for real-time routing to stolen vehicles / C. L. Oesterling, A. J. Sumcad, J. M. Stefan, E. B. Rennells. - № 10/740878; Заявлено 19.12.2003; Опубл. 04.04.2006. - 12 с.↑

A1992. Пат. 7023377 США, МПК G01S13/42. Noise modulated remote distance measurement / S. Axelsson. - № 10/473816; Заявлено 22.03.2002; Опубл. 04.04.2006. - 26 с.↑

A1993. Пат. 7019686 США, МПК G01S7/40, G01S13/28. RF channel calibration for non-linear FM waveforms / J. A. Hester, D. M. Gidner, G. M. Logan. - № 10/788932; Заявлено 27.02.2004; Опубл. 28.03.2006. - 10 с.↑

A1994. Пат. 7019685 США, МПК G01S13/00. Vehicle-onboard signal processing device and vehicle-onboard radar system / M. Suzuki, K. Takano, R. Fukute. - № 10/614180; Заявлено 08.07.2003; Опубл. 28.03.2006. - 15 с.↑

A1995. Пат. 7012561 США, МПК G01S13/18. Device and method for registering, detecting, and/or analyzing at least one object / T. Toennesen, M. Reiche. - № 10/978132; Заявлено 29.10.2004; Опубл. 14.03.2006. - 12 с.↑

A1996. Пат. 7012560 США, МПК G01S13/93. Object sensing apparatus / G. Braeuchle, M. Heinebrodt, J. Bocker. - № 10/491466; Заявлено 17.09.2002; Опубл. 14.03.2006. - 10 с.↑

A1997. Пат. 6999896 США, МПК G01S13/60. Identical object determination method and apparatus and displacement correction method and apparatus / Y. Takahashi. - № 10/609578; Заявлено 01.07.2003; Опубл. 14.02.2006. - 24 с.↑

A1998. Пат. 6999025 США, МПК G01S13/528. Clutter rejection in a passive radar receiver of OFDM signals with antenna array / D. Poullin. - № 10/469188; Заявлено 19.02.2002; Опубл. 14.02.2006. - 15 с.↑

A1999. Пат. 6999024 США, МПК G01S13/93. Method and apparatus for discriminating a target objective, and related program / H. Kumon, Y. Tamatsu. - № 10/730270; Заявлено 09.12.2003; Опубл. 14.02.2006. - 22 с.↑

A2000. Пат. 6999021 США, МПК G01V3/12, G01S13/89. Method and apparatus for detecting, mapping and locating underground utilities / D. W. A. Taylor, J.A. G. R. Bell, J. S. Rolland, M. W. McGarvey, W. H. A. McBride и др. - № 10/095110; Заявлено 12.03.2002; Опубл. 14.02.2006. - 15 с.↑

A2001. Пат. 6993425 США, МПК G01S13/00, G08G1/16. Automotive lane deviation avoidance system / S. Tange, G. Naito, S. Matsumoto, H. Yoshizawa. - № 10/375475; Заявлено 28.02.2003; Опубл. 31.01.2006. - 19 с. ↑

A2002. Пат. 6992616 США, МПК G01S13/89. Millimeter-wave active imaging system / T. W. Grudkowski, R. L. Rowe, R. R. Blasing, S. T. Trosper, T. W. Trawick и др. - № 10/728456; Заявлено 05.12.2003; Опубл. 31.01.2006. - 21 с.↑

A2003. Пат. 6992613 США, МПК G01S13/04, G01S13/08, G01S13/93. Object detecting device / K. Yoneda. - № 10/930903; Заявлено 01.09.2004; Опубл. 31.01.2006. - 19 с.↑

A2004. Пат. 6989782 США, МПК G01S7/28, G01S13/00. Ultra-wideband radar system using sub-band coded pulses / M. L. Walker, D. S. Furuno, N. K. Askar, G. D. Rogerson. - № 10/851635; Заявлено 21.05.2004; Опубл. 24.01.2006. - 41 с.↑

A2005. Пат. 6982668 США, МПК G01S13/524. Tangential velocity measurement using interferometric MTI radar / A. W. Doerry, B. P. Mileshosky, D. L. Bickel. - № 10/675328; Заявлено 30.09.2003; Опубл. 03.01.2006. - 15 с. ↑

A2006. Пат. 6982667 США, МПК G01S13/72. Method for target-tracking of objects / R. Artebrant, A. Tyrberg. - № 10/481788; Заявлено 19.06.2002; Опубл. 03.01.2006. - 8 с.↑

A2007. Пат. 6967993 США, МПК G01S13/02, G01S13/00, H04B1/69, H04L25/49, H04L27/00 и др. Ultrawide bandwidth system and method for fast synchronization using sub-code spins / T. R. Miller. - № 09/684401; Заявлено 10.10.2000; Опубл. 22.11.2005. - 33 с.↑

A2008. Пат. 6966493 США, МПК G01V15/00, H03H9/00, H03H9/64, G01S13/00, G01S13/75 и др. Surface acoustic wave identification tag having enhanced data content and methods of operation and manufacture thereof / C. S. Hartmann. - № 10/024624; Заявлено 18.12.2001; Опубл. 22.11.2005. - 25 с.↑

A2009. Пат. 6963289 США, МПК G01S13/00, G01S13/87, G01S5/06, G01S13/76, G08B005/22 и др. Wireless local area network (WLAN) channel radio-frequency identification (RFID) tag system and method therefor / D. Aljadeff, Y. Granot, S. Tsruya, R. Amsalem. - № 10/274698; Заявлено 18.10.2002; Опубл. 08.11.2005. - 8 с.↑

A2010. Пат. 6960986 США, МПК A61B5/00, G01S13/00, G01S13/82, A61B5/0205, A61B5/021 и др. Support system using data carrier system / H. Asama, D. Kurabayashi. - № 09/851986; Заявлено 10.05.2001; Опубл. 01.11.2005. - 9 с.↑

A2011. Пат. 6956523 США, МПК G01S13/00, G01S13/58, G01S7/02, G01S013/06, G01S013/32 и др. Method and apparatus for remotely deriving the velocity vector of an in-flight ballistic projectile / P. Mohan. - № 10/462525; Заявлено 16.06.2003; Опубл. 18.10.2005. - 10 с.↑

A2012. Пат. 6956521 США, МПК G01S13/34, G01S13/00, G01S13/58, G01S7/02, G01S7/35 и др. Radar device for detecting a distance and relative speed of an object / K. Kai. - № 10/408447; Заявлено 08.04.2003; Опубл. 18.10.2005. - 15 с.↑

A2013. Пат. 6954404 США, МПК G01S13/00, G01S13/87, G01S13/58, G01S003/80, G01S013/08. Method for determining position and velocity of targets from signals scattered by the targets / M. Herberthson. - № 10/476492; Заявлено 10.11.2003; Опубл. 11.10.2005. - 8 с.↑

A2014. Пат. 6954172 США, МПК G01S7/40, G01S13/93, G01S13/00, G01S007/40, G01S013/93 и др. Power monitor for radar system / P. Hofmann, R. Schneider. - № 10/382145; Заявлено 05.03.2003; Опубл. 11.10.2005. - 8 с.↑

A2015. Пат. 6950014 США, МПК B60R21/01, B60R19/20, B60R19/18, G01S11/12, G01S11/00 и др. Method for operating a pre-crash sensing system in a vehicle having external airbags / M. K. Rao, G. S. Strumoto, K. O. Prakah-Asante, S. D. Barbat, P. J. Schuster. - № 10/604801; Заявлено 18.08.2003; Опубл. 27.09.2005. - 11 с.↑

A2016. Пат. 6948194 США, МПК E03D13/00, E03D3/00, E03D5/00, E03D5/10, G01S13/00 и др. Stool flushing device / K. Todoroki, K. Shinohara, T. Koguro, Y. Furuta, M. Ikushima. - № 10/487748; Заявлено 07.02.2005; Опубл. 27.09.2005. - 43 с.↑

A2017. Пат. 6947841 США, МПК G01S13/93, G01S13/00, G01S13/87, G01S013/93, G06F017/10. Method for identifying obstacles for a motor vehicle, using at least three distance sensors for identifying the lateral extension of an object / U. Zimmermann, A. Pruksch. - № 10/467538; Заявлено 14.01.2004; Опубл. 20.09.2005. - 8 с.↑

A2018. Пат. 6947492 США, МПК G01S13/00, G01S13/87, H04L1/08, H04L1/16, H04B1/69 и др. Encoding and decoding ultra-wideband information / J. H. Santhoff, R. T. Arrieta. - № 09/802590; Заявлено 09.03.2001; Опубл. 20.09.2005. - 17 с.↑

A2019. Пат. 6946989 США, МПК G06K19/07, G01S13/00, G01S13/87, H04L12/56, H04B1/30 и др. Transponder, including transponder system / G. M. Vavik. - № 10/220747; Заявлено 06.11.2002; Опубл. 20.09.2005. - 28 с.↑

A2020. Пат. 6945346 США, МПК B60K31/00, G01S13/93, G01S13/00, G06K9/32, B60K031/00. Method for operating a driver support system for motor vehicles / J. Massen. - № 10/363932; Заявлено 07.03.2003; Опубл. 20.09.2005. - 11 с.↑

A2021. Пат. 6944544 США, МПК G01S13/93, G01S13/00, G01S013/93. Adaptive vehicle safety system for collision compatibility / K. O. Prakah-Asante, M. K. Rao. - № 10/711314; Заявлено 10.09.2004; Опубл. 13.09.2005. - 15 с.↑

A2022. Пат. 6944543 США, МПК B60R21/01, G08G1/16, G01S11/12, G01S11/00, G01S13/93 и др. Integrated collision prediction and safety systems control for improved vehicle safety / K. O. Prakah-Asante, M. K. Rao, G. S. Strumolo. - № 10/076405; Заявлено 15.02.2002; Опубл. 13.09.2005. - 11 с.↑

A2023. Пат. 6943727 США, МПК G01S13/93, G01S13/00, G01S13/58, G01S13/87, G01S7/02 и др. Length measurement with radar / M.-M. Meinecke, R. Mende, M. Behrens. - № 10/734819; Заявлено 12.12.2003; Опубл. 13.09.2005. - 11 с.↑

A2024. Пат. 6943726 США, МПК B60Q1/48, B60Q1/26, G01S13/93, G01S13/00, G01S7/02 и др. Device for searching a parking space / R. Schneider. - № 10/430034; Заявлено 06.05.2003; Опубл. 13.09.2005. - 5 с.↑

A2025. Пат. 6943723 США, МПК G01S13/00, G01S13/86, G01S7/02, G01S7/48, G01S5/14 и др. Combined radar and laser detector having GPS receiver and using wireless communication / D.-R. Kim, S.-W. Jung. - № 10/829184; Заявлено 22.04.2004; Опубл. 13.09.2005. - 8 с.↑

A2026. Пат. 6942248 США, МПК B60N2/00, B60N2/26, B60J10/00, B60N2/02, B60R1/08 и др. Occupant restraint device control system and method / D. S. Breed, W. E. DuVall, W. C. Johnson. - № 10/114533; Заявлено 02.04.2002; Опубл. 13.09.2005. - 75 с.↑

A2027. Пат. 6941225 США, МПК A01B79/00, A01C7/10, A01C7/08, G01S13/00, G01S13/60 и др. Method and apparatus for ultra precise GPS-based mapping of seeds or vegetation during planting / S. Upadhyaya, M. Ehsani, M. L. Mattson. - № 10/358088; Заявлено 03.02.2003; Опубл. 06.09.2005. - 15 с.↑

A2028. Пат. 6941216 США, МПК B60K31/00, G01S13/93, G01S13/00, B60K031/04, G06F007/00 и др. Cruise control apparatus performing automatic adjustment of object recognition processing in response to driver actions relating to vehicle speed alteration / A. Isogai, Y. Tamatsu, H. Kumon, E. Teramura. - № 10/384769; Заявлено 11.03.2003; Опубл. 06.09.2005. - 39 с.↑

A2029. Пат. 6941211 США, МПК B60K31/00, G01S13/34, G01S13/00, G01S13/86, G08G1/16 и др. Measurement controller for vehicle / H. Kuroda, H. Takenaga, H. Morizane, S. Izumi. - № 10/239151; Заявлено 20.09.2002; Опубл. 06.09.2005. - 17 с.↑

Method and apparatus for detecting position of object present in a surrounding detection zone of automotive vehicle / S. Watanabe, Y. Satoh, H. Takahashi. - № 09/973718; Заявлено 11.10.2001; Опубл. 07.12.2004. - 13 с.↑

A2141. Пат. 6825794 США, МПК G01S13/75, G01S13/00, H03H9/00, H03H9/64, G01S013/75. Wireless communication system using surface acoustic wave (SAW) second harmonic techniques / P. J. Edmonson, C. K. Campbell. - № 09/863944; Заявлено 23.05.2001; Опубл. 30.11.2004. - 18 с.↑

A2142. Пат. 6825793 США, МПК G01S13/88, G01S13/00, G01V3/12, G01S013/00, G01V003/10. System and method for detecting and locating underground objects / D. W. A. Taylor, J.A. G. R. Bell. - № 10/373095; Заявлено 26.02.2003; Опубл. 30.11.2004. - 9 с.↑

A2143. Пат. 6825757 США, МПК B60R1/12, G01S13/93, G01S13/00, G01S7/03, H01Q1/32 и др. Vehicle perimeter monitor / Y. Yamada. - № 09/844280; Заявлено 30.04.2001; Опубл. 30.11.2004. - 8 с.↑

A2144. Пат. 6825756 США, МПК G01S13/93, G01S13/00, B60Q001/00, G08G001/16, B62D001/24. Automotive radar system / J. Bai, H. Kuroda. - № 10/419793; Заявлено 22.04.2003; Опубл. 30.11.2004. - 20 с.↑

A2145. Пат. 6823284 США, МПК G01S13/82, G01S13/00, H04L12/28, G01S5/14, G04F001/00 и др. Geolocation subsystem / F. Gfeller, P. Chevillat, W. Schott. - № 10/408171; Заявлено 04.04.2003; Опубл. 23.11.2004. - 12 с.↑

A2146. Пат. 6822604 США, МПК G01S13/02, G01S13/04, G01S13/42, G01S13/00, G01S7/28 и др. System and method for detecting an intruder using impulse radio technology / D. J. Hall, S. M. Yano, H. G. Schantz. - № 10/632425; Заявлено 01.08.2003; Опубл. 23.11.2004. - 46 с.↑

A2147. Пат. 6821003 США, МПК G01S13/00, G01S13/86, G01S7/03, G01S13/93, F21V001/00. Vehicle lamp and vehicle illumination and data transmission system incorporating same / J. D.A. Baker, L. L.R. Kneisel, P. K. Zoratti, J. Attard, A. Z. Glovatsky. - № 10/197275; Заявлено 16.07.2002; Опубл. 23.11.2004. - 9 с.↑

A2148. Пат. 6820897 США, МПК B60N2/00, B60N2/26, B60N2/02, B60R1/08, B60N2/48 и др. Vehicle object detection system and method / D. S. Breed, W. E. DuVall, W. C. Johnson. - № 10/151615; Заявлено 20.05.2002; Опубл. 23.11.2004. - 56 с.↑

A2149. Пат. 6820031 США, МПК G01S13/84, G01S13/00, G01S7/40, G01D018/00, G01D021/00 и др. Method and device for distance detection / T. Hayakawa. - № 10/019270; Заявлено 03.01.2002; Опубл. 16.11.2004. - 13 с.↑

A2150. Пат. 6819991 США, МПК B60R21/01, G01S13/93, G01S13/00, B60R021/32, G06F019/00 и др. Vehicle sensing based pre-crash threat assessment system / M. K. Rao, K. O. Prakah-Asante, M. A. Masrur. - № 09/995504; Заявлено 29.11.2001; Опубл. 16.11.2004. - 10 с.↑

A2151. Пат. 6819284 США, МПК B60Q1/48, B60Q1/26, G01S13/93, G01S13/00, H01Q1/32 и др. System for assisting the parking of motor vehicles in parking spaces / D. Maier, F. Gensler. - № 10/229179; Заявлено 28.08.2002; Опубл. 16.11.2004. - 5 с.↑

A2152. Пат. 6819283 США, МПК G01S13/93, G01S13/00, G01S7/02, G01S7/41, G01S7/40 и др. Vehicle control apparatus / F. Okai, H. Kuroda. - № 10/083473; Заявлено 27.02.2002; Опубл. 16.11.2004. - 16 с.↑

A2153. Пат. 6819222 США, МПК G01S13/74, G01S13/00, G06Q10/00, G06K7/10, G06K7/08 и др. Inventory control system using R.F. object identification / F.-J. Lin, S. Zhu. - № 09/506509; Заявлено 17.02.2000; Опубл. 16.11.2004. - 10 с.↑

A2154. Пат. 6816109 США, МПК G01S13/524, G01S13/72, G01S13/00, G01S7/295, G01S013/52 и др. Method for automatic association of moving target indications from entities traveling along known route / S. A. Schwartz. - № 10/633825; Заявлено 04.08.2003; Опубл. 09.11.2004. - 11 с.↑

A2155. Пат. 6816106 США, МПК G01S13/78, G01S13/00, G01S013/78. Identification and location system for personnel and vehicles / W. Butler. - № 10/430167; Заявлено 06.05.2003; Опубл. 09.11.2004. - 11 с.↑

A2156. Пат. 6816105 США, МПК G01S13/78, G01S13/87, G01S13/00, G01S13/91, G01S13/72 и др. Vehicle surveillance system / K. Winner, B. Khen. - № 10/275934; Заявлено 08.11.2002; Опубл. 09.11.2004. - 15 с.↑

A2157. Пат. 6816084 США, МПК B60K31/00, G01S13/93, G01S13/00, G08G1/16, G01S13/87 и др. Process and device for detecting and monitoring a number of preceding vehicles / F. Stein. - № 09/788856; Заявлено 20.02.2001; Опубл. 09.11.2004. - 8 с.↑

A2158. Пат. 6813562 США, МПК G01S13/93, G01S13/00, G08G1/16, G06F017/10. Threat assessment algorithm for forward collision warning / O. D. Altan, R. C. Colgin. - № 10/272532; Заявлено 15.10.2002; Опубл. 02.11.2004. - 10 с.↑

A2159. Пат. 6812883 США, МПК G01S13/93, G01S13/34, G01S13/00, G01S7/02, G01S7/41 и др. In-vehicle radar system / H. Kumon, Y. Tamatsu. - № 10/747221; Заявлено 30.12.2003; Опубл. 02.11.2004. - 15 с.↑

A2160. Пат. 6812882 США, МПК G01S13/93, G01S13/34, G01S13/536, G01S13/00, G01S013/93. Stationary on-road object detection method for use with radar / D. Ono. - № 10/276832; Заявлено 19.11.2002; Опубл. 02.11.2004. - 17 с.↑

A2161. Пат. 6809682 США, МПК G01S13/24, G01S13/524, G01S13/526, G01S13/53, G01S13/00 и др. Method and device for the detection and track of targets in high clutter / J. M. Madewell. - № 10/346157; Заявлено 16.01.2003; Опубл. 26.10.2004. - 14 с.↑

A2162. Пат. 6809681 США, МПК G01S13/58, G01S13/00, G01S013/00, G01S013/58. Random-modulation radar signal-induced interference cancellation method and apparatus / A. Niechayev. - № 07/934398; Заявлено 25.08.1992; Опубл. 26.10.2004. - 19 с.↑

A2163. Пат. 6809680 США, МПК G01S13/87, G01S13/93, G01S13/42, G01S13/00, G01S013/93. Obstacle detecting apparatus of vehicle / M. Tojima. - № 10/277188; Заявлено 22.10.2002; Опубл. 26.10.2004. - 15 с.↑

A2164. Пат. 6806826 США, МПК G01S13/87, G01S13/32, G01S13/00, G01S7/02, G01S7/35 и др. Vehicle obstacle warning radar / E. K. Walton, C.-C. Chen. - № 10/294507; Заявлено 14.11.2002; Опубл. 19.10.2004. - 13 с.↑

A2165. Пат. 6806821 США, МПК G01S13/02, G01S13/04, G01S13/00, G01S7/02, G01S7/41 и др. Apparatus and method for rapid detection of objects with time domain impulsive signals / D. P. McLemore. - № 10/385629; Заявлено 12.03.2003; Опубл. 19.10.2004. - 11 с.↑

A2166. Пат. 6805216 США, МПК B60K31/00, G08G1/16, G01S13/72, G01S13/93, G01S13/00 и др. Method for regulating the distance between a vehicle and another vehicle traveling ahead and a distance-regulating system / G. Noecker. - № 10/324086; Заявлено 20.12.2002; Опубл. 19.10.2004. - 8 с.↑

A2167. Пат. 6803878 США, МПК G01S13/00, G01S13/86, G01S5/14, G01S7/292, G01S7/40 и др. Methods and apparatus for terrain correlation / J. R. Hager, J. B. Oven, J. I. Formo. - № 10/144877; Заявлено 13.05.2002; Опубл. 12.10.2004. - 15 с.↑

A2168. Пат. 6803876 США, МПК G01S7/02, G01S13/22, G01S13/00, G01S7/41, G01S13/524 и др. Irregular PRT deconvolution method and systems, and its uses / R. Erkocevic-Pribic. - № 10/453892; Заявлено 04.06.2003; Опубл. 12.10.2004. - 9 с.↑

A2169. Пат. 6803875 США, МПК G01S13/00, G01S7/02, G01S13/95, G01S7/03, G01S013/00. Simulatneous dual polarization radar system / J. L. Alford, J. R. Helvin. - № 10/393732; Заявлено 21.03.2003; Опубл. 12.10.2004. - 12 с.↑

A2170. Пат. 6801843 США, МПК B60R21/01, G08G1/16, G01S13/93, G01S13/00, G06F007/00 и др. Vehicle pre-crash sensing based conic target threat assessment system / M. K. Rao, K. O. Prakah-Asante, G. S. Strumolo. - № 10/155627; Заявлено 24.05.2002; Опубл. 05.10.2004. - 11 с.↑

A2171. Пат. 6801138 США, МПК G01S11/00, G01S11/04, G01S5/04, G01S5/00, G08G1/16 и др. Positional data utilizing inter-vehicle communication method and traveling control apparatus / S. Koike. - № 10/198934; Заявлено 22.07.2002; Опубл. 05.10.2004. - 49 с.↑

A2172. Пат. 6799138 США, МПК G01S13/72, G01S13/00, G01P015/00, F41G007/00. Breaklock detection system and method / N. J. Lawrence, T. K. Lo, J. A. Whorf, M. S. Moellenhoff. - № 10/135158; Заявлено 30.04.2002; Опубл. 28.09.2004. - 9 с.↑

A2173. Пат. 6798374 США, МПК G01S13/87, G01S13/92, G01S13/58, G01S13/536, G01S13/00 и др. Traffic surveillance radar using ranging for accurate target identification / K. J. Smith. - № 10/288010; Заявлено 05.11.2002; Опубл. 28.09.2004. - 32 с.↑

A2174. Пат. 6795491 США, МПК G01S13/87, G01S13/00, G01S5/00, H04B1/707, G01S11/00 и др. Spread spectrum localizers / R. A. Fleming, C. E. Kushner. - № 09/734118; Заявлено 11.12.2000; Опубл. 21.09.2004. - 76 с.↑

A2194. Пат. 6778127 США, МПК F41H11/12, G01V3/30, F41H11/00, G01V3/18, G01V3/12 и др. Drillstring radar / L. G. Stolarczyk, G. L. Stolarczyk. - № 10/287041; Заявлено 04.11.2002; Опубл. 17.08.2004. - 17 с.↑

A2195. Пат. 6775617 США, МПК G01S7/02, G01S13/00, G01S13/89, G01S7/41, G01S013/89 и др. Method for determining hydrographic parameters which describe a sea swell field in situ using a radar device / J. Seemann, C. M. Senet, F. Ziemer. - № 10/348607; Заявлено 21.01.2003; Опубл. 10.08.2004. - 18 с.↑

A2196. Пат. 6775616 США, МПК G01S13/87, G01S15/00, G01S13/75, G01S15/87, G01S13/00 и др. Environmental location system / P. A. Nysen. - № 10/646140; Заявлено 20.08.2003; Опубл. 10.08.2004. - 22 с.↑

A2197. Пат. 6775605 США, МПК B60R21/01, G01S13/93, G01S13/00, B60R022/00, G05D001/00 и др. Remote sensing based pre-crash threat assessment system / M. K. Rao, K. O. Prakah-Asante, M. A. Masrur. - № 09/995503; Заявлено 29.11.2001; Опубл. 10.08.2004. - 9 с.↑

A2198. Пат. 6775520 США, МПК H04B1/707, H04B7/01, G01S13/90, G01S13/00, H04B015/00 и др. Synthetic-aperture communications receivers / N. Subotic, C. Roussi, J. Burns. - № 10/348736; Заявлено 22.01.2003; Опубл. 10.08.2004. - 7 с.↑

A2199. Пат. 6774846 США, МПК G01S13/76, G01S13/42, G01S13/00, G01S001/24. System and method for position determination by impulse radio / L. W. Fullerton, J. L. Richards, I. A. Cowie. - № 10/441078; Заявлено 20.05.2003; Опубл. 10.08.2004. - 26 с.↑

A2200. Пат. 6774837 США, МПК G01S13/00, G01S13/89, G01S13/86, G01S7/35, G01S13/02 и др. Ocean surface current mapping with bistatic HF radar / D. E. Barrick, P. M. Lilleboe, B. J. Lipa, J. Isaacson. - № 10/694154; Заявлено 27.10.2003; Опубл. 10.08.2004. - 17 с.↑

A2201. Пат. 6774817 США, МПК G01S13/82, G01S13/00, G05D1/02, G08G1/0962, G08G1/0967 и др. Reflection multiplier radio wave marker system and traffic system / Y. Tanji, S. Handa. - № 10/156966; Заявлено 29.05.2002; Опубл. 10.08.2004. - 11 с.↑

A2202. Пат. 6771972 США, МПК G01S13/74, G01S13/00, H04Q007/20, C12Q001/64, G06F007/00. System and method for a distributed search for a lost asset / J. T. E. McDonnell, J. D. Waters, S. E. Crouch. - № 09/821302; Заявлено 29.03.2001; Опубл. 03.08.2004. - 8 с.↑

A2203. Пат. 6771207 США, МПК G01S13/00, G01S7/40, G01S13/95, G01S013/00. Establishing radar coverage, blockage, and clutter region maps for radar product data based on terrain elevation data / J. C. Lang. - № 10/606341; Заявлено 25.06.2003; Опубл. 03.08.2004. - 35 с.↑

A2204. Пат. 6771206 США, МПК G01S3/14, G01V9/00, G01V9/02, G01S7/02, G01V3/12 и др. Method for obtaining underground imagery using a ground-penetrating radar / J.-J. Berthelier, R. Ney, A. Meyer. - № 10/168351; Заявлено 04.02.2003; Опубл. 03.08.2004. - 10 с.↑

A2205. Пат. 6768446 США, МПК G01S7/02, G01S13/93, G01S13/00, G01S7/41, G01S013/93. Vehicle-mounted radar apparatus providing improved accuracy of detection of lateral position of preceding vehicle / Y. Tamatsu, H. Kumon, A. Isogai. - № 10/443796; Заявлено 23.05.2003; Опубл. 27.07.2004. - 40 с.↑

A2206. Пат. 6766141 США, МПК G01S13/75, G01S13/00, H01Q3/46, H01Q3/26, H01Q3/00 и др. Remote down-hole well telemetry / S. D. Briles, D. L. Neagley, D. M. Coates, S. M. Freund. - № 10/187025; Заявлено 28.06.2002; Опубл. 20.07.2004. - 22 с.↑

A2207. Пат. 6765525 США, МПК G01S13/524, G01S13/00, G01S7/292, G01S013/52. Method for reducing false alarm rate in radar images / B. Bickert, J. Meyer-Hilberg. - № 10/370111; Заявлено 21.02.2003; Опубл. 20.07.2004. - 16 с.↑

A2208. Пат. 6765523 США, МПК G01S7/02, G01S13/93, G01S13/00, G01S7/41, G01S13/34 и др. Stationary object detection method for use with scanning radar / D. Ono. - № 10/182086; Заявлено 24.07.2002; Опубл. 20.07.2004. - 13 с.↑

A2209. Пат. 6765491 США, МПК G01S15/00, G01S15/93, G01S7/52, G01S13/93, G01S13/00 и др. Distance detecting device / T. Nass. - № 09/579103; Заявлено 25.05.2000; Опубл. 20.07.2004. - 7 с.↑

A2210. Пат. 6763904 США, МПК B60K31/00, B60K31/04, B60K31/02, G01S13/93, G01S13/72 и др. Method for adjusting the speed of a motor vehicle / H. Winner, J. Lueder. - № 10/018149; Заявлено 04.04.2002; Опубл. 20.07.2004. - 11 с.↑

A2211. Пат. 6763318 США, МПК G01S13/93, G01S13/00, B60K31/00, G01S7/40, G01S7/497 и др. Distance sensor with a compensation device for an angle misalignment on a vehicle / K. Winter, H. Winner, R. Marchthaler, J. Lueder, S. Leinbaum. - № 09/869507; Заявлено 02.11.2001; Опубл. 13.07.2004. - 7 с.↑

A2212. Пат. 6760591 США, МПК G01S13/87, G01S13/00, G01S5/22, G01S5/06, G01S5/00 и др. Method and apparatus for determining a position of a transmitter in three dimensions / J. Klinger. - № 09/577053; Заявлено 22.05.2000; Опубл. 06.07.2004. - 7 с.↑

A2213. Пат. 6759976 США, МПК G01F23/284, G01S7/02, G01S13/10, G01S13/00, G01S13/88 и др. Method and apparatus for radar-based level gauging / K. O. Edvardsson. - № 10/327426; Заявлено 20.12.2002; Опубл. 06.07.2004. - 11 с.↑

A2214. Пат. 6756940 США, МПК G01S13/87, G01S13/00, G01S15/00, G01S15/87, G01S001/24. Remote terminal location algorithm / J. Oh, W.-C. Peng. - № 10/023216; Заявлено 18.12.2001; Опубл. 29.06.2004. - 16 с. ↑

A2215. Пат. 6756935 США, МПК G01S13/524, G01S7/02, G01S13/00, G01S7/41, G01S013/00 и др. Full polarization ground moving target indicator radar automatic target detection algorithm / W. L. Cameron, M. A. Curry. - № 10/356224; Заявлено 31.01.2003; Опубл. 29.06.2004. - 14 с.↑

A2216. Пат. 6756880 США, МПК G01S13/75, G01S13/00, G06K7/00, H04Q005/22. Reader and response control system for discrimination between multiple surface acoustic wave identification tags and method of operation thereof / C. S. Hartmann. - № 10/103684; Заявлено 21.03.2002; Опубл. 29.06.2004. - 10 с.↑

A2217. Пат. 6755273 США, МПК B60N2/00, B60N2/02, B60N2/26, B60R21/01, B60R22/32 и др. Combined airbag inflation and occupant displacement enabling method and apparatus / D. S. Breed. - № 10/097082; Заявлено 13.03.2002; Опубл. 29.06.2004. - 48 с.↑

A2218. Пат. 6753804 США, МПК G01S13/93, G01S13/72, G01S13/00, B60K31/00, G01S013/93. Target vehicle identification based on the theoretical relationship between the azimuth angle and relative velocity / S. Miyahara. - № 10/153026; Заявлено 21.05.2002; Опубл. 22.06.2004. - 20 с.↑

A2219. Пат. 6751547 США, МПК G01C21/26, G01S7/02, G01S13/00, G01S13/86, G01S7/41 и др. Method and apparatus for estimation of forward path geometry of a vehicle based on a two-clothoid road model / D. Khosla. - № 09/994515; Заявлено 26.11.2001; Опубл. 15.06.2004. - 11 с.↑

A2220. Пат. 6750810 США, МПК G01S13/44, G01S13/00, G01S13/93, G01S3/14, G01S3/46 и др. Monopulse radar system / H. Shinoda, H. Kondoh. - № 10/385617; Заявлено 12.03.2003; Опубл. 15.06.2004. - 19 с.↑

A2221. Пат. 6750657 США, МПК G01F23/284, G01S13/88, G01S13/00, H01Q1/22, H01Q13/00 и др. Combination of a feedthrough element for an electric high-frequency signal and a probe, and a level meter metering device including a combination of this type / K. Griessbaum, J. Fehrenbach, J. Motzer. - № 09/989089; Заявлено 19.11.2001; Опубл. 15.06.2004. - 19 с.↑

A2222. Пат. 6749218 США, МПК B60N2/00, B60N2/02, B60N2/26, B60R21/01, B60R22/32 и др. Externally deployed airbag system / D. S. Breed. - № 10/097086; Заявлено 13.03.2002; Опубл. 15.06.2004. - 47 с.↑

A2223. Пат. 6748312 США, МПК B60K31/00, B60Q1/50, B60Q1/26, B60Q1/52, G01S13/87 и др. Safe distance algorithm for adaptive cruise control / M. E. Russell, M. J. Delcheccolo, W. G. Woodington, H. B. V. Rees, J. M. Firda и др. - № 09/931630; Заявлено 16.08.2001; Опубл. 08.06.2004. - 10 с.↑

A2224. Пат. 6747592 США, МПК G01S13/34, G01S13/58, G01S13/00, G01S007/34. Radar system for detecting relative velocity and relative speed of a preceding vehicle / K. Nakamura. - № 10/436176; Заявлено 13.05.2003; Опубл. 08.06.2004. - 14 с.↑

A2225. Пат. 6745110 США, МПК G01S7/02, G01S13/93, G01S13/00, G01S7/41, G01S013/93. Motor vehicle trajectory measurement / M. J. Richardson, P. A. Barber, N. J. Clarke, E. G. Hoare. - № 10/203129; Заявлено 05.11.2002; Опубл. 01.06.2004. - 8 с.↑

A2226. Пат. 6744399 США, МПК G01S7/40, H01Q1/12, H01Q1/32, G01S13/93, G01S13/00 и др. Radar apparatus in which the direction of the antenna is recognizable from outside / Y. Tohyama, R. Katsuoka, T. Ishii. - № 10/374823; Заявлено 25.02.2003; Опубл. 01.06.2004. - 24 с.↑

A2227. Пат. 6744398 США, МПК G01S13/87, G01S13/82, G01S13/00, G01S013/78. Distancing and positioning systems and methods / D. J. Pyner, R. A. Fretenburg, S. S. J. Kazemir. - № 10/420641; Заявлено 21.04.2003; Опубл. 01.06.2004. - 21 с.↑

A2228. Пат. 6744397 США, МПК G01C21/00, G01S13/94, G01S13/06, G01S13/00, G01S13/89 и др. Systems and methods for target location / J. R. Hager, L. D. Almsted, T. Jicha. - № 10/458950; Заявлено 11.06.2003; Опубл. 01.06.2004. - 9 с.↑

A2229. Пат. 6744379 США, МПК G01S13/92, G01S13/58, G01S13/00, G01S7/04, G01S7/26 и др. System and method for displaying radar data / J. L. Aker, A. B. Mead, R. S. Gammenthaler, R. V. Vanman. - № 09/931269; Заявлено 16.08.2001; Опубл. 01.06.2004. - 20 с.↑

A2230. Пат. 6744364 США, МПК G07C9/00, G01S13/76, G01S13/00, G08B001/08. Distance sensitive remote control systems / D. L. Wathen. - № 10/052358; Заявлено 25.10.2001; Опубл. 01.06.2004. - 8 с.↑

A2231. Пат. 6744353 США, МПК G01S13/93, G01S15/00, G01S13/00, G01S17/93, G01S17/00 и др. Blind spot detector / G. Sjonell. - № 10/149573; Заявлено 18.09.2002; Опубл. 01.06.2004. - 10 с.↑

A2232. Пат. 6741209 США, МПК G01S13/76, G01S13/84, G01S13/00, G01S5/02, G01S5/00 и др. Positioning system / N. C. Lee. - № 10/266940; Заявлено 09.10.2002; Опубл. 25.05.2004. - 8 с.↑

A2233. Пат. 6741204 США, МПК G01S7/02, G01S13/93, G01S13/34, G01S13/00, G01S7/35 и др. Signal process apparatus for an on-vehicle radar and method thereof / H. Kumon, Y. Tamatsu. - № 10/391198; Заявлено 19.03.2003; Опубл. 25.05.2004. - 20 с.↑

A2234. Пат. 6741178 США, МПК G01S13/76, G01S13/75, G01S13/00, G06K19/077, G06K19/07 и др. Electrically powered postage stamp or mailing or shipping label operative with radio frequency (RF) communication / J. R. Tuttle. - № 09/481807; Заявлено 11.01.2000; Опубл. 25.05.2004. - 11 с.↑

A2235. Пат. 6738563 США, МПК G01S13/524, G01S13/00, G01S7/40, G01S7/292, G01S13/94 и др. Methods and apparatus for weighting radar return data / J. R. Hager, L. Jordan, T. W. Heidemann. - № 10/459201; Заявлено 11.06.2003; Опубл. 18.05.2004. - 35 с.↑

A2236. Пат. 6738011 США, МПК G01S13/00, G01S7/18, G01C23/00, G01C21/00, G01S7/04 и др. Ground elimination technique in vertical profile radar displays / J. B. Evans. - № 10/439880; Заявлено 16.05.2003; Опубл. 18.05.2004. - 12 с.↑

A2237. Пат. 6735524 США, МПК G01C21/10, G01C21/16, G01S13/87, G01S13/00, G01S5/02 и др. Spatially resolved and spatially aware antenna for radio navigation / A. D. Challoner, J. M. Bornholdt. - № 10/315872; Заявлено 10.12.2002; Опубл. 11.05.2004. - 14 с.↑

A2238. Пат. 6735506 США, МПК B60N2/00, B60N2/02, B60N2/26, B60R22/18, B60R21/01 и др. Telematics system / D. S. Breed, W. E. DuVall, W. C. Johnson. - № 10/174709; Заявлено 19.06.2002; Опубл. 11.05.2004. - 35 с.↑

A2239. Пат. 6735238 США, МПК G01S13/02, G01S13/00, H04B1/69, H04L25/49, H04L27/00 и др. Ultra wideband communication system, method, and device with low noise pulse formation / J. W. McCorkle. - № 09/684400; Заявлено 10.10.2000; Опубл. 11.05.2004. - 31 с.↑

A2240. Пат. 6734819 США, МПК G01S13/00, G01F23/284, G01S13/88, G01S13/10, G01S7/288 и др. Level measuring device operating with microwaves / D. Spanke. - № 10/067312; Заявлено 07.02.2002; Опубл. 11.05.2004. - 13 с.↑

A2241. Пат. 6734807 США, МПК G01S13/00, G01S7/02, G01S13/93, G08G001/16. Polarametric blind spot detector with steerable beam / J. D. King. - № 09/283035; Заявлено 01.04.1999; Опубл. 11.05.2004. - 6 с.↑

A2242. Пат. 6731908 США, МПК G01S13/00, G01S13/84, H04B1/69, H04B1/713, H04B017/00. Distance measurement using half-duplex RF techniques / S. Berliner, U. Holzkaner, E. Mirodin. - № 09/759602; Заявлено 16.01.2001; Опубл. 04.05.2004. - 23 с.↑

A2783. Пат. 6084503 США, МПК G01S13/00, G01S13/75, H04Q005/22. Radio-interrogated surface-wave technology sensor / W. Ruile, G. Scholl, T. Ostertag, L. Reindl, V. Magori. - № 08/945294; Заявлено 17.10.1997; Опубл. 04.07.2000. - 7 с.↑

A2784. Пат. 6081223 США, МПК G01S13/00, G01S13/93, G01S013/93. Vehicle on which millimeter wave radar is mounted / Y. Kitahara, T. Murakami, K. Yamasaki. - № 09/308024; Заявлено 11.05.1999; Опубл. 27.06.2000. - 20 с.↑

A2785. Пат. 6081221 США, МПК G01S13/95, G01S13/00, G01S13/22, G01S013/95. Signal processing and systematic phase coding for mitigation of range and velocity ambiguities in Doppler weather radars / D. S. Zrnic, M. Sachidananda. - № 09/140739; Заявлено 27.08.1998; Опубл. 27.06.2000. - 22 с.↑

A2786. Пат. 6081220 США, МПК G01S13/95, G01S13/00, G01S7/02, G01S13/58, G01S013/95. Radar system for observing weather phenomena with improved radar system parameters / T. Fujisaka, T. Wakayama, R. Usui. - № 09/023212; Заявлено 13.02.1998; Опубл. 27.06.2000. - 11 с.↑

A2787. Пат. 6081187 США, МПК G01S13/00, G01S13/87, G01S13/93, G05D1/02, B60Q001/00. Vehicle position detection system / E. Akutsu. - № 08/919109; Заявлено 28.08.1997; Опубл. 27.06.2000. - 16 с.↑

A2788. Пат. 6078791 США, МПК G01S13/00, G01S13/75, G01S13/76, G06K19/077, H01Q9/28 и др. Radio frequency identification transceiver and antenna / J. R. Tuttle, R. C. Lake. - № 08/908134; Заявлено 06.08.1997; Опубл. 20.06.2000. - 19 с.↑

A2789. Пат. 6078280 США, МПК G01F23/284, G01S13/00, G01S13/02, G01S13/88, G01S7/40 и др. Periodic probe mapping / K. L. Perdue, W. P. McCarthy, D. D. Cummings, G. Wartmann. - № 09/219787; Заявлено 23.12.1998; Опубл. 20.06.2000. - 30 с.↑

A2790. Пат. 6076622 США, МПК B60K31/00, F16H61/70, G01S13/00, G01S13/93, B60K031/00. System and method for intelligent cruise control using standard engine control modes / S. Chakraborty, W. J. Mack. - № 09/064278; Заявлено 22.04.1998; Опубл. 20.06.2000. - 18 с.↑

A2791. Пат. 6075492 США, МПК H01Q17/00, H01Q15/00, H01Q1/32, H01Q19/00, H01Q15/02 и др. Microwave antenna array for a motor vehicle radar system / E. Schmidt, K. Voigtlaender, J. Zeiher, B. Lucas, T. Beez и др. - № 09/155829; Заявлено 24.03.1999; Опубл. 13.06.2000. - 6 с.↑

A2792. Пат. 6075479 США, МПК G01S13/00, G01S13/93, G01S7/02, G01S7/41, G01S7/292 и др. Radar apparatus installed on vehicle for producing correct detecting result / H. Kudoh. - № 09/250376; Заявлено 16.02.1999; Опубл. 13.06.2000. - 14 с.↑

A2793. Пат. 6073078 США, МПК G01S13/00, G01S13/93, G01S7/03, G01S7/02, G06F015/50. Vehicle with millimeter-wave radar / Y. Kitahara, K. Yamasaki, T. Murakami. - № 09/101977; Заявлено 30.07.1998; Опубл. 06.06.2000. - 11 с.↑

A2794. Пат. 6072425 США, МПК G01S13/00, G01S15/60, G01S13/60, G01S15/00, G01S13/88 и др. Terrain bias compensator for doppler navigation systems / R. W. Vopat. - № 09/251891; Заявлено 19.02.1999; Опубл. 06.06.2000. - 11 с.↑

A2795. Пат. 6072424 США, МПК G01S13/00, G01S13/60, G01S13/34, G01S13/93, G01S013/60. Method for measuring the ground speed of a vehicle by means of radar using reflection of electromagnetic waves from the driving surface / P. Cremona, M. Kunert. - № 09/077724; Заявлено 05.06.1998; Опубл. 06.06.2000. - 4 с.↑

A2796. Пат. 6072421 США, МПК G01S13/00, G01S13/87, G01S17/00, G01S17/87, G08G1/017 и др. Moving object high-accuracy position locating method and system / T. Fukae, N. Tamiya, T. Tani, T. Ishigami, H. Sato. - № 09/086570; Заявлено 29.05.1998; Опубл. 06.06.2000. - 19 с.↑

A2797. Пат. 6072391 США, МПК B60K35/00, B60R1/00, B60Q1/50, B60R1/12, B60Q1/52 и др. Information indicator for vehicle / A. Suzuki, M. Tamaki, O. Yamanaka, T. Iwasa, H. Ito. - № 08/662860; Заявлено 12.06.1996; Опубл. 06.06.2000. - 76 с.↑

A2798. Пат. 6072173 США, МПК B60K31/00, B60Q1/50, B60Q1/52, G01S13/00, G01S13/93 и др. Animal body detecting system utilizing electromagnetic waves / K. Soshi, T. Nakane. - № 09/081616; Заявлено 20.05.1998; Опубл. 06.06.2000. - 16 с.↑

A2799. Пат. 6070461 США, МПК G01S13/86, G01S13/00, G01S13/95, G01F013/00. System for detection and measurement of atmospheric movement / D. T. Gjessing, J. Hjelmstad, A. Tonning. - № 08/945012; Заявлено 16.10.1997; Опубл. 06.06.2000. - 10 с.↑

A2800. Пат. 6069581 США, МПК G01S13/00, G01S13/18, G01S13/93, H01Q3/24, H01Q1/32 и др. High performance vehicle radar system / D. A. Bell, J. M. K. Li, K. C. Lee, R. R. Taur. - № 09/027996; Заявлено 23.02.1998; Опубл. 30.05.2000. - 32 с.↑

A2801. Пат. 6067673 США, МПК E03D5/00, E03D5/10, E03C1/05, G01S13/00, G01S13/02 и др. Bathroom fixture using radar detector having leaky transmission line to control fluid flow / A. J. Paese, S. M. Tervo, C. J. Thomas, W. R. Burnett, D. C. Shafer и др. - № 09/118255; Заявлено 17.07.1998; Опубл. 30.05.2000. - 18 с.↑

A2802. Пат. 6067039 США, МПК G01S13/00, G01S13/79, G01S013/08, G01B007/14. Systems and methods for determining the distance between two locations / D. J. Pyner, R. A. Fretenburg, S. S. J. Kazemir. - № 09/201592; Заявлено 30.11.1998; Опубл. 23.05.2000. - 26 с.↑

A2803. Пат. 6067038 США, МПК G01S13/00, G01S13/58, G01S13/34, G01S13/93, G01S13/42 и др. Vehicle-mounted radar apparatus / N. Uehara, M. Watanabe. - № 09/017162; Заявлено 02.02.1998; Опубл. 23.05.2000. - 14 с.↑

A2804. Пат. 6067031 США, МПК G01S13/00, G01S15/93, G01S15/00, G01S13/93, G01S5/00 и др. Dynamic monitoring of vehicle separation / J. M. Janky, D. S. Smith, J. F. Schipper. - № 08/993693; Заявлено 18.12.1997; Опубл. 23.05.2000. - 20 с.↑

A2805. Пат. 6064330 США, МПК G01S13/00, G01S13/60, G01S13/87, G01S13/86, G01S13/93 и др. Fog piercing ranging apparatus and method / S. Elliott, E. A. Miller, J. G. Dunne. - № 09/072565; Заявлено 05.05.1998; Опубл. 16.05.2000. - 10 с.↑

A2806. Пат. 6064320 США, МПК G08G1/017, G07B15/00, G01S13/00, G01S13/76, G08G001/01. Automatic vehicle identification system capable of vehicle lane discrimination / L. d'Hont, A. Tip. - № 09/054952; Заявлено 03.04.1998; Опубл. 16.05.2000. - 10 с.↑

A2807. Пат. 6061015 США, МПК B60K31/00, B60T7/22, G01S13/00, G01S13/93, G01S17/93 и др. Vehicle obstacle detecting system / Y. Sugimoto. - № 09/225569; Заявлено 05.01.1999; Опубл. 09.05.2000. - 17 с.↑

A2808. Пат. 6061014 США, МПК G01S13/00, G01S13/86, G01S13/56, G01S13/42, G01S13/04 и др. Surveillance method for wide areas / J. Rautanen, J. Korja. - № 09/101211; Заявлено 02.07.1998; Опубл. 09.05.2000. - 5 с.↑

A2809. Пат. 6061013 США, МПК G01S13/95, G01S7/02, G01S13/00, G01S013/95. Method for determining the precipitation ratio by double polarization radar and meteorological radar for implementing such process / H. Sauvageot, D. Beguin, R. Devinne. - № 09/091828; Заявлено 26.06.1998; Опубл. 09.05.2000. - 9 с.↑

A2810. Пат. 6057797 США, МПК G01S7/03, G01S13/00, G01S13/93, G01S7/02, G01S007/521 и др. Radar sensor for use in motor vehicles / K.-P. Wagner. - № 09/194956; Заявлено 07.12.1998; Опубл. 02.05.2000. - 4 с. ↑

A2811. Пат. 6055287 США, МПК G01S13/00, G01S13/18, G01S13/28, H03K5/15, H03L7/081 и др. Phase-comparator-less delay locked loop / T. E. McEwan. - № 09/084541; Заявлено 26.05.1998; Опубл. 25.04.2000. - 8 с.↑

A2812. Пат. 6055042 США, МПК G01S13/00, G01S13/93, G01S15/93, G01S15/00, G01S17/93 и др. Method and apparatus for detecting obstacles using multiple sensors for range selective detection / J. Sarangapani. - № 08/991495; Заявлено 16.12.1997; Опубл. 25.04.2000. - 11 с.↑

A2813. Пат. 6052080 США, МПК G01S13/00, G01S13/34, G01S7/02, G01S7/35, G01S7/40 и др. Rangefinder / V. Magori. - № 09/029911; Заявлено 09.03.1998; Опубл. 18.04.2000. - 7 с.↑

A2814. Пат. 6052079 США, МПК G01S13/00, G01S13/34, G01S13/93, G01S7/02, G01S7/41 и др. Vehicle with millimeter-wave radar / Y. Kitahara, K. Yamasaki, T. Murakami. - № 09/117522; Заявлено 30.07.1998; Опубл. 18.04.2000. - 8 с.↑

A2815. Пат. 6045652 США, МПК G01S13/00, G01S13/75, G01S13/82, G01S13/76, G06K19/073 и др. Method of manufacturing an enclosed transceiver / M. E. Tuttle, J. R. Tuttle, R. C. Lake. - № 09/115492; Заявлено 14.07.1998; Опубл. 04.04.2000. - 23 с.↑

A2816. Пат. 6043774 США, МПК B61K9/00, B61K9/12, G01S13/00, G01S13/36, G01S13/92 и др. Near-range proximity sensor having a fast-tracking analog / D. R. Singh, W. A. Witt. - № 09/047642; Заявлено 25.03.1998; Опубл. 28.03.2000. - 18 с.↑

A2817. Пат. 6043773 США, МПК G01S13/00, G01S13/93, G01S013/93. Vehicle-mounted radar apparatus / M. Watanabe. - № 09/008545; Заявлено 16.01.1998; Опубл. 28.03.2000. - 11 с.↑

A2818. Пат. 6040797 США, МПК G01S13/00, G01S13/524, G01S7/292, G01S013/534. Method for detecting a radar target / F.-X. Hofele. - № 09/297515; Заявлено 20.07.1999; Опубл. 21.03.2000. - 6 с.↑

A2819. Пат. 6040795 США, МПК G01S13/00, G01S13/93, G01S13/44, G01S013/93. Vehicle-mounted radar apparatus / M. Watanabe. - № 09/008546; Заявлено 16.01.1998; Опубл. 21.03.2000. - 15 с.↑

A2820. Пат. 6040774 США, МПК G01S13/00, G01S13/74, G06K7/00, G08B013/14. Locating system and method employing radio frequency tags / J. L. Schepps. - № 09/085410; Заявлено 27.05.1998; Опубл. 21.03.2000. - 10 с.↑

A2821. Пат. 6038502 США, МПК G01S13/00, G01S13/93, G05D1/02, G08G1/16, G06F015/00. Apparatus and method for fleet control when unmanned and manned vehicles travel together / T. Sudo. - № 09/125488; Заявлено 19.08.1998; Опубл. 14.03.2000. - 14 с.↑

A2822. Пат. 6037895 США, МПК G01S7/03, G01S7/28, G01S7/282, G01S13/00, G01S13/93 и др. Vehicle mounted radar apparatus / N. Uehara. - № 09/248259; Заявлено 11.02.1999; Опубл. 14.03.2000. - 29 с.↑

A2823. Пат. 6037860 США, МПК G01S13/00, G01S13/93, G01S13/89, G01S13/86, G01S17/93 и др. Method and arrangement for avoiding and/or minimizing vehicle collisions in road traffic / A. Zander, U. Wiesner. - № 09/156931; Заявлено 18.09.1998; Опубл. 14.03.2000. - 5 с.↑

A2824. Пат. 6035057 США, МПК G01S7/02, G06K9/32, G01S7/41, G01S7/12, G06K9/62 и др. Hierarchical data matrix pattern recognition and identification system / E. H. Hoffman. - № 08/814473; Заявлено 10.03.1997; Опубл. 07.03.2000. - 43 с.↑

A2825. Пат. 6035053 США, МПК G01S13/00, G01S13/42, G01S13/93, G01S7/02, G01S7/41 и др. Moving subject recognizing system for automotive vehicle / T. Yoshioka, T. Adachi. - № 08/940639; Заявлено 30.09.1997; Опубл. 07.03.2000. - 22 с.↑

A2826. Пат. 6034642 США, МПК G01S13/00, G01S13/93, H01Q3/20, H01Q3/00, G01S7/02 и др. Antenna apparatus / J. Kojima, K.-I.-C. Tohya, N. Yamamoto. - № 08/961518; Заявлено 30.10.1997; Опубл. 07.03.2000. - 13 с.↑

A2999. Пат. 5796362 США, МПК G01S13/82, G01S13/34, G01S13/00, G01S13/78, G01S13/32 и др. Post launch on-board identification friend or foe system / Y. Ayasli, P. Katzin. - № 08/258966; Заявлено 13.06.1994; Опубл. 18.08.1998. - 10 с. ↑

A3000. Пат. 5793309 США, МПК B60Q1/52, B60Q1/26, B60Q1/50, B60Q1/48, G01S13/00 и др. Short range electromagnetic proximity detection / G. F. Nellson. - № 08/702411; Заявлено 14.08.1996; Опубл. 11.08.1998. - 10 с. ↑

A3001. Пат. 5786787 США, МПК G01S13/68, G01S13/93, G01S13/66, G01S13/00, G01S13/58 и др. Method for determining the course of another vehicle / L. Eriksson, B.-E. Tullsson. - № 08/750588; Заявлено 06.12.1996; Опубл. 28.07.1998. - 7 с. ↑

A3002. Пат. 5786772 США, МПК B60R21/01, B60R1/12, G01S13/93, G01S13/00, B60R25/10 и др. Vehicle blind spot detection display system / K. Schofield, N. R. Lynam. - № 08/799734; Заявлено 12.02.1997; Опубл. 28.07.1998. - 11 с. ↑

A3003. Пат. 5781147 США, МПК G01S13/60, G01S13/86, G01S13/93, G01S13/87, G01S13/00 и др. Fog piercing ranging apparatus and method / S. Elliott, E. A. Miller, J. G. Dunne. - № 08/853609; Заявлено 09.05.1997; Опубл. 14.07.1998. - 9 с. ↑

A3004. Пат. 5781146 США, МПК G01S13/95, G01S7/22, G01S13/00, G01S13/94, G01S7/04 и др. Automatic horizontal and vertical scanning radar with terrain display / P. R. Frederick. - № 08/613017; Заявлено 11.03.1996; Опубл. 14.07.1998. - 17 с. ↑

A3005. Пат. 5779839 США, МПК G01S13/76, G01S13/75, G01S13/00, G06K19/07, G06K19/073 и др. Method of manufacturing an enclosed transceiver / M. E. Tuttle, J. R. Tuttle, R. C. Lake. - № 08/947681; Заявлено 26.09.1997; Опубл. 14.07.1998. - 23 с. ↑

A3006. Пат. 5777580 США, МПК G01S13/82, G01S13/87, G01S1/04, G01S13/00, G01S1/00 и др. Vehicle location system / J. M. Janky, D. G. Bird. - № 08/396977; Заявлено 01.03.1995; Опубл. 07.07.1998. - 16 с. ↑

A3007. Пат. 5777575 США, МПК G01S13/00, G01S13/92, G01S013/58. Radar switching system / M. E. Shelton, T. E. Mitchell. - № 08/731057; Заявлено 09.10.1996; Опубл. 07.07.1998. - 11 с. ↑

A3008. Пат. 5777563 США, МПК B60Q1/26, B60Q1/48, G01S13/93, G01S13/00, G01S13/87 и др. Method and assembly for object detection by a vehicle / E. P. Minissale, T. Fry, W. J. Hull, I.I.I. - № 08/541548; Заявлено 10.10.1995; Опубл. 07.07.1998. - 10 с. ↑

A3009. Пат. 5777451 США, МПК B61L23/34, B61L23/00, G01S5/00, G05D1/02, G08G1/16 и др. Vehicle longitudinal spacing controller / M. Kobayashi, T. Kawabe. - № 08/719676; Заявлено 25.09.1996; Опубл. 07.07.1998. - 29 с. ↑

A3010. Пат. 5776278 США, МПК G01S13/76, G01S13/75, G01S13/00, G06K19/07, G06K19/077 и др. Method of manufacturing an enclosed transceiver / M. E. Tuttle, J. R. Tuttle, R. C. Lake. - № 08/781107; Заявлено 09.01.1997; Опубл. 07.07.1998. - 24 с. ↑

A3011. Пат. 5774876 США, МПК G01S13/76, G01S13/74, G01S13/00, G01S5/02, G01S7/00 и др. Managing assets with active electronic tags / L. A. Woolley, C. F. Ferrara, I. Greasley, J. H. Weimar. - № 08/671491; Заявлено 26.06.1996; Опубл. 30.06.1998. - 97 с. ↑

A3012. Пат. 5774091 США, МПК G01C3/08, G01F23/284, G01S17/00, G01S13/02, G01S17/10 и др. Short range micro-power impulse radar with high resolution swept range gate with damped transmit and receive cavities / T. E. McEwan. - № 08/451876; Заявлено 26.05.1995; Опубл. 30.06.1998. - 20 с. ↑

A3013. Пат. 5774045 США, МПК B61L29/00, G01S13/00, G01S13/04, H01Q3/00, H01Q3/46 и др. Arrangement for detecting objects in a region to be monitored / H. Helma, B. Lubbe. - № 08/776461; Заявлено 19.05.1997; Опубл. 30.06.1998. - 7 с.↑

A3014. Пат. 5771020 США, МПК G01S11/06, G01R29/08, G01S11/00, H05F3/00, G01S5/06 и др. Lightning locating system / R. J. Markson, L. H. Ruhnke. - № 08/687751; Заявлено 25.07.1996; Опубл. 23.06.1998. - 24 с. ↑

A3015. Пат. 5771007 США, МПК B60K31/00, G01S13/93, G01S13/00, G08G001/16. Auto-cruise system for vehicle / T. Arai, Y. Fujita. - № 08/755469; Заявлено 22.11.1996; Опубл. 23.06.1998. - 9 с.↑

A3016. Пат. 5770944 США, МПК G01V3/12, G01S13/88, G01S13/00, G01R019/00, G01V003/08 и др. Method and probe arrangement for the electromagnetic detection of metal objects / K. Ebinger, A. Gunnewig. - № 08/645792; Заявлено 14.05.1996; Опубл. 23.06.1998. - 5 с.↑

A3017. Пат. 5768131 США, МПК G01S13/93, G01S13/34, G01S13/00, G01S13/28, G01S13/72 и др. Computerised radar process for measuring distances and relative speeds between a vehicle and obstacles located in front of it / E. Lissel, H. Rohling, W. Plagge. - № 08/492079; Заявлено 10.10.1995; Опубл. 16.06.1998. - 14 с. ↑

A3018. Пат. 5767794 США, МПК G01P1/10, G01P1/12, G01P1/00, G01S17/88, G01S17/00 и др. traffic surveillance process and device / M. Borsch, R. Pfaff. - № 08/578547; Заявлено 24.01.1996; Опубл. 16.06.1998. - 4 с.↑

A3019. Пат. 5767793 США, МПК G01S13/93, G01S7/03, G01S13/00, H01Q25/00, H01Q21/20 и др. Compact vehicle based rear and side obstacle detection system including multiple antennae / H. H. Agravante, B. I. Hauss, P. J. Moffa. - № 08/426376; Заявлено 21.04.1995; Опубл. 16.06.1998. - 10 с.↑

A3020. Пат. 5767679 США, МПК G01V3/12, H01Q1/04, H01Q7/06, G01S13/02, H01Q7/00 и др. Geophysical prospecting apparatus utilizing pulsed electromagnetic signals and having a scanned four-cycle transmitter / D.-A. Schroder. - № 08/726418; Заявлено 07.10.1996; Опубл. 16.06.1998. - 10 с.↑

A3021. Пат. 5767409 США, МПК G01N22/00, G01S17/00, G01S13/36, G01N22/04, G01S13/00 и др. Phase difference measuring apparatus and method using a first and second receive signal / S. Yamaguchi. - № 08/753683; Заявлено 27.11.1996; Опубл. 16.06.1998. - 19 с.↑

A3022. Пат. 5766208 США, МПК A61B5/08, A61B5/024, A61B5/053, A61B8/08, G01S13/58 и др. Body monitoring and imaging apparatus and method / T. E. McEwan. - № 08/747131; Заявлено 12.11.1996; Опубл. 16.06.1998. - 24 с.↑

A3023. Пат. 5764162 США, МПК B61L1/16, B61L1/00, G01S13/00, G01S13/04, G01S13/88 и др. Micropower impulse radar based wheel detector / K. P. Ehrlich. - № 08/643224; Заявлено 02.05.1996; Опубл. 09.06.1998. - 13 с.↑

A3024. Пат. 5764161 США, МПК G01B11/16, G01L11/02, G01L1/24, G01S13/08, G01D5/243 и др. Sensing apparatus using frequency changes / J. A. Schier. - № 08/698813; Заявлено 16.08.1996; Опубл. 09.06.1998. - 10 с.↑

A3025. Пат. 5762160 США, МПК B62D5/04, B62D15/02, B62D15/00, G01S13/93, G01S13/00 и др. Power steering device / Y. Shimizu. - № 08/625851; Заявлено 04.04.1996; Опубл. 09.06.1998. - 16 с.↑

A3026. Пат. 5761629 США, МПК B60K31/00, G01S13/93, G01S13/00, G06F165/00. Method and apparatus for cruise control / S. P. Gilling. - № 08/567984; Заявлено 11.12.1995; Опубл. 02.06.1998. - 11 с.↑

A3027. Пат. 5760733 США, МПК G01S13/84, G01S13/00, G01S13/93, G01S7/288, G01S7/285 и др. Apparatus for avoiding crosstalk problems when locating a vehicle travelling along means for propagating electromagnetic waves / D. Fournier. - № 08/668701; Заявлено 24.06.1996; Опубл. 02.06.1998. - 11 с.↑

A3028. Пат. 5760731 США, МПК G01S13/88, G01S13/56, G01S13/00, G01S7/03, G01S013/00. Sensors and methods for sensing displacement using radar / D. W. Holmes. - № 08/574617; Заявлено 19.12.1995; Опубл. 02.06.1998. - 13 с.↑

A3029. Пат. 5760708 США, МПК B60Q1/52, B60Q1/50, G01S17/00, G01S17/93, G01S13/93 и др. Signaling means / N. Seith. - № 07/809015; Заявлено 17.12.1991; Опубл. 02.06.1998. - 7 с.↑

A3030. Пат. 5758298 США, МПК G01S15/93, G01S15/00, G05D1/02, G01S13/93, G01S13/00 и др. Autonomous navigation system for a mobile robot or manipulator / J. Guldner. - № 08/404552; Заявлено 15.03.1995; Опубл. 26.05.1998. - 21 с.↑

A3031. Пат. 5757320 США, МПК G01C3/08, G01F23/284, G01S17/00, G01S13/02, G01S17/10 и др. Short range, ultra-wideband radar with high resolution swept range gate / T. E. McEwan. - № 08/769033; Заявлено 17.12.1996; Опубл. 26.05.1998. - 18 с.↑

A3032. Пат. 5754123 США, МПК B60Q1/26, B60Q1/48, G01S15/93, G01S15/00, G01S15/02 и др. Hybrid ultrasonic and radar based backup aid / P. J. Nashif, R. H. Benedict, S. J. Tracy. - № 08/643714; Заявлено 06.05.1996; Опубл. 19.05.1998. - 7 с.↑

A3033. Пат. 5754099 США, МПК B60T7/22, G01S17/00, G01S17/93, G01S13/93, G01S13/00 и др. Obstacle warning system for a vehicle / T. Nishimura, K. Hibino, N. Shirai. - № 08/410638; Заявлено 24.03.1995; Опубл. 19.05.1998. - 41 с.↑

A3034. Пат. 5752214 США, МПК B60K31/00, B60T13/66, B60T7/12, G01S13/93, G01S13/00 и др. Method and apparatus for controller power train of motor vehicle / T. Minowa, H. Kuroda, S. Kuragaki, K. Kurata, T. Ochi. - № 08/654971; Заявлено 28.05.1996; Опубл. 12.05.1998. - 21 с.↑

A3035. Пат. 5751973 США, МПК G01S13/76, G01S13/00, G07C5/00, G06Q30/00, G07B15/02 и др. Electronic parking and dispatching management method and apparatus / J. J. Hassett. - № 07/945523; Заявлено 16.09.1992; Опубл. 12.05.1998. - 14 с.↑

A3036. Пат. 5751241 США, МПК G01S13/60, G01S13/00, G01S13/34, G01S13/88, G01S013/60. Method and apparatus for measuring the speed of a moving body / J. Lewiner, E. Carreel. - № 08/765285; Заявлено 10.03.1997; Опубл. 12.05.1998. - 10 с.↑

A3037. Пат. 5751240 США, МПК G01S13/536, G01S13/87, G01S13/00, G01S13/34, G01S7/288 и др. FMCW radar system for detecting distance, relative velocity and azimuth of a target obstacle / A. Fujita, H. Hazumi, H. Mizuno, H. Nakatani, H. Naganawa. - № 08/764627; Заявлено 11.12.1996; Опубл. 12.05.1998. - 19 с.↑

A3038. Пат. 5751211 США, МПК B60K28/10, G01S17/00, G01S17/93, G01S13/93, G01S13/00 и др. Obstacle warning system for a vehicle / N. Shirai, K. Hibino, T. Nishimura. - № 08/777196; Заявлено 27.12.1996; Опубл. 12.05.1998. - 28 с.↑

A3039. Пат. 5749426 США, МПК B60K31/00, G01S13/93, G01S13/00, B60K031/00. Apparatus and method for cruise control / S. P. Gilling. - № 08/571302; Заявлено 12.12.1995; Опубл. 12.05.1998. - 8 с.↑

A3040. Пат. 5748891 США, МПК G01S13/87, G01S1/04, G01S13/00, G01S1/00, G01S5/00 и др. Spread spectrum localizers / R. A. Fleming, C. E. Kushner. - № 08/279329; Заявлено 22.07.1994; Опубл. 05.05.1998. - 75 с.↑

A3041. Пат. 5748477 США, МПК B60T7/22, G01S17/00, G01S17/93, G01S13/93, G01S13/00 и др. Vehicle collision control system / S. Katoh. - № 08/574553; Заявлено 19.12.1995; Опубл. 05.05.1998. - 11 с.↑

A3042. Пат. 5748473 США, МПК B60R16/02, B60N2/00, B60N2/02, B60R22/20, B60R22/18 и др. Automatic vehicle seat adjuster / D. S. Breed, W. E. DuVall. - № 08/474784; Заявлено 07.06.1995; Опубл. 05.05.1998. - 20 с.↑

A3043. Пат. 5748141 США, МПК G01S13/00, G01S13/93, G01S13/34, G01S7/35, G01S7/02 и др. Radar device with reduced power emission / A. Hoess. - № 08/694104; Заявлено 08.08.1996; Опубл. 05.05.1998. - 9 с. ↑

A3044. Пат. 5748139 США, МПК G01S13/00, G01S13/76, G01S013/76. Radar transponder / Y. Kawakami, T. Dochi. - № 08/647800; Заявлено 15.05.1996; Опубл. 05.05.1998. - 17 с.↑

System for determining and registering location of mobile terminal for communication system with non-geosynchronous satellites / N. Araki, H. Shinonaga, Y. Itoh. - № 08/282309; Заявлено 29.07.1994; Опубл. 06.08.1996. - 10 с.↑

A3219. Пат. 5539412 США, МПК G01S13/00, G01R23/16, G01S13/524, G01S7/288, G01S7/285 и др. Radar system with adaptive clutter suppression / H. B. Mendelson. - № 08/235391; Заявлено 29.04.1994; Опубл. 23.07.1996. - 39 с.↑

A3220. Пат. 5539410 США, МПК F42C13/00, F42C13/04, G01S13/00, G01S13/50, G01S13/24 и др. Pulse doppler proximity sensor / J. E. Zveglich. - № 07/844334; Заявлено 02.03.1992; Опубл. 23.07.1996. - 8 с.↑

A3221. Пат. 5537511 США, МПК G01S13/00, G01S13/72, G01S5/00, G01S15/00, G01S15/66 и др. Neural network based data fusion system for source localization / C. M. DeAngelis, R. W. Green. - № 08/324641; Заявлено 18.10.1994; Опубл. 16.07.1996. - 10 с.↑

A3222. Пат. 5537119 США, МПК G01S13/00, G01S13/72, G01S013/00. Method and system for tracking multiple regional objects by multi-dimensional relaxation / A. B. Poore, J. - № 08/404024; Заявлено 14.03.1995; Опубл. 16.07.1996. - 32 с.↑

A3223. Пат. 5537118 США, МПК G01S13/00, G01S13/86, G01S13/72, G01S013/66. Method for tracking moving objects / A. Appriou. - № 08/412200; Заявлено 28.03.1995; Опубл. 16.07.1996. - 15 с.↑

A3224. Пат. 5534871 США, МПК G01S13/00, G01S13/60, G01S13/32, G01S13/44, G01S13/58 и др. Apparatus for measuring physical quantity related to relative movement between two objects / K. Hidaka, Y. Suzuki. - № 08/232529; Заявлено 25.04.1994; Опубл. 09.07.1996. - 14 с.↑

A3225. Пат. 5534870 США, МПК G01S13/00, G01S13/93, G01S13/48, G08G001/16. Anticollision device, notably for motor vehicles / B. Avignon, C. Barre, Y. Canal. - № 08/355550; Заявлено 14.12.1994; Опубл. 09.07.1996. - 14 с.↑

A3226. Пат. 5532701 США, МПК G01S13/00, G01S13/78, G01S7/40, G01S001/04. Arrangement for comparing two temporally separated bursts of signal at two different frequencies / D. Biella. - № 08/065591; Заявлено 21.05.1993; Опубл. 02.07.1996. - 6 с.↑

A3227. Пат. 5532697 США, МПК G01S13/00, G01S13/60, G01S13/58, G01S7/02, G01S13/06 и др. Non-contact speed measuring apparatus for railroad vehicle / K. Hidaka, S. Uehara. - № 08/478821; Заявлено 07.06.1995; Опубл. 02.07.1996. - 15 с.↑

A3228. Пат. 5530448 США, МПК G01S13/528, G01S13/30, G01S13/00, G01S13/28, G01S13/10 и др. Three-pulse MTI without blind speeds / B. L. Lewis. - № 06/559062; Заявлено 05.12.1983; Опубл. 25.06.1996. - 9 с.↑

A3229. Пат. 5530447 США, МПК G01S13/00, G01S13/93, G01S7/288, G01S7/285, G01S013/52. Blind-zone target discrimination method and system for road vehicle radar / M. F. Henderson, J. C. Reed, P. A. May, Z. Zhang. - № 08/372259; Заявлено 13.01.1995; Опубл. 25.06.1996. - 14 с.↑

A3230. Пат. 5529139 США, МПК B60K31/00, G01S13/00, G01S13/93, G01S17/00, G01S17/93 и др. Vehicle speed control system / A. Kurahashi, K. Hibino, M. Shimamoto, M. Hashimoto. - № 08/204572; Заявлено 02.03.1994; Опубл. 25.06.1996. - 33 с.↑

A3231. Пат. 5528246 США, МПК G01S13/00, G01S7/02, G01S13/92, G01S7/41, G01S13/536 и др. Traffic radar with digital signal processing / R. L. Henderson, J. M. Kusek, D. R. Bradrick. - № 08/268621; Заявлено 30.06.1994; Опубл. 18.06.1996. - 42 с.↑

A3232. Пат. 5528245 США, МПК G01S13/00, G01S7/00, G01S7/03, G01S13/92, G01S7/02 и др. Police traffic radar using double balanced mixer for even order harmonic suppression / J. L. Aker, R. S. Gammenthaler, A. B. Mead. - № 08/386551; Заявлено 10.02.1995; Опубл. 18.06.1996. - 71 с.↑

A3233. Пат. 5528217 США, МПК B60Q1/50, B60Q1/52, G01S15/10, G01S15/93, G01S15/00 и др. Collision avoidance system for vehicles using digital logic circuitry and retro-fitting techniques / C. Adams. - № 08/423042; Заявлено 17.04.1995; Опубл. 18.06.1996. - 14 с.↑

A3234. Пат. 5526357 США, МПК G01S13/00, G01S13/87, G01S5/02, G01S5/00, G08G1/127 и др. Communication system and method for determining the location of a transponder unit / L. H. M. Jandrell. - № 08/276480; Заявлено 18.07.1994; Опубл. 11.06.1996. - 103 с.↑

A3235. Пат. 5525996 США, МПК G01S13/528, G01S13/00, G01S13/58, G01S13/92, G01S7/00 и др. Police traffic radar for calculating and simultaneously displaying fastest target speed / J. L. Aker, R. S. Gammenthaler, A. B. Mead. - № 08/386545; Заявлено 10.02.1995; Опубл. 11.06.1996. - 71 с.↑

A3236. Пат. 5525994 США, МПК G01S13/00, G01S13/76, G01S013/76. Transponder interface circuit / D. S. Hurta, G. Froschermeier. - № 08/483608; Заявлено 07.06.1995; Опубл. 11.06.1996. - 27 с.↑

A3237. Пат. 5525992 США, МПК G01S13/00, G01S13/76, G08G1/017, G01S13/74, G01S013/75. Method and system for conserving power in a recognition system / G. Froschermeier. - № 08/339091; Заявлено 14.11.1994; Опубл. 11.06.1996. - 28 с.↑

A3238. Пат. 5525991 США, МПК G01S13/00, G01S13/75, G01S13/76, G08G1/017, G07B15/00 и др. Mobile object identification system / M. Nagura, M. Matsumoto, T. Ando, M. Yamashita, T. Katoh и др. - № 08/204179; Заявлено 24.02.1994; Опубл. 11.06.1996. - 42 с.↑

A3239. Пат. 5523760 США, МПК G01F23/284, G01S13/02, G01S13/00, G01S13/18, G01S13/04 и др. Ultra-wideband receiver / T. E. McEwan. - № 08/301924; Заявлено 06.09.1994; Опубл. 04.06.1996. - 17 с.↑

A3240. Пат. 5521600 США, МПК G01S13/56, G01S13/02, G01S13/00, G01S13/18, G01S13/34 и др. Range-gated field disturbance sensor with range-sensitivity compensation / T. E. McEwan. - № 08/300769; Заявлено 06.09.1994; Опубл. 28.05.1996. - 13 с.↑

A3241. Пат. 5521579 США, МПК B60K31/00, B60Q1/50, B60Q1/52, G01S13/93, G01S13/00 и др. Method for providing guiding assistance for a vehicle in changing lane / W. Bernhard. - № 08/233761; Заявлено 26.04.1994; Опубл. 28.05.1996. - 10 с.↑

A3242. Пат. 5519381 США, МПК A47F9/00, A47F9/04, G01S13/75, G01S13/00, G01S13/24 и др. Detection of multiple articles / M. J. C. Marsh, A. Lenarcik, C. A. V. Zyl, A. C. V. Schalkwyk, M. J. R. Oosthuizen. - № 08/154329; Заявлено 18.11.1993; Опубл. 21.05.1996. - 17 с.↑

A3243. Пат. 5519377 США, МПК B60Q1/48, B60Q1/26, G01S13/93, G01S13/00, B60Q001/00. Vehicle obstacle monitoring system / S. L. Murphy. - № 08/115581; Заявлено 03.09.1993; Опубл. 21.05.1996. - 9 с.↑

A3244. Пат. 5517429 США, МПК G01S13/00, G01S13/04, G08B25/14, G01S17/02, G01S17/00 и др. Intelligent area monitoring system / D. C. Harrison. - № 07/880754; Заявлено 08.05.1992; Опубл. 14.05.1996. - 13 с.↑

A3245. Пат. 5517196 США, МПК G01S13/93, G01S13/52, G01S13/00, G01S13/58, G01S13/34 и др. Smart blind spot sensor with object ranging / A. G. Pakett, J. R. Asbury. - № 08/267424; Заявлено 28.06.1994; Опубл. 14.05.1996. - 27 с.↑

A3246. Пат. 5517193 США, МПК G01S13/95, G01W1/00, G01W1/02, G01S13/00, G01S7/00 и др. Meteorological workstation / C. L. Allison, D. T. Cookson. - № 08/056198; Заявлено 30.04.1993; Опубл. 14.05.1996. - 15 с.↑

A3247. Пат. 5515287 США, МПК G01S7/22, G01S13/93, G01S13/00, G01S7/24, G01S7/04 и др. Navigation display apparatus for collison avoidance utilizing polygonal safety regions and predicted danger areas / T. Hakoyama, Y. Kato, S. Maeda, H. Yamaguchi, O. Yagi. - № 08/397794; Заявлено 03.03.1995; Опубл. 07.05.1996. - 25 с.↑

A3248. Пат. 5515055 США, МПК G01S15/00, G01S15/58, G01S13/58, G01S13/00, G01S013/53. System for processing returns from a target from transmissions containing repeated signals to detect the doppler velocity of the target / D. P. Hollinger. - № 08/415820; Заявлено 03.04.1995; Опубл. 07.05.1996. - 7 с.↑

A3249. Пат. 5512901 США, МПК G01S13/93, G01S7/03, G01S13/34, G01S13/00, H01Q1/32 и др. Built-in radiation structure for a millimeter wave radar sensor / C.-H. H. Chen, H.-S. E. Tsou. - № 08/117266; Заявлено 07.09.1993; Опубл. 30.04.1996. - 17 с.↑

A3250. Пат. 5510990 США, МПК B60K31/00, G01S13/93, G01S17/00, G01S17/93, G01S13/00 и др. System for distinguishing a vehicle traveling ahead based on an adjustable probability distribution / K. Hibino, A. Kurahashi, M. Hashimoto. - № 08/162276; Заявлено 07.12.1993; Опубл. 23.04.1996. - 24 с.↑

A3251. Пат. 5510796 США, МПК G01S13/524, G01S13/00, H01Q3/26, G01S7/28, G01S013/534. Apparatus for wind shear compensation in an MTI radar system / S. P. Applebaum. - № 06/687922; Заявлено 31.12.1984; Опубл. 23.04.1996. - 19 с.↑

A3252. Пат. 5510795 США, МПК G01S13/82, G01S13/00, G01S013/58. Single antenna location and direction finding system / A. R. Koelle. - № 08/338008; Заявлено 10.11.1994; Опубл. 23.04.1996. - 10 с.↑

A3253. Пат. 5510794 США, МПК G01S13/53, G01S13/93, G01S13/56, G01S13/70, G01S13/52 и др. Vehicular radar wayside transponder system / J. R. Asbury, J. W. Davis. - № 08/185135; Заявлено 21.01.1994; Опубл. 23.04.1996. - 31 с.↑

A3254. Пат. 5510793 США, МПК G01S13/60, G01S13/00, G01S13/86, G01S7/02, G01S007/40 и др. Combined radar detector, speed measuring device and printer for verifying vehicle speed / E. S. Gregg, I.I.I.J. A. Mittler. - № 08/413834; Заявлено 30.03.1995; Опубл. 23.04.1996. - 6 с.↑

A3255. Пат. 5508705 США, МПК G01S13/78, G01S13/92, G01S13/00, G08G1/017, G07B15/00 и др. Vehicle identification classification and communication system / N. E. Spiess. - № 08/179521; Заявлено 10.01.1994; Опубл. 16.04.1996. - 9 с.↑

A3256. Пат. 5506864 США, МПК G01S13/82, G01S13/00, G01S5/14, G01S5/00, H04B7/204 и др. CDMA communications and geolocation system and method / D. L. Schilling. - № 08/311773; Заявлено 23.09.1994; Опубл. 09.04.1996. - 19 с.↑

A3257. Пат. 5506585 США, МПК G01S13/62, G01S13/00, G01S13/93, G01S7/02, G01S7/35 и др. Continuous wave radar effective for preventing collision of mobile object / H. Shiratori. - № 08/272261; Заявлено 08.07.1994; Опубл. 09.04.1996. - 13 с.↑

A3258. Пат. 5506584 США, МПК G01S13/00, G01S13/76, G01S13/87, G01S13/32, G01S13/58 и др. Radar sensor/processor for intelligent vehicle highway systems / S. Boles. - № 08/388877; Заявлено 15.02.1995; Опубл. 09.04.1996. - 10 с.↑

A3259. Пат. 5504488 США, МПК G01S13/00, G01S7/02, G01S13/92, G01S7/41, G01S13/536 и др. Traffic radar with digital signal processing / R. L. Henderson, J. M. Kusek, D. R. Bradrick. - № 08/321536; Заявлено 11.10.1994; Опубл. 02.04.1996. - 42 с.↑

A3260. Пат. 5504482 США, МПК G01S13/00, G01C21/26, G01S13/93, G08G1/0969, G08G001/123. Automobile navigation guidance, control and safety system / K. D. Schreder. - № 08/076502; Заявлено 11.06.1993; Опубл. 02.04.1996. - 11 с.↑

A3261. Пат. 5502449 США, МПК G01S1/00, G01S13/00, G01S1/02, G01S1/70, G01S1/68 и др. Ground unit for the detection, identification, and direction determination of a marker beacon / F. F. Hiltz, C. E. Wilson. - № 08/216560; Заявлено 23.03.1994; Опубл. 26.03.1996. - 37 с.↑

A3262. Пат. 5502444 США, МПК G01S7/32, G01S7/292, G01S7/285, G01V3/15, G01V3/17 и др. Method and apparatus for improving the signal-to-clutter ratio of an airborne earth penetrating radar / I. Kohlberg. - № 08/311674; Заявлено 23.09.1994; Опубл. 26.03.1996. - 11 с.↑

A3263. Пат. 5502432 США, МПК G01S13/00, G01S13/93, B60Q001/00. Apparatus and method of warning rear-end collision / Y. Ohmamyuda, S. Kimura, T. Tanabe, K. Iwasaki, T. Seto и др. - № 07/988675; Заявлено 10.12.1992; Опубл. 26.03.1996. - 7 с.↑

A3264. Пат. 5500649 США, МПК E21C35/00, E21C35/24, E21C41/00, E21C41/16, G01S13/00 и др. Method and apparatus for monitoring the thickness of a coal rib during rib formation / G. L. Mowrey, C. W. Ganoe, W. D. Monaghan. - № 08/326301; Заявлено 20.10.1994; Опубл. 19.03.1996. - 8 с.↑

A3265. Пат. 5500646 США, МПК G01S13/00, G01S7/02, G01S13/95, G01S7/03, G01S7/41 и др. Simultaneous differential polymetric measurements and co-polar correlation coefficient measurement / D. S. Zrnic. - № 08/282630; Заявлено 29.07.1994; Опубл. 19.03.1996. - 7 с.↑

A3266. Пат. 5499199 США, МПК G01S13/10, G01S13/76, G01S13/00, G01S7/40, G01B007/14 и др. Distance measuring system / J. G. Demas, N. G. Demas, J. G. Demas, L. G. Demas, F. Cornett. - № 08/131755; Заявлено 05.10.1993; Опубл. 12.03.1996. - 29 с.↑

A3267. Пат. 5499195 США, МПК G01S13/52, G01S7/41, G01S13/00, G01S7/02, G01S15/52 и др. Fine-grained multi-planar clutter rejection processor / P. F. Castelaz. - № 08/230041; Заявлено 19.04.1994; Опубл. 12.03.1996. - 11 с.↑

A3268. Пат. 5499030 США, МПК G01S7/292, G01S7/295, G01S13/86, G01S7/41, G01S13/00 и др. Expert system constant false alarm rate (CFAR) processor / M. C. Wicks, W. J. Baldygo, J.R. D. Brown. - № 08/215073; Заявлено 18.03.1994; Опубл. 12.03.1996. - 19 с.↑

A3269. Пат. 5499029 США, МПК G01S13/28, G01S13/32, G01S13/34, G01S13/02, G01S13/00 и др. Wide band stepped frequency ground penetrating radar / M. B. Bashforth, D. Gardner, D. Patrick, T. A. Lewallen, S. R.

Nammath и др. - № 08/234441; Заявлено 28.04.1994; Опубл. 12.03.1996. - 10 с.↑

A3270. Пат. 5497140 США, МПК G01S13/00, G01S13/75, G01S13/76, G06K19/073, G06K19/07 и др. Electrically powered postage stamp or mailing or shipping label operative with radio frequency (RF) communication / J. R. Tuttle. - № 08/168909; Заявлено 17.12.1993; Опубл. 05.03.1996. - 13 с.↑

A3271. Пат. 5495254 США, МПК G01S13/00, G01S13/93, G01S7/40, G01S013/00, G01S007/40. Detection and calibration of horizontal error in a scanning type radar device / H. Uemura, T. Niibe, A. Doi, T. Yoshioka, K.- Okuda и др. - № 08/153976; Заявлено 18.11.1993; Опубл. 27.02.1996. - 16 с.↑

A3272. Пат. 5495251 США, МПК B60K31/04, B60K31/02, B60K31/00, B60Q1/52, B60Q1/50 и др. Method of and apparatus for cruise control / S. P. Gilling, D. Ponsford, R. Shokoufandeh. - № 08/197761; Заявлено 16.02.1994; Опубл. 27.02.1996. - 7 с.↑

A3273. Пат. 5493303 США, МПК G01S13/00, G01S13/93, G01S13/44, H01Q25/00, H01Q25/02 и др. Monopulse transceiver / F. S. Kolak. - № 08/273833; Заявлено 12.07.1994; Опубл. 20.02.1996. - 6 с.↑

A3274. Пат. 5493302 США, МПК B60K31/00, G01S13/00, G01S13/93, G01S13/52, G01S013/60. Autonomous cruise control / J. Woll, J. Olds. - № 08/130585; Заявлено 01.10.1993; Опубл. 20.02.1996. - 17 с.↑

A3275. Пат. 5491483 США, МПК G06K19/07, G01S13/00, G01S13/75, G01S013/00. Single loop transponder system and method / L. J. D'Hont. - № 08/177510; Заявлено 05.01.1994; Опубл. 13.02.1996. - 7 с.↑

A3276. Пат. 5488376 США, МПК G01S13/00, G01S13/76, G01S013/76. Transponder interface circuit / D. S. Hurta, G. Froschermeier. - № 08/233871; Заявлено 26.04.1994; Опубл. 30.01.1996. - 29 с.↑

A3277. Пат. 5486833 США, МПК G01S13/00, G01S13/10, G01S13/02, G01S7/41, G01S7/02 и др. Active signalling systems / T. W. Barrett. - № 08/042272; Заявлено 02.04.1993; Опубл. 23.01.1996. - 61 с.↑

A3278. Пат. 5485520 США, МПК G07B15/00, G06K7/00, G01S13/00, G01S13/75, G01S13/76 и др. Automatic real-time highway toll collection from moving vehicles / D. Chaum, P. L. Hendrick. - № 08/132984; Заявлено 07.10.1993; Опубл. 16.01.1996. - 33 с.↑

A3279. Пат. 5483962 США, МПК G01F1/66, G01S13/00, G01S15/52, G01S13/524, G01S15/00 и др. Complex MTI filter / A. Shiba. - № 08/121642; Заявлено 16.09.1993; Опубл. 16.01.1996. - 32 с.↑

A3280. Пат. 5483455 США, МПК G01S13/00, G01S17/00, G01S13/86, G01S13/34, G01S13/87 и др. Method and apparatus for determining the location of a vehicle / N. K. Lay, C. A. Kemner, J. L. Peterson, W. E. Allen, R. B. League. - № 08/371657; Заявлено 11.01.1995; Опубл. 09.01.1996. - 13 с.↑

A3281. Пат. 5483242 США, МПК G01S13/00, G01S13/58, G01S7/35, G01S13/34, G01S7/02 и др. Method for measuring the distance and velocity of objects / N. Grein, H. Winner. - № 08/166781; Заявлено 14.12.1993; Опубл. 09.01.1996. - 7 с.↑

A3282. Пат. 5483240 США, МПК G01S13/00, F41G7/22, F41G7/20, G01S13/524, G01S13/53 и др. Radar terrain bounce jamming detection using ground clutter tracking / Y. S. Hsu, A. G. Laquer. - № 08/314028; Заявлено 28.09.1994; Опубл. 09.01.1996. - 9 с.↑

Cylindrical phased array antenna system to produce wide-open coverage of a wide angular sector with high directive gain and moderate capability to resolve multiple signals / R. M. Rudish, S. F. Hall. - № 07/081959; Заявлено 29.06.1987; Опубл. 04.07.1995. - 8 с.↑

A3328. Пат. 5430450 США, МПК B60Q1/52, B60Q1/14, B60Q1/50, G01S13/56, G01S13/00 и др. Method and apparatus for automatically dimming motor vehicle headlights using radar signal / D. N. Holmes. - № 08/235259; Заявлено 29.04.1994; Опубл. 04.07.1995. - 9 с.↑

A3329. Пат. 5428359 США, МПК G01S13/60, G01S15/00, G01S13/00, G01S15/60, G01S013/60. Doppler-effect vehicle speed sensor using different speed determining rules depending upon receiver output / M. Yoneyama, S. Ikeda, H. Naganawa. - № 08/136819; Заявлено 18.10.1993; Опубл. 27.06.1995. - 23 с.↑

A3330. Пат. 5428358 США, МПК G01S13/95, G01S5/14, H04B17/00, G01S013/00. Apparatus and method for ionospheric mapping / S. B. Gardner. - № 08/237568; Заявлено 03.05.1994; Опубл. 27.06.1995. - 11 с.↑

A3331. Пат. 5428278 США, МПК E05F3/00, E05F3/22, E05F15/20, G01S17/00, G01S17/02 и др. Operating delay means for a hydraulic door closer / D. E. Bollengier, K. R. Freeberg. - № 08/337908; Заявлено 14.11.1994; Опубл. 27.06.1995. - 8 с.↑

A3332. Пат. 5426435 США, МПК F42C13/00, F42C13/04, G01S13/50, G01S7/02, G01S13/00 и др. Open loop proximity detector / G. J. Moore, D. G. Bird. - № 07/263832; Заявлено 28.10.1988; Опубл. 20.06.1995. - 8 с.↑

A3333. Пат. 5424747 США, МПК G01S1/00, G01S13/74, G01S13/93, G01S13/76, G01S13/00 и др. Process and system for determining the position and orientation of a vehicle, and applications / J. Chazelas, P. Souchay. - № 08/167830; Заявлено 16.12.1993; Опубл. 13.06.1995. - 11 с.↑

A3334. Пат. 5424745 США, МПК G01S13/56, G01S13/00, H01Q13/22, H01Q13/20, E05F15/00 и др. Detection method and system / P. Fonsny. - № 08/053257; Заявлено 28.04.1993; Опубл. 13.06.1995. - 12 с.↑

A3335. Пат. 5424744 США, МПК G01S13/00, G08B013/18. Sensor arrangement for sensing a threat / R. Westphal. - № 08/184698; Заявлено 21.01.1994; Опубл. 13.06.1995. - 7 с.↑

A3336. Пат. 5424726 США, МПК B60Q1/50, B60Q1/52, G08G1/16, G01S13/93, G01S13/00 и др. Method, apparatus and system for transmitting and receiving data in a moving linear chain / B. A. Beymer. - № 07/954791; Заявлено 30.09.1992; Опубл. 13.06.1995. - 13 с.↑

A3337. Пат. 5423549 США, МПК A63B43/00, G01S13/75, G01S13/00, A63B043/00. Apparatus with a signal receiving unit for locating golf balls / M. Englmeier. - № 07/920443; Заявлено 26.08.1992; Опубл. 13.06.1995. - 9 с.↑

A3338. Пат. 5422830 США, МПК G01S13/00, G01S13/72, G06F015/20. Method for tracking a maneuvering target with a slow scan rate sensor / E. L. Post. - № 08/003275; Заявлено 12.01.1993; Опубл. 06.06.1995. - 8 с. ↑

A3339. Пат. 5422829 США, МПК G01S13/58, G01S13/00, G01S13/72, G01S007/00. Closed-loop control for scanning application / E. J. Pollock. - № 07/913671; Заявлено 14.07.1992; Опубл. 06.06.1995. - 11 с.↑

A3340. Пат. 5422646 США, МПК G01S13/00, G01S13/528, G01S13/524, G01S013/528. High frequency MTI radar / B. L. Lewis. - № 06/470862; Заявлено 24.02.1983; Опубл. 06.06.1995. - 7 с.↑

A3341. Пат. 5420903 США, МПК A63B71/06, G01S13/88, G01S13/00, G01S13/82, A63B071/06. Microwave object counter and method / D. M. Newton. - № 08/079373; Заявлено 21.06.1993; Опубл. 30.05.1995. - 10 с.↑

A3342. Пат. 5420792 США, МПК B60K31/00, B60T8/48, B60Q1/50, B60Q1/52, B60T7/22 и др. Automatic brake control system / T. Butsuen, T. Yoshioka. - № 08/037634; Заявлено 26.03.1993; Опубл. 30.05.1995. - 13 с.↑

A3343. Пат. 5420591 США, МПК G01F23/284, G01S13/24, G01S7/02, G01S13/60, G01S13/00 и др. Method for the discriminating of obstacles by means of radar, and applications / G. Annee, P. Garrec, P. Cornic. - № 08/078393; Заявлено 16.06.1993; Опубл. 30.05.1995. - 10 с.↑

A3344. Пат. 5420589 США, МПК G01S13/02, G01S13/00, G01V3/12, H01Q13/08, G01S13/88 и др. System for evaluating the inner medium characteristics of non-metallic materials / C. T. Wells, R. Peterson. - № 08/073451; Заявлено 07.06.1993; Опубл. 30.05.1995. - 45 с.↑

A3345. Пат. 5418537 США, МПК G01S1/00, G01S13/00, G01S13/87, G01S1/04, G01S13/82 и др. Location of missing vehicles / D. G. Bird. - № 07/978272; Заявлено 18.11.1992; Опубл. 23.05.1995. - 13 с.↑

A3346. Пат. 5416464 США, МПК B60R25/10, G01S13/00, G01S13/04, G08B13/24, B62H005/00. Vehicle anti-theft alarm system / P. D. Rimback, D. D. Voiculescu, J. Rutkoski, L. D. Carlo. - № 08/051173; Заявлено 22.04.1993; Опубл. 16.05.1995. - 9 с.↑

A3347. Пат. 5414427 США, МПК B67D5/01, B67D5/04, G01S13/76, G01S13/00, G06K19/077 и др. Device for information transmission / S. Gunnarsson. - № 07/961939; Заявлено 21.01.1993; Опубл. 09.05.1995. - 11 с.↑

A3348. Пат. 5410314 США, МПК G01S13/95, G01S13/00, G01S13/50, G01S013/08. Bistatic multiple-doppler radar network / C. L. Frush, J. M. A. R. Wurman. - № 08/158762; Заявлено 30.11.1993; Опубл. 25.04.1995. - 17 с.↑

A3349. Пат. 5410304 США, МПК B60Q1/50, B60Q1/52, G01S13/93, G01S13/00, G01S7/26 и др. Method and apparatus for displaying the impending danger due to speed associated with the driving situation of a vehicle / H. Hahn, W. Lauer, S. Reiniger. - № 08/053397; Заявлено 28.04.1993; Опубл. 25.04.1995. - 7 с.↑

A3350. Пат. 5406481 США, МПК G01W1/10, G01S15/88, G01S15/00, G01S13/00, G01S13/95 и др. Rainfall, snowfall forecast apparatus and method / K. Shinozawa, N. Sonehara, T. Uchiyama. - № 08/266541; Заявлено 28.06.1994; Опубл. 11.04.1995. - 18 с.↑

A3351. Пат. 5406289 США, МПК G01S13/00, G01S13/72, G01S013/00. Method and system for tracking multiple regional objects / T. N. Barker, J. A. Persichetti, A. B. Poore, J.N. Rijavec. - № 08/171327; Заявлено
↑

21.12.1993; Опубл. 11.04.1995. - 23 с.

A3352. Пат. 5406275 США, МПК G01S13/76, G01S13/00, G06Q30/00, G07C9/00, G08G1/017 и др. Object location process and apparatus / J. J. Hassett, W. A. Hartman, K. E. Kowal. - № 07/901277; Заявлено 19.06.1992; Опубл. 11.04.1995. - 12 с.↑

A3353. Пат. 5402469 США, МПК G01S13/75, G01S17/00, G01S13/78, G01S13/00, G07C9/00 и др. Carrier locating system / A. Hopper, R. Want, R. M. Needham, D. J. Wheeler. - № 07/973264; Заявлено 09.11.1992; Опубл. 28.03.1995. - 7 с.↑

A3354. Пат. 5402346 США, МПК G01S13/92, G01S13/64, G01S13/00, G08G1/015, G08G1/01 и др. System for the calculation of at least one vehicular traffic check parameter / D. Lion, E. Poulpiquet. - № 08/112842; Заявлено 25.08.1993; Опубл. 28.03.1995. - 10 с.↑

A3828. Пат. 4517566 США, МПК G01S13/60, G01S13/00, G01S013/60. True ground speed sensor / J. H. Bryant, S. M. Schultz. - № 06/415061; Заявлено 07.09.1982; Опубл. 14.05.1985. - 14 с.↑

A3829. Пат. 4516125 США, МПК G01S13/93, G01S13/00, G01S13/52, G01S013/52. Method and apparatus for monitoring vehicle ground movement in the vicinity of an airport / C. E. Schwab, D. P. Rost, W. Hackenberg, P. Holcombe. - № 06/419886; Заявлено 20.09.1982; Опубл. 07.05.1985. - 21 с.↑

A3830. Пат. 4516085 США, МПК G01S13/00, G01S13/24, H03B21/00, H03B21/02, H03B021/01. Microwave frequency synthesizer using plural switchable low noise oscillators / D. D. Effinger, R. Docter. - № 06/404161; Заявлено 02.08.1982; Опубл. 07.05.1985. - 7 с.↑

A3831. Пат. 4513285 США, МПК G01S13/00, G01S13/79, G01S013/08. Quasi coherent two-way ranging apparatus / L. W. Pike, J. W. Zscheile, J.B. M. Spencer. - № 06/289688; Заявлено 03.08.1981; Опубл. 23.04.1985. - 8 с.↑

A3832. Пат. 4510495 США, МПК A01K11/00, B61L25/04, B61L25/00, G01S13/75, G01S13/00 и др. Remote passive identification system / N. A. Sigrimis, N. R. Scott. - № 06/406471; Заявлено 09.08.1982; Опубл. 09.04.1985. - 14 с.↑

A3833. Пат. 4509050 США, МПК G01S13/89, G01S13/00, G01S7/285, G01S7/34, G01S007/34. Automatic adaptive sensitivity time control for a ground mapping radar / S. Amoroso, J.R. W. Conklin. - № 06/413007; Заявлено 30.08.1982; Опубл. 02.04.1985. - 5 с.↑

A3834. Пат. 4505351 США, МПК B60K31/08, B60K31/06, B60K31/00, B60T13/44, B60T13/10 и др. Automatic braking system for vehicles / M. Nishikawa, T. Aoki. - № 06/317112; Заявлено 02.11.1981; Опубл. 19.03.1985. - 16 с.↑

A3835. Пат. 4504833 США, МПК G01S13/10, G01S13/00, G01S13/02, G01S13/88, G01S007/28 и др. Synthetic pulse radar system and method / J. C. Fowler, H. S. Wheatley, J. L. Davis. - № 06/329042; Заявлено 09.12.1981; Опубл. 12.03.1985. - 13 с.↑

A3836. Пат. 4499466 США, МПК G01S13/70, G01S13/00, G01S013/70. Method of producing velocity-aided range gates / A. J. Torino, J.G. A. Bouchard, P. A. Keane. - № 06/394243; Заявлено 01.07.1982; Опубл. 12.02.1985. - 8 с.↑

A3837. Пат. 4496949 США, МПК G01S13/524, G01S13/00, G01S13/24, G01S7/36, G01S013/52. MTI Radar adaptable to different environmental conditions / G. Bettini, L. Penso, G. Rodriguez. - № 06/281479; Заявлено 08.07.1981; Опубл. 29.01.1985. - 5 с.↑

A3838. Пат. 4495501 США, МПК G01S13/00, G01S13/24, G01S13/526, G01S013/52, G01S013/24. Method and means for providing frequency agile operation of MTI _radar / D. L. Creed. - № 06/373084; Заявлено 28.04.1982; Опубл. 22.01.1985. - 5 с.↑

A3839. Пат. 4491840 США, МПК B60Q1/50, B60Q1/52, G01S13/93, G01S13/00, G01S13/34 и др. Intervehicle distance control system for vehicles / M. Nishikawa, T. Aoki. - № 06/365159; Заявлено 05.04.1982; Опубл. 01.01.1985. - 10 с.↑

A3840. Пат. 4489321 США, МПК G01S13/58, G01S13/00, G01S13/60, G01S013/60. Radar ground speed sensing system / R. J. Hoffa, C. M. Burde. - № 06/491696; Заявлено 05.05.1983; Опубл. 18.12.1984. - 12 с.↑

A3841. Пат. 4489320 США, МПК G01S13/00, G01S13/52, G01S13/526, G01S7/292, G01S009/02 и др. Interference suppressor for radar MTI / B. L. Lewis, F. F. Kretschmer. - № 06/290757; Заявлено 07.08.1981; Опубл. 18.12.1984. - 5 с.↑

A3842. Пат. 4486755 США, МПК G01S13/78, G01S13/00, G01S013/78. Collision avoidance system / B. L. Hulland, G. B. Litchford. - № 06/351275; Заявлено 22.02.1982; Опубл. 04.12.1984. - 9 с.↑

A3843. Пат. 4467326 США, МПК G01S13/78, G01S13/76, G01S13/00, G01S009/56. Method and apparatus for preventing the response of a radar beacon to receive radar pulses originating from the side lobes of a transmitter and an arrangement / P. M. Charas, P.-O. G. Gustavsson, B. A. Morwing. - № 06/284184; Заявлено 17.07.1981; Опубл. 21.08.1984. - 9 с.↑

A3844. Пат. 4466068 США, МПК G01S13/93, G01C21/20, G01S13/00, G06F015/50, G01C021/20 и др. Apparatus for the detection and prevention of collision risks in deep sea and coastal navigation / T. Degre, F. Lefevre, X. Lefevre. - № 06/232049; Заявлено 26.01.1981; Опубл. 14.08.1984. - 13 с.↑

A3845. Пат. 4463356 США, МПК G01S13/00, G01S13/526, G01S009/42. Apparatus for control of clutter breakthrough in MTI radar / R. D. Short, I.I.I.C. L. Bennett, J.R. M. Barnes, R. S. Smith, H. W. Pyle. - № 06/293730; Заявлено 17.08.1981; Опубл. 31.07.1984. - 7 с.↑

A3846. Пат. 4459592 США, МПК G01S13/00, G01S13/524, G01S009/02. Methods of and circuits for suppressing doppler radar clutter / M. W. Long. - № 06/278436; Заявлено 24.06.1981; Опубл. 10.07.1984. - 20 с. ↑

A3847. Пат. 4458235 США, МПК G01S13/74, G01S13/00, G01S13/75, G01S009/56. Foreground subject-identifying apparatus / M. Ohyama. - № 06/237845; Заявлено 25.02.1981; Опубл. 03.07.1984. - 5 с.↑

A3848. Пат. 4457206 США, МПК F42C17/04, F42C17/00, G01S13/58, G01P3/64, F41G5/00 и др. Microwave-type projectile communication apparatus for guns / P. P. Toulios, K. D. Hartman. - № 06/269489; Заявлено 02.06.1981; Опубл. 03.07.1984. - 37 с.↑

A3849. Пат. 4438436 США, МПК G01S13/00, G01S13/44, G01S013/00. Millimeter wave monopulse comparator circuit / E. R. Murphy. - № 06/327334; Заявлено 04.12.1981; Опубл. 20.03.1984. - 6 с.↑

A3850. Пат. 4435707 США, МПК G01S13/95, G01S13/00, G01S013/95. Weather radar with signal compensation for precipitation / J. F. Clark. - № 06/241782; Заявлено 09.03.1981; Опубл. 06.03.1984. - 12 с.↑

A3851. Пат. 4430654 США, МПК G01S13/00, G01S13/52, G01S013/00. Method and apparatus for suppressing clutter / H. Kupfer. - № 06/392624; Заявлено 28.06.1982; Опубл. 07.02.1984. - 12 с.↑

A3852. Пат. 4430653 США, МПК G01V3/30, G01S13/00, G01S13/02, G01S13/06, G01V3/18 и др. Earth probing radar system / J. B. Coon, C. J. Schafers. - № 06/218437; Заявлено 19.12.1980; Опубл. 07.02.1984. - 19 с.↑

A3853. Пат. 4426134 США, МПК G01S13/58, G01S13/00, G02F1/11, G02F1/01, G06E3/00 и др. Three and four product surface-wave acousto-optic time integrating correlators / I. J. Abramovitz, N. J. Berg, M. W. Casseday. - № 06/317687; Заявлено 02.11.1981; Опубл. 17.01.1984. - 11 с.↑

A3854. Пат. 4425793 США, МПК G01S13/522, G01S13/88, G01S13/18, G01S13/00, G01F023/28. Level gauging systems / D. Turton, L. R. F. Thompson. - № 06/266869; Заявлено 26.05.1981; Опубл. 17.01.1984. - 6 с. ↑

A3855. Пат. 4417157 США, МПК G01S13/00, G01S13/56, H03K017/74. Radio frequency switch for coupling an RF source to a load / D. N. Gershberg, A. Y. Lee, J.W. B. Moore. - № 06/238849; Заявлено 27.02.1981; Опубл. 22.11.1983. - 12 с.↑

A3856. Пат. 4414548 США, МПК G01S13/00, G01S13/60, G01S009/44. Doppler speed sensing apparatus / D. D. Carpenter, R. L. Lanning. - № 06/249073; Заявлено 30.03.1981; Опубл. 08.11.1983. - 10 с.↑

A3857. Пат. 4413665 США, МПК E06B9/50, E06B9/24, E06B9/90, E06B9/80, G01S13/00 и др. Device for preventing overwinding of a roller blind / S. Corcoran. - № 06/209211; Заявлено 21.11.1980; Опубл. 08.11.1983. - 10 с.↑

A3858. Пат. 4412219 США, МПК G01S13/76, G01S13/00, G01S013/80. Secondary radar responders / J. N. Briggs. - № 06/221732; Заявлено 31.12.1980; Опубл. 25.10.1983. - 10 с.↑

A3859. Пат. 4403220 США, МПК G01S13/93, G01S13/00, G01S13/60, G01S013/60. Radar system for collision avoidance / J. S. Donovan. - № 06/142288; Заявлено 17.04.1980; Опубл. 06.09.1983. - 11 с.↑

A3860. Пат. 4399441 США, МПК B61L25/04, B61L25/00, G01S13/76, G01S13/00, G01K1/02 и др. Apparatus for remote temperature reading / R. Vaughan, P. H. Cole. - № 06/226518; Заявлено 19.01.1981; Опубл. 16.08.1983. - 12 с.↑

A3861. Пат. 4390880 США, МПК B61L25/04, B61L25/00, G01S13/76, G01S13/00, G01D5/48 и др. Radio communication system and transmitter and receiver equipment therefor / B. Henoch. - № 06/191501; Заявлено 29.09.1980; Опубл. 28.06.1983. - 7 с.↑

A3862. Пат. 4389648 США, МПК G01S13/00, G01S13/60, G01S013/60. Doppler radar system / A. P. Luscombe, S. R. Brooks. - № 06/173912; Заявлено 30.07.1980; Опубл. 21.06.1983. - 11 с.↑

A3863. Пат. 4385298 США, МПК G01S13/00, G01S13/24, G01S13/526, G01S013/24, G01S013/52. MTI-Filter in a trackding radar receiver / L. G. Josefsson, K.-E. I. Oderland, J.-O. Winnberg. - № 06/227083; Заявлено 23.12.1980; Опубл. 24.05.1983. - 5 с.↑

A3864. Пат. 4377811 США, МПК G01S13/00, G01S13/53, G01S013/04. Medium PRF pulse doppler radar having simplified ground moving target rejection capabilities / D. H. Mooney, J.K. A. Harriger. - № 06/223177; Заявлено 07.01.1981; Опубл. 22.03.1983. - 10 с.↑

A3865. Пат. 4373161 США, МПК B60Q1/54, B60Q1/50, G01S13/00, G01S13/60, H01Q1/32 и др. Doppler radar mounting structure for motor vehicles / A. Matsumura. - № 06/179982; Заявлено 21.08.1980; Опубл. 08.02.1983. - 8 с.↑

A3866. Пат. 4370652 США, МПК G01S13/95, G01S13/00, G01S7/285, G01S7/34, G01S007/34. Control systems for radar receivers / G. A. Lucchi. - № 06/165937; Заявлено 02.07.1980; Опубл. 25.01.1983. - 22 с.↑

A3867. Пат. 4364049 США, МПК G01S13/76, G01S13/00, G01S013/87. Radar transponders / A. R. Moore, J. Waterworth. - № 06/151531; Заявлено 19.05.1980; Опубл. 14.12.1982. - 7 с.↑

A3868. Пат. 4359734 США, МПК G01S13/58, G01S13/00, G01S007/34, G01S013/58. Signal processing system / W. J. Bachman. - № 06/008057; Заявлено 31.01.1979; Опубл. 16.11.1982. - 9 с.↑

A3869. Пат. 4358759 США, МПК G01S13/00, G01S13/56, G08B013/22, G01S009/02. Microwave movement detector / J. A. C. Stewart, B. M. Armstrong, H. S. Gamble, J. Mallon, F. C. Monds и др. - № 06/158141; Заявлено 10.06.1980; Опубл. 09.11.1982. - 6 с.↑

A3870. Пат. 4357608 США, МПК G01S13/00, G01S13/87, G01S13/42, G15, G15 и др. Scanning radar system / B. L. Lewis. - № 06/183697; Заявлено 03.09.1980; Опубл. 02.11.1982. - 5 с.↑

A3871. Пат. 4356489 США, МПК G01S13/00, G01S13/60, G01S013/93. Vehicle speed sensing apparatus with electromagnetic wave interference detector / Y. Hirota, A. Endo, K. Sekine. - № 06/142816; Заявлено 22.04.1980; Опубл. 26.10.1982. - 11 с.↑

A3942. Пат. 4223233 США, МПК G01S13/58, G01S13/00, H01L29/768, G11C19/00, H01L29/66 и др. Charge transfer device input circuitry / A. M. Cappon, J. P. Sage. - № 05/800829; Заявлено 26.05.1977; Опубл. 16.09.1980. - 18 с.↑

A3943. Пат. 4222050 США, МПК G01S13/532, G01S13/00, G01S7/292, G01S009/42. Moving target indication radar / E. Kiuchi, T. Irabu. - № 05/961169; Заявлено 16.11.1978; Опубл. 09.09.1980. - 18 с.↑

A3944. Пат. 4219878 США, МПК G01S13/92, G01P3/64, G01P3/42, G01P3/54, G01P3/66 и др. Speed measuring device / W. D. Goodson, J. R. Alden, D. L. Hyder. - № 05/896373; Заявлено 14.04.1978; Опубл. 26.08.1980. - 11 с.↑

A3945. Пат. 4219813 США, МПК G01S13/00, G01S13/64, G01S009/42. Signal processor / J. D. Collins. - № 05/800993; Заявлено 26.05.1977; Опубл. 26.08.1980. - 18 с.↑

A3946. Пат. 4217583 США, МПК G01S13/00, G01S13/52, G01S009/42. Moving target indicator (MTI) radar systems / E. R. Hiller, P. D. Kaplan, J. M. Nicosia, J.H. D. Zuerndorfer. - № 05/582965; Заявлено 30.05.1975; Опубл. 12.08.1980. - 14 с.↑

A3947. Пат. 4217582 США, МПК G01S13/58, G01S13/62, G01S13/93, G01S13/00, G01S13/10 и др. Radar system for detecting approaching vehicles from behind / H. Endo, M. Adachi. - № 05/935908; Заявлено 23.08.1978; Опубл. 12.08.1980. - 9 с.↑

A3948. Пат. 4217563 США, МПК G01S13/00, G01S13/44, G06G7/00, G06G7/195, H03H009/30 и др. Surface wave phase correlator and monopulse radar system employing the same / C. R. Vale. - № 05/642802; Заявлено 22.12.1975; Опубл. 12.08.1980. - 9 с.↑

A3949. Пат. 4216473 США, МПК G01S13/00, G01S13/60, G01S009/44. MIPS Hover attachment / L. I.

Goldfischer, G. Stavis, A. Shrekenhamer. - № 05/961315; Заявлено 16.11.1978; Опубл. 05.08.1980. - 11 с.↑

A3950. Пат. 4214243 США, МПК G01S13/92, G01S13/00, G01S009/44. Harmonic detector for traffic radar / R. E. Patterson. - № 05/943199; Заявлено 18.09.1978; Опубл. 22.07.1980. - 8 с.↑

A3951. Пат. 4214240 США, МПК F42C13/04, F42C13/00, G01S13/00, G01S13/30, F42C013/04. Coded pulse radar fuze / F. Weiss. - № 04/416684; Заявлено 03.12.1964; Опубл. 22.07.1980. - 8 с.↑

A3952. Пат. 4213123 США, МПК G01S13/00, G01S13/56, G08B13/24, G08B013/18. Integral enable-disable means for guided wave radar intrusion detector system portals / J. L. Poirier. - № 06/010093; Заявлено 07.02.1979; Опубл. 15.07.1980. - 6 с.↑

A3953. Пат. 4213093 США, МПК G01V3/15, G01V3/12, G01S13/88, G01S13/00, G01V003/08. Portable buried object detection system with error reducing signal processing / P. M. Pecori. - № 05/923511; Заявлено 10.07.1978; Опубл. 15.07.1980. - 8 с.↑

A3954. Пат. 4210900 США, МПК G01S13/00, G01S13/75, G06K19/067, G06K7/10, H04Q003/00. Surface acoustic wave code reader / G. Shavit. - № 05/934155; Заявлено 16.08.1978; Опубл. 01.07.1980. - 15 с.↑

A3955. Пат. 4208658 США, МПК B60Q1/50, B60Q1/52, G01S13/93, G01S13/00, G01S7/04 и др. Radar-operated vehicle safety assurance system / N. Fujiki, K. Baba, A. Mimura. - № 05/954853; Заявлено 26.10.1978; Опубл. 17.06.1980. - 15 с.↑

A3956. Пат. 4207569 США, МПК B61L23/00, B61L23/06, G01S13/76, G01S13/00, G01S009/56. Railroad radio frequency waveguide / J. R. Meyer. - № 05/933508; Заявлено 14.08.1978; Опубл. 10.06.1980. - 11 с.↑

A3957. Пат. 4206463 США, МПК G01S13/00, G01S7/285, G01S7/34, G01S13/24, G01S13/30 и др. Radar systems / J. A. Glasgow. - № 05/926733; Заявлено 21.07.1978; Опубл. 03.06.1980. - 6 с.↑

A3958. Пат. 4205314 США, МПК G01S13/58, G01S13/00, G01S009/44, G01S009/02, G01S009/23. Device for measuring the range of a moving target and the speed at which it approaches or recedes / R. Strauch. - № 05/862005; Заявлено 19.12.1977; Опубл. 27.05.1980. - 5 с.↑

A3959. Пат. 4203111 США, МПК G01S13/00, G01S13/524, G01S009/42. Radar device including a circuit arrangement for reducing interference / W. Buehring. - № 05/924162; Заявлено 13.07.1978; Опубл. 13.05.1980. - 5 с.↑

A3960. Пат. 4200871 США, МПК G01S13/58, G01S13/00, G01S13/34, G01S009/02. Acquisition system for continuous-wave frequency modulation object detector / R. S. Roeder, L. C. Bomar, I.I. - № 05/906291; Заявлено 15.05.1978; Опубл. 29.04.1980. - 17 с.↑

A3961. Пат. 4198632 США, МПК G01S13/76, G01S13/00, G01S009/56. Transponder reply limiting by means of recognition of fixed interrogation periods / W. B. Bishop. - № 03/151973; Заявлено 10.06.1971; Опубл. 15.04.1980. - 14 с.↑

A3962. Пат. 4193074 США, МПК G01S13/00, G01S13/44, G01S009/22. Enhancing radar returns from targets having a small radar cross section / E. C. Schwartz, T. F. Leney. - № 05/530566; Заявлено 03.12.1974; Опубл. 11.03.1980. - 5 с.↑

A3963. Пат. 4192002 США, МПК G01S13/00, G01S13/91, G06F015/50. Apparatus and methods for position determining and plotting / G. L. Draper. - № 05/875009; Заявлено 03.02.1978; Опубл. 04.03.1980. - 28 с.↑

A3964. Пат. 4190837 США, МПК G01S13/00, G01S7/36, G01S13/44, G01S009/22, G01S007/36. System for protecting a vehicle-borne tracking radar against an off-target jammer / L. Salvaudon, J.-C. Charlot. - № 05/915983; Заявлено 16.06.1978; Опубл. 26.02.1980. - 9 с.↑

A3965. Пат. 4189732 США, МПК G01S13/00, G01S13/06, G01S009/00. Motor actuating circuitry / J. B. Atwater. - № 05/782746; Заявлено 30.03.1977; Опубл. 19.02.1980. - 5 с.↑

A3966. Пат. 4188629 США, МПК G01S13/00, G01S13/75, G01S009/233, G01S009/56. Passive navigation system with frequency coding / R. H. Johnson. - № 05/706659; Заявлено 19.07.1976; Опубл. 12.02.1980. - 5 с.↑

A3967. Пат. 4186397 США, МПК G01S13/32, G01S13/00, G01S009/04. Short range precision navigation and tracking system and method therefor / W. I. Sternberger, L. R. LeBlanc. - № 05/830408; Заявлено 06.09.1977; Опубл. 29.01.1980. - 8 с.↑

A3968. Пат. 4185284 США, МПК G01S13/76, G01S13/00, G01S009/56. Ground station for the DME distance measuring system / H. Vogel, H. Kleiber. - № 05/962961; Заявлено 22.11.1978; Опубл. 22.01.1980. - 6 с.↑

A3969. Пат. 4184155 США, МПК G01S13/00, G01S13/08, H01Q15/14, G01S009/60, H01Q015/00. Radar target for remotely sensing hydrological phenomena / W. E. S. Jr. - № 05/945041; Заявлено 22.09.1978; Опубл. 15.01.1980. - 7 с.↑

A3970. Пат. 4184154 США, МПК G01S13/32, G01S13/42, G01S13/00, G01S009/37. Range and angle determining Doppler radar / D. F. Albanese, H. R. Kennedy, J. W. Goodwin. - № 05/698192; Заявлено 21.06.1976; Опубл. 15.01.1980. - 15 с.↑

A3971. Пат. 4180814 США, МПК G01S3/14, G01S13/42, G01S3/46, G01S13/00, H01Q3/26 и др. Multiple beam receiving array signal processor / P. Barton. - № 05/885607; Заявлено 13.03.1978; Опубл. 25.12.1979. - 7 с.↑

A3972. Пат. 4177466 США, МПК G01S13/74, G01S5/04, G01S13/00, G01S011/00. Auto theft detection system / W. R. Reagan. - № 05/851835; Заявлено 16.11.1977; Опубл. 04.12.1979. - 5 с.↑

A3973. Пат. 4177463 США, МПК G01P5/24, G01S15/00, G01P5/00, G01P5/18, G01S17/50 и др. Method and device for measuring the velocity of an object relative to a reference / I. Andermo. - № 05/862609; Заявлено 20.12.1977; Опубл. 04.12.1979. - 22 с.↑

A3974. Пат. 4176749 США, МПК B03B5/24, B03B5/20, B03B5/00, G01S15/00, G01S13/00 и др. Materials separation / W. M. Wallace, G. F. Craven. - № 05/868931; Заявлено 12.01.1978; Опубл. 04.12.1979. - 18 с.↑

A3975. Пат. 4176352 США, МПК G01S13/60, G01S13/00, G01S009/50. Apparatus for deriving information concerning the movements of a vehicle / R. A. Tyler. - № 05/645714; Заявлено 31.12.1975; Опубл. 27.11.1979. - 6 с.↑

A3976. Пат. 4172256 США, МПК G01S13/92, G01S13/00, G01S009/44. Circuit for speed measurement of vehicles according to the Doppler-radar principle / P. Pacozzi. - № 05/874506; Заявлено 02.02.1978; Опубл. 23.10.1979. - 7 с.↑

A3977. Пат. 4172255 США, МПК G01S13/95, G01S13/58, G01S13/89, G01S13/87, G01S13/02 и др. HF coastal current mapping radar system / D. E. Barrick, M. W. Evans. - № 05/822868; Заявлено 08.08.1977; Опубл. 23.10.1979. - 9 с.↑

A3978. Пат. 4170774 США, МПК G01S3/14, G01S3/22, G01S3/32, G01S3/46, G01S13/00 и др. Amplitude selected phase interferometer angle measuring radar / C. F. Schaefer. - № 05/219775; Заявлено 24.01.1972; Опубл. 09.10.1979. - 8 с.↑

A3979. Пат. 4168499 США, МПК G01S13/93, G01S13/00, B60T007/12, G01S009/02. Anti-collision radar system provided with circuitry for monitoring driver's / A. Matsumura, N. Fujiki. - № 05/920339; Заявлено 29.06.1978; Опубл. 18.09.1979. - 11 с.↑

A3980. Пат. 4167007 США, МПК G01S13/78, G01S13/00, G01S009/56. Method and apparatus for identifying radar targets / I. L. M. McGeoch, W. B. Stawell. - № 05/811428; Заявлено 29.06.1977; Опубл. 04.09.1979. - 11 с. ↑

A3981. Пат. 4165511 США, МПК G01S13/93, G01S13/00, G01S009/02. Reduction of echoes of irrelevant targets in a vehicle anti-collision radar system / B. Wocher, H. Pfitzmaier, T. Pfendler. - № 05/841707; Заявлено 13.10.1977; Опубл. 21.08.1979. - 8 с.↑

A3982. Пат. 4164740 США, МПК G01S13/90, G01S7/04, G01S7/10, G01S13/00, G01S009/02. Synthetic aperture using image scanner / J. N. Constant. - № 05/897907; Заявлено 19.04.1978; Опубл. 14.08.1979. - 12 с. ↑

A3983. Пат. 4164738 США, МПК G01S13/90, G01S7/04, G01S13/00, G01S009/42. Focused synthetic array / P. Swerling. - № 04/560386; Заявлено 23.06.1966; Опубл. 14.08.1979. - 7 с.↑

A3984. Пат. 4163973 США, МПК G01S13/00, G01S13/44, G01S009/22. Means for developing a radar tracking error signal / R. E. Jacobson, J. - № 05/549402; Заявлено 18.02.1975; Опубл. 07.08.1979. - 4 с.↑

A3985. Пат. 4161730 США, МПК G01S11/00, G01S13/76, G01S13/86, G01S11/08, G01S13/00 и др. Radio determination using satellites transmitting timing signals with correction by active range measurement / R. E. Anderson. - № 05/842402; Заявлено 17.10.1977; Опубл. 17.07.1979. - 10 с.↑

A3986. Пат. 4161715 США, МПК E21B47/08, E21B47/00, E21B47/04, G01S13/88, G01S11/00 и др. Method and apparatus for measuring the interior dimensions of a hollow body / L. A. Harris. - № 05/830210; Заявлено 02.09.1977; Опубл. 17.07.1979. - 8 с.↑

A3987. Пат. 4160251 США, МПК G01S7/02, G01K11/00, G01S13/04, G01S7/41, G01S13/00 и др. Hybrid dual mode radiometric system / R. E. Lazarchik, R. S. Roeder. - № 05/861752; Заявлено 19.12.1977; Опубл. 03.07.1979. - 11 с.↑

A3988. Пат. 4158841 США, МПК G01S13/93, G01S7/40, G01S13/00, G08G1/16, G01S13/72 и др. Method and apparatus for the control of the safety distance of a vehicle relative to preceding vehicles / E. Wuchner, U. Heitmeyer, W. Kostelezky. - № 05/796869; Заявлено 16.05.1977; Опубл. 19.06.1979. - 9 с.↑

A4174. Пат. 3946388 США, МПК G01S13/89, G01S13/90, G01S13/00, G01S7/28, G01S7/292 и др. System for and method of analyzing electromagnetic waves / J. Schifrine. - № 05/352081; Заявлено 17.04.1973; Опубл. 23.03.1976. - 11 с.↑

A4175. Пат. 3936825 США, МПК G01S13/64, G01S13/00, G01S009/44. Combined contiguous filter and acceleration and velocity analyzer for radar / G. K. Jensen, J. E. McGeogh. - № 05/154234; Заявлено 16.06.1971; Опубл. 03.02.1976. - 6 с.↑

A4176. Пат. 3936824 США, МПК G01S13/60, G01S13/58, G01S13/00, G01S13/92, G01S13/524 и др. Method and apparatus for digitally measuring speed / J. L. Aker, D. L. Geist, F. R. Kittle, F. M. Berry. - № 05/361822; Заявлено 18.05.1973; Опубл. 03.02.1976. - 15 с.↑

A4177. Пат. 3936761 США, МПК G01S13/02, G01S13/00, G01S13/52, H04B001/10, H04B015/00. Plural channel filter / G. K. Jensen, J. E. McGeogh. - № 04/649795; Заявлено 27.06.1967; Опубл. 03.02.1976. - 6 с.↑

A4178. Пат. 3935572 США, МПК G01S13/44, H01Q1/42, G01S13/00, G01S009/44. System for resolving velocity ambiguity in pulse-doppler radar / L. E. Broniwitz, M. I. Landau, J. B. Pearson, I.I.I. - № 05/418692; Заявлено 23.11.1973; Опубл. 27.01.1976. - 121 с.↑

A4179. Пат. 3934252 США, МПК G01S13/60, G01S13/93, G01S13/00, G01S7/285, G01S7/34 и др. Closed loop tunnel diode receiver for operation with a base band semiconductor transmitter / G. F. Ross, K. W. Robbins. - № 05/458967; Заявлено 08.04.1974; Опубл. 20.01.1976. - 8 с.↑

A4180. Пат. 3931420 США, МПК G01S13/28, G01S13/00, G10K11/00, G10K11/36, H03H3/10 и др. Temperature compensated acoustic surface wave device / M. B. Schulz, M. G. Holland. - № 05/359801; Заявлено 14.05.1973; Опубл. 06.01.1976. - 11 с.↑

Тематический реферативный сборник патентов США сгенерирован в автоматическом режиме с использованием специализированного программного обеспечения.
Сборник сформирован в рамках выполнения проекта **РФФИ 18-07-01270** "*Создание методики выявления и прогнозирования перспективных направлений развития радиоэлектронных систем, использующих отражение и вторичное излучение радио, акустических и электромагнитных волн в космической, авиационной и наземной технике на базе патентного анализа*"
